Directory Server Release Notes

PingDirectory 8.2.0.8 release notes

The release notes for the 8.2.0.8 release of the PingDirectory server.

Critical fixes

This release of the PingDirectory server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the PingDirectory server.

Ticket ID	Description
DS-45164	Updated Jetty Server to version 9.4.44.
DS-45813	Updated PingDirectory products to use Kafka v2.8.1.
DS-45863	Resolved an issue where SCIM POST requests that violated a unique attribute constraint received an error response with status 400 (Bad Request) instead of 409 (Conflict).
DS-46017	Resolved an issue with slow response time on PingDirectory servers configured with a large number (10,000 or more) of virtual static groups.

PingDirectory Server 8.2.0.7 release notes

The release notes for the 8.2.0.7 release of PingDirectory Server.

Critical fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or **`remove-defunct-server`** tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

  The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a

reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

> ⓘ **Note:**
>
> Since this change only applies to the most recent version of **`remove-defunct-server`** and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past **`dsreplication`** and **`remove-defunct-server`** could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

- Fixed in: 8.2.0.7
- Introduced in: 7.0.0.0
- Support identifiers: DS-44591

Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-42961	To help with replication backlog analysis the replication summary monitor will now include a `replica-partial-backlog` attribute that will show how each origin replica contributes partial backlog with the `per-origin-replication-backlog` property. The `replica-partial-backlog` attribute will also show the change numbers used for the calculation.
DS-43959, DS-44924	Added new global configuration properties that can be used to impose limits on the maximum number of attributes that can be present in an add request and the maximum number of modifications in a **`modify`** request, which can be used to avoid potential denial of service attacks. Both limits are set to 1000 by default, which is likely to be adequate for all legitimate use cases, and neither property affects the number of values that may be provided for an attribute.

Ticket ID	Description
DS-44591	Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or **`remove-defunct-server`** tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed. The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology. ⓘ **Note:** Since this change only applies to the most recent version of **`remove-defunct-server`** and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past **`dsreplication`** and **`remove-defunct-server`** could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.
DS-44892	Addressed a connection error in **`remove-defunct-server`** when the tool tried to migrate secret keys on a single-instance topology (i.e., a server that is not part of a replication topology). The tool now only moves secret keys if the server is part of a topology.
DS-45032	Addressed an issue that caused **`remove-defunct-server`** to hang when performing replication artifact cleanup in non-interactive mode.
DS-45115	Fixed a Ping Directory Server performance issue involving high CPU usage when writing LDAP data to certain clients using TLSv1.3 connection security.

Ticket ID	Description
DS-45124	Removed `-XX:RefDiscoveryPolicy=1` from the default start-server Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.
DS-45154	Fixed an issue where a server with a newly initialized database (through `dsreplication initialize`) could go into lockdown mode and report that the server may have missed one or more update(s). This generally occurred only if the initialized server was restarted right after initialization completed.
DS-45190	Added support for the use of JDKs obtained through BellSoft.
DS-45449	Updated the server to create the `esTokenizer.ping` file if it does not exist for a backend containing encrypted data. This file may be needed to open the database environment for a backend containing encrypted indexes, but it would not have been automatically created when upgrading from a pre-7.0 server to a later version with support for encrypted indexes.
DS-45654	Resolved an issue where SCIM POST requests that violated a unique attribute constraint got an internal error instead of the expected SCIM error response.

PingDirectory Server 8.2.0.6 release notes

Critical fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-43576	Added the ability to retry operation failures from replication if the failures are likely due to dependent writes being played out of order. This issue only affected environments that were sending writes to different servers, and also were not able to use the appropriate level of replication assurance. To enable this setting, update the `on-replay-failure-wait-for-dependent-ops-timeout` configuration property on a replication domain.

Ticket ID	Description
DS-43632	Fixed an issue where the `format` field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43898	Addressed an issue where the backend would store an incorrect count for a database key that had exceeded the index entry limit. This would only happen for composite indexes when the server started up after not being shut down cleanly. Normal search processing was unaffected, but the matching entry count request control processing would return incorrect results.
DS-43999	Updated the server to allow the operation purpose control to be used for operations that are part of an LDAP transaction.
DS-44259	Fixed an issue that could prevent password policy state changes made through the `ds-pwp-modifiable-state-json` operational attribute from being properly replicated.

PingDirectory Server 8.2.0.5 release notes

Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-44025	Fixed an issue where the server was incorrectly displaying an `Unknown vendor` warning when using JDKs obtained on Red Hat and Ubuntu systems.
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a `must change password` state. The server will now only permit the operation if it attempts to set a new password for the target user.

PingDirectory Server 8.2.0.3 release notes

Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server.

Ticket ID	Description
DS-43926	Significantly improved the performance of delete and modify operations that require removing IDs from very large composite index ID sets.

PingDirectory Server 8.2.0.2 release notes

Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.
DS-43838	Updated the server's support for the uniqueness request control so that if a conflict prevention details entry is requested, the server may be able to use a minimal version of the proposed target entry instead of a full copy. This can help improve performance when using this option.
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the oidc-trust-store-file and oidc-trust-store-type settings. Also, you can set the console to skip hostname and/or certification verification through the oidc-strict-hostname-verification and oidc-trust-all configuration settings.

PingDirectory Server 8.2.0.1 Release Notes

Critical Fixes

Resolved Issues

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-43024	Updated the purge expired data plugin to support deleting entries with multiple concurrent threads. Deletes will still be performed in a single thread by default, and this is the recommended configuration for most deployments, but the value of the num-delete-threads configuration property may be increased if expired entries accumulate faster than a single thread can delete them.
DS-43745	Fix an issue in the server causing PingDirectory 8.2.0.0 to be incompatible with version 4.2.0 of the Delegated Admin app, which prevented upgrade to Delegated Admin version 4.4.0 without some downtime.
DS-43770	Fixed an issue that could prevent pre-operation add plugins created with the Server SDK from accessing some changes to the content of the add operation. For example, a Server SDK pre-operation add plugin could not access an attribute created by a composed attribute plugin that had been invoked before the Server SDK plugin.

PingDirectory Server 8.2 release notes

Enhancements

These are new features for this release of PingDirectory Server:

- To improve our support for containerization, PingDirectory Server can now determine that it is running in a container and stores this state in the isDocker property within the System Information monitor (cn=System Information, cn=monitor).
- The Administrative Console now supports using OpenID Connect for admin SSO, allowing you to set up the PingOne administration console to have one-click SSO access without typing a password.
- To ensure that PingDirectory Server is protected against online password guessing attacks, PingDirectory Server can now inject a delay before sending failure responses back to the client for basic HTTP authentication failures.
- The Dictionary password validator includes approximately 10,000 more entries in the dictionary file and can now check for capitalization, reversed passwords, leading or trailing non-alphabetical characters and ignore diacritical marks.

- A new operational attribute has been defined to contain information about recent successful and failed bind attempts. Also, you can configure the server to maintain recent login history such as the number of records of successful and/or failed authentication attempts.
- The **`setup`** command can now create a populated `config/tools.properties` file from the properties set either on the command or input using interactive mode. There are several modes for adding the bind password to the file. By default, no properties file is created unless the --populateToolPropertiesFile argument is used (non-interactive mode) or the option to create the file is specified while running setup.
- The **`validate-ldap-schema`** tool has been added allowing for administrators to verify any LDIF file used to create schema and/or entries and report any potential issues they may contain.
- Typically, passwords are only validated when they are set, changed or reset for an entry. However, this might lead to a weak password since these evens are infrequent. PingDirectory Server now supports the ability to periodically run password validation on bind requests. By default, this is not enabled but can be added to any password policy by setting both the bind-password-validator and the minimum-bind-password-validation-frequency properties. If, at the time of the bind, the password does not meet the specified password policies, the bind-password-validation-failure-action property specifies what action to take like requiring a password change.
- Customers want a better way to perform a sorted search on a large dataset using SCIM 2.0. In this version of PingDirectory Server, SCIM searches with the proper search parameters can be the returned in pages. The PingDirectory Server needs to be configured with Virtual List View (VLV) indexes for the desired SCIM Resource Type.
- You can now configure password policies to keep a record of recent login history, successes, and failures, per account. The possible configuration options include tracking every success and failure or collapsing to a single event per day.
- To improve logging and monitoring, administrators can now configure the Syslog, Audit Log, HTTP Operation Log, and the Sync Log to produce output in the JSON format so other tools can more easily consume the information. These log publishers are disabled by default.

Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in *Upgrade overview and considerations* on page 268.

Known issues and limitations

The following are known issues in the current version of PingDirectory Server:

When signing on to the Administrative Console, you must specify an LDAPS port in the **Server** field. For example, to use port 636, you would specify pingdirectory:636. If you do not specify a port, you get a `"Server unavailable"` message.

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-644, DS-42031	Added a new validate-ldap-schema tool that can be used to examine schema definitions in a set of LDIF files and report any issues that it detects.
DS-1766	Updated the ldap-diff tool to make it possible to control the column at which long lines should be wrapped. Previously, long lines were always wrapped at 80 characters. Now, no wrapping is performed by default, but the --wrapColumn argument can be used to enable wrapping with a specified maximum line length.
DS-5040	Improved the **`dsframework`** tool to support multivalued server properties.

Ticket ID	Description
DS-5143, DS-11035	Updated support for logging access and error log messages to a syslog server. While the server previously supported logging these messages to a syslog server (through the "syslog-based access log publisher" and "syslog-based error log publisher" logger implementations), these loggers used an older version of the syslog protocol (described in RFC 3164) and only offered support for communicating over UDP. These loggers are still available for legacy backward compatibility, but we now also offer new "syslog text access log publisher" and "syslog text error log publisher" implementations that use a newer version of the syslog protocol (syslog version 1, described in RFC 5424) and support communicating over UDP or the more reliable TCP. When using TCP, it is also possible to encrypt communication with TLS, and it is possible to configure multiple servers for better redundancy. These loggers use the same space-delimited text format as the former loggers. We also offer new "syslog JSON access log publisher" and "syslog JSON error log publisher" implementations that offer the same set of capabilities, but that format the message text as JSON objects, which can be more easily parsed by third-party software.
DS-7475, DS-7605, DS-11725, DS-37707, DS-40342, DS-41940	Made several improvements to the parallel-update tool, which can use multiple concurrent threads for improved performance when applying add, delete, modify, and modify DN changes read from an LDIF file. The enhancements include: ▪ Added support for several additional controls, including proxied authorization, manageDsaIT, ignore NO-USER-MODIFICATION, password update behavior, operation purpose, name with entryUUID, assured replication, replication repair, suppress operational attribute update, and suppress referential integrity updates. The tool also now supports specifying arbitrary controls for inclusion in add, bind, delete, modify, and modify DN requests. ▪ Made its communication more robust. The tool would previously establish connections only when it was first started, but it can now detect when a connection is no longer valid and can re-establish connections as needed to continue processing. Further, if an operation failed because it was attempted on an invalid connection, that operation can be automatically retried immediately on a newly established connection. ▪ Added support for failover directory servers. You can now provide the --hostname and --port arguments multiple times to specify information about multiple directory server instances. In the event that the first server listed is not available (or becomes unavailable in the middle of processing), it can automatically try establishing a connection to an alternative server to continue processing there. ▪ Improved the ability to determine whether all changes were processed successfully. Previously, the tool would always use an exit code of zero if it was able to attempt all of the changes read from the LDIF file, even if some of the changes were not successfully applied. That is still the default behavior, but a new --useFirstRejectResultCodeAsExitCode argument can be used to indicate that if any operations are rejected, the result code from the first rejected operation should be used as the exit code. ▪ Added support for encrypted LDIF files. If the LDIF file was encrypted with a key from the server's encryption settings database, then the tool will automatically attempt to retrieve the appropriate key. Otherwise, the new --encryptionPassphraseFile argument can be used to supply the encryption passphrase, or the passphrase can be interactively requested from the user. ▪ The tool is now parallel by default. Previously, if you did not specify a value for the --numThreads argument, it would use a single thread. It now defaults to using eight threads. ▪ The tool now provides a --followReferrals argument that allows it to automatically attempt to follow any referrals that are returned. ▪ The tool now provides a menu-driven interactive mode that can be used to provide values for all of the command-line arguments.

Ticket ID	Description
DS-10320, DS-12550, DS-12551, DS-12552, DS-42116, DS-42162, DS-42179, DS-42222, DS-42223, DS-42224, DS-42225, DS-42416, DS-42437	Added a config/sample-dsconfig-batch-files directory with set of well commented dsconfig batch files that may be useful in enabling or configuring a variety of features in the server.
DS-10775	Updated the dictionary password validator to support additional options: ▪ It can now ignore non-alphabetic characters that appear at the beginning or end of the password before checking the dictionary. ▪ It can strip characters of diacritical marks, including accents, cedillas, circumflexes, diaereses, tildes, and umlauts, before checking the dictionary. If this option is used, then any character with such a mark will be replaced with a base version of the character without that mark (for example, a lowercase letter n with a tilde over it would be replaced with just a lowercase letter n). ▪ You can define maps with information about character substitutions to use for checking alternative versions of the provided password. For example, if you indicate that "0" might map to "o", "1" or "!" might map to "i", "7" might map to "t", and "3" might map to "e", then the validator can reject a proposed password of "pr0h1b!73d" if the dictionary contains the word "prohibited". ▪ It can reject a proposed password if a value from the provided dictionary makes up more than a specified percentage of that password.
DS-11524, DS-41860, DS-42112	Added support for new administrative alert types: ▪ We have added a new admin alert account status notification handler, which can generate administrative alerts whenever an applicable account status notification is generated within the server. For example, this account status notification handler can be added to the root password policy to generate an alert whenever a root user's password is updated or their account is locked as a result of too many failed authentication attempts. A separate alert type has been defined for each account status notification type. ▪ We have added a new "privilege-assigned" administrative alert that can be raised whenever a new entry is added or an existing entry is updated to include one or more privileges. ▪ We have added a new "insecure-request-rejected" administrative alert that can be raised whenever the server rejects a request as a result of the reject-insecure-requests global configuration property.
DS-13853	Added support for the OAUTHBEARER SASL mechanism (as described in RFC 7628) to allow LDAP clients to authenticate with OAuth 2.0 bearer tokens.
DS-15123	Updated the password policy to add support for maintaining a history of recent successful and failed bind attempts for each account. A new "get recent login history" control can be used to obtain this history during a successful bind, and it can also be obtained from the ds-pwp-state-json virtual attribute or the password policy state extended operation.

Ticket ID	Description
DS-15848, DS-42360	Added support for invoking a specified set of password validators during bind operations. If the password used to authenticate fails to satisfy one or more of the configured validators, the bind attempt can be rejected, the user can be forced to change their password, or the server can generate an account status notification to take some alternative action (for example, notifying the end user or server administrators).
DS-15864	Replaced the ldappasswordmodify tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.
DS-17422, DS-37387	Added a new "Modifiable Password Policy State" plugin with support for a new ds-pwp-modifiable-state-json operational attribute whose value is a JSON object with fields that reflect elements of the associated user's current password policy state. Authorized clients may replace the value of that attribute (with a modify request using LDAP or with a PUT or PATCH request using the Directory REST API) to update that user's password policy state. Elements of the password policy state that may be updated include: ▪ The time the user's password was last changed ▪ The user's account activation time ▪ The user's account expiration time ▪ The user's password expiration warned time ▪ Whether the account is administratively disabled ▪ Whether the account is locked as a result of too many failed authentication attempts ▪ Whether the user will be required to change their password before they will be allowed to perform any other operations
DS-17664	Fixed an issue that could cause the server to return the password expired control (as defined in draft-vchu-ldap-pwd-policy) in response to a bind request that included invalid credentials. The server will now only return that control if the provided credentials were valid. The password policy configuration has also been updated to make it possible to better specify when the server should return the password expired or password expiring control. Previously, the server would only return these controls if the bind request did not include the password policy request control (as defined in draft-behera-ldap-password-policy), as the response to that control may also indicate whether the user's password is expired or is about to expire. This is still the default behavior, but it is now possible to configure the server to return the password expired or password expiring control when appropriate, even if the password policy response control will also be returned. Alternatively, the server can be configured to never return the password expired or password expiring controls.
DS-17903	Updated setup to provide a --populateToolPropertiesFile argument that will allow it to populate the config/tools.properties file with default values for command-line tool arguments. If requested, properties will be provided for the server address, port, and communication security, and may also include a default bind DN and optionally a bind password. When running setup interactively, it will now prompt to determine which properties (if any) should be populated in the properties file.

Ticket ID	Description
DS-36088	Updated the crypto manager to make it possible to augment the set of enabled TLS cipher suites with specific suites to add to or remove from the default set of enabled suites. To enable one or more suites in addition to those in the default set, prefix the names of those suites with the "+" symbol. To disable one or more suites in the default set of enabled suites, prefix the names of those suites with the "-" symbol. This was already possible when configuring cipher suites for the LDAP and HTTP connection handlers, but it was not an option for the crypto manager.
DS-38110	Updated the System Information monitor with an "isDocker" attribute to identify if the server is running in a Docker container.
DS-38118, DS-42495	Made several updates related to the server's handling of data written to standard output and standard error: ▪ The server can now be configured to rotate the logs/server.out file once it reaches a given size, and it will retain a configurable number of those log files. By default, the server will rotate the file once it reaches 100 megabytes and will keep up to ten files. ▪ To better facilitate capturing log data in containerized environments, the server now supports writing JSON-formatted access and error log messages to the JVM's original standard output and error streams (which will be separate from the server.out file when the server is started with the --nodetach argument). ▪ It is now possible to prevent the server from logging messages during startup in non-JSON format. It is also possible to prevent messages about administrative alerts from being written to standard error, or to write those messages in JSON format. These options are especially useful when using JSON-based logging to the console in no-detach mode, as they can help ensure that everything written to standard output and standard error will be formatted as JSON objects.
DS-38816, DS-41995	Updated support for the uniqueness request control to provide a more reliable mechanism for preventing conflicts that arise from operations processed concurrently in the same or different servers. If indicated in the request control, a temporary conflict prevention details entry can be added to the server before searching for existing conflicts, and that entry can be detected during pre-commit processing for other operations with uniqueness request controls that attempt to make a conflicting change. The server has also been updated to make it possible to generate an administrative alert if a uniqueness conflict is detected during post-commit processing for the uniqueness request control. Even though the conflict cannot be prevented at this stage in processing, the alert can let administrators know about it as soon as it happens so they can take any appropriate corrective action.
DS-38868	Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

Ticket ID	Description
DS-39257	The **`dsreplication enable`** subcommand options `--preferredID1` and `--preferredID2` allow you to specify a preferred value for new replicationIDs for the first and second server respectively. By default, replication IDs are randomly chosen. The lowest unused value that is greater than or equal to the value specified is used, subject to being even or odd as required. Replication server IDs must be even, and replicaIDs must be odd. Each value specified must be in the range [0, 32766] inclusive. If the maximum value is reached while searching, the search wraps to 0.
DS-39789	Updated the JVM memory usage monitor provider to fix an issue that could prevent the monitor from reporting the total amount of memory held by all memory consumers. Also, fixed an issue that could cause the memory-consumer attribute to use an incomplete message for consumers without a defined maximum size and added an additional memory-consumer-json attribute whose values are JSON objects with data that can be more easily extracted by automated processes.
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-40967	Eliminated a misleading error message that could be logged at startup if the server was configured with one or more ACIs that only apply when using specific SASL mechanisms.
DS-41228	Missing changes will now be detected when the backend is reverted and there are insufficient changes in the changelog database. When in this particular missing changes state the local replica will not accept changes from the local replication server.
DS-41230	To assist with recovering from the split-brain state the "dsreplication initialize" command will have a new "--force" option that overrides the lockdown check.
DS-41350	Fixed an issue where disabling certain backends (such as 'alarms') caused an internal monitor to log unnecessary error messages every few seconds, about not being able to gather data from that backend. Note that deliberately disabling the 'alarms' backend is not recommended in normal operation, but may occur during backup/restore operations.
DS-41521	The SCIM 2 service on PingDirectory and PingDirectoryProxy now automatically generates a Swagger 2 specification document based on the server's SCIM 2 configuration. To view this document, go to https://<your-server>/api-docs in a web browser.
DS-41707	To help with multi-tenant and delegated admin ACI parameterization implement the ($attr.attrName) macro. In particular the ($attr.attrName) macro can be used to build bind DNs.
DS-41865	PingDirectory and PingDirectoryProxy can now perform SCIM 2 paged searches on result sets greater than the configured lookthrough limit. To perform such a search, you must first configure a virtual list view (VLV) index.

Ticket ID	Description
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-41989	Fixed an issue that could result in duplicate column headers being produced by the Periodic Stats Logger, even when the header-prefix-per-column attribute was set to true.
DS-42045	Updated the Stats Collector Plugin with a new generate-collector-files configuration property. When using the plugin exclusively for providing metrics to one or more StatsD Monitoring Endpoints, set this property to false to prevent unnecessary I/O.
DS-42059, DS-42060	Updated setup to add options for improving communication security: ▪ Non-interactive setup now offers a --rejectInsecureRequests argument that will configure the server to reject any request received over a connection that is not encrypted with SSL or StartTLS. ▪ Non-interactive setup now offers a --rejectUnauthenticatedRequests argument that will configure the server to reject any request received over a connection that is not authenticated (or that is authenticated as the anonymous user). ▪ Interactive setup now allows you to configure the server with the LDAP connection handler disabled (which was already an option when using non-interactive setup), or enabled but only for communication encrypted with StartTLS. The --rejectInsecureRequests and --rejectUnauthenticatedRequests arguments can also be used with manage-profile by including them in the setup-arguments.txt file of the server profile.
DS-42061	Updated the interactive command-line tool framework to prefer establishing secure LDAP connections over insecure connections. Previously, when prompting for the information needed to establish a connection, the default option was to create an unencrypted LDAP connection. Now, tools will default to creating an SSL-encrypted connection if the server supports it, or to creating a StartTLS-encrypted connection if that is available but SSL is not. Tools will also default to using streamlined settings when establishing secure connections. Previously, they would always prompt about how to determine whether the server's certificate chain should be trusted. When using the streamlined settings, the tools will only prompt about certificates that cannot automatically be considered trusted using information in the JVM's default trust store, the server's default trust store (config/truststore), or the server's topology registry.
DS-42062	Updated the root password policy so that LDAP bind responses for root users and topology administrators will be delayed by one second after five consecutive failed authentication attempts.
DS-42063	Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non-LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.

Ticket ID	Description
DS-42115	Updated the server's command-line tool framework to make it easier and more convenient to communicate with the server over a secure connection when no trust-related arguments are provided. Most non-interactive tools will now check the server's default trust store, the topology registry, and the JVM's default trust store to see if the presented certificate chain can be automatically trusted without the need to prompt the user. If the presented chain cannot be automatically trusted, the user may be interactively prompted to determine whether it should be trusted.
DS-42157, DS-43033	Updated the CRAM-MD5 and DIGEST-MD5 mechanism handlers so that they are no longer considered secure. Although the credentials are encoded in transit, their protection relies on the weak MD5 digest. Further, they require that user passwords be encoded in a reversible form so the server can retrieve them in the clear for use in authentication processing, which increases the risk that they will be exposed in a data breach. This primarily affects the ability to use these SASL mechanisms over an unencrypted connection for users that are required to authenticate in a secure manner (for example, if their password policy has require-secure-authentication set to true, or if their entry has a ds-auth-require-secure-authentication operational attribute with a value of true). These SASL mechanisms are still enabled by default for legacy backward compatibility purposes, but we discourage their use. To assist with that, we have also provided a sample dsconfig batch file that can be used to disable these SASL mechanism handlers.
DS-42164, DS-43015	Added a new AES256 password storage scheme that can encode passwords with 256-bit AES encryption. Although non-reversible schemes are recommended in most deployments, reversible schemes may be necessary under certain circumstances, and the new scheme provides support for stronger encryption and better integrity protection than the existing 128-bit AES scheme. The key used to encrypt passwords will be derived from an encryption settings definition. Clients with access to an AES256-encoded password and the passphrase used to encrypt it may obtain the original plaintext representation of the password. The UnboundID LDAP SDK for Java provides support for decoding and decrypting these passwords through the AES256EncodedPassword class, and the Javadoc for that class provides documentation that may be used to implement support those passwords in other programming languages.
DS-42199	Optimized some searches commonly used by the status tool. This should improve the performance of the tool in more complex or large-scale environments.
DS-42265	Upgrade to jetty 9.4
DS-42276	Fixed an issue where using the encryption-settings tool to import definitions with the set-preferred flag could result in none of the imported definitions being set as the preferred definition.
DS-42279	Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.
DS-42298	Replaced the ldifsearch, ldifmodify, and ldif-diff command-line tools with more full-featured and robust implementations.
DS-42331	Replaced the ldapcompare tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).

Ticket ID	Description
DS-42347	Updated the server to use /dev/urandom (on non-Windows systems where that path exists and is readable) instead of /dev/random as the primary source for secure random data. Attempts to read from /dev/random can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from /dev/urandom will not block, and the data that it provides is no less secure than data from /dev/random in any way that matters for the server.
DS-42349, DS-43209, DS-43210, DS-43323, DS-43324	Added support for JSON-formatted audit loggers, which complement the existing file-based LDIF-formatted error logger. The JSON-formatted audit log messages provide a record of changes to data in the server and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server. Added support for JSON-formatted HTTP operation loggers, which complement the existing file-based loggers using the W3C common log format and a proprietary space-delimited text format. The JSON-formatted HTTP operation log messages provide a record of interaction with HTTP clients and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server. Fixed an issue that caused JSON-formatted loggers to use a timestamp format that was not strictly compliant with the ISO 8601 format described in RFC 3339. Timestamps incorrectly omitted the colon between the hour and minute components of the time zone offset.
DS-42362	Fixed an issue in which the server could incorrectly evaluate a matched values request control containing an extensible match filter that specified both an attribute type and a matching rule. The server incorrectly used the attribute type's equality matching rule instead of the matching rule specified in the filter.
DS-42373	Fixed an issue where unindexed LDAP searches filtered on virtual attributes sometimes omitted objectClass from the returned result.
DS-42381	Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.
DS-42405	Fixed an issue that could raise an internal error when trying to undelete a non-soft-deleted entry.
DS-42438	Fixed an issue that could cause the remove-defunct-server tool to not remove certain replication attributes when run with a topology json file.
DS-42504	Updated manage-profile replace-profile to set encryption settings definitions defined in the newer server profile as preferred in the encryption settings db.
DS-42505	Previously, even if LDAP SDK debug logging was enabled, messages would be suppressed while running dsreplication. Now if LDAP SDK debug logging is enabled, messages will get printed to the console while running dsreplication.
DS-42527	Fixed an issue that could cause an exception when creating a resource in SCIM 1.1 using certain types of DNTemplate.
DS-42547	Fixed an issue where manage-profile generate-profile would print "null" as the generated profile directory when writing to an existing directory.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.

Ticket ID	Description
DS-42609	Fixed an issue in which the Consent API could fail to decode certain credentials when using basic authentication.
DS-42632	Added support for creating or importing a key pair configuration object using an elliptic curve (EC) key algorithm. You can use this to designate the encryption key pair for a JWT access token validator that handles EC-encrypted access tokens.
DS-42634	The JWT Access Token Validator can now validate JWT access tokens signed using the elliptic curve digital signature algorithms ES256, ES384, and ES512.
DS-42635	The JWT Access Token Validator can now validate JWT access tokens encrypted using elliptic curve cryptographic algorithms. The following key encryption algorithms are now supported in addition to RSA-OAEP: ECDH-ES, ECDH-ES+A128KW, ECDH-ES+A192KW, and ECDH-ES +A256KW. To support best practices for JWT security, you must now also configure the JWT Access Token Validator with explicit allow lists for key encryption and content encryption algorithms. For backward compatibility, the key encryption allow list defaults to RSA-OAEP, while the content encryption allow list defaults to A128CBC-HS256, A192CBC-HS384, and A256CBC-HS512. We recommend setting both allow lists to the strict minimum set of algorithms needed by the Access Token Validator.
DS-42651	Updated the manage-profile replace-profile subcommand to better support updating the server's keystore and truststore files. When using the --generateSelfSignedCertificate argument in a server profile's setup-arguments.txt file, the server will maintain the original keystore and truststore files during replace-profile. Otherwise, replace-profile will use the keystore and truststore specified in the profile's setup-arguments.txt file.
DS-42667	Updated the server to set a unique cluster name when started for the first time.
DS-42669, DS-42748	Updated the online dsconfig step of the manage-profile replace-profile subcommand to support getting LDAP connection arguments from a tools.properties file on the server being updated. Fixed an issue where boolean LDAP connection arguments like --useSSL and --trustAll would cause manage-profile replace-profile to fail when applying dsconfig online.
DS-42673	Updated the manage-profile setup subcommand to fail if the start-server command has a non-zero exit code.
DS-42681, DS-42684	Performance statistics generated by the Sideband API can now be published by the Periodic Stats Logger. To enable this, use the "included-http-servlet-stat" property of the Periodic Stats Logger.
DS-42687	Upgrade to Jetty 9.4.30
DS-42720	Updated the ds-pwp-state-json virtual attribute provider to include information about the requirements that passwords must satisfy for adds, self password changes, administrative password resets, and binds.
DS-42740	Fixed an issue where the **`dsconfig ilst`** subcommand would not display requested properties.

Ticket ID	Description
DS-42749	To support best practices for JWT security, you must now configure the JWT Access Token Validator with an explicit list of the JWT signing algorithms that it accepts. For backward compatibility, this list defaults to the RSA signing algorithms RS256, RS384, and RS512, but we recommend setting this list to the strict minimum set of signing algorithms needed by the Access Token Validator.
DS-42751	Added new override-status-code and additional-response-contents attributes to the Availability State HTTP Servlet Extension. These new attributes can be used to customize the response code and JSON response body of the servlet.
DS-42756	Fixed a bug where backup retention attempted to purge old backups out of order, which lead to errors.
DS-42790	Fixed an issue where new replicas incorrectly went into lockdown mode after initialization. This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.
DS-42815	Added a remove-attribute-type-from-schema tool that can be used to safely remove an attribute type definition from the server schema. It will ensure that the attribute type is not in use, and it will clean up metadata references to that attribute type that could have previously required re-importing the data before the attribute type could actually be removed from the schema. The remove attribute type processing can also be requested programmatically through an administrative task.
DS-42834	Fixed an issue that could inappropriately allow HTTP-based clients (for example, those using SCIM, the Directory REST API, or the Consent API) to issue requests when the server is in lockdown mode.
DS-42850	Fixed a typo in the password-expiring template that caused "password_expiration_time_of_day" to be printed instead of the password expiration time.
DS-42861	Updated the manage-profile tool logs to include the duration of each step the tool takes. The new --verbose argument can also be used to display timing information in the tool's console output.
DS-42865	Added an aggregate identity mapper that uses Boolean AND or OR combinations of other identity mappers.
DS-42866	Updated the exact match and regular expression identity mappers to make it possible to only include entries matching a given filter.
DS-42872	Added a JSON-formatted stats logger to the server's default configuration. The stats logger is disabled by default.
DS-42886	Updated non-interactive setup (including manage-profile setup) to allow the password for the initial root user to be provided in pre-encoded form using the PBKDF2, SSHA256, SSHA384, or SSHA512 password storage scheme. This eliminates the need to have access to the clear-text password when setting up the server.

Ticket ID	Description
DS-42922	Fixed a bug where restoring an incremental backup could result in the server not being able to start.
DS-42926	Fixed an issue where Ping Directory products configured to run as Microsoft Windows services were sometimes unable to automatically restart following an unplanned reboot, due to errors reading a corrupted server status file.
DS-42939	The Administrative Console configuration settings have been updated to account for the new SSO functionality.
DS-42952	For Windows only, there can be a hang on start when global configuration property `startup-error-logger-output-location` is set to values that contain `standard-error`. For Windows only, `standard-error` values are silently mapped to equivalent `standard-output` values.
DS-42963	Updated the manage-profile generate-profile subcommand to ignore files larger than 100 megabytes when generating a server profile. Fixed an issue where many large files in the server root could cause the tool to run out of memory.
DS-43027	Added a new --adminPasswordFile argument to the manage-topology add-server command, to allow specifying the administrator password with a file rather than with the command line.
DS-43043	Fixed an issue where paged subtree searches posted to the Directory Rest API failed with error message: "Unable to decode the cookie in the simple paged results control value", whenever the search returned entries with DN length approaching or exceeding 127 characters.
DS-43047	Fixed an issue that could result in isMemberOf and isDirectMemberOf attributes not being updated appropriately when updating groups with multiple threads.
DS-43064	Fixed an issue that caused the server to return an objectClassViolation result code instead of the more appropriate attributeOrValueExists result code when trying to modify an entry to add an object class that already exists in that entry.

Ticket ID	Description
DS-43068	Added a new export-reversible-passwords tool that can be used to create an LDIF export containing the clear-text representations of reversibly encoded passwords. The export may optionally include non-password attributes from the entries, entries containing non-reversible passwords, and entries without passwords. This tool can be used to help rotate the keys used to encrypt passwords if the need arises. There are a number of safeguards in place to help ensure that this tool cannot be used inappropriately. These include: ▪ The tool invokes the export over LDAP and therefore requires that the server be online. It cannot be invoked with the server offline. ▪ The tool can only be invoked by a user with the permit-export-reversible-passwords privilege. This privilege is not granted to any users (even root users) by default. ▪ The tool can only be used if the server is configured with an instance of the "export reversible passwords" extended operation handler. The requester must also have access control permission to invoke this extended operation. ▪ The tool can only be run from the server system itself and the request must be received over the loopback interface. The export cannot be requested by a remote client. ▪ The request must be issued over a secure connection. ▪ The output file will be written to the server filesystem. It may only be written to a file that is beneath the instance root, and that file must not already exist (although its parent directory must exist). ▪ The exported file will be encrypted using the UnboundID LDAP SDK for Java's PassphraseEncryptedOutputStream, using a key generated from either a user-supplied passphrase or an encryption settings definition. This encrypted file may be directly imported by the import-ldif tool. If the contents of the file are needed, the LDAP SDK may be used to access its contents programmatically, or the encrypt-file tool may be used to decrypt it. ▪ The server will generate administrative alert notifications whenever it begins and ends the export process.
DS-43073, DS-43198	Added support for ID Token Validators, which validate the integrity and content of ID tokens issued by OpenID Connect providers. Use these validators with the OAuth Bearer SASL Mechanism Handler to enable single sign-on (SSO) for the Administrative Console using an OpenID Connect provider such as PingOne. Currently, only PingOne is supported for SSO.
DS-43074	Added three built-in identity mappers that you can use to look up administrative accounts stored in the server configuration: Root DN Users, Topology Admin Users, and All Admin Users.

Ticket ID	Description
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: ▪ When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. ▪ When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. ▪ When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.
DS-43305	Increased the maximum number of RDN components that a DN may have from 50 to 100.
DS-43376	Updated log publisher logic to reduce the amount of CPU that the server consumes when it is idle.
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43517	Updated the jose4j library used for JWT signing and encryption to version 0.7.2.
DS-43651	The Security Guide is now available online at pingidentity.com. The guide has been removed from the server packaging.
DS-43666	Fixed an issue in which a server in lockdown mode could incorrectly allow an operation to be processed if a connection authenticated as a user with the lockdown-mode privilege issued a request with an alternate authorization identity that did not have the lockdown-mode privilege. The server now requires that both the authentication and authorization identities have the lockdown-mode privilege.

Critical fixes

Critical Fixes

Critical Fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue that could inappropriately allow HTTP-based clients (for example, those using SCIM, the Directory REST API, or the Consent API) to issue requests when the server is in lockdown mode.
  - Fixed in: 8.2.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-42834
- Fixed an issue where new replicas incorrectly went into lockdown mode after initialization.

  This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.
  - Fixed in: 8.2.0.0
  - Introduced in: 8.1.0.0
  - Support identifiers: DS-42790 SF#00695648
- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-41762 SF#00675207 SF#00683777
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.3.0.0
  - Support identifiers: DS-40955
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788

- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

  In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

  We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': InvalidKeyException: The provided passphrase is invalid."

  - Fixed in: 7.2.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-37313
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that

were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.

  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

  The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.6
  - Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.

  - Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.

  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the

changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.

  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.

  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where

  1) Server B had not received changes directly from a client for a long time (beyond the purge delay),

  2) Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,

  3) Server A is shutdown, and

  4) While Server A is shutdown, the Server B processes one or more changes directly from the client.

  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).

  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.

  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3

  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an IllegalStateException that references "exploded-index-background-deletes" when there are several backend exploded indexes.
  - Fixed in: 6.0.0.0
  - Introduced in: 4.6.0.0
  - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
  - Fixed in: 5.0.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

  SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered

secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782
- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
  - Fixed in: 4.6.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-10470
- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
  - Fixed in: 4.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-9268 SF#2002
- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
  - Fixed in: 4.0.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing get-changelog-batch-requests at the same time that live traffic is happening.
  - Fixed in: 3.6.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-5656

- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
  - Fixed in: 3.2.0.0
  - Introduced in: 3.1.0.0
  - Support identifiers: DS-3592

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where new replicas incorrectly went into lockdown mode after initialization.

  This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.

  Fixed in: 8.2.0.0

  Introduced in: 8.1.0.0

  Support identifiers: DS-42790 SF#00695648
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.3.0.0
  - Support identifiers: DS-40955
- Fixed a memory leak when performing SCIM queries on the PingDirectory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788

- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

  In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

  We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period.   - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.

  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

  The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.6
  - Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.

  - Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.

  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3

The release notes for the 8.1.0.6 release of PingDirectory Server.

Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-42961	To help with replication backlog analysis, the replication summary monitor now includes a 'replica-partial-backlog' attribute that shows how each origin replica contributes partial backlog with the 'per-origin-replication-backlog' property. The 'replica-partial-backlog' attribute also shows the change numbers used for the calculation.
DS-43898	Addressed an issue where the backend would store an incorrect count for a database key that had exceeded the index entry limit. This only happened for composite indexes when the server started up after not being shut down cleanly. Normal search processing was unaffected, but the matching entry count request control processing would return incorrect results.

Ticket ID	Description
DS-43959, DS-44924	Added new global configuration properties that can be used to impose limits on the maximum number of attributes that can be present in an **`add`** request and the maximum number of modifications in a **`modify`** request, which can be used to avoid potential denial of service attacks. Both limits are set to 1000 by default, which is likely to be adequate for all legitimate use cases, and neither property affects the number of values that can be provided for an attribute.

PingDirectory Server 8.1.0.5 release notes

Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: * When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. * When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. * When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43576	Added the ability to retry operation failures from replication if the failures are likely due to dependent writes being played out of order. This issue only affected environments that were sending writes to different servers, and also were not able to use the appropriate level of replication assurance. To enable this setting, update the on-replay-failure-wait-for-dependent-ops-timeout configuration property on a replication domain.
DS-44037	Avoid lockdown due to missing changes during enable caused by a missing timestamp that indicates the enable time. The problem resulted in change numbers and error messages with dates around the year 1970.
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

PingDirectory Server 8.1.0.2 Release Notes

Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where new replicas incorrectly went into lockdown mode after initialization. This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.
  - Fixed in: 8.1.0.2
  - Introduced in: 8.1.0.0
  - Support identifiers: DS-42790 SF#00695648

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.3.0.0
  - Support identifiers: DS-40955
- Fixed a memory leak when performing SCIM queries on PingDirectory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': InvalidKeyException: The provided passphrase is invalid."
  - Fixed in: 7.2.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-37313
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.6
  - Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
  - Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942

- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216

- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an IllegalStateException that references "exploded-index-background-deletes" when there are several backend exploded indexes.
  - Fixed in: 6.0.0.0
  - Introduced in: 4.6.0.0
  - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
  - Fixed in: 5.0.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.
  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782
- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
  - Fixed in: 4.6.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-10470
- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
  - Fixed in: 4.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-9268 SF#2002

- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
  - Fixed in: 4.0.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing get-changelog-batch-requests at the same time that live traffic is happening.
  - Fixed in: 3.6.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-5656
- Update PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
  - Fixed in: 3.2.0.0
  - Introduced in: 3.1.0.0
  - Support identifiers: DS-3592

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.

Ticket ID	Description
DS-42438	Fixed an issue that could cause the remove-defunct-server tool to not remove certain replication attributes when run with a topology json file.
DS-42687	Upgrade to Jetty 9.4.30
DS-42790	Fixed an issue where new replicas incorrectly went into lockdown mode after initialization. This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.

PingDirectory Server 8.1 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of PingDirectory Server:

> ⓘ **Important:**
>
> If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

- If you have upgraded a server that is in a cluster (that has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you can create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- The bypass-pw-policy privilege was intended to provide a way for administrators to bypass certain password restrictions that would normally be imposed when managing passwords for other users. A user with this privilege could use it to bypass password validation for their own entry. The bypass-pw-policy privilege now only applies when changing another user's password (that is, an administrative password reset), and only in the following scenarios:
  - A user with this privilege will be permitted to set pre-encoded passwords.
  - A user with this privilege will be permitted to set passwords that would otherwise be rejected by one or more password validators.
  - A user with this privilege will be permitted to set passwords that match the current password or that are in the password history.

  The privilege will only apply when changing the password for another user, and it will have no effect for a self password change. Further, a user with this privilege will no longer be exempted from any other restrictions in their own password policy. Before upgrading, you should search for users that have

the bypass-pw-policy privilege and check for compatibility issues. You can use the existing password validators and a custom password policy to enforce passwords for administrative users.

- Missing changes will now be detected when the backend is reverted and there are insufficient changes in the changelog database. When in this particular missing-changes state the local replica will not accept changes from the local replication server.
- Fixed an issue in which the server could incorrectly evaluate a matched values request control containing an extensible match filter that specified both an attribute type and a matching rule. The server incorrectly used the attribute type's equality matching rule instead of the matching rule specified in the filter.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.
- Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.

Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.3.0.0
  - Support identifiers: DS-40955
- Fixed a memory leak when performing SCIM queries on PingDirectory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1

    Introduced in: 5.2.0.0

    Support identifiers: DS-41301

- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
  - The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38344 SF#00655578
  - The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38335 SF#00655578
  - Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
    - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
    - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

    In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Furthermore, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular

users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908

The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

- Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
- Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': InvalidKeyException: The provided passphrase is invalid."
  - Fixed in: 7.2.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-37313
- Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
  - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been

inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

- When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

  The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.6
  - Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
  - Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942

What's New

These are new features for this release of PingDirectory Server:

- The collect-support-data tool will now collect additional files if Delegated Admin is configured within PingDirectory Server. These files include the `config.js` configuration file, the version file, and any custom files used to create customized UI fields. This information can be useful when troubleshooting issues with the Delegated Admin application.
- In an ongoing effort to improve the use of containers for PingDirectory Server, several features have been implemented:

  - The --outputFile option has been added to the collect-support-data tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the collect-support-data tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.

    - For the **`collect-support-data`** tool, you can now specify either a path, a file name, or a path and file name for the resulting csd file. This means an administrator can run the **`collect-support-data`** tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
    - The **`collect-support-data`** tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
    - The **`manage-profile`** command used for creating server profiles can also be run as a recurring task from the Administration Console. Running **`manage-profile`** as a task creates an archive file that can be downloaded with the HTTP File Servlet. This allows updated server profiles to be created from PingDirectory Server running in a container.
    - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this and the --remoteServer option added to the **`collect-support-data`** tool itself can be used to send the request to another server. In other words, you can now run **`collect-support-data`** on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- The SCIMv2 REST API was added to PingDirectory Server 8.0. Now developers can "join" separate objects into one query that allows PingDirectory Server to present distinct objects in LDAP as a single SCIM Resource object. There are two general scenarios where this functionality will be used:

  - Primary and Secondary resources, where the secondary resource is represented as a field of the primary resource
  - Composite resources, where the SCIM endpoint server stitches together scattered data into a coherent resource with which the user can interact
- PingDirectory Server has a Consent REST API that allows users to create and store consents. This new feature now allows users to search for consents that have been granted to them by another party.
- PingDirectory Server now supports the ability to create composed attributes that are derived from other attributes like virtual attributes. However, composed attributes can be stored in the backend, they are persistent and can be indexed.
- To address the need for clients to obtain information about account and password policy states, a new virtual attribute Password Policy State JSON, that is a JSON object, provides read-only access to a number of account state and password policy state properties. Since the value is a JSON object, it should be easily consumable by HTTP clients using SCIM and the Directory REST API.
- PingDirectory Server currently has an HTTP file servlet extension that can be used to access files on the server filesystem. This can be used for several purposes such as serving static HTML pages. In this version, the HTTP file servlet now supports basic authentication. Users can authenticate with either a distinguished name or username. Additionally, a new file servlet will be configured automatically when creating a PingDirectory Server instance. This servlet will have as the base directory the install directory for the instance and can be used to access items such as configuration, log files, and

backups.. Directory indexing is enabled so you can browse available files. When using this file servlet, authentication is required, and access is restricted to users with the file-servlet-access privilege.

- To assist with recovering from the split-brain state the "dsreplication initialize" command will have a new "--force" option that overrides the lockdown check.
- Missing changes will now be detected when the backend is reverted and there are insufficient changes in the changelog database. While in this particular missing-changes state, the local replica will not accept changes from the local replication server.

Known Issues/Workarounds

The following are known issues in the current version of PingDirectory Server:

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.

Ticket ID	Description
DS-1103,DS-41138,DS-41956,DS-41957	Updated the password policy configuration to add support for alternate failure lockout actions, which can customize the behavior the server exhibits for an account with too many outstanding authentication failures. Available implementations include: * A "Lock Account" action that will prevent the user from authenticating or from being used as an alternate authorization identity. This matches the behavior that the server exhibited in the past when the password policy was configured to lock accounts after too many failed authentication attempts, and it remains the default behavior unless an alternative is configured. * A "Delay Bind Response" action that will allow the user to authenticate if they provide the correct credentials and their account is not otherwise unusable, but it will delay the bind response (regardless of its ultimate success or failure) by a specified duration to limit the rate at which an attacker can attempt to guess the password. The account will be permitted as an alternate authorization identity without any delay imposed for those operations. * A "No Operation" action that will not prevent or otherwise interfere with the ability to use the account to authenticate or as an alternate authorization identity, but it will still be reported as having too many failed authentication attempts for the purposes of account status notifications, the password policy state extended operation, and the password policy state JSON virtual attribute.
DS-10216	Updated the GSSAPI SASL mechanism handler to support integrity and confidentiality protection for client communication.

Ticket ID	Description
DS-11505	Changed the behavior the server exhibits for users with the bypass-pw-policy privilege. Although this privilege was primarily intended to allow administrators to be exempted from certain password policy restrictions while managing other user accounts, it also previously exempted the user from restrictions that should be imposed by their own password policy. As a result of these changes, the bypass-pw-policy privilege now only permits the following: * An account with this privilege will be permitted to set pre-encoded passwords in other user entries, regardless of the value of the allow-pre-encoded-passwords setting in the target user's password policy. This does not apply when the privileged user is changing their own password. * An account with this privilege will be permitted to set passwords in other user entries that would otherwise be rejected by one or more password validators configured in the target user's password policy. This does not apply when the privileged user is changing their own password. * An account with this privilege will be permitted to set passwords in other user entries when the new password is in the target user's password history. This does not apply when the privileged user is changing their own password. If the previous behavior (in which a privileged user is not subject to password policy restrictions for their own account) is desired, the user should be assigned a password policy that is not configured with the restrictions that are not wanted.
DS-36573	The minimum required heap size for installing PingDirectory Server has been increased to 768 MB. Other product sizes are unchanged.
DS-36726	Improved performance when adding entries that match very large composite index keys.
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.

Ticket ID	Description
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-38585	Added gauge "Replication Purge Delay" in order to protect against missing changes. The new gauge will have a warning and critical threshold with respect to the effective purge delay, which can be configured by selecting "Gauges" in dsconfig.
DS-38790	Added support for a new ds-pwp-state-json virtual attribute, whose value is a JSON object that provides information about the state and configuration for the password policy with which that entry is associated.
DS-38879	Added a populate composed attribute values task that can be used to update existing entries with composed attribute values without the need to export data to LDIF and re-import. A command-line tool to invoke the task is also provided.
DS-38879	Added a "composed attribute" plugin that allows creating attributes whose values are constructed from the values of other attributes in the same entry. Its behavior is similar to that of the constructed virtual attribute, but composed values are actually stored in the entry rather than being dynamically generated at the time the entry is retrieved, and therefore may be indexed. Composed attribute values may be generated when entries are created by LDAP add operations or in an LDIF import, and their values may be updated if the source attributes are changed by modify or modify DN operations.
DS-39238	Updated the attribute value password validator to provide the ability to specify a minimum substring length when determining whether to reject a proposed password because it contains the value of another attribute in the entry.
DS-39442	Added the X-Frame-Options header in the Administrative console to prevent clickjacking attacks.

Ticket ID	Description
DS-39539,DS-41417,DS-41478	Fixed an issue where the manage-profile replace-profile subcommand was unable to create new local DB backends through dsconfig. Also fixed an issue where replace-profile could not export and re-import data from a server with multiple backends.
DS-39649,DS-40115	Optimized the searches for replication data performed by the status tool.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-39911	Updated the character set password validator to make it possible to require that a proposed password contain characters from at least a specified minimum number of character sets. For example, you may define four optional sets containing lowercase letters, uppercase letters, numeric digits, and symbols, and then require that proposed passwords include characters from at least three of those sets.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.
DS-40379	Fixed an issue that could cause the load-balancing-algorithm-name configuration property of a directory server instance to be lost when joining a topology.
DS-40530	Fixed XSS vulnerabilities in the Administrative console.
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.

Ticket ID	Description
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40817	PATCH operations on SCIM 2 for PingDirectory Server now require that the value of the schemas attribute in the request body to be "urn:ietf:params:scim:api:messages:2.0:PatchOp", in accordance with RFC 7644.
DS-40869	Made JSON the default SCIM 1.1 response content type for requests that did not specify an accept content type.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-40902	Fixed an issue that could cause the server to report an error when disabling a PingOne for Customers pass-through authentication plugin.
DS-40951	Improved import-ldif indexing performance.
DS-40953	Added detection for buffer issues that could cause connections to get stuck during TLS handshake.
DS-40955	Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
DS-41033	Before starting replication calculates the total backlog for each replica by adding up the outstanding changes for each remote replica. With this change obsolete replicas will no longer be included in the calculation.

Ticket ID	Description
DS-41051	Improved the logic used to determine an appropriate replication database cache size. The previous fixed size of 5MB was found to be too small in some cases, and the replication database could grow larger than expected. In deployments in which the JVM has access to at least 500MB of memory, the replication database cache will now be permitted to use up to 10f that memory. The former 5MB cache size will still be used in deployments with access to less than 500MB of memory.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41056	Updated the dictionary of commonly used passwords to include new values from studies released at the end of 2019.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41079	Trimming of replication changes database no longer gets stuck when the sequence number of the first change is greater than the sequence number of the last change, which can happen when "dsreplication initialize" is used to initialize a target with changes that are older than the changes the target previously had.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on PingDirectory Server.

Ticket ID	Description
DS-41215	Updated the manage-profile replace-profile subcommand to check for encryption-related arguments in setup-arguments.txt when determining if an export and re-import of user data is necessary.
DS-41221	A new collaborator field has been added to consents. This field is for storing users with whom the consent has been shared with, in order to search consents that have been shared with a user.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41239	Missing changes are now detected for new replicas that have not yet had any changes.
DS-41252	Obsolete changes are now removed from the replication database of the target system when the target system is initialized.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41270	Fixed an intermittent hang in dsreplication initialize due to replication failing to send an internal replication message. When the hang happens a message containing "the destination server is currently unavailable" is logged on the target of the initialize. The fix is to retry sending the internal replication message.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.

Ticket ID	Description
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41441	Changed a validator error to a warning since it was deemed to be relatively harmless. The validator error was "Validator Error: The server experienced an unexpected error. Please report this problem and include this log file. Received an update requiring replication assurance, but without a location option"
DS-41465	Obsolete replicas will no longer be purged by default. To turn on the purging of obsolete replicas use "dsconfig" to set "replication-purge-obsolete-replicas" to true in the global configuration.
DS-41471	Added a global ACI that grants clients access to the pre-read and post-read request controls by default. The server will only process these controls if the requester has permission to perform the associated write operation, and the entries returned will only include attributes the requester has permission to read.
DS-41516	Added a --addBaseEntry argument to dsreplication enable. This argument can be used to add a base entry when enabling replication for an empty base DN.
DS-41622	The use-administrative-operation-request-control property is now hidden on unsupported products.

Ticket ID	Description
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41763	Updated the server behavior when returning entries in response to a search request in which the client explicitly specified a list of attributes to be returned. If any of the requested attributes exists in the entry but is not defined in the server schema, the server would have previously returned that attribute with a name formatted in all lowercase characters. The attribute will now be returned with a name that uses the same capitalization that the client used for it in the list of requested attributes.
DS-41818	Added the --zip argument to the manage-profile generate-profile subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to /instance-root by authenticated users with the file-servlet-access privilege will be granted access to files within the server instance root.
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has memory.swappiness set to a nonzero value.
DS-41851	Enabled Correlated LDAP Data Views for SCIM 2 resource types on PingDirectory Server and PingDirectoryProxy Server.
DS-41939	Fixed an issue with in which the server may not generate an account status notification for the account-updated notification type for modify operations unless the operation also qualifies for other types of account status notifications.
DS-41941	Fixed an issue that prevented enabling the LDAP changelog backend with the manage-profile replace-profile tool.

Ticket ID	Description
DS-41987	Updated the PUT request in the consent service to reject requests that have duplicate collaborators to make it consistent with POST and PATCH requests.
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a NullPointerException if a server was configured with a custom global result code map.
DS-42387	Updated the **`manage-profile generate-profile`** subcommand to exclude files in the `ldif/` and `bak/` directories by default when generating a server profile. If necessary, you can manually include those directories using the `--includePath` argument.

PingDirectory Server 8.0.0.5 release notes

Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.

PingDirectory Server 8.0.0.3 release notes

Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-42373	Fixed an issue where unindexed LDAP searches filtered on virtual attributes sometimes omitted objectClass from the returned result.
DS-42922	Fixed a bug where restoring an incremental backup could result in the server not being able to start.

Ticket ID	Description
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: * When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. * When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. * When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.

PingDirectory Server 8.0.0.2 Release Notes

Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-39539,DS-41417,DS-41478	Fixed an issue where the manage-profile replace-profile subcommand was unable to create new local DB backends through dsconfig. Also fixed an issue where replace-profile could not export and re-import data from a server with multiple backends.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41033	Before starting replication calculates the total backlog for each replica by adding up the outstanding changes for each remote replica. With this change obsolete replicas will no longer be included in the calculation.
DS-41051	Improved the logic used to determine an appropriate replication database cache size. The previous fixed size of 5MB was found to be too small in some cases, and the replication database could grow larger than expected. In deployments in which the JVM has access to at least 500MB of memory, the replication database cache will now be permitted to use up to 1% of that memory. The former 5MB cache size will still be used in deployments with access to less than 500MB of memory.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41079	Trimming of replication changes database no longer gets stuck when the sequence number of the first change is greater than the sequence number of the last change, which can happen when "dsreplication initialize" is used to initialize a target with changes that are older than the changes the target previously had.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.

Ticket ID	Description
DS-41215	Updated the manage-profile replace-profile subcommand to check for encryption-related arguments in setup-arguments.txt when determining if an export and re-import of user data is necessary.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41252	Obsolete changes are now removed from the replication database of the target system when the target system is initialized.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41658	Fixed an issue where schema changes to a user-defined object class with one or more subordinate classes were not written to the schema file until additional schema changes were made.
DS-41939	Fixed an issue with in which the server may not generate an account status notification for the account-updated notification type for modify operations unless the operation also qualifies for other types of account status notifications.

Ticket ID	Description
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42812	Upgrade to jetty 9.4.30
DS-42815	Added a remove-attribute-type-from-schema tool that can be used to safely remove an attribute type definition from the server schema. It will ensure that the attribute type is not in use, and it will clean up metadata references to that attribute type that could have previously required re-importing the data before the attribute type could actually be removed from the schema. The remove attribute type processing can also be requested programmatically through an administrative task.
DS-43043	Fixed an issue where paged subtree searches posted to the Directory Rest API failed with error message: "Unable to decode the cookie in the simple paged results control value", whenever the search returned entries with DN length approaching or exceeding 127 characters.

PingDirectory Server 8.0.0.1 Release Notes

Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on PingDirectory Server.
  - Fixed in: 8.0.0.1

    Introduced in: 7.2.0.0

    Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1

    Introduced in: 5.2.0.0

    Support identifiers: DS-41301

- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788

The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

- Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
- Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
  - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

  In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Furthermore, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any

other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

- Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
- Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': InvalidKeyException: The provided passphrase is invalid."
  - Fixed in: 7.2.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-37313
- Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
  - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-

config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

  The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.6
  - Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
  - Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074

- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where:
  - Server B had not received changes directly from a client for a long time (beyond the purge delay),
  - Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
  - Server A is shutdown, and
  - While Server A is shutdown, the Server B processes one or more changes directly from the client.
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216

- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where:
  - Server B had not received changes directly from a client for a long time (beyond the purge delay),
  - Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,

  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an IllegalStateException that references "exploded-index-background-deletes" when there are several backend exploded indexes.
  - Fixed in: 6.0.0.0
  - Introduced in: 4.6.0.0
  - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
  - Fixed in: 5.0.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

  ⓘ **Note:**

  SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered

secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782
- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
  - Fixed in: 4.6.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-10470
- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
  - Fixed in: 4.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-9268 SF#2002
- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
  - Fixed in: 4.0.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing get-changelog-batch-requests at the same time that live traffic is happening.
  - Fixed in: 3.6.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-5656

- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
  - Fixed in: 3.2.0.0
  - Introduced in: 3.1.0.0
  - Support identifiers: DS-3592

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40902	Fixed an issue that could cause the server to report an error when disabling a PingOne for Customers pass-through authentication plugin.
DS-40951	Improved import-ldif indexing performance.
DS-41206	Fixed a memory leak when performing SCIM queries on the PingDirectory Server.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41280	The Admin Console is now deployable to an external container running Java 11 with no further downloads or updates necessary.

Ticket ID	Description
DS-41206	Fixed a memory leak when performing SCIM queries on the PingDirectory Server.

PingDirectory Server 8.0.0.0 Release Notes

Upgrade considerations

> ⓘ **Important:**
>
> If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

For other upgrade considerations, see *Upgrade overview and considerations*.

Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788

What's New

These are new features for this release of the PingDirectory Server:

- Improved end user experience with several feature additions to user e-mail notifications. Now administrators can configure the server to send multi-part emails, including plain text and HTML. Also, in addition to changes to account state, such as when a user account is locked, administrators can configure notifications to send whenever any configured profile attributes are changed. For example, this can be used for confirmations of self-service account changes, or as notifications for changes made by administrators.
- Better insight to server health and the performance of connected applications. Administrators can now push metrics to application insight and monitoring applications such as Splunk using two new methods. A new StatsD monitoring endpoint pushes metrics to StatsD-compatible services. Also, the periodic stats logger has been updated to use JSON-format log files, greatly simplifying the use of log forwarding tools like Splunk's Universal Forwarder or Elastic's FileBeats.
- Several password-related improvements. A new password validator has been added that rejects passwords known to have been breached or stolen, as collected by the *haveibeenpwned.com* service. Also, administrators can take advantage of a new Argon2 algorithm and password storage scheme, as well as new options to the PBKDF2 algorithm and password storage scheme.
- New SCIMv2 REST API to create, read, update, and delete (CRUD) users and other resources using JSON over HTTP. This complements the Directory REST API introduced in 7.2. While the Directory REST API is intended for custom application development, the SCIMv2 REST API is more intended for integrations with third party software and services. With SCIMv2, administrators configure the data

conventions used in PingDirectory Server – resource types that map to directory object classes, their attributes, and their locations within the Directory Information Tree (DIT).

- A new tool to easily update the security certificates used by the server. The `replace-certificate` tool allows administrators to replace the certificates presented by the server for external client connections, both HTTPS and LDAPS. If required, the replace-certificate also allows the administrator to replace the certificates used for inter-server communication, like replication.

Known Issues/Workarounds

The following are known issues in this version of the PingDirectory Server:

- The following are suggested solutions for problems with slow DNS:
  - Maintain a connection pool in the client app rather than opening new connections for each bind.
  - Add appropriate records, including PTR records, to DNS.
  - Add `options timeout:1` in the `/etc/resolv.conf` file and/or `options single-request`.
  - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory Server's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- SCIM2 PATCH operations require ACI read permissions for any required attributes in the resource's SCIM schema, even if the operation itself does not modify the required attribute itself. Otherwise, PATCH operations will fail with the error message "Applying patch ops results in an invalid resource". The following is an example of an ACI to grant read permission to the required attributes for Passthrough SCIM resource types of objectClass inetOrgPerson for a particular oauthscope:
  - `aci: (targetfilter="(objectClass=inetOrgPerson)") (targetattr="objectClass||uid||cn||givenName||sn")(version 3.0; acl "Allow read access to inetOrgPerson required attributes with OAuth scope inetOrgPersonScope"; allow (read) oauthscope="inetOrgPersonScope";)`
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.
  - **Workaround:** Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.
- The working directory value used by exec tasks is not implemented for recurring exec tasks.
- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
  - groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2
  - groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2

  Workaround: Deploy the Console in an external container using JDK 8.

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-17278	Added a `cn=Server Status Timeline,cn=monitor` monitor entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37042	Added an account status notification handler that can send multi-part email messages (including a plain-text part, HTML part, and optional attachments) in response to notable events affecting user accounts.
DS-37745	Added support for an `oauthscope` access control bind rule, which can be used to grant or deny access control permissions based on a set of scopes associated with an OAuth token.
DS-37859	Added the `--exportImportLocalDBData` option to the `revert-update` tool. This option will perform an export and re-import of any local db backends if there are changes that require it between the two versions. The new option does not handle the LDAP changelog and replication changelog.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, `endpoint-cache-refresh`, has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the `Resource` column in the output of `status`. This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.
DS-38243	Added a password validator that can use the *Pwned Passwords service (https://haveibeenpwned.com/)* to reject passwords that are known to have been compromised in data breaches.
DS-38371	Added a password storage scheme that uses the Argon2i password hashing algorithm. This scheme requires the free and open source Bouncy Castle library cryptographic, which is not included with the server. This library must be obtained from *https://bouncycastle.org/* and placed in the server `lib` directory before the storage scheme may be used.
DS-38528	Added support for a `generate password` request control that can be included in an `add` request to request that the server generate a password for the new entry. The generated password will be provided to the client in a corresponding response control.

Ticket ID	Description
DS-38560	Updated `manage-profile replace-profile` to apply configuration changes directly, when possible. If the new server profile used by `replace-profile` has changed only the `dsconfig` batch files from the original profile, then only the `dsconfig` files are applied. If no changes are detected between profiles, `replace-profile` takes no action. If changes other than `dsconfig` are detected, the full `replace-profile` process is followed.
DS-38699	Avoid sending replication messages for LDAP operations where the required associated replication information is missing.
DS-38777	Added support for updating the server version during `manage-profile replace-profile`. The server must have been originally set up with a server profile.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-38863	Updated the `manage-profile setup` subcommand to set a server's cluster name to match its instance name by default. This prevents servers in the same replication topology from being in the same cluster, reducing the risk of unintentionally overwriting parts of an existing server's configuration in a DevOps environment. The `--useDefaultClusterName` argument can be used to leave the cluster name unchanged.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions. Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the `remove-defunct-server` tool's `--ignoreOnline` option. When using `--ignoreOnline` in a mixed-version environment, all servers must support the option.
DS-39099	Fixed an issue where error log notifications were generated regardless of whether the account status notification handler has the property enabled or disabled.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit *groovy-lang.org* and view the Groovy 2.5 release notes. As of this release, only the core Groovy runtime and the groovy-json module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as groovy-xml or groovy-sql, download the appropriate jar file from *groovy-lang.org* and place it in the server's `lib/extensions` directory.

Ticket ID	Description
DS-39253	Added a `replace-certificate` tool, which can help an administrator replace the listener or inter-server certificate for a server instance.
DS-39325	Removed the legacy product-specific scripts for starting and stopping the server. These include: ▪ `start-ds` and `stop-ds` for PingDirectory Server ▪ `start-proxy` and `stop-proxy` for PingDirectoryProxy Server ▪ `start-sync` and `stop-sync` for Data Sync Server ▪ `start-metrics-engine` and `stop-metrics-engine` for Data Metrics Server These legacy scripts had been deprecated for several releases in favor of the more `general start-server` and `stop-server` scripts, and they displayed a warning message about their pending removal if they were invoked. If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general start-server and stop-server scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point at the start-server and stop-server scripts.
DS-39347	Fixed an issue where Delegated Admin would not work properly if the name of the REST Resource Type was not the same as the resource endpoint.
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as `X-VALUE-REGEX`), this could cause unexpected or incorrect behavior.
DS-39525, DS-39526	Delegated Admin enhancements for constructed attributes. ▪ Allow a required attribute to be read-only if it is constructed. ▪ Add a configured list of "Update Constructed Attributes" on the REST resource type, similar to the "Post Create Constructed Attributes", so that constructed attributes can be updated when dependent attributes change. ▪ Handle constructed attributes which reference other constructed attributes.
DS-39589	Fixed an issue that could cause access log messages for bind and StartTLS results to report the client connection policy that had previously been assigned to the connection rather than the new policy that is in place as a result of the operation.
DS-39592	HTTP External Servers have a new attribute, `ssl-cert-nickname`, which defines the alias of a specific certificate within their keystore to be used as a client certificate.

Ticket ID	Description
DS-39603	Fixed an issue where Server SDK extensions could not be configured by `dsconfig` batch files in the manage-profile tool.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.
DS-39654	Added support for the `--topologyFilePath` argument to the `manage-topology add-server` subcommand.
DS-39671	Updated the `manage-topology add-server` subcommand to require being run from the older server in a mixed-version environment.
DS-39693	Fixed an issue where Delegated Admin search results were truncated and invalid upon encountering a Directory entry containing a Boolean or Integer syntax attribute whose values were invalid because they did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results and a warning message is logged to the server errors log.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39762	Added support for a "generate password" extended operation that can be used to request that the server generate one or more passwords that may be suggested as possible values when creating a new user or changing the password for an existing user.
DS-39787	Fix verify-index errors on multibyte UTF-8 strings.
DS-39796	Added support for two new account status notification types. The account-created notification type can be used to generate a notification whenever a new entry is created in an add request that matches a given set of criteria. The account-updated notification type can be used to generate a notification whenever an entry is updated in a modify or modify DN request that matches a given set of criteria.
DS-39797	Updated the account status notification handler framework to make several new properties available for use in constructing notification messages. These properties provide information about the password policy configuration and the user's password policy state, including: ▪ The time the notification was generated ▪ The DN of the account with which the notification is associated ▪ The time the account password was last changed ▪ Whether the account is in a usable state and information about any issues that might affect its usability ▪ Whether the account is administratively disabled ▪ Whether the account is expired or not yet active ▪ Information about any account lockout that may be in effect ▪ Information about password expiration ▪ Whether a new password was generated for a self-change or administrative reset

Ticket ID	Description
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39872	Updated Summarize Access Log Rotation Listener and Copy Log File Rotation Listener to run on a background thread.
DS-39873	Fixed an issue that allowed replicated subtree deletes to cause OutOfMemory errors on replicas. Also fixed a related issue that would cause the replication log to fill up with mild errors.
DS-39882	Fixed an issue that could prevent the simple request criteria from properly evaluating a target entry filter or group membership for a modify DN operation after the change had already been applied to the backend.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40114	Added a new `cn=Status Health Summary,cn=monitor` monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.
DS-40154	Fixed an issue where the restore tool was not restoring all dependencies of an incremental backup.
DS-40177	Fixed an issue that could interfere with the server's ability to purge an earlier, full backup when the following conditions are satisfied: Retention is used. Multiple levels of incremental backups depend on the full backup."
DS-40210	Fixed an issue that prevented uniqueMembers from adding themselves to a groupOfUniqueNames.
DS-40249	Fix an issue where an LDAP search across entry-balanced server sets sometimes returned 0 (success) even though all servers in one of the sets failed with a timeout. The search should return 52 (unavailable) in this situation.
DS-40317	Created a new function that takes index objects rather than the counts so that we can avoid adding to a `long.max_value`, creating a long overflow.
DS-40354	Fixed a problem with `config-diff` when writing properties that span multiple lines using the `--prettyPrint` argument.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.

Ticket ID	Description
DS-40409	Updated the `ldif-diff` tool so that it provides a `--stripTrailingSpaces` option that can cause the LDIF parser to strip off illegal trailing spaces rather than reject the associated entry or change record.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40543	Updated `manage-profile replace-profile` to copy the tool log file to the server being updated.
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40561	Fixed an issue that prevented assured replication from working for requests received via SCIM or the REST API.
DS-40674	Added the `--addMissingRdnAttributes` argument to `manage-profile` setup. This argument can be used when including LDIF files in the server profile. It will automatically add any missing RDN values to the set of entry attributes when they are not already present.
DS-40730	Updated the `encrypt-file` tool to prevent using the same path for both the input file and the output file.
DS-40744	Fixed an issue with the interaction between deprecated password storage schemes and forced password reset. If a user's password is reset by an administrator using a password storage scheme that is subsequently configured as deprecated, the act of re-encoding the password with the new default scheme would have incorrectly cleared the password reset flag.
DS-40771	Added a `--duration` argument to collect-support-data. When used, only the log files covering the specified duration before the current time will be collected.
DS-40788	Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
DS-40799	Fixed an issue in which an account that had been temporarily locked after too many failed authentication attempts could become re-locked with fewer than the expected number of subsequent failed attempts after the previous lockout period had elapsed.

PingDirectoryProxy Server Release Notes

PingDirectoryProxy 8.2.0.8 release notes

The release notes for the 8.2.0.8 release of the PingDirectoryProxy server.

Critical fixes

This release of the PingDirectoryProxy server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the PingDirectoryProxy server.

Ticket ID	Description
DS-45164	Updated Jetty Server to version 9.4.44.
DS-45813	Updated PingDirectory products to use Kafka v2.8.1.

PingDirectoryProxy Server 8.2.0.7 release notes

The release notes for the 8.2.0.7 release of PingDirectoryProxy Server.

Critical fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or **`remove-defunct-server`** tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

  The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

  ⓘ **Note:**

  Since this change only applies to the most recent version of **`remove-defunct-server`** and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past **`dsreplication`** and **`remove-defunct-server`** could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

  - Fixed in: 8.2.0.7
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-44591

Resolved Issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-44591	Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or **`remove-defunct-server`** tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed. The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology. ⓘ **Note:** Since this change only applies to the most recent version of **`remove-defunct-server`** and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past **`dsreplication`** and **`remove-defunct-server`** could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.
DS-45124	Removed `-XX:RefDiscoveryPolicy=1` from the default start-server Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.
DS-45190	Added support for the use of JDKs obtained through BellSoft.

PingDirectoryProxy Server 8.2.0.6 release notes

Critical fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the DirectoryProxy Server.

Ticket ID	Description
DS-36257, DS-43909	Updated the logic the server uses to maintain the `entry-balancing` global index. Improvements include: ▪ In some cases, the server could have incorrectly populated attribute indexes in the course of processing an **`add`** operation. This could have led to scenarios in which the global index had incomplete information for some attribute values, which could have caused the Directory Proxy Server to only return entries from a subset of the backend sets that contained those entries. Global attribute indexes now provide a `guaranteed-unique` configuration property, and they will now only be populated with new records after an **`add`** operation for indexes that are marked as guaranteed unique. ▪ Global attribute indexes were previously not updated for **`add`** operations that contained an indexed attribute in the relative distinguished name (RDN) but that attribute was not included in the set of attributes for the **`add`** operation. The appropriate index updates will now be performed for the operation. ▪ The global index was previously not updated for operations that were part of a successful transaction or **`multi-update`** extended operation. The appropriate updates will now be made. ▪ Global attribute indexes were previously not updated as a result of modifications used to remove specific attribute values from an entry. Indexes that are marked as guaranteed unique will now be updated for delete modifications that list the values to remove from the entry. ▪ Global attribute indexes were previously not updated for **`delete`** operations. The server has been updated so that if the entry's RDN includes attributes for which there are indexes marked as guaranteed unique, the index will be updated to remove those RDN values.
DS-43632	Fixed an issue where the `format` field is omitted from the list of operational attribute schemas in the Directory REST API.

PingDirectoryProxy Server 8.2.0.5 release notes

Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-44025	Fixed an issue where the server was incorrectly displaying an `Unknown vendor` warning when using JDKs obtained on Red Hat and Ubuntu systems.
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.

PingDirectoryProxy Server 8.2.0.2 release notes

Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.
DS-43939	Fixed an issue where PingDirectoryProxy Server sometimes returns incorrect result code 80 ("Other") or 81 ("Server down") instead of 32 ("No Such Entry") when adding child entries with missing parents to an entry-balanced set with only one backend server.

Ticket ID	Description
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the oidc-trust-store-file and oidc-trust-store-type settings. Also, you can set the console to skip hostname and/or certification verification through the oidc-strict-hostname-verification and oidc-trust-all configuration settings.

PingDirectoryProxy Server 8.2.0.1 Release Notes

Critical Fixes

Resolved Issues

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-43745	Fix an issue in the server causing PingDirectory Server 8.2.0.0 to be incompatible with version 4.2.0 of the Delegated Admin app, which prevented upgrade to Delegated Admin version 4.4.0 without some downtime.

PingDirectoryProxy Server 8.2 release notes

Enhancements

The following is a new feature for this release of PingDirectoryProxy Server:

- With SCIMv2, client applications might need to perform a sorted search on a large dataset. In this version of PingDirectory, SCIMv2 searches with the proper search parameters come back in pages.
- The Administrative Console now supports using OpenID Connect for admin SSO, allowing you to set up the PingOne administration console to have one-click SSO access without typing a password.

Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in *Upgrade overview and considerations* on page 891.

Known issues and limitations

The following are known issues in the current version of PingDirectoryProxy Server:

When signing on to the Administrative Console, you must specify an LDAPS port in the **Server** field. For example, to use port 636, you would specify pingdirectory:636. If you do not specify a port, you get a

```
"Server
      unavailable"
```

message.

Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-644, DS-42031	Added a new validate-ldap-schema tool that can be used to examine schema definitions in a set of LDIF files and report any issues that it detects.
DS-5040	Improved the **`dsframework`** tool to support multivalued server properties.
DS-5143, DS-11035	Updated support for logging access and error log messages to a syslog server. While the server previously supported logging these messages to a syslog server (through the "syslog-based access log publisher" and "syslog-based error log publisher" logger implementations), these loggers used an older version of the syslog protocol (described in RFC 3164) and only offered support for communicating over UDP. These loggers are still available for legacy backward compatibility, but we now also offer new "syslog text access log publisher" and "syslog text error log publisher" implementations that use a newer version of the syslog protocol (syslog version 1, described in RFC 5424) and support communicating over UDP or the more reliable TCP. When using TCP, it is also possible to encrypt communication with TLS, and it is possible to configure multiple servers for better redundancy. These loggers use the same space-delimited text format as the former loggers. We also offer new "syslog JSON access log publisher" and "syslog JSON error log publisher" implementations that offer the same set of capabilities, but that format the message text as JSON objects, which can be more easily parsed by third-party software.

Ticket ID	Description
DS-7475, DS-7605, DS-11725, DS-37707, DS-40342, DS-41940	Made several improvements to the parallel-update tool, which can use multiple concurrent threads for improved performance when applying add, delete, modify, and modify DN changes read from an LDIF file. The enhancements include: * Added support for several additional controls, including proxied authorization, manageDsaIT, ignore NO-USER-MODIFICATION, password update behavior, operation purpose, name with entryUUID, assured replication, replication repair, suppress operational attribute update, and suppress referential integrity updates. The tool also now supports specifying arbitrary controls for inclusion in add, bind, delete, modify, and modify DN requests. * Made its communication more robust. The tool would previously establish connections only when it was first started, but it can now detect when a connection is no longer valid and can re-establish connections as needed to continue processing. Further, if an operation failed because it was attempted on an invalid connection, that operation can be automatically retried immediately on a newly established connection. * Added support for failover directory servers. You can now provide the --hostname and --port arguments multiple times to specify information about multiple directory server instances. In the event that the first server listed is not available (or becomes unavailable in the middle of processing), it can automatically try establishing a connection to an alternative server to continue processing there. * Improved the ability to determine whether all changes were processed successfully. Previously, the tool would always use an exit code of zero if it was able to attempt all of the changes read from the LDIF file, even if some of the changes were not successfully applied. That is still the default behavior, but a new --useFirstRejectResultCodeAsExitCode argument can be used to indicate that if any operations are rejected, the result code from the first rejected operation should be used as the exit code. * Added support for encrypted LDIF files. If the LDIF file was encrypted with a key from the server's encryption settings database, then the tool will automatically attempt to retrieve the appropriate key. Otherwise, the new --encryptionPassphraseFile argument can be used to supply the encryption passphrase, or the passphrase can be interactively requested from the user. * The tool is now parallel by default. Previously, if you did not specify a value for the --numThreads argument, it would use a single thread. It now defaults to using eight threads. * The tool now provides a --followReferrals argument that allows it to automatically attempt to follow any referrals that are returned. * The tool now provides a menu-driven interactive mode that can be used to provide values for all of the command-line arguments.
DS-10320, DS-12550, DS-12551, DS-12552, DS-42116, DS-42162, DS-42179, DS-42222, DS-42223, DS-42224, DS-42225, DS-42416, DS-42437	Added a config/sample-dsconfig-batch-files directory with set of well commented dsconfig batch files that may be useful in enabling or configuring a variety of features in the server.

Ticket ID	Description
DS-10775	Updated the dictionary password validator to support additional options: * It can now ignore non-alphabetic characters that appear at the beginning or end of the password before checking the dictionary. * It can strip characters of diacritical marks, including accents, cedillas, circumflexes, diaereses, tildes, and umlauts, before checking the dictionary. If this option is used, then any character with such a mark will be replaced with a base version of the character without that mark (for example, a lowercase letter n with a tilde over it would be replaced with just a lowercase letter n). * You can define maps with information about character substitutions to use for checking alternative versions of the provided password. For example, if you indicate that "0" might map to "o", "1" or "!" might map to "i", "7" might map to "t", and "3" might map to "e", then the validator can reject a proposed password of "pr0h1b!73d" if the dictionary contains the word "prohibited". * It can reject a proposed password if a value from the provided dictionary makes up more than a specified percentage of that password.
DS-11524, DS-41860, DS-42112	Added support for new administrative alert types: * We have added a new admin alert account status notification handler, which can generate administrative alerts whenever an applicable account status notification is generated within the server. For example, this account status notification handler can be added to the root password policy to generate an alert whenever a root user's password is updated or their account is locked as a result of too many failed authentication attempts. A separate alert type has been defined for each account status notification type. * We have added a new "privilege-assigned" administrative alert that can be raised whenever a new entry is added or an existing entry is updated to include one or more privileges. * We have added a new "insecure-request-rejected" administrative alert that can be raised whenever the server rejects a request as a result of the reject-insecure-requests global configuration property.
DS-12143	Updated the PingDirectoryProxy Server to improve support for the PLAIN, UNBOUNDID-DELIVERED-OTP, UNBOUNDID-TOTP, and UNBOUNDID-YUBIKEY-OTP SASL mechanisms. Previously, the PingDirectoryProxy Server itself performed all of the processing for those SASL mechanisms and would only work if the PingDirectoryProxy Server could retrieve the appropriate encoded credentials from the backend Directory Server. It will now forward the bind request to the backend server for processing, which allows it to work in deployments in which the backend server prevents the PingDirectoryProxy Server from accessing the stored credentials.
DS-13853	Added support for the OAUTHBEARER SASL mechanism (as described in RFC 7628) to allow LDAP clients to authenticate with OAuth 2.0 bearer tokens.
DS-15848, DS-42360	Added support for invoking a specified set of password validators during bind operations. If the password used to authenticate fails to satisfy one or more of the configured validators, the bind attempt can be rejected, the user can be forced to change their password, or the server can generate an account status notification to take some alternative action (for example, notifying the end user or server administrators).
DS-15864	Replaced the ldappasswordmodify tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.

Ticket ID	Description
DS-17903	Updated setup to provide a --populateToolPropertiesFile argument that will allow it to populate the config/tools.properties file with default values for command-line tool arguments. If requested, properties will be provided for the server address, port, and communication security, and may also include a default bind DN and optionally a bind password. When running setup interactively, it will now prompt to determine which properties (if any) should be populated in the properties file.
DS-36088	Updated the crypto manager to make it possible to augment the set of enabled TLS cipher suites with specific suites to add to or remove from the default set of enabled suites. To enable one or more suites in addition to those in the default set, prefix the names of those suites with the "+" symbol. To disable one or more suites in the default set of enabled suites, prefix the names of those suites with the "-" symbol. This was already possible when configuring cipher suites for the LDAP and HTTP connection handlers, but it was not an option for the crypto manager.
DS-38110	Updated the System Information monitor with an "isDocker" attribute to identify if the server is running in a Docker container.
DS-38118, DS-42495	Made several updates related to the server's handling of data written to standard output and standard error: * The server can now be configured to rotate the logs/server.out file once it reaches a given size, and it will retain a configurable number of those log files. By default, the server will rotate the file once it reaches 100 megabytes and will keep up to ten files. * To better facilitate capturing log data in containerized environments, the server now supports writing JSON-formatted access and error log messages to the JVM's original standard output and error streams (which will be separate from the server.out file when the server is started with the --nodetach argument). * It is now possible to prevent the server from logging messages during startup in non-JSON format. It is also possible to prevent messages about administrative alerts from being written to standard error, or to write those messages in JSON format. These options are especially useful when using JSON-based logging to the console in no-detach mode, as they can help ensure that everything written to standard output and standard error will be formatted as JSON objects.
DS-38816, DS-41995	Updated support for the uniqueness request control to provide a more reliable mechanism for preventing conflicts that arise from operations processed concurrently in the same or different servers. If indicated in the request control, a temporary conflict prevention details entry can be added to the server before searching for existing conflicts, and that entry can be detected during pre-commit processing for other operations with uniqueness request controls that attempt to make a conflicting change. The server has also been updated to make it possible to generate an administrative alert if a uniqueness conflict is detected during post-commit processing for the uniqueness request control. Even though the conflict cannot be prevented at this stage in processing, the alert can let administrators know about it as soon as it happens so they can take any appropriate corrective action.

Ticket ID	Description
DS-38868	Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.
DS-39789	Updated the JVM memory usage monitor provider to fix an issue that could prevent the monitor from reporting the total amount of memory held by all memory consumers. Also, fixed an issue that could cause the memory-consumer attribute to use an incomplete message for consumers without a defined maximum size and added an additional memory-consumer-json attribute whose values are JSON objects with data that can be more easily extracted by automated processes.
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-40967	Eliminated a misleading error message that could be logged at startup if the server was configured with one or more ACIs that only apply when using specific SASL mechanisms.
DS-41350	Fixed an issue where disabling certain backends (such as 'alarms') caused an internal monitor to log unnecessary error messages every few seconds, about not being able to gather data from that backend. Note that deliberately disabling the 'alarms' backend is not recommended in normal operation, but may occur during backup/restore operations.
DS-41521	The SCIM 2 service on PingDirectory and PingDirectoryProxy now automatically generates a Swagger 2 specification document based on the server's SCIM 2 configuration. To view this document, go to https://<your-server>/api-docs in a web browser.
DS-41865	PingDirectory and PingDirectoryProxy can now perform SCIM 2 paged searches on result sets greater than the configured lookthrough limit. To perform such a search, you must first configure a virtual list view (VLV) index.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-41989	Fixed an issue that could result in duplicate column headers being produced by the Periodic Stats Logger, even when the header-prefix-per-column attribute was set to true.
DS-42045	Updated the Stats Collector Plugin with a new generate-collector-files configuration property. When using the plugin exclusively for providing metrics to one or more StatsD Monitoring Endpoints, set this property to false to prevent unnecessary I/O.

Ticket ID	Description
DS-42059, DS-42060	Updated setup to add options for improving communication security: * Non-interactive setup now offers a --rejectInsecureRequests argument that will configure the server to reject any request received over a connection that is not encrypted with SSL or StartTLS. * Non-interactive setup now offers a --rejectUnauthenticatedRequests argument that will configure the server to reject any request received over a connection that is not authenticated (or that is authenticated as the anonymous user). * Interactive setup now allows you to configure the server with the LDAP connection handler disabled (which was already an option when using non-interactive setup), or enabled but only for communication encrypted with StartTLS. The --rejectInsecureRequests and --rejectUnauthenticatedRequests arguments can also be used with manage-profile by including them in the setup-arguments.txt file of the server profile.
DS-42061	Updated the interactive command-line tool framework to prefer establishing secure LDAP connections over insecure connections. Previously, when prompting for the information needed to establish a connection, the default option was to create an unencrypted LDAP connection. Now, tools will default to creating an SSL-encrypted connection if the server supports it, or to creating a StartTLS-encrypted connection if that is available but SSL is not. Tools will also default to using streamlined settings when establishing secure connections. Previously, they would always prompt about how to determine whether the server's certificate chain should be trusted. When using the streamlined settings, the tools will only prompt about certificates that cannot automatically be considered trusted using information in the JVM's default trust store, the server's default trust store (config/truststore), or the server's topology registry.
DS-42062	Updated the root password policy so that LDAP bind responses for root users and topology administrators will be delayed by one second after five consecutive failed authentication attempts.
DS-42063	Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non-LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
DS-42115	Updated the server's command-line tool framework to make it easier and more convenient to communicate with the server over a secure connection when no trust-related arguments are provided. Most non-interactive tools will now check the server's default trust store, the topology registry, and the JVM's default trust store to see if the presented certificate chain can be automatically trusted without the need to prompt the user. If the presented chain cannot be automatically trusted, the user may be interactively prompted to determine whether it should be trusted.

Ticket ID	Description
DS-42157, DS-43033	Updated the CRAM-MD5 and DIGEST-MD5 mechanism handlers so that they are no longer considered secure. Although the credentials are encoded in transit, their protection relies on the weak MD5 digest. Further, they require that user passwords be encoded in a reversible form so the server can retrieve them in the clear for use in authentication processing, which increases the risk that they will be exposed in a data breach. This primarily affects the ability to use these SASL mechanisms over an unencrypted connection for users that are required to authenticate in a secure manner (for example, if their password policy has require-secure-authentication set to true, or if their entry has a ds-auth-require-secure-authentication operational attribute with a value of true). These SASL mechanisms are still enabled by default for legacy backward compatibility purposes, but we discourage their use. To assist with that, we have also provided a sample dsconfig batch file that can be used to disable these SASL mechanism handlers.
DS-42199	Optimized some searches commonly used by the status tool. This should improve the performance of the tool in more complex or large-scale environments.
DS-42265	Upgrade to jetty 9.4
DS-42276	Fixed an issue where using the encryption-settings tool to import definitions with the set-preferred flag could result in none of the imported definitions being set as the preferred definition.
DS-42279	Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.
DS-42298	Replaced the ldifsearch, ldifmodify, and ldif-diff command-line tools with more full-featured and robust implementations.
DS-42331	Replaced the ldapcompare tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).
DS-42347	Updated the server to use /dev/urandom (on non-Windows systems where that path exists and is readable) instead of /dev/random as the primary source for secure random data. Attempts to read from /dev/random can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from /dev/urandom will not block, and the data that it provides is no less secure than data from /dev/random in any way that matters for the server.
DS-42349, DS-43209, DS-43210, DS-43323, DS-43324	Added support for JSON-formatted audit loggers, which complement the existing file-based LDIF-formatted error logger. The JSON-formatted audit log messages provide a record of changes to data in the server and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server. Added support for JSON-formatted HTTP operation loggers, which complement the existing file-based loggers using the W3C common log format and a proprietary space-delimited text format. The JSON-formatted HTTP operation log messages provide a record of interaction with HTTP clients and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server. Fixed an issue that caused JSON-formatted loggers to use a timestamp format that was not strictly compliant with the ISO 8601 format described in RFC 3339. Timestamps incorrectly omitted the colon between the hour and minute components of the time zone offset.

Ticket ID	Description
DS-42381	Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.
DS-42447	Fixed an issue where PingDirectoryProxy Server sometimes logged a null pointer exception if search requests across multiple load-balanced backend servers resulted in a timeout.
DS-42504	Updated manage-profile replace-profile to set encryption settings definitions defined in the newer server profile as preferred in the encryption settings db.
DS-42527	Fixed an issue that could cause an exception when creating a resource in SCIM 1.1 using certain types of DNTemplate.
DS-42547	Fixed an issue where manage-profile generate-profile would print "null" as the generated profile directory when writing to an existing directory.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42609	Fixed an issue in which the Consent API could fail to decode certain credentials when using basic authentication.
DS-42632	Added support for creating or importing a key pair configuration object using an elliptic curve (EC) key algorithm. You can use this to designate the encryption key pair for a JWT access token validator that handles EC-encrypted access tokens.
DS-42634	The JWT Access Token Validator can now validate JWT access tokens signed using the elliptic curve digital signature algorithms ES256, ES384, and ES512.
DS-42635	The JWT Access Token Validator can now validate JWT access tokens encrypted using elliptic curve cryptographic algorithms. The following key encryption algorithms are now supported in addition to RSA-OAEP: ECDH-ES, ECDH-ES+A128KW, ECDH-ES+A192KW, and ECDH-ES +A256KW. To support best practices for JWT security, you must now also configure the JWT Access Token Validator with explicit allow lists for key encryption and content encryption algorithms. For backward compatibility, the key encryption allow list defaults to RSA-OAEP, while the content encryption allow list defaults to A128CBC-HS256, A192CBC-HS384, and A256CBC-HS512. We recommend setting both allow lists to the strict minimum set of algorithms needed by the Access Token Validator.
DS-42651	Updated the manage-profile replace-profile subcommand to better support updating the server's keystore and truststore files. When using the --generateSelfSignedCertificate argument in a server profile's setup-arguments.txt file, the server will maintain the original keystore and truststore files during replace-profile. Otherwise, replace-profile will use the keystore and truststore specified in the profile's setup-arguments.txt file.
DS-42667	Updated the server to set a unique cluster name when started for the first time.
DS-42669, DS-42748	Updated the online dsconfig step of the manage-profile replace-profile subcommand to support getting LDAP connection arguments from a tools.properties file on the server being updated. Fixed an issue where boolean LDAP connection arguments like --useSSL and --trustAll would cause manage-profile replace-profile to fail when applying dsconfig online.

Ticket ID	Description
DS-42673	Updated the manage-profile setup subcommand to fail if the start-server command has a non-zero exit code.
DS-42681, DS-42684	Performance statistics generated by the Sideband API can now be published by the Periodic Stats Logger. To enable this, use the "included-http-servlet-stat" property of the Periodic Stats Logger.
DS-42687	Upgrade to Jetty 9.4.30
DS-42740	Fixed an issue where the **`dsconfig list`** subcommand would not display requested properties.
DS-42749	To support best practices for JWT security, you must now configure the JWT Access Token Validator with an explicit list of the JWT signing algorithms that it accepts. For backward compatibility, this list defaults to the RSA signing algorithms RS256, RS384, and RS512, but we recommend setting this list to the strict minimum set of signing algorithms needed by the Access Token Validator.
DS-42751	Added new override-status-code and additional-response-contents attributes to the Availability State HTTP Servlet Extension. These new attributes can be used to customize the response code and JSON response body of the servlet.
DS-42850	Fixed a typo in the password-expiring template that caused "password_expiration_time_of_day" to be printed instead of the password expiration time.
DS-42861	Updated the manage-profile tool logs to include the duration of each step the tool takes. The new --verbose argument can also be used to display timing information in the tool's console output.
DS-42872	Added a JSON-formatted stats logger to the server's default configuration. The stats logger is disabled by default.
DS-42886	Updated non-interactive setup (including manage-profile setup) to allow the password for the initial root user to be provided in pre-encoded form using the PBKDF2, SSHA256, SSHA384, or SSHA512 password storage scheme. This eliminates the need to have access to the clear-text password when setting up the server.
DS-42926	Fixed an issue where Ping Directory products configured to run as Microsoft Windows services were sometimes unable to automatically restart following an unplanned reboot, due to errors reading a corrupted server status file.
DS-42939	The Administrative Console configuration settings have been updated to account for the new SSO functionality.
DS-42952	For Windows only, there can be a hang on start when global configuration property `startup-error-logger-output-location` is set to values that contain `standard-error`. For Windows only, `standard-error` values are silently mapped to equivalent `standard-output` values.
DS-42963	Updated the manage-profile generate-profile subcommand to ignore files larger than 100 megabytes when generating a server profile. Fixed an issue where many large files in the server root could cause the tool to run out of memory.

Ticket ID	Description
DS-43027	Added a new --adminPasswordFile argument to the manage-topology add-server command, to allow specifying the administrator password with a file rather than with the command line.
DS-43073, DS-43198	Added support for ID Token Validators, which validate the integrity and content of ID tokens issued by OpenID Connect providers. Use these validators with the OAuth Bearer SASL Mechanism Handler to enable single sign-on (SSO) for the Administrative Console using an OpenID Connect provider such as PingOne. Currently, only PingOne is supported for SSO.
DS-43074	Added three built-in identity mappers that you can use to look up administrative accounts stored in the server configuration: Root DN Users, Topology Admin Users, and All Admin Users.
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: * When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. * When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. * When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.
DS-43305	Increased the maximum number of RDN components that a DN may have from 50 to 100.
DS-43376	Updated log publisher logic to reduce the amount of CPU that the server consumes when it is idle.
DS-43466	Updated PingDirectoryProxy so that in entry balanced environments, the JoinRequestControl on a search operation is passed through to the directory server instance in more scenarios. This enables more efficient processing, which leads to faster response times.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43517	Updated the jose4j library used for JWT signing and encryption to version 0.7.2.
DS-43651	The Security Guide is now available online at pingidentity.com. The guide has been removed from the server packaging.

Critical fixes

Critical Fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

  In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

  We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

  In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

  We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a

network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
  - Fixed in: 4.5.0.0
  - Introduced in: 4.1.0.7
  - Support identifiers: DS-9726
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854

Release Notes Archive

Release notes for previous versions of PingDirectoryProxy Server are included for reference.

PingDirectoryProxy Server 8.1.0.6 release notes
The release notes for the 8.1.0.6 release of PingDirectoryProxy Server.

Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

PingDirectoryProxy Server 8.1.0.5 release notes

Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: * When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. * When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. * When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

PingDirectoryProxy Server 8.1.0.2 Release Notes

Critical Fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the directory server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a

network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
  - Fixed in: 4.5.0.0
  - Introduced in: 4.1.0.7
  - Support identifiers: DS-9726
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Update PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854

Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-42687	Upgrade to Jetty 9.4.30

PingDirectoryProxy Server 8.1 Release Notes

Critical Fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.

The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Support identifiers: DS-38897 DS-38908

Upgrade Considerations

Important considerations for upgrading to this version of PingDirectoryProxy Server:

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the

new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.
- Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.

What's New

These are new features for this release of PingDirectoryProxy Server:

- The SCIM v2 REST API was added to PingDirectory Server in version 8.0. PingDirectoryProxy Server now supports the SCIMv2 REST API to create, read, update and delete (CRUD) users and other resources using JSON over HTTP. PingDirectoryProxy Server supports all the same endpoints and HTTP methods that PingDirectory Server supports.
- In an ongoing effort to improve the use of containers for PingDirectory Server, several features have been implemented:

  - The --outputFile option has been added to the collect-support-data tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the collect-support-data tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.

  - The collect-support-data tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.

  - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the --remoteServer added to the collect-support-data tool can be used to send the request to another server. In other words, you can now run collect-support-data on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectoryProxy Server has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party.
- Updated PingDirectoryProxy Server to improve support for the PLAIN, UNBOUNDID-DELIVERED-OTP, UNBOUNDID-TOTP, and UNBOUNDID-YUBIKEY-OTP SASL mechanisms. Previously, PingDirectoryProxy Server itself performed all of the processing for those SASL mechanisms, and it would only work if PingDirectoryProxy Server could retrieve the appropriate encoded credentials from the backend PingDirectory Server. It will now forward the bind request to the backend server for processing, which allows it to work in deployments in which the backend server prevents PingDirectoryProxy Server from accessing the stored credentials.
- Added a new validate-ldap-schema tool that can be used to examine schema definitions in a set of LDIF files and report any issues that it detects.

Known Issues/Workarounds

The following are known issues in the current version of the PingDirectoryProxy Server:

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.
DS-10216	Updated the GSSAPI SASL mechanism handler to support integrity and confidentiality protection for client communication.
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.
DS-38008,DS-41192	Updated PingDirectoryProxy Server to improve its support for retrying operations that fail in a manner that suggests they may succeed if attempted in a different server or on a newly established connection. Previously, PingDirectoryProxy Server would automatically enable retry support for all types of operations except add. At the time this retry support was initially implemented, retrying an add operation on a different server had the potential to result in a replication conflict if the entry was ultimately created on multiple servers. The Directory Server's replication logic has since been updated to detect and automatically resolve conflicts that result from attempts to add the same entry concurrently on multiple servers. As it is safe to enable automatic retry support for add operations (along with all other types of operations), that is now the default configuration. PingDirectoryProxy Server has also been updated to improve its retry support for the case in which connections to multiple backend servers have become invalidated in a manner that it cannot immediately detect (for example, as the result of an issue with a network switch or hardware load-balancer). As a result of this change, if all of the PingDirectoryProxy Server's usual attempts to process an operation fail in a manner that could indicate that connections are no longer valid, it may now attempt to establish a new connection to a backend server for one additional retry attempt.

Ticket ID	Description
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.

Ticket ID	Description
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40817	PATCH operations on SCIM 2 for PingDirectory Server now require that the value of the schemas attribute in the request body to be "urn:ietf:params:scim:api:messages:2.0:PatchOp", in accordance with RFC 7644.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-40953	Added detection for buffer issues that could cause connections to get stuck during TLS handshake.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41136	Enabled SCIM 2 API for PingDirectoryProxy Server.
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on PingDirectory Server.

Ticket ID	Description
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41299	Fixed an issue where the Ping Directory Proxy could incorrectly return duplicate entries after timing out on an unindexed search.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41622	The use-administrative-operation-request-control property is now hidden on unsupported products.

Ticket ID	Description
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41818	Added the --zip argument to the manage-profile generate-profile subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to /instance-root by authenticated users with the file-servlet-access privilege will be granted access to files within the server instance root.
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has memory.swappiness set to a nonzero value.
DS-41851	Enabled Correlated LDAP Data Views for SCIM 2 resource types on PingDirectory Server and Nokia8661DirectoryProxyServerAdministrationGuid.
DS-41987	Updated the PUT request in the consent service to reject requests that have duplicate collaborators to make it consistent with POST and PATCH requests.
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a NullPointerException if a server was configured with a custom global result code map.
DS-42387	Updated the **`manage-profile generate-profile`** subcommand to exclude files in the `ldif/` and `bak/` directories by default when generating a server profile. If necessary, you can manually include those directories using the `--includePath` argument.

PingDirectoryProxy Server 8.0.0.5 release notes

Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.

PingDirectoryProxy Server 8.0.0.3 release notes

Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.

Ticket ID	Description
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: * When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. * When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. * When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.

PingDirectoryProxy Server 8.0.0.2 Release Notes

Critical Fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41054	Fixed an issue that stopped new extensions from being installed.

Ticket ID	Description
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41299	Fixed an issue where PingDirectoryProxy Server could incorrectly return duplicate entries after timing out on an unindexed search.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42812	Upgrade to jetty 9.4.30

PingDirectoryProxy Server 8.0.0.1 Release Notes

Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.0.0.1

    Introduced in: 7.2.0.0

    Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1

    Introduced in: 5.2.0.0

    Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-

lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

  SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

  It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-

NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
  - Fixed in: 4.5.0.0
  - Introduced in: 4.1.0.7
  - Support identifiers: DS-9726
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Update the PingDirectoryProxy Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.

Ticket ID	Description
DS-41206	Fixed a memory leak when performing SCIM queries on the PingDirectory Server.

PingDirectoryProxy Server 8.0.0.0 Release Notes

Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

What's New

These are new features for this release of the PingDirectoryProxy Server:

- Better insight to server health and the performance of connected applications. Administrators can now push metrics to application insight and monitoring applications such as Splunk using two new methods. A new StatsD monitoring endpoint pushes metrics to StatsD-compatible services. Also, the periodic stats logger has been updated to use JSON-format log files, greatly simplifying the use of log forwarding tools like Splunk's Universal Forwarder or Elastic's FileBeats.
- Better support by Directory Proxy Server for orchestrated Directory Server clusters in automated environments like Kubernetes or AWS EC2 Auto Scaling. Administrators can connect the topology of a PingDirectoryProxy Server cluster to the topology of a PingDirectory Server cluster in order to automatically adapt to cluster changes within the PingDirectory Server cluster. This greatly simplifies the configuration management of PingDirectoryProxy Server when PingDirectory Server clusters are being added, removed, or replaced by automated infrastructure orchestrators.
- Use Server Profiles to reduce risk and improve consistency following the DevOps principle of infrastructure-as-code. Administrators can export the configuration of the PingDirectoryProxy Server server to a directory of text files called a Server Profile, track changes to these files in version control like Git, and install new instances of PingDirectoryProxy Server or update existing instances of Directory Proxy Server from a Server Profile. Server Profiles support variable substitution in order to remove the settings unique to each pre-production or production environment from the Server Profile that is stored in version control.

Known Issues/Workarounds

The following are known issues in the current version of the PingDirectoryProxy Server:

- The following are suggested solutions for problems with slow DNS:
  - Maintain a connection pool in the client app rather than opening new connections for each bind.
  - Add appropriate records, including PTR records, to DNS.
  - Add `options timeout:1` in the `/etc/resolv.conf` file and/or `options single-request`
  - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in Directory Server's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.

  Workaround: Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.
- The working directory value used by exec tasks is not implemented for recurring exec tasks.

- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
  - groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2
  - groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2

  Workaround: Deploy the Console in an external container using JDK 8.

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-17278	Added a `cn=Server Status Timeline,cn=monitor` monitor entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, `endpoint-cache-refresh`, has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the `Resource` column in the output of `status`. This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.
DS-38560	Updated `manage-profile replace-profile` to apply configuration changes directly, when possible. If the new server profile used by `replace-profile` has changed only the `dsconfig` batch files from the original profile, then only the `dsconfig` files are applied. If no changes are detected between profiles, `replace-profile` takes no action. If changes other than `dsconfig` are detected, the full `replace-profile` process is followed.
DS-38777	Added support for updating the server version during `manage-profile replace-profile`. The server must have been originally set up with a server profile.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.

Ticket ID	Description
DS-38863	Updated the `manage-profile setup` subcommand to set a server's cluster name to match its instance name by default. This prevents servers in the same replication topology from being in the same cluster, reducing the risk of unintentionally overwriting parts of an existing server's configuration in a DevOps environment. The `--useDefaultClusterName` argument can be used to leave the cluster name unchanged.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions. Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the `remove-defunct-server` tool's `--ignoreOnline` option. When using `--ignoreOnline` in a mixed-version environment, all servers must support the option.
DS-39155	Updated the default value for `maximum-degraded-missing-changes` to 1000000, and for `minimum-unavailable-missing-changes` to 100000. Servers that used the previous default values became unavailable prematurely, leading to outages.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit groovy-lang.org and view the Groovy 2.5 release notes. As of this release, only the core Groovy runtime and the groovy-json module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as groovy-xml or groovy-sql, download the appropriate jar file from *groovy-lang.org* and place it in the server's `lib/extensions` directory.
DS-39253	Added a `replace-certificate` tool, which can help an administrator replace the listener or inter-server certificate for a server instance.
DS-39321	Added support for PingDirectoryProxy Server to the `manage-profile` tool and its subcommands.

Ticket ID	Description
DS-39325	Removed the legacy product-specific scripts for starting and stopping the server. These include: ▪ `start-ds` and `stop-ds` for Directory Server ▪ `start-proxy` and `stop-proxy` for Directory Proxy Server ▪ `start-sync` and `stop-sync` for Data Sync Server ▪ start-metrics-engine and stop-metrics-engine for Data Metrics Server These legacy scripts had been deprecated for several releases in favor of the more general start-server and stop-server scripts, and they displayed a warning message about their upcoming removal if they were invoked. If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general start-server and stop-server scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point at the start-server and stop-server scripts.
DS-39347	Fixed an issue where Delegated Admin would not work properly if the name of the REST Resource Type was not the same as the resource endpoint.
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as `X-VALUE-REGEX`), this could cause unexpected or incorrect behavior.
DS-39525, DS-39526	Delegated Admin enhancements for constructed attributes. ▪ Allow a required attribute to be read-only if it is constructed. ▪ Add a configured list of "Update Constructed Attributes" on the REST resource type, similar to the "Post Create Constructed Attributes", so that constructed attributes can be updated when dependent attributes change. ▪ Handle constructed attributes which reference other constructed attributes.
DS-39592	HTTP External Servers have a new attribute, `ssl-cert-nickname`, which defines the alias of a specific certificate within their keystore to be used as a client certificate.
DS-39603	Fixed an issue where Server SDK extensions could not be configured by dsconfig batch files in the manage-profile tool.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.
DS-39654	Added support for the `--topologyFilePath` argument to the `manage-topology add-server` subcommand.
DS-39671	Updated the `manage-topology add-server` subcommand to require being run from the older server in a mixed-version environment.

Ticket ID	Description
DS-39693	Fixed an issue where Delegated Admin search results were truncated and invalid upon encountering a Directory entry containing a Boolean or Integer syntax attribute whose values were invalid because they did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results and a warning message is logged to the server errors log.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39762	Added support for a "generate password" extended operation that can be used to request that the server generate one or more passwords that may be suggested as possible values when creating a new user or changing the password for an existing user.
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40114	Added a new `cn=Status Health Summary,cn=monitor` monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.
DS-40249	Fixed an issue where an LDAP search across entry-balanced server sets sometimes returned 0 (success) even though all servers in one of the sets failed with a timeout. The search should return 52 (unavailable) in this situation.
DS-40252	Update the PingDirectoryProxy Server setup process to support joining an existing Ping Identity Platform topology.
DS-40255, DS-40256, DS-40257	Updated the fewest operations and failover load-balancing algorithms to support automatically discovering the set of backend Directory Server instances from the topology registry.
DS-40274	Updated the proxy to check if the proxy's backend has been sufficiently initialized prior to performing a health check.
DS-40354	Fixed a problem with `config-diff` when writing properties that span multiple lines using the `--prettyPrint` argument.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40543	Updated `manage-profile replace-profile` to copy the tool log file to the server being updated.

Ticket ID	Description
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40730	Updated the `encrypt-file` tool to prevent using the same path for both the input file and the output file.
DS-40771	Added a `--duration` argument to collect-support-data. When used, only the log files covering the specified duration before the current time will be collected.

PingDataMetrics Release Notes

PingDataMetrics 8.2.0.8 release notes

The release notes for the 8.2.0.8 release of PingDataMetrics.

Critical fixes

This release of PingDataMetrics addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of PingDataMetrics.

Ticket ID	Description
DS-45164	Updated Jetty Server to version 9.4.44.
DS-45813	Updated PingDirectory products to use Kafka v2.8.1.

PingDataMetrics Server 8.2.0.7 release notes

The release notes for the 8.2.0.7 release of PingDataMetrics Server.

Critical fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or **`remove-defunct-server`** tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

  The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

  ⓘ **Note:**

  Since this change only applies to the most recent version of **`remove-defunct-server`** and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past **`dsreplication`** and **`remove-defunct-server`**

could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

- Fixed in: 8.2.0.7
- Introduced in: 7.0.0.0
- Support identifiers: DS-44591

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server.

Ticket ID	Description
DS-44591	Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or **`remove-defunct-server`** tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed. The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology. ⓘ **Note:** Since this change only applies to the most recent version of **`remove-defunct-server`** and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past **`dsreplication`** and **`remove-defunct-server`** could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

Ticket ID	Description
DS-45124	Removed `-XX:RefDiscoveryPolicy=1` from the default start-server Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.
DS-45190	Added support for the use of JDKs obtained through BellSoft.

PingDataMetrics Server 8.2.0.6 release notes

Critical fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the DataMetrics Server.

Ticket ID	Description
DS-43632	Fixed an issue where the `format` field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-44224	Addressed an issue where icons on the dashboards were not properly displayed.

PingDataMetrics 8.2.0.5 release notes

Critical fixes

This release of the PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the PingDataMetrics Server.

Ticket ID	Description
DS-44025	Fixed an issue where the server was incorrectly displaying an `Unknown vendor` warning when using JDKs obtained on Red Hat and Ubuntu systems.

PingDataMetrics Sever 8.2.0.2 release notes

Critical Fixes

This release of the PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDataMetrics Server:

Ticket ID	Description
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the oidc-trust-store-file and oidc-trust-store-type settings. Also, you can set the console to skip hostname and/or certification verification through the oidc-strict-hostname-verification and oidc-trust-all configuration settings.

PingDataMetrics Server 8.2.0.1 release notes

Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Data Metrics Server 8.2.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the Data Metrics Server

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.

- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

What's New

These are new features for this release of the Data Metrics Server

- In an ongoing effort to improve the use of containers for PingDirectory, several features have been implemented:

  - The --outputFile option has been added to the collect-support-data tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the collect-support-data tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.

  - The collect-support-data tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.

  - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the --remoteServer added to the collect-support-data tool can be used to send the request to another server. In other words, you can now run collect-support-data on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectory has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party.

Known Issues/Workarounds

The following are known issues in the current version of the Data Metrics Server

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-5143, DS-11035	Updated support for logging access and error log messages to a syslog server. While the server previously supported logging these messages to a syslog server (through the "syslog-based access log publisher" and "syslog-based error log publisher" logger implementations), these loggers used an older version of the syslog protocol (described in RFC 3164) and only offered support for communicating over UDP. These loggers are still available for legacy backward compatibility, but we now also offer new "syslog text access log publisher" and "syslog text error log publisher" implementations that use a newer version of the syslog protocol (syslog version 1, described in RFC 5424) and support communicating over UDP or the more reliable TCP. When using TCP, it is also possible to encrypt communication with TLS and to configure multiple servers for better redundancy. These loggers use the same space-delimited text format as the former loggers. We also offer new "syslog JSON access log publisher" and "syslog JSON error log publisher" implementations that offer the same set of capabilities, but that format the message text as JSON objects, which can be more easily parsed by third-party software.
DS-10320, DS-12550, DS-12551, DS-12552, DS-42116, DS-42162, DS-42179, DS-42222, DS-42223, DS-42224, DS-42225, DS-42416, DS-42437	Added a config/sample-dsconfig-batch-files directory with set of well commented dsconfig batch files that may be useful in enabling or configuring a variety of features in the server.
DS-10775	Updated the dictionary password validator to support additional options: ▪ It can now ignore non-alphabetic characters that appear at the beginning or end of the password before checking the dictionary. ▪ It can strip characters of diacritical marks, including accents, cedillas, circumflexes, diaereses, tildes, and umlauts, before checking the dictionary. If this option is used, then any character with such a mark will be replaced with a base version of the character without that mark (for example, a lowercase letter n with a tilde over it would be replaced with just a lowercase letter n). ▪ You can define maps with information about character substitutions to use for checking alternative versions of the provided password. For example, if you indicate that "0" might map to "o", "1" or "!" might map to "i", "7" might map to "t", and "3" might map to "e", then the validator can reject a proposed password of "pr0h1b!73d" if the dictionary contains the word "prohibited". ▪ It can reject a proposed password if a value from the provided dictionary makes up more than a specified percentage of that password.

Ticket ID	Description
DS-11524, DS-41860, DS-42112	Added support for new administrative alert types. ▪ We have added a new admin alert account status notification handler, which can generate administrative alerts whenever an applicable account status notification is generated within the server. For example, this account status notification handler can be added to the root password policy to generate an alert whenever a root user's password is updated or their account is locked as a result of too many failed authentication attempts. A separate alert type has been defined for each account status notification type. ▪ We have added a new "privilege-assigned" administrative alert that can be raised whenever a new entry is added or an existing entry is updated to include one or more privileges. ▪ We have added a new "insecure-request-rejected" administrative alert that can be raised whenever the server rejects a request as a result of the reject-insecure-requests global configuration property.
DS-13853	Added support for the OAUTHBEARER SASL mechanism (as described in RFC 7628) to allow LDAP clients to authenticate with OAuth 2.0 bearer tokens.
DS-15848, DS-42360	Added support for invoking a specified set of password validators during bind operations. If the password used to authenticate fails to satisfy one or more of the configured validators, the bind attempt can be rejected, the user can be forced to change their password, or the server can generate an account status notification to take some alternative action (for example, notifying the end user or server administrators).
DS-15864	Replaced the ldappasswordmodify tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.
DS-17903	Updated setup to provide a --populateToolPropertiesFile argument that will allow it to populate the config/tools.properties file with default values for command-line tool arguments. If requested, properties will be provided for the server address, port, and communication security, and may also include a default bind DN and optionally a bind password. When running setup interactively, it will now prompt to determine which properties (if any) should be populated in the properties file.
DS-38110	Updated the System Information monitor with an "isDocker" attribute to identify if the server is running in a Docker container.
DS-38118, DS-42495	Made several updates related to the server's handling of data written to standard output and standard error: ▪ The server can now be configured to rotate the logs/server.out file once it reaches a given size, and it will retain a configurable number of those log files. By default, the server will rotate the file once it reaches 100 megabytes and will keep up to ten files. ▪ To better facilitate capturing log data in containerized environments, the server now supports writing JSON-formatted access and error log messages to the JVM's original standard output and error streams (which will be separate from the server.out file when the server is started with the --nodetach argument). ▪ It is now possible to prevent the server from logging messages during startup in non-JSON format. It is also possible to prevent messages about administrative alerts from being written to standard error, or to write those messages in JSON format. These options are especially useful when using JSON-based logging to the console in no-detach mode, as they can help ensure that everything written to standard output and standard error will be formatted as JSON objects.

Ticket ID	Description
DS-38868	Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.
DS-39789	Updated the JVM memory usage monitor provider to fix an issue that could prevent the monitor from reporting the total amount of memory held by all memory consumers. Also, fixed an issue that could cause the memory-consumer attribute to use an incomplete message for consumers without a defined maximum size and added an additional memory-consumer-json attribute whose values are JSON objects with data that can be more easily extracted by automated processes.
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-40967	Eliminated a misleading error message that could be logged at startup if the server was configured with one or more ACIs that only apply when using specific SASL mechanisms.
DS-41989	Fixed an issue that could result in duplicate column headers being produced by the Periodic Stats Logger, even when the header-prefix-per-column attribute was set to true.
DS-42045	Updated the Stats Collector Plugin with a new generate-collector-files configuration property. When using this plugin with the Data Metrics Server, leave this property at its default value of true. When using the plugin exclusively for providing metrics to one or more StatsD Monitoring Endpoints, set this property to false to prevent unnecessary I/O.
DS-42059, DS-42060	Updated setup to add options for improving communication security: ▪ Non-interactive setup now offers a --rejectInsecureRequests argument that will configure the server to reject any request received over a connection that is not encrypted with SSL or StartTLS. ▪ Non-interactive setup now offers a --rejectUnauthenticatedRequests argument that will configure the server to reject any request received over a connection that is not authenticated (or that is authenticated as the anonymous user). ▪ Interactive setup now allows you to configure the server with the LDAP connection handler disabled (which was already an option when using non-interactive setup), or enabled but only for communication encrypted with StartTLS. The --rejectInsecureRequests and --rejectUnauthenticatedRequests arguments can also be used with manage-profile by including them in the setup-arguments.txt file of the server profile.

Ticket ID	Description
DS-42061	Updated the interactive command-line tool framework to prefer establishing secure LDAP connections over insecure connections. Previously, when prompting for the information needed to establish a connection, the default option was to create an unencrypted LDAP connection. Now, tools default to creating an SSL-encrypted connection if the server supports it, or to creating a StartTLS-encrypted connection if that is available but SSL is not. Tools also default to using streamlined settings when establishing secure connections. Previously, they would always prompt about how to determine whether the server's certificate chain should be trusted. When using the streamlined settings, the tools only prompt about certificates that cannot automatically be considered trusted using information in the JVM's default trust store, the server's default trust store (config/truststore), or the server's topology registry.
DS-42062	Updated the root password policy so that LDAP bind responses for root users and topology administrators will be delayed by one second after five consecutive failed authentication attempts.
DS-42063	Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non-LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
DS-42115	Updated the server's command-line tool framework to make it easier and more convenient to communicate with the server over a secure connection when no trust-related arguments are provided. Most non-interactive tools will now check the server's default trust store, the topology registry, and the JVM's default trust store to see if the presented certificate chain can be automatically trusted without the need to prompt the user. If the presented chain cannot be automatically trusted, the user may be interactively prompted to determine whether it should be trusted.
DS-42279	Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.
DS-42298	Replaced the ldifsearch, ldifmodify, and ldif-diff command-line tools with more full-featured and robust implementations.
DS-42331	Replaced the ldapcompare tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).
DS-42347	Updated the server to use /dev/urandom (on non-Windows systems where that path exists and is readable) instead of /dev/random as the primary source for secure random data. Attempts to read from /dev/random can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from /dev/urandom will not block, and the data that it provides is no less secure than data from /dev/random in any way that matters for the server.
DS-42504	Updated manage-profile replace-profile to set encryption settings definitions defined in the newer server profile as preferred in the encryption settings db.
DS-42547	Fixed an issue where **`manage-profile generate-profile`** would print `null` as the generated profile directory when writing to an existing directory.

Ticket ID	Description
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42632	Added support for creating or importing a key pair configuration object using an elliptic curve (EC) key algorithm. You can use this to designate the encryption key pair for a JWT access token validator that handles EC-encrypted access tokens.
DS-42634	The JWT Access Token Validator can now validate JWT access tokens signed using the elliptic curve digital signature algorithms ES256, ES384, and ES512.
DS-42635	The JWT Access Token Validator can now validate JWT access tokens encrypted using elliptic curve cryptographic algorithms. The following key encryption algorithms are now supported in addition to RSA-OAEP: ECDH-ES, ECDH-ES+A128KW, ECDH-ES+A192KW, and ECDH-ES +A256KW. To support best practices for JWT security, you must now also configure the JWT Access Token Validator with explicit allow lists for key encryption and content encryption algorithms. For backward compatibility, the key encryption allow list defaults to RSA-OAEP, while the content encryption allow list defaults to A128CBC-HS256, A192CBC-HS384, and A256CBC-HS512. We recommend setting both allow lists to the strict minimum set of algorithms needed by the Access Token Validator.
DS-42651	Updated the **`manage-profile replace-profile`** subcommand to better support updating the server's keystore and truststore files. When using the `--generateSelfSignedCertificate` argument in a server profile's `setup-arguments.txt` file, the server maintains the original keystore and truststore files during **`replace-profile`**. Otherwise, **`replace-profile`** uses the keystore and truststore specified in the profile's `setup-arguments.txt` file.
DS-42667	Updated the server to set a unique cluster name when started for the first time.
DS-42669, DS-42748	Updated the online dsconfig step of the manage-profile replace-profile subcommand to support getting LDAP connection arguments from a tools.properties file on the server being updated. Fixed an issue where boolean LDAP connection arguments like --useSSL and --trustAll would cause manage-profile replace-profile to fail when applying dsconfig online.
DS-42681, DS-42684	Performance statistics generated by the Sideband API can now be published by the Periodic Stats Logger. To enable this, use the "included-http-servlet-stat" property of the Periodic Stats Logger.
DS-42673	Updated the **`manage-profile setup`** subcommand to fail if the **`start-server`** command has a non-zero exit code.
DS-42687	Upgrade to Jetty 9.4.30.
DS-42740	Fixed an issue where the **`dsconfig list`** subcommand would not display requested properties.
DS-42749	To support best practices for JWT security, you must now configure the JWT Access Token Validator with an explicit list of the JWT signing algorithms that it accepts. For backward compatibility, this list defaults to the RSA signing algorithms RS256, RS384, and RS512, but we recommend setting this list to the strict minimum set of signing algorithms needed by the Access Token Validator.

Ticket ID	Description
DS-42751	Added new override-status-code and additional-response-contents attributes to the Availability State HTTP Servlet Extension. These new attributes can be used to customize the response code and JSON response body of the servlet.
DS-42861	Updated the **`manage-profile`** tool logs to include the duration of each step the tool takes. The new `--verbose` argument can also be used to display timing information in the tool's console output.
DS-42886	Updated non-interactive **`setup`** (including **`manage-profile setup`**) to allow the password for the initial root user to be provided in pre-encoded form using the PBKDF2, SSHA256, SSHA384, or SSHA512 password storage scheme. This eliminates the need to have access to the clear-text password when setting up the server.
DS-42926	Fixed an issue where Ping Directory products configured to run as Microsoft Windows services were sometimes unable to automatically restart following an unplanned reboot, due to errors reading a corrupted server status file.
DS-42952	For Windows only, there can be a hang on start when global configuration property `startup-error-logger-output-location` is set to values that contain `standard-error`. For Windows only, `standard-error` values are silently mapped to equivalent `standard-output` values.
DS-42963	Updated the **`manage-profile generate-profile`** subcommand to ignore files larger than 100 megabytes when generating a server profile. Fixed an issue where many large files in the server root could cause the tool to run out of memory.
DS-43376	Updated log publisher logic to reduce the amount of CPU that the server consumes when it is idle.
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that can be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments might include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server now only includes values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems and that are not expected to contain sensitive information.
DS-43517	Updated the jose4j library used for JWT signing and encryption to version 0.7.2.
DS-43651	The Security Guide is now available online at pingidentity.com. The guide has been removed from the server packaging.

Critical fixes

Critical Fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301

- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed a memory leak when performing SCIM queries on PingDataMetrics Server.
  - Fixed in: 8.0.0.1

    Introduced in: 7.2.0.0

    Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1

    Introduced in: 5.2.0.0

    Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-

endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

Release Notes Archive

Release notes for previous versions of Ping Data Metrics Server are included for reference.

PingDataMetrics Server 8.1.0.6 release notes
The release notes for the 8.1.0.6 release of PingDataMetrics Server.

Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Data Metrics Server.

Ticket ID	Description
DS-44224	Addressed an issue where icons on the dashboards were not properly displayed.

PingDataMetrics 8.1.0.5 release notes

Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Data Metrics Server.

Ticket ID	Description
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: * When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. * When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. * When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

Data Metrics Server 8.1.0.2 Release Notes

Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.
  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-42687	Upgrade to Jetty 9.4.30

PingDataMetrics Server 8.1 Release Notes

Critical Fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0

  - Fixed in: 8.0.0.1

    Introduced in: 7.2.0.0

    Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1

    Introduced in: 5.2.0.0

    Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

  In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

  We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

- Support identifiers: DS-38897 DS-38908

Upgrade Considerations

Important considerations for upgrading to this version of the Data Metrics Server

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

What's New

These are new features for this release of the Data Metrics Server

- In an ongoing effort to improve the use of containers for PingDirectory, several features have been implemented:

  - The --outputFile option has been added to the collect-support-data tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the collect-support-data tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.

  - The collect-support-data tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.

  - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the --remoteServer added to the collect-support-data tool can be used to send the request to another server. In other words, you can now run collect-support-data on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectory has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party.

Known Issues/Workarounds

The following are known issues in the current version of the Data Metrics Server

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.

Ticket ID	Description
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.

Ticket ID	Description
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41818	Added the --zip argument to the manage-profile generate-profile subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to /instance-root by authenticated users with the file-servlet-access privilege will be granted access to files within the server instance root.
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has memory.swappiness set to a nonzero value.
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a NullPointerException if a server was configured with a custom global result code map.
DS-42387	Updated the **`manage-profile generate-profile`** subcommand to exclude files in the `ldif/` and `bak/` directories by default when generating a server profile. If necessary, you can manually include those directories using the `--includePath` argument.

PingDataMetrics 8.0.0.5 release notes

Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Ping Data Metrics Server 8.0.0.3 release notes

Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.

Ticket ID	Description
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: * When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. * When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. * When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.

Ping Data Metrics Server 8.0.0.2 Release Notes

Critical Fixes

This release of the Ping Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the Ping Data Metrics Server :

Ticket ID	Description
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.

Ticket ID	Description
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42812	Upgrade to jetty 9.4.30

PingDataMetrics Server 8.0.0.1 Release Notes

Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on .
  - Fixed in: 8.0.0.1

    Introduced in: 7.2.0.0

    Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1

    Introduced in: 5.2.0.0

    Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that

were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-

lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

  SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

  It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition,

if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.

PingDataMetrics Server 8.0.0.0 Release Notes

Critical Fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Known Issues and Workarounds

The following are known issues in the current version of PingDataMetrics Server:

- The following are suggested solutions for problems with slow DNS:
  - Maintain a connection pool in the client app rather than opening new connections for each bind.
  - Add appropriate records, including PTR records, to DNS.
  - Add `options timeout:1` in the `/etc/resolv.conf` file and/or `options single-request`.
  - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.
  - **Workaround:** Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.
- The working directory value used by exec tasks is not implemented for recurring exec tasks.

Resolved Issues

The following issues have been resolved with this release of PingDataMetrics Server:

Ticket ID	Description
DS-17278	Added a `cn=Server Status Timeline,cn=monitor` monitor entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, `endpoint-cache-refresh`, has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the `Resource` column in the output of `status`. This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions. Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the `remove-defunct-server` tool's `--ignoreOnline` option. When using `--ignoreOnline` in a mixed-version environment, all servers must support the option.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit *groovy-lang.org* and view the Groovy 2.5 release notes. As of this release, only the core Groovy runtime and the groovy-json module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as groovy-xml or groovy-sql, download the appropriate jar file from *groovy-lang.org* and place it in the server's `lib/extensions` directory.
DS-39253	Added a `replace-certificate` tool, which can help an administrator replace the listener or inter-server certificate for a server instance.

Ticket ID	Description
DS-39325	Removed the legacy product-specific scripts for starting and stopping the server. These include: ▪ `start-ds` and `stop-ds` for Directory Server ▪ `start-proxy` and `stop-proxy` for Directory Proxy Server ▪ `start-sync` and `stop-sync` for Data Sync Server ▪ `start-metrics-engine` and `stop-metrics-engine` for These legacy scripts had been deprecated for several releases in favor of the more general start-server and stop-server scripts, and they displayed a warning message about their upcoming removal if they were invoked. If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general start-server and stop-server scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point at the start-server and stop-server scripts.
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as `X-VALUE-REGEX`), this could cause unexpected or incorrect behavior.
DS-39592	HTTP External Servers have a new attribute, `ssl-cert-nickname`, which defines the alias of a specific certificate within their keystore to be used as a client certificate.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.
DS-39654	Added support for the `--topologyFilePath` argument to the `manage-topology add-server` subcommand.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40114	Added a new `cn=Status Health Summary,cn=monitor` monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.
DS-40354	Fixed a problem with `config-diff` when writing properties that span multiple lines using the `--prettyPrint` argument.

Ticket ID	Description
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40730	Updated the `encrypt-file` tool to prevent using the same path for both the input file and the output file.
DS-40771	Added a `--duration` argument to `collect-support-data`. When used, only the log files covering the specified duration before the current time will be collected.

Delegated Admin Release Notes

Delegated Admin 4.4.0 - December 2020

The following enhancements and resolved issues are included in this release.

Enhancements

These are new features for this release of the Delegated Administration application:

- Delegated administrative users can now create a user account without setting a password if the password is not required by the server. This is only true for user creation. Resetting a password still requires a valid value for the password.
- Previously, users could download a full report of users and group membership. Now the administrative user can preview the report and apply filters to limit either the entries themselves or to filter which columns are displayed. The user can also sort the report by columns. The user can then download the resulting report with all the filters applied.
- The Delegated Administrator user interface now allows you to move and display the password field anywhere on the **Create User** form. Specify this in the configuration of the REST Resource Type with the Password Attribute Category and Password Display Order Index properties. If you do not specify a category, the password field appears at the top of the page.
- The Delegated Administration application does not require delegated administrative users to understand the underlying technology supporting the account management features, such as LDAP. PingDirectory is an LDAP server and, therefore, uses Distinguished Names (DNs) to identify entries in the directory. The Delegated Administration application allows the user to select a user entry based on its DN without displaying the actual value of the DN.
- Account management improvements allow administrators to view information about account and password state, such as password expiration date, account lockout status, and last login date and time.
- Administrative users can now bulk upload user entries from a CSV file. The users need the proper rights for the resource types on which they wish to create user entries. The information in the file to upload must be based on the attributes configured for the resource type. The upload creates user entries if they do not exist, and optionally adds the entries to a group. If a user entry exists, the upload updates the entry. You can also upload generic entries.
- Previously, administrative users could create, preview, and download reports of users, group membership, or other generic resources to a CSV file. With this release, you can choose to not present the download and/or upload options to certain administrative users.

- Completing the basic entry management functionality, administrative users with the proper rights for the resource type can now delete user, group, and generic entries.

Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in *Upgrade considerations* on page 1244.

Resolved issues

The following table identifies issues that have been resolved with this release of Delegated Admin.

Ticket ID	Description
DS-42793	Fixed an issue where an infinite spinner would intermittently appear when signing on.
DS-41913	Added the ability to move the Password field on the **Create User** form.

Known issues and limitations

- Delegated Admin 4.2.0 has an intermittent, infinite spinner issue when signing on. To address the issue and continue using PingDirectory 8.1.0.0, install Delegated Admin 4.2.1. Alternatively, you can upgrade to Delegated Admin 4.4.0 to address the issue; however, that upgrade requires upgrading to PingDirectory 8.2.0.0.
- For versions 4.2.0-4.4.0, Delegated Admin produces an error on edit or create of resource types that contain an attribute with an unrecognized data type. For supported data types, see *Configuring attributes and attribute search on PingDirectory Server* on page 1254. Delegated Admin 4.4.1 addresses this error.

Previous releases

Release Notes for earlier versions of Delegated Admin are included for reference.

Delegated Admin 4.2.0 Release Notes

Upgrade Considerations

If you are running Delegated Administration application version 3.5 or older, you will need to upgrade it to the latest version if you want to use PingDirectory 8.0 or newer.

What's New

These are new features for this release of PingDirectory Delegated Admin:

- Delegated Admin 4.1
  - For Delegated Admin, administrators can be assigned rights to manage different types of resources such as users and groups. Previously, administrators who can only manage users in specified groups could not create users to put them in the one of the groups they managed. Now, administrators with the ability to manage and create groups can create users within the group(s) they manage.
  - REST resource types define the types of objects that can be managed by delegated administrators. Typical REST resource types include users and groups which can be configured based on the sub-tree and a predefined search filter. A new include-filter property has been added to REST resource types to differentiate different resource types that are within the same subtree and have the same objectclass.

- Delegated Admin 4.2
  - Administrative users can now create and download reports of users, group membership or other generic resource to a CSV file. The users need the proper rights for the resource types on which they wish to report. The information stored in the downloaded file will be based on the attributes configured for the resource type. For group resource types, each report generated will be for a single group.
  - Added a new reference permission to Delegated Admin resource rights configuration which allows the administrator to reference resources when selecting a parent for a new resource. This permission differs from read permission in that the app will not show an option to manage the parent resource type in the Delegated Administrator app.
  - In many circumstances, LDAP attributes within an entry contain multiple values. The application can now display multi-valued attributes which are not handled by custom UI form fields.
  - A privileged administrator for a hosting company can onboard a new tenant administrator to manage resources for the tenant's own organization without requiring additional configuration from the Administrative Console or command line.

Known Issues/Workarounds

The following are known issues in the current version of PingDirectory Delegated Admin:

- PingDirectory Delegated Admin does not always show the account locked status correctly if the server password policy is configured to require the user to reset their password after the password has been administratively reset. This can be corrected by enabling the Password Policy State JSON virtual attribute for the user object class. For example:

```
dsconfig set-virtual-attribute-prop --name "Password Policy State JSON" \
--set enabled:true --set require-explicit-request-by-name:true \
--set "filter:(objectClass=person)"
```

Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin:

Ticket ID	Description
DS-41819	Fixed an issue where a Delegated Administrator was unable to add or remove themselves to or from a group to which they had rights to manage group membership.
DS-41848	Fixed an issue where edits modifying only the case or capitalization of an attribute value did not take effect.
DS-42387	Updated the **`manage-profile generate-profile`** subcommand to exclude files in the `ldif/` and `bak/` directories by default when generating a server profile. If necessary, you can manually include those directories using the `--includePath` argument.

Delegated Admin 4.1.0 Release Notes

Upgrade Considerations

Upgrade directly to this release from versions prior to 7.0 is not supported. As a workaround, upgrade from a pre-7.0 version to 8.0, and then upgrade to this version.

What's New

These are new features for this release of :

- Administrators can be assigned rights to manage different types of resources such as users and groups. Previously, administrators who can only manage users in specified groups could not create users to put them in the one of the groups they managed. Now, administrators with the ability to manage and create groups can create users within the group(s) they manage.
- When the Delegated admin rights for a User REST resource type have admin scope resources-in-specific-groups, a user is added to one of the configured groups when the user is created.
- An example file for JSON attributes, example-json.html, has been added and can be located alongside other existing example files for custom UI form fields. This example file supports a single value and uses the expected JSON structure of ubidEmailJSON, an available JSON attribute type for Ping Directory. Multiple values are also supported, please see the example-multivalue.html for an example of how to handle that use-case. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.
- Multivalue attributes may now be handled as part of custom UI form fields. Contrary to single value attributes, an array of values will need to be sent up to the form when building out the custom field. An example file, example-multivalue.html, has been provided to demonstrate a string-based, multivalue attribute as a custom UI form field and can be located alongside other existing example files. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.

Known Issues/Workarounds

The following are known issues in this version of Delegated Admin:

- In environments with Proxy and multiple backend servers, there is a known issue using the fewest-operation load-balancing algorithm with the Delegated Admin app. Constructed attributes sometimes do not get updated when the attributes they reference are edited. Using a failover load-balancing algorithm is a workaround for this issue. (DS-40977)

Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin:

Ticket ID	Description
DS-40938	Fixed an issue when Delegated Admin is installed on the Directory Proxy Server where a constructed attribute that is set to be read-only may not update in the app immediately after one of the attributes it references is updated.
DS-41066	Fixed an issue where JSON object values for attributes caused an application error when attempting to display them in the UI.

Ticket ID	Description
DS-41275	It is now a configuration error to enable two REST resource types with the same endpoint (ignoring differences in case) at the same time. It is allowed to have two resource types with the same endpoint if one or both of them are not enabled.
DS-41669	An example file for JSON attributes, example-json.html, has been added and can be located alongside other existing example files for custom UI form fields. This example file supports a single value and uses the expected JSON structure of ubidEmailJSON, an available JSON attribute type for Ping Directory. Multiple values are also supported, please see the example-multivalue.html for an example of how to handle that use-case. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.
DS-41715	Multivalue attributes may now be handled as part of custom UI form fields. Contrary to single value attributes, an array of values will need to be sent up to the form when building out the custom field. An example file, example-multivalue.html, has been provided to demonstrate a string-based, multivalue attribute as a custom UI form field and can be located alongside other existing example files. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.

Delegated Admin 4.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of Delegated Admin:

PingDirectory 8.0.0.0 is now the minimum required version to use with Delegated Admin 4.0.0. If you are on an older version of PingDirectory, it will be necessary to upgrade to PingDirectory 8.0.0.0 to maintain compatibility.

Delegated Admin 3.5.1 is compatible with PingDirectory Server 8.0.0.0. However, versions of Delegated Admin that are earlier than 4.0.0 will not be compatible with versions of PingDirectory Server that are later than 8.0.0.0.

By default, the display name for the logged in delegated admin will no longer display. To re-configure this functionality, please see the section on enabling the `name` attribute to be returned with the OIDC id token. See the Delegated Admin Guide for more information.

The `delegated-admin-template.dsconfig` file has been updated to allow for `generate-password` extended requests and password validation details request controls. This change is not applied during an update. You must run the following two **`dsconfig`** commands when updating :

```
dsconfig set-access-control-handler-prop --add \
'global-aci:(extop="1.3.6.1.4.1.30221.2.6.62")(version 3.0; \
acl "Authenticated access to the generate-password extended \
```

```
request for the Delegated Admin API"; allow (read) userdn="ldap:///all";)'
```

```
dsconfig set-access-control-handler-prop \
--add 'global-aci:(targetcontrol="1.3.6.1.4.1.30221.2.5.40")\
(version 3.0;acl "Authenticated access to the password validation details
 request \
control for the Delegated Admin API"; allow (read) userdn="ldap:///all";)'
```

What's New

These are new features for this release of :

- Invite new users via e-mail: Taking advantage of the new e-mail notification capabilities of 8.0.0.0, now administrators can configure the service so that when a delegated admin creates a new user, the server can send an HTML e-mail to tell the new user their password and invite them to use their new account. Combine this with PingFederate self-service profile management to invite the new user to complete their profile.
- When creating users or resetting passwords, delegated admins now have the option to type in the new password or have the server generate a password. Previously the application only supported server-generated passwords.
- More flexibility in delegating the management of user profiles: Now administrators can configure the service so that delegated admins of one type, such as Employee, can create and manage users of other types, such as Customers or Members. Previously delegated admins could only create and manage users of their own type.

Known Issues/Workarounds

The following are known issues in this version of Delegated Admin:

-
- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
  - groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2
  - groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2

  Workaround: Deploy the Console in an external container using JDK 8.

Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin:

Ticket ID	Description
DS-39352	When adding a user to groups and there were no non-member groups to display, the notice text did not use proper context to reflect this state.
DS-39782	Constructed attributes were not updated in the application after their associated attributes were edited. A page refresh or subsequent data request was required to reflect the change for the constructed attribute in the application.

Ticket ID	Description
DS-40690	This scenario occurred when a delegated admin only had permission to edit users in certain groups. If the delegated admin then went to a user's profile and removed them from the group which governed permission over that user, this action resulted in an application error.
DS-41715	Multivalue attributes may now be handled as part of custom UI form fields. Contrary to single value attributes, an array of values will need to be sent up to the form when building out the custom field. An example file, example-multivalue.html, has been provided to demonstrate a string-based, multivalue attribute as a custom UI form field and can be located alongside other existing example files. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.

Delegated Admin 3.5.1 Release Notes

Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin.

Ticket ID	Description
DS-38745, DS-39639	Previously, when port 443 was used but not specified in the PingFederate Base URL, the system returned an `Invalid issuer in token` message. With this fix, the value for **`window.PF_PORT`** can be left blank in `config.js` to match the expected Base URL that the PingFederate token supplies.

Delegated Admin 3.5.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of Delegated Admin:

The file `remove-sample-directory-data-aci.ldif`, which is provided with the Delegated Admin installation package, was updated to reinstate permissions for users to change their own passwords (self-service password reset). If you have used an earlier version of this LDIF file, consider manually adding the following ACI from the updated version:

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr="userPassword")(version 3.0; acl "Allow users to update
 their own password"; allow (write) userdn="ldap:///self";)
```

What's New

The following features are new with this release of Delegated Admin:

- Added the ability for developers to customize attribute form fields and form behaviors. Previously, `Delegated User Admin` did not support attributes whose types were neither strings nor numbers, like JSON attribute types. With the ability to override the form fields for any attribute type, developers can now extend `Delegated User Admin` to handle these attribute types and more. Requires PingDirectory Server 7.3.0.0 or later.
- Added more capabilities for attributes that are constructed from other attributes. The *constructed attribute* feature can now be used for attributes that the LDAP schema requires. Further, administrators can configure constructed attributes to update automatically when their referenced attributes change. For example, if `displayName` is constructed from `givenName` and `sn`, the `displayName` attribute updates whenever the delegated administrator updates either `givenName` or `sn`. Requires PingDirectory Server 7.3.0.1 or later.

Known Issues and Workarounds

The following issues are known in this release of Delegated Admin:

- Changes to custom form field HTML files are not displayed.

  This issue relates to the browser and server. Because PingDirectory Server does not send the appropriate cache headers for static files, some browsers might cache them aggressively.

  Workaround: Refer to the "Next steps" section in *Customizing UI form fields* on page 1266.
- Constructed attributes do not update automatically when editing a resource.

  This issue relates to the user interface (UI). When a constructed attribute is computed and saved in PingDirectory Server, the UI does not immediately display the new value.

  Workaround: To verify the changes visually, try one or both of the following suggestions:

  - Refresh the browser.
  - Visit another page, and then navigate back to the edited resource.

Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin.

Ticket ID	Description
DS-39347	Fixed an issue in which Delegated Admin did not work properly if the name of the REST resource type was not the same as the resource endpoint.
DS-39693	Fixed an issue in which Delegated Admin search results were truncated and invalid upon encountering a Directory entry that contained a Boolean or Integer syntax attribute whose values did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results, and a warning message is logged to the server errors log.

PingDataSync Server Release Notes

PingDataSync 8.2.0.8 release notes

The release notes for the 8.2.0.8 release of the PingDataSync server.

Critical fixes

This release of the PingDataSync server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the PingDataSync server.

Ticket ID	Description
DS-45164	Updated Jetty Server to version 9.4.44.
DS-45813	Updated PingDirectory products to use Kafka v2.8.1.

PingDataSync Server 8.2.0.7 release notes

The release notes for the 8.2.0.7 release of PingDataSync Server.

Critical fixes

This release of PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or **`remove-defunct-server`** tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

  The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

  > ⓘ **Note:**
  >
  > Since this change only applies to the most recent version of **`remove-defunct-server`** and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past **`dsreplication`** and **`remove-defunct-server`** could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

  - Fixed in: 8.2.0.7
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-44591

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
DS-44591	Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or **`remove-defunct-server`** tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed. The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology. ⓘ **Note:** Since this change only applies to the most recent version of **`remove-defunct-server`** and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past **`dsreplication`** and **`remove-defunct-server`** could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.
DS-45124	Removed `-XX:RefDiscoveryPolicy=1` from the default start-server Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.
DS-45190	Added support for the use of JDKs obtained through BellSoft.

PingDataSync Server 8.2.0.6 release notes

Critical fixes

This release of PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the DataSync Server.

Ticket ID	Description
DS-43632	Fixed an issue where the `format` field is omitted from the list of operational attribute schemas in the Directory REST API.

PingDataSync Server 8.2.0.5 release notes

Critical Fixes

This release of the PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the PingDataSync Server.

Ticket ID	Description
DS-44025	Fixed an issue where the server was incorrectly displaying an `Unknown vendor` warning when using JDKs obtained on Red Hat and Ubuntu systems.

PingDataSync 8.2.0.2 release notes

Critical Fixes

This release of PingDataSync addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of PingDataSync:

Ticket ID	Description
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.

Ticket ID	Description
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the oidc-trust-store-file and oidc-trust-store-type settings. Also, you can set the console to skip hostname and/or certification verification through the oidc-strict-hostname-verification and oidc-trust-all configuration settings.

PingDataSync 8.2.0.1 release notes

Critical Fixes

This release of PingDataSync addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

PingDataSync 8.2 release notes

Enhancements

The new feature for this release is:

- The Administrative Console now supports using OpenID Connect for admin SSO, allowing you to set up the PingOne administration console to have one-click SSO access without typing a password.

Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in *Upgrade overview and considerations* on page 1292.

Known issues and limitations

The following are known issues in the current version of Data Sync Server:

When signing on to the Administrative Console, you must specify an LDAPS port in the **Server** field. For example, to use port 636, you would specify pingdirectory:636. If you do not specify a port, you get a

```
"Server
      unavailable"
```

message.

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-5040	Improved the **`dsframework`** tool to support multivalued server properties.

Ticket ID	Description
DS-5143, DS-11035	Updated support for logging access and error log messages to a syslog server. While the server previously supported logging these messages to a syslog server (through the "syslog-based access log publisher" and "syslog-based error log publisher" logger implementations), these loggers used an older version of the syslog protocol (described in RFC 3164) and only offered support for communicating over UDP. These loggers are still available for legacy backward compatibility, but we now also offer new "syslog text access log publisher" and "syslog text error log publisher" implementations that use a newer version of the syslog protocol (syslog version 1, described in RFC 5424) and support communicating over UDP or the more reliable TCP. When using TCP, it is also possible to encrypt communication with TLS, and it is possible to configure multiple servers for better redundancy. These loggers use the same space-delimited text format as the former loggers. We also offer new "syslog JSON access log publisher" and "syslog JSON error log publisher" implementations that offer the same set of capabilities, but that format the message text as JSON objects, which can be more easily parsed by third-party software.
DS-10320, DS-12550, DS-12551, DS-12552, DS-42116, DS-42162, DS-42179, DS-42222, DS-42223, DS-42224, DS-42225, DS-42416, DS-42437	Added a config/sample-dsconfig-batch-files directory with set of well commented dsconfig batch files that may be useful in enabling or configuring a variety of features in the server.
DS-10775	Updated the dictionary password validator to support additional options: * It can now ignore non-alphabetic characters that appear at the beginning or end of the password before checking the dictionary. * It can strip characters of diacritical marks, including accents, cedillas, circumflexes, diaereses, tildes, and umlauts, before checking the dictionary. If this option is used, then any character with such a mark will be replaced with a base version of the character without that mark (for example, a lowercase letter n with a tilde over it would be replaced with just a lowercase letter n). * You can define maps with information about character substitutions to use for checking alternative versions of the provided password. For example, if you indicate that "0" might map to "o", "1" or "!" might map to "i", "7" might map to "t", and "3" might map to "e", then the validator can reject a proposed password of "pr0h1b!73d" if the dictionary contains the word "prohibited". * It can reject a proposed password if a value from the provided dictionary makes up more than a specified percentage of that password.

Ticket ID	Description
DS-11524, DS-41860, DS-42112	Added support for new administrative alert types: * We have added a new admin alert account status notification handler, which can generate administrative alerts whenever an applicable account status notification is generated within the server. For example, this account status notification handler can be added to the root password policy to generate an alert whenever a root user's password is updated or their account is locked as a result of too many failed authentication attempts. A separate alert type has been defined for each account status notification type. * We have added a new "privilege-assigned" administrative alert that can be raised whenever a new entry is added or an existing entry is updated to include one or more privileges. * We have added a new "insecure-request-rejected" administrative alert that can be raised whenever the server rejects a request as a result of the reject-insecure-requests global configuration property.
DS-13853	Added support for the OAUTHBEARER SASL mechanism (as described in RFC 7628) to allow LDAP clients to authenticate with OAuth 2.0 bearer tokens.
DS-15848, DS-42360	Added support for invoking a specified set of password validators during bind operations. If the password used to authenticate fails to satisfy one or more of the configured validators, the bind attempt can be rejected, the user can be forced to change their password, or the server can generate an account status notification to take some alternative action (for example, notifying the end user or server administrators).
DS-15864	Replaced the ldappasswordmodify tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.
DS-16228	Added support for JSON-formatted Sync loggers and Sync Failed Ops loggers, which complement the existing file-based Sync logger and file- based Sync Failed Ops logger, respectively. The JSON-formatted Sync log messages provide information about synchronization events the server has processed, and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server.
DS-17903	Updated setup to provide a --populateToolPropertiesFile argument that will allow it to populate the config/tools.properties file with default values for command-line tool arguments. If requested, properties will be provided for the server address, port, and communication security, and may also include a default bind DN and optionally a bind password. When running setup interactively, it will now prompt to determine which properties (if any) should be populated in the properties file.
DS-36088	Updated the crypto manager to make it possible to augment the set of enabled TLS cipher suites with specific suites to add to or remove from the default set of enabled suites. To enable one or more suites in addition to those in the default set, prefix the names of those suites with the "+" symbol. To disable one or more suites in the default set of enabled suites, prefix the names of those suites with the "-" symbol. This was already possible when configuring cipher suites for the LDAP and HTTP connection handlers, but it was not an option for the crypto manager.

Ticket ID	Description
DS-37890	Added a new property to sync classes called replace-all-attr-values- limit. The property is only used when replace-all-attr-values is true and the sync destination is an LDAP server. If a modification would replace more values of the same attribute than the value of replace-all- attr-values-limit, then the modification will use ADD or DELETE operations rather than a REPLACE operation.
DS-38110	Updated the System Information monitor with an "isDocker" attribute to identify if the server is running in a Docker container.
DS-38118, DS-42495	Made several updates related to the server's handling of data written to standard output and standard error: * The server can now be configured to rotate the logs/server.out file once it reaches a given size, and it will retain a configurable number of those log files. By default, the server will rotate the file once it reaches 100 megabytes and will keep up to ten files. * To better facilitate capturing log data in containerized environments, the server now supports writing JSON-formatted access and error log messages to the JVM's original standard output and error streams (which will be separate from the server.out file when the server is started with the --nodetach argument). * It is now possible to prevent the server from logging messages during startup in non-JSON format. It is also possible to prevent messages about administrative alerts from being written to standard error, or to write those messages in JSON format. These options are especially useful when using JSON-based logging to the console in no-detach mode, as they can help ensure that everything written to standard output and standard error will be formatted as JSON objects.
DS-38868	Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.
DS-39646	Updated the manage-topology add-server command to configure failover for Data Sync servers when they are added to a topology.
DS-39789	Updated the JVM memory usage monitor provider to fix an issue that could prevent the monitor from reporting the total amount of memory held by all memory consumers. Also, fixed an issue that could cause the memory-consumer attribute to use an incomplete message for consumers without a defined maximum size and added an additional memory-consumer-json attribute whose values are JSON objects with data that can be more easily extracted by automated processes.
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.

Ticket ID	Description
DS-40967	Eliminated a misleading error message that could be logged at startup if the server was configured with one or more ACIs that only apply when using specific SASL mechanisms.
DS-41350	Fixed an issue where disabling certain backends (such as 'alarms') caused an internal monitor to log unnecessary error messages every few seconds, about not being able to gather data from that backend. Note that deliberately disabling the 'alarms' backend is not recommended in normal operation, but may occur during backup/restore operations.
DS-41807	Fixed an issue where LDAP DELETE operations were sometimes not synchronized from an Oracle Unified Directory sync source, due to variations in the format of the 'targetUniqueID' attribute obtained from the Oracle changelog.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-41989	Fixed an issue that could result in duplicate column headers being produced by the Periodic Stats Logger, even when the header-prefix-per-column attribute was set to true.
DS-42004	Added a new configuration property, changes-queue-size, that controls the size of the changes queue on a Sync Pipe. This was previously only configurable via a system property, and it would change the queue size of all Sync Pipes. DataSync will continue to accept the system property, but it is encouraged to migrate the setting into the configuration.
DS-42045	Updated the Stats Collector Plugin with a new generate-collector-files configuration property. When using the plugin exclusively for providing metrics to one or more StatsD Monitoring Endpoints, set this property to false to prevent unnecessary I/O.
DS-42049	Fixed an issue with Sync server where retry ops could get the server stuck and unable to process changes at the source.
DS-42059, DS-42060	Updated setup to add options for improving communication security: * Non-interactive setup now offers a --rejectInsecureRequests argument that will configure the server to reject any request received over a connection that is not encrypted with SSL or StartTLS. * Non-interactive setup now offers a --rejectUnauthenticatedRequests argument that will configure the server to reject any request received over a connection that is not authenticated (or that is authenticated as the anonymous user). * Interactive setup now allows you to configure the server with the LDAP connection handler disabled (which was already an option when using non-interactive setup), or enabled but only for communication encrypted with StartTLS. The --rejectInsecureRequests and --rejectUnauthenticatedRequests arguments can also be used with manage-profile by including them in the setup-arguments.txt file of the server profile.

Ticket ID	Description
DS-42061	Updated the interactive command-line tool framework to prefer establishing secure LDAP connections over insecure connections. Previously, when prompting for the information needed to establish a connection, the default option was to create an unencrypted LDAP connection. Now, tools will default to creating an SSL-encrypted connection if the server supports it, or to creating a StartTLS-encrypted connection if that is available but SSL is not. Tools will also default to using streamlined settings when establishing secure connections. Previously, they would always prompt about how to determine whether the server's certificate chain should be trusted. When using the streamlined settings, the tools will only prompt about certificates that cannot automatically be considered trusted using information in the JVM's default trust store, the server's default trust store (config/truststore), or the server's topology registry.
DS-42062	Updated the root password policy so that LDAP bind responses for root users and topology administrators will be delayed by one second after five consecutive failed authentication attempts.
DS-42063	Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non-LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
DS-42115	Updated the server's command-line tool framework to make it easier and more convenient to communicate with the server over a secure connection when no trust-related arguments are provided. Most non-interactive tools will now check the server's default trust store, the topology registry, and the JVM's default trust store to see if the presented certificate chain can be automatically trusted without the need to prompt the user. If the presented chain cannot be automatically trusted, the user may be interactively prompted to determine whether it should be trusted.
DS-42199	Optimized some searches commonly used by the status tool. This should improve the performance of the tool in more complex or large-scale environments.
DS-42265	Upgrade to jetty 9.4
DS-42276	Fixed an issue where using the encryption-settings tool to import definitions with the set-preferred flag could result in none of the imported definitions being set as the preferred definition.
DS-42279	Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.
DS-42298	Replaced the ldifsearch, ldifmodify, and ldif-diff command-line tools with more full-featured and robust implementations.
DS-42331	Replaced the ldapcompare tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).

Ticket ID	Description
DS-42347	Updated the server to use /dev/urandom (on non-Windows systems where that path exists and is readable) instead of /dev/random as the primary source for secure random data. Attempts to read from /dev/random can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from /dev/urandom will not block, and the data that it provides is no less secure than data from /dev/random in any way that matters for the server.
DS-42349, DS-43209, DS-43210, DS-43323, DS-43324	Added support for JSON-formatted audit loggers, which complement the existing file-based LDIF-formatted error logger. The JSON-formatted audit log messages provide a record of changes to data in the server and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server. Added support for JSON-formatted HTTP operation loggers, which complement the existing file-based loggers using the W3C common log format and a proprietary space-delimited text format. The JSON-formatted HTTP operation log messages provide a record of interaction with HTTP clients and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server. Fixed an issue that caused JSON-formatted loggers to use a timestamp format that was not strictly compliant with the ISO 8601 format described in RFC 3339. Timestamps incorrectly omitted the colon between the hour and minute components of the time zone offset.
DS-42504	Updated manage-profile replace-profile to set encryption settings definitions defined in the newer server profile as preferred in the encryption settings db.
DS-42547	Fixed an issue where manage-profile generate-profile would print "null" as the generated profile directory when writing to an existing directory.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42632	Added support for creating or importing a key pair configuration object using an elliptic curve (EC) key algorithm. You can use this to designate the encryption key pair for a JWT access token validator that handles EC-encrypted access tokens.
DS-42634	The JWT Access Token Validator can now validate JWT access tokens signed using the elliptic curve digital signature algorithms ES256, ES384, and ES512.
DS-42635	The JWT Access Token Validator can now validate JWT access tokens encrypted using elliptic curve cryptographic algorithms. The following key encryption algorithms are now supported in addition to RSA-OAEP: ECDH-ES, ECDH-ES+A128KW, ECDH-ES+A192KW, and ECDH-ES +A256KW. To support best practices for JWT security, you must now also configure the JWT Access Token Validator with explicit allow lists for key encryption and content encryption algorithms. For backward compatibility, the key encryption allow list defaults to RSA-OAEP, while the content encryption allow list defaults to A128CBC-HS256, A192CBC-HS384, and A256CBC-HS512. We recommend setting both allow lists to the strict minimum set of algorithms needed by the Access Token Validator.
DS-42651	Updated the manage-profile replace-profile subcommand to better support updating the server's keystore and truststore files. When using the --generateSelfSignedCertificate argument in a server profile's setup-arguments.txt file, the server will maintain the original keystore and truststore files during replace-profile. Otherwise, replace-profile will use the keystore and truststore specified in the profile's setup-arguments.txt file.

Ticket ID	Description
DS-42665	Fixed an issue that caused the resync tool to not take the attribute-comparison-method of the sync class into account. This caused resync to ignore when byte-for-byte comparison was configured.
DS-42667	Updated the server to set a unique cluster name when started for the first time.
DS-42669, DS-42748	Updated the online dsconfig step of the manage-profile replace-profile subcommand to support getting LDAP connection arguments from a tools.properties file on the server being updated. Fixed an issue where boolean LDAP connection arguments like --useSSL and --trustAll would cause manage-profile replace-profile to fail when applying dsconfig online.
DS-42673	Updated the manage-profile setup subcommand to fail if the start-server command has a non-zero exit code.
DS-42681, DS-42684	Performance statistics generated by the Sideband API can now be published by the Periodic Stats Logger. To enable this, use the "included-http-servlet-stat" property of the Periodic Stats Logger.
DS-42687	Upgrade to Jetty 9.4.30
DS-42740	Fixed an issue where the **`dsconfig list`** subcommand would not display requested properties.
DS-42749	To support best practices for JWT security, you must now configure the JWT Access Token Validator with an explicit list of the JWT signing algorithms that it accepts. For backward compatibility, this list defaults to the RSA signing algorithms RS256, RS384, and RS512, but we recommend setting this list to the strict minimum set of signing algorithms needed by the Access Token Validator.
DS-42751	Added new override-status-code and additional-response-contents attributes to the Availability State HTTP Servlet Extension. These new attributes can be used to customize the response code and JSON response body of the servlet.
DS-42850	Fixed a typo in the password-expiring template that caused "password_expiration_time_of_day" to be printed instead of the password expiration time.
DS-42861	Updated the manage-profile tool logs to include the duration of each step the tool takes. The new --verbose argument can also be used to display timing information in the tool's console output.
DS-42872	Added a JSON-formatted stats logger to the server's default configuration. The stats logger is disabled by default.
DS-42886	Updated non-interactive setup (including manage-profile setup) to allow the password for the initial root user to be provided in pre-encoded form using the PBKDF2, SSHA256, SSHA384, or SSHA512 password storage scheme. This eliminates the need to have access to the clear-text password when setting up the server.
DS-42926	Fixed an issue where Ping Directory products configured to run as Microsoft Windows services were sometimes unable to automatically restart following an unplanned reboot, due to errors reading a corrupted server status file.

Ticket ID	Description
DS-42939	The Administrative Console configuration settings have been updated to account for the new SSO functionality.
DS-42952	For Windows only, there can be a hang on start when global configuration property `startup-error-logger-output-location` is set to values that contain `standard-error`. For Windows only, `standard-error` values are silently mapped to equivalent `standard-output` values.
DS-42963	Updated the manage-profile generate-profile subcommand to ignore files larger than 100 megabytes when generating a server profile. Fixed an issue where many large files in the server root could cause the tool to run out of memory.
DS-43027	Added a new --adminPasswordFile argument to the manage-topology add-server command, to allow specifying the administrator password with a file rather than with the command line.
DS-43073, DS-43198	Added support for ID Token Validators, which validate the integrity and content of ID tokens issued by OpenID Connect providers. Use these validators with the OAuth Bearer SASL Mechanism Handler to enable single sign-on (SSO) for the Administrative Console using an OpenID Connect provider such as PingOne. Currently, only PingOne is supported for SSO.
DS-43074	Added three built-in identity mappers that you can use to look up administrative accounts stored in the server configuration: Root DN Users, Topology Admin Users, and All Admin Users.
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: * When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. * When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. * When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43305	Increased the maximum number of RDN components that a DN may have from 50 to 100.
DS-43376	Updated log publisher logic to reduce the amount of CPU that the server consumes when it is idle.
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43517	Updated the jose4j library used for JWT signing and encryption to version 0.7.2.
DS-43651	The Security Guide is now available online at pingidentity.com. The guide has been removed from the server packaging.

Critical fixes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

  In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

  We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

  SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

  It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.

  The Sync Server has a specialized mutex that ensures that changes to the same entry are processed serially. The primary reason for this mutex is to ensure that the server can safely process changes

in parallel to achieve high throughput. However, we also use this mutex to ensure that two Sync Pipes don't process the same entry at the same time for deployments that synchronize changes bi-directionally. A consequence of this locking is that if one Sync Pipe is failing (because the destination is unavailable) then it retains the lock on an entry, and when other Sync Pipes try to process changes to that entry they will block that change and all changes that follow it while they wait on the lock.

This change turns off using a shared mutex by default, but adds a new advanced configuration option on the Sync Pipe, shared-mutex-name, that specifies the name of a mutex that is shared by other Sync Pipes. This gives greater control over the locking so that two Sync Pipes that share end points can ensure that two changes to the same logical user are not processed concurrently, while not impacting other Sync Pipes.

See the shared-mutex-name property for more information.

This property is subject to change in a future release.

- Fixed in: 3.2.0.0
- Introduced in: 3.0.0.0
- Support identifiers: DS-4202 SF#1527

PingDataSync Server Release Notes archive

Release Notes for earlier versions of PingDataSync Server are included for reference.

PingDataSync Server 8.1.0.6 release notes
The release notes for the 8.1.0.6 release of PingDataSync Server.

Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
DS-42049	Fixed an issue with the Data Sync server where retry operations could get the server stuck and unable to process changes at the source.

PingDataSync Server 8.1.0.5 release notes

Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: * When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. * When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. * When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

PingDataSync 8.1.0.2 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a

network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.
  - Fixed in: 3.2.0.0
  - Introduced in: 3.0.0.0
  - Support identifiers: DS-4202 SF#1527

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-42687	Upgrade to Jetty 9.4.30

PingDataSync 8.1 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

  In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other

data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. - Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

Upgrade Considerations

Important considerations for upgrading to this version of the Data Sync Server:

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

What's New

These are new features for this release of the Data Sync Server

- In an ongoing effort to improve the use of containers for PingDirectory, several features have been implemented:

  - The --outputFile option has been added to the collect-support-data tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can

run the collect-support-data tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.

- The collect-support-data tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.

- A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the --remoteServer added to the collect-support-data tool can be used to send the request to another server. In other words, you can now run collect-support-data on the command line and reference another server, possibly in a container, and retrieve the output file remotely.

- PingDirectory has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party
- Updated the server to use /dev/urandom (on non-Windows systems where that path exists and is readable) instead of /dev/random as the primary source for secure random data. Attempts to read from /dev/random can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from /dev/urandom will not block, and the data that it provides is no less secure than data from /dev/random in any way that matters for the server.
- Replaced the ldapcompare tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).
- Replaced the ldifsearch, ldifmodify, and ldif-diff command-line tools with more full-featured and robust implementations.
- Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.
- Replaced the ldappasswordmodify tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.
- Added a config/sample-dsconfig-batch-files directory with set of well commented dsconfig batch files that may be useful in enabling or configuring a variety of features in the server.

Known Issues/Workarounds

The following are known issues in the current version of the Data Sync Server

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.

Ticket ID	Description
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-39862	Improved support for the PingOne Sync Source and Destination in the create-sync-pipe-config tool by adding Sync Classes tailored to the PingOne endpoint.
DS-40025,DS-42041	When using an Active Directory Sync Source, the base DN of the Sync Source can now be set to a descendant of the root directory partition of the AD instance(s). When detecting changes, the Sync Source will adjust the value to be the root directory partition if it is not already set to this value, but when synchronizing changes, the Sync Source will only consider changes that have a DN under the base DN provided to the Sync Source.
DS-40241	Updated create-sync-pipe-config to support creating a sync pipe that does not synchronize any attributes. This will be suggested as the default option when either the source or destination is Active Directory or a relational database. The previous default of synchronizing all attributes will still be used when both the source and destination are non-Active Directory LDAP servers.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.

Ticket ID	Description
DS-40413	Updated the behavior of the resync tool when an invalid DN is detected. Instead of stopping the process, the offending entry will be reported and skipped, allowing for the remaining entries to be processed. This issue only affected ActiveDirectory and Changelog Sync Sources (LDAP Sync Sources that detect changes using cn=changelog, such as PingDirectory or ODSEE).
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.

Ticket ID	Description
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41263	Updated the README for the Ping Identity Active Directory Password Sync Agent to indicate support for Windows Server 2016 and Windows Server 2019 and the removal of support for Windows Server 2008.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.

Ticket ID	Description
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41579	Fixes issue with reatime-sync Password Files and Pin Files displaying contents in clear text.
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41784	Fixed a bug that could cause the duration of a sync operation to be miscalculated.
DS-41818	Added the --zip argument to the manage-profile generate-profile subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to /instance-root by authenticated users with the file-servlet-access privilege will be granted access to files within the server instance root.
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has memory.swappiness set to a nonzero value.

Ticket ID	Description
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a NullPointerException if a server was configured with a custom global result code map.
DS-42117	Updated Constructed Attribute Mapping's exclude-value property to accept multiple values with different capitalizations.
DS-42387	Updated the **`manage-profile generate-profile`** subcommand to exclude files in the `ldif/` and `bak/` directories by default when generating a server profile. If necessary, you can manually include those directories using the `--includePath` argument.

PingDataSync Server 8.0.0.5 release notes

Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

PingDataSync 8.0.0.3 release notes

Critical Fixes

This release of PingDataSync addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of PingDataSync:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-41807	Fixed an issue where LDAP DELETE operations were sometimes not synchronized from an Oracle Unified Directory sync source, due to variations in the format of the 'targetUniqueID' attribute obtained from the Oracle changelog.

Ticket ID	Description
DS-43288	Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients. To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime. Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines: * When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well. * When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list. * When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.

PingDataSync 8.0.0.2 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-37890	Added a new property to sync classes called replace-all-attr-values- limit. The property is only used when replace-all-attr-values is true and the sync destination is an LDAP server. If a modification would replace more values of the same attribute than the value of replace-all- attr-values-limit, then the modification will use ADD or DELETE operations rather than a REPLACE operation.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.

Ticket ID	Description
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42665	Fixed an issue that caused the resync tool to not take the attribute-comparison-method of the sync class into account. This caused resync to ignore when byte-for-byte comparison was configured.
DS-42812	Upgrade to jetty 9.4.30

PingDataSync 8.0.0.1 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on PingDataMetrics Server.
  - Fixed in: 8.0.0.1

    Introduced in: 7.2.0.0

    Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1

    Introduced in: 5.2.0.0

    Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

  In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

  We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.

  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

  * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

  * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

  In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

  We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.

  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.

  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763

- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

  SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

  It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.
  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.

  The Sync Server has a specialized mutex that ensures that changes to the same entry are processed serially. The primary reason for this mutex is to ensure that the server can safely process changes in parallel to achieve high throughput. However, we also use this mutex to ensure that two Sync Pipes don't process the same entry at the same time for deployments that synchronize changes bi-directionally. A consequence of this locking is that if one Sync Pipe is failing (because the destination is unavailable) then it retains the lock on an entry, and when other Sync Pipes try to process changes to that entry they will block that change and all changes that follow it while they wait on the lock.

  This change turns off using a shared mutex by default, but adds a new advanced configuration option on the Sync Pipe, shared-mutex-name, that specifies the name of a mutex that is shared by other Sync Pipes. This gives greater control over the locking so that two Sync Pipes that share end points can

ensure that two changes to the same logical user are not processed concurrently, while not impacting other Sync Pipes.

See the shared-mutex-name property for more information.

This property is subject to change in a future release.

- Fixed in: 3.2.0.0
- Introduced in: 3.0.0.0
- Support identifiers: DS-4202 SF#1527

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.

PingDataSync 8.0.0.0 Release Notes

Critical Fixes

This release of the PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

What's New

These are new features for this release of the PingDataSync Server:

- Use Server Profiles to reduce risk and improve consistency following the DevOps principle of infrastructure-as-code. Administrators can export the configuration of the PingDataSync Server server to a directory of text files called a Server Profile, track changes to these files in version control such as Git, and install new instances of PingDataSync Server or update existing instances of PingDataSync Server from a Server Profile. Server Profiles support variable substitution in order to remove the settings unique to each pre-production or production environment from the Server Profile that is stored in version control.
- Improved consistency for user passwords that are managed in PingOne for Customers. Now when PingDataSync Server recognizes a password change in the source PingOne for Customer environment, the password is removed from the destination PingDirectory. Upon the next on-prem LDAP bind, the validated password is saved in the destination PingDirectory by the pass-through authentication plugin.

Known Issues/Workarounds

The following are known issues in the current version of the PingDataSync Server:

- The following are suggested solutions for problems with slow DNS:
  - Maintain a connection pool in the client app rather than opening new connections for each bind.
  - Add appropriate records, including PTR records, to DNS.
  - Add `options timeout:1` in the `/etc/resolv.conf` file and/or `options single-request`
  - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` file, run **`bin/dsjavaproperties`**, and restart the server to stop the issuance of IPv6 PTR requests.
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.

  Workaround: Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.
- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
  - groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2
  - groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2

  Workaround: Deploy the Console in an external container using JDK 8.

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-17278	Added a `cn=Server Status Timeline,cn=monitor` monitor entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, endpoint-cache-refresh, has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the `Resource` column in the output of `status`. This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.

Ticket ID	Description
DS-38493	Updated the PingOne for Customer Sync Source to remove a user's password from a destination (for example, PingDirectory) when the corresponding user's password has changed in PingOne for Customers. This behavior requires the `password` attribute in PingOne for Customers to be mapped to the password attribute (for example, `userPassword`) in the destination schema.
DS-38560	Updated `manage-profile replace-profile` to apply configuration changes directly, when possible. If the new server profile used by `replace-profile` has changed only the `dsconfig` batch files from the original profile, then only the `dsconfig` files are applied. If no changes are detected between profiles, replace-profile takes no action. If changes other than dsconfig are detected, the full replace-profile process is followed.
DS-38777	Added support for updating the server version during `manage-profile replace-profile`. The server must have been originally set up with a server profile.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-38863	Updated the manage-profile setup subcommand to set a server's cluster name to match its instance name by default. This prevents servers in the same replication topology from being in the same cluster, reducing the risk of unintentionally overwriting parts of an existing server's configuration in a DevOps environment. The `--useDefaultClusterName` argument can be used to leave the cluster name unchanged.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions. Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the `remove-defunct-server` tool's `--ignoreOnline` option. When using `--ignoreOnline` in a mixed-version environment, all servers must support the option.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit *groovy-lang.org* and view the Groovy 2.5 release notes. As of this release, only the core Groovy runtime and the groovy-json module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as groovy-xml or groovy-sql, download the appropriate jar file from *groovy-lang.org* and place it in the server's `lib/extensions` directory.

Ticket ID	Description
DS-39191	Updated the `auto-mapped-source-attribute` property on Sync Class configuration objects to not have a default value since the previous default of `-all-` caused confusion. Existing dsconfig batch files used for automated deployments might need to be updated to provide a value for this property. A value of `-all-` is recommended when synchronizing between two systems with the same schema, such as when migrating from a legacy LDAP server to PingDirectory.
DS-39253	Added a `replace-certificate` tool, which can help an administrator replace the listener or inter-server certificate for a server instance.
DS-39320	Added support for PingDataSync Server to the `manage-profile` tool and its subcommands.
DS-39325	Removed the legacy product-specific scripts for starting and stopping the server. These include: ▪ start-ds and stop-ds for Directory Server ▪ start-proxy and stop-proxy for Directory Proxy Server ▪ start-sync and stop-sync for Data Sync Server ▪ start-metrics-engine and stop-metrics-engine for Data Metrics Server These legacy scripts had been deprecated for several releases in favor of the more general `start-server` and `stop-server` scripts, and they displayed a warning message about their upcoming removal if they were invoked. If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general `start-server` and `stop-server` scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point to the `start-server` and `stop-server scripts`.
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as `X-VALUE-REGEX`), this could cause unexpected or incorrect behavior.
DS-39540	Released an updated Password Sync Agent for Active Directory that uses SSHA256 as a default for its password hashing algorithm instead of SSHA, since SSHA is soon to be deprecated in PingDirectory. If SSHA256 is not supported by a directory or if it is not wanted, a registry value was added that can be set to specify the password hashing algorithm.
DS-39592	HTTP External Servers have a new attribute, ssl-cert-nickname, which defines the alias of a specific certificate within their keystore to be used as a client certificate.
DS-39603	Fixed an issue where Server SDK extensions could not be configured by dsconfig batch files in the manage-profile tool.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.

Ticket ID	Description
DS-39654	Added support for the `--topologyFilePath` argument to the `manage-topology add-server` subcommand.
DS-39671	Updated the `manage-topology add-server` subcommand to require being run from the older server in a mixed-version environment.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39853	Added support for the PingOne for Customers Sync Source and Destination to the `create-sync-pipe-config` tool.
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40020	Fixed an issue in Active Directory Sync Source where the persistent state was updated before applying changes, so changes could be missed when stopping the Sync Pipe.
DS-40114	Added a new `cn=Status Health Summary,cn=monitor` monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.
DS-40354	Fixed a problem with `config-diff` when writing properties that span multiple lines using the `--prettyPrint` argument.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40543	Updated `manage-profile replace-profile` to copy the tool log file to the server being updated.
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40730	Updated the `encrypt-file` tool to prevent using the same path for both the input file and the output file.
DS-40771	Added a `--duration` argument to collect-support-data. When used, only the log files covering the specified duration before the current time will be collected.

PingDirectory Server Administration Guide

PingDirectory™ Product Documentation

Support

https://support.pingidentity.com/

Introduction to PingDirectory Server

PingDirectory Server is a high-performance, extensible directory and PingData Platform, written completely in Java.

The Directory Server centralizes consumer and user identity management information, subscriber data management, application configurations, and user credentials into a network, enterprise, or virtualized database environment. It provides seamless data management over a distributed system based on a standardized solution that meets the constant performance demands for today's markets. The Directory Server simplifies administration, reduces costs, and secures information in systems that scale for large numbers of users.

The following topics provide an overview of the Directory Server's features and components:

Server features

The Directory Server provides an extensive feature-rich set of tools that can meet the production needs of your system.

Full LDAP version 3 implementation

The Directory Server fully supports LDAPv3, which supports the Request For Comments (RFCs) specified in the protocol. The Directory Server provides a feature-rich solution that supports the core LDAPv3 protocol in addition to server-specific controls and extended operations.

High availability

The Directory Server supports N-way multi-master replication that eliminates single points of failure and ensures high availability for a networked topology. The Directory Server allows data to be stored across multiple machines and disk partitions for fast replication. The Directory Server supports replication in entry-balancing proxy server deployments.

Administration tools

The Directory Server provides a full set of command-line tools, an administrative console, and a Java-based setup tool to configure, monitor, and manage any part of the server. The Directory Server has a task-based subsystem that provides automated scheduling of basic functions, such as backups, restores, imports, exports, restarts, and shutdowns. The set of utilities includes a troubleshooting support tool that aggregates system metrics into a `.zip` file, which administrators can send to your authorized support provider for analysis.

Self-service account manager application

The Self Service Account Manager project, hosted at *https://github.com/pingidentity/ssam*, is a customizable web application allowing users to perform their own account registration, profile updates, and password changes. The project is for testing and development purposes only and is not a supported application.

Delegated admin application

A Javascript-based web application can be installed for business users to manage identities stored in the Directory Server. The application provides delegated administration of identities for help desk or customer service representatives initiating a password reset and unlock, an employee in HR updating an address stored within another employee profile, or an application administrator updating identity attributes or group membership to allow application single sign-on (SSO) access.

Security mechanisms

The Directory Server provides extensive security mechanisms to protect data and prevent unauthorized access. Access control list (ACL) instructions are available down to the attribute value level and can be stored within each entry. The Directory Server allows connections over SSL through an encrypted communication tunnel. Clients can also use the StartTLS extended operation over standard, non-encrypted ports. Other security features include a privilege subsystem for fine-grained granting of rights, a password policy subsystem that allows configurable password validators and storage schemes, and SASL authentication mechanisms to secure data integrity, such as PLAIN, ANONYMOUS, EXTERNAL, CRAM-MD5, Digest-MD5, and GSSAPI. The Directory Server supports various providers and mappers for certificate-based authentication in addition to the ability to encrypt specific entries or sensitive attributes. For more information, see the PingDirectory Server Security Guide.

Monitoring and notifications

The Directory Server supports monitoring entries using the PingDataMetrics Server, JConsole, SNMP, or using the Administrative Console. Administrators can track the response times for LDAP operations using a monitoring histogram as well as record performance statistics down to sub-second granularity. The Directory Server supports configurable notifications, auditing, and logging subsystems with filtered logging capabilities.

Powerful LDAP SDK

The Directory Server is based on a feature-rich LDAP SDK for Java, designed by Ping Identity. The LDAP SDK is a Java API standard that overcomes the limitations of the Java Naming and Directory Interface (JNDI) model. For example, JNDI does not address the use of LDAP controls and extended operations. The LDAP SDK for Java provides support for controls and extended operations to leverage Ping Identity's extensible architecture for their applications.

ⓘ **Note:**

For more information on the LDAP SDK for Java, go to *http://www.LDAP.com*.

System for Cross-domain Identity Management (SCIM) extension

The Directory Server provides a SCIM servlet extension to facilitate moving users to, from, and between cloud-based software as a service (SaaS) applications in a secure and fast manner.

Server SDK

Ping Identity also provides the Server SDK, which is a library of Java packages, classes, and build tools to help in-house or third-party developers create client extensions for:

- PingDirectory Server
- PingDirectoryProxy Server
- Data Sync Server

The servers have a highly extensible and scalable architecture with multiple plugin points for your customization needs. The Server SDK provides APIs to alter the behavior of each server's components without affecting its code base.

Administration framework

The Directory Server provides an administration and configuration framework capable of managing stand-alone servers, server groups, and highly-available deployments that include multiple redundant server instances.

Administrators can configure changes locally or remotely:

- On a single server
- On all servers in a server group

Each server configuration is stored as a flat file (LDIF) that can be accessed under the `cn=config` branch of the directory information tree (DIT). Administrators can tune the configuration and perform maintenance functions over LDAP using a suite of command-line tools or an administrative console (for configuration and monitoring). The Directory Server provides plugins to extend the functionality of its components.

Server tools location

The Directory Server stores a full set of command-line tools for maintaining your system in the `PingDirectory/bin` directory for UNIX or Linux machines and the `PingDirectory\bat` directory for Microsoft Windows machines.

Ping Identity distributes the Directory Server, administrative console, and LDAP SDK for Java in `.zip` format. After extracting the file, you can access the **`setup`** utility in the server root directory, located at `PingDirectory`.

Before installing the directory server, see *Prepare your environment* on page 237for important information on setting up your machines. See *Installing the Server* on page 236 for information on installing a server instance using the **`setup`** utility. You can run this utility in either interactive command-line or non-interactive command-line. For information on modifying the configuration of a server instance or a group of servers using the command-line tools and the administrative console, see *Configuring the Server* on page 298.

Installing the Server

After you have prepared your hardware and software system, you can set up the server using PingDirectory Server's installation modes.

This section details the various installation options and procedures available to the administrator.

Prepare your environment

PingDirectory Server offers a highly portable and scalable architecture that runs on multiple platforms and operating systems.

The Directory Server is specifically optimized for operating systems used in environments that process a large number of entries.

See the following topics for information on setting up your server machines for optimal processing efficiency:

- *Before You Begin*
- *System requirements*
- *Platforms*
- *Docker*
- *Java Runtime Environment*
- *Browser*
- *Installing Java*
- *Preparing the Operating System (Linux)*
- *Configuring the Number of File Descriptors*
- *File System Tuning*
- *Raising the Maximum User Processes*
- *Setting Operating System Environment Variables*
- *Install systat and pstack (Red Hat)*
- *Install dstat (SUSE)*
- *Disabling File System Swapping*
- *Omit vm.overcommit_memory*
- *Managing System Entropy*
- *Setting file system event monitoring (inotify)*
- *Tuning the IO Scheduler*
- *Running as a Non-Root User (Linux)*

Before you begin

The Directory Server requires certain software packages for the proper operation of the server.

For optimal performance, PingDirectory Server requires Java for 64-bit architectures. To view the minimum required Java version, access the Customer Support Center portal or contact your authorized support provider for the latest supported software versions.

> ⓘ **Tip:**
>
> Implement a Network Time Protocol (NTP) system so that multi-server environments are synchronized and timestamps are accurate.

System requirements

The following section details system requirements that are qualified and certified to be compatible with the PingDirectory Server.

Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software are suspected of causing issues.

Platforms

The following operating systems support a PingDirectory Server installation and deployment.

- Windows Server 2019
- Windows Server 2016
- Red Hat Enterprise Linux ES 8.1

- Red Hat Enterprise Linux ES 7.7
- CentOS 8.1
- CentOS 7.7
- SUSE Linux Enterprise 15 SP1
- SUSE Linux Enterprise 12 SP5
- Ubuntu 18.04 LTS
- Ubuntu 16.04 LTS
- Amazon Linux 2

> ⓘ **Attention:**
>
> This product has been tested with the default configurations of all operating system components. Customized implementations or installed third-party plugins from your organization might affect the deployment of this product.

Docker
The following Docker version and operating systems are a pre-installation requirement.

- Version: Docker 19.03.5
- Host operating system: Ubuntu 18.04 LTS
- Base image operating system: Ubuntu 18.04 LTS
- Base image operating system: Alpine Linux 3.11

For more information, view the Directory Server Docker Image on DockerHub at *pingidentity/pingdirectory* and visit the *PingIdentity DevOps documentation*.

> ⓘ **Note:**
>
> Only the Directory Server software is licensed under Ping Identity's end user license agreement, and any other software components contained within the image are licensed solely under the terms of the applicable open source/third-party license.
>
> Ping Identity accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

Java Runtime Environment
The following Java Development Kit versions are a pre-installation requirement.

- Oracle JDK 8 64-bit
- Oracle JDK 11 LTS 64-bit
- OpenJDK 8 64-bit
- OpenJDK 11
- Corretto 8
- Corretto 11

> ⓘ **Note:**

Installing Java
Even if your system already has Java installed, you might want to create a separate Java installation for use by the PingDirectory Server so that updates to the system-wide Java installation do not impact the Directory Server.

About this task

PingDirectory Server requires Java. For optimized performance, use Java for 64-bit architectures. View the minimum required Java version on your Customer Support Center portal, or contact your authorized support provider for the latest software versions supported.

> ⓘ **Note:**
>
> A separate Java installation requires that you download the Java Development Kit (JDK) instead of the Java Runtime Environment (JRE) for the 64-bit version.

Steps

1. Go to the *Oracle download site*.
2. Click JDK Download.
3. On the download page, select the download file for your operating system and accept the license agreement to start the download.

Preparing the operating system (Linux)
Several operating system customizations can improve the performance of PingDirectory Server on Linux systems.

These customizations include:

- *Increasing the file descriptor limit on Linux systems*
- *Setting the file system flushes* on page 241
- *Editing OS-level environment variables*
- *Downloading some useful monitoring tools for Redhat Linux systems*

Configuring the file descriptor limits
Operating system default file descriptor limitsrestrict the number of PingDirectory Server connections. Change the descriptor limits to allow more connections.

About this task

The Directory Server allows for an unlimited number of connections by default, but the file descriptor limit on the operating system restrict the number of connections. Many Linux distributions have a default file descriptor limit of 1024 per process, which might be too low for the server if it needs to handle a large number of concurrent connections.

If the operating system relies on `systemd`, see the Linux operating system documentation for instructions on setting the file descriptor limit.

After you set the operating system limit, you can configure the number of file descriptors that the server will use either by using a **NUM_FILE_DESCRIPTORS** environment variable, or by creating a **config/num-file-descriptors** file with a single line such as **NUM_FILE_DESCRIPTORS=12345**. If these are not set, the operating system uses the default of 65535 descriptors. This is an optional change you can make if you want to ensure that the server shuts down safely prior to reaching the file descriptor limit.

Steps

1. Display the current `fs.file-max` limit of the system.

   ```
   sysctl fs.file-max
   ```

   The `fs.file-max` limit is the maximum server-wide file limit you can set without tuning the kernel parameters in the `proc` file system.
2. Edit the `/etc/sysctl.conf` file.

   If there is a line that sets the value of the `fs.file-max` property, make sure that its value is set to at least 1.5 times the per-process limit.

   If there is no line that sets a value for this property, add the following to the end of the file:

   ```
   fs.file-max = 100000
   ```

   ⓘ **Note:**

   100000 is just an example here. Specify a value of at least 1.5 times the per-process limit.
3. Display the current hard limit of the system.

   ```
   ulimit -aH
   ```

   The `open files (-n)` value is the maximum number of open files per process limit.

   The value should be set to at least 65535.
4. Edit the `/etc/security/limits.conf` file.

   If the file has lines that set the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines before `#End of file`, making certain to insert a tab between the columns.

   ```
   *   soft   nofile   65535
   *   hard   nofile   65535
   ```

   ⓘ **Note:**

   The number of open file descriptors is limited by the physical memory available to the host. You can determine this limit with the following command.

   ```
   cat /proc/sys/fs/file-max
   ```

   If the file-max value is significantly higher than the 65535 limit, consider increasing the file descriptor limit to between 10% and 15% of the system-wide file descriptor limit. For example, if the file-max value is 810752, you could set the file descriptor limit to 100000. If the file-max value is lower than 65535, the host is likely not sized appropriately.

5. Reboot your system, and then use the **`ulimit`** command to verify that the file descriptor limit is set to 65535.

```
# ulimit -n
```

Results

ⓘ **Note:**

For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits.

```
/etc/security/limits.d/20-nproc.conf

 Add or edit the following lines if they do not already exist:

 *          soft    nproc     65536
 *          soft    nofile    65536
 *          hard    nproc     65536
 *          hard    nofile    65536
 root       soft    nproc     unlimited
```

Tuning the file system

Administrators can tune ext3 and ext4 file systems by setting the file system flushes and noatime to improve server performance.

Newer ext4 systems use delayed allocation to improve performance. This delays block allocation until it writes data to disk. Delayed allocation improves performance and reduces fragmentation by using the actual file size to improve block allocation.

This feature might increase the risk of data loss in cases where a system loses power before all of the data has been written to disk. This can occur if a program is replacing the contents of a file without forcing a write to the disk with **`fsync`**. To reduce this risk, make sure the default **`auto_da_alloc`** option is enabled on ext4 file systems.

The following changes can be made in the `/etc/fstab` file.

Setting the file system flushes

Improve Directory Server performance by reducing the span between file system flushes.

About this task

By default, Linux servers running the ext3 file system flush the data to disk every five seconds.

Steps

1. If the Directory Server is running on a Linux server using the ext3 file system, consider editing the mount options for that file system to include the following command.

```
commit=1
```

   This variable changes the flush frequency from five seconds to one second.
2. You should also set the flush frequency in the `/etc/fstab` file.

   Changing the mount command alone does not survive across reboots.

Setting noatime on ext3 and ext4 Systems
If your Linux server uses an ext3 or ext4 file system, set `noatime` to improve performance by turning off any *atime* updates during read access.

About this task

Additionally, set the flush frequency to the `/etc/fstab` file. Performing the change through the **`mount`** command alone does not survive across reboots.

Steps

- Run the **`mount`** command for the relevant system.
  - ext3 system:

    ```
    # mount -t ext3 -o noatime /dev/fs1
    ```

    .
  - ext4 system:

    ```
    # mount -t ext4 -o noatime /dev/fs1
    ```

    .

Setting the maximum user processes
To address memory problems when running multiple servers, increase the default maximum user process limit.

About this task

Some Linux distributions, such as Redhat Enterprise Linux Server and CentOS 6.0 or later, set the default maximum number of user processes to 1024. This is considerably lower than the same parameter on older distributions. The default value of 1024 leads to some Java virtual machine memory errors when running multiple servers on a machine because each Linux thread counts as a user process.

At startup, the Directory Server and its tools automatically attempt to raise the maximum user processes limit to 16,383 if the value reported by **`ulimit`** is less than that. If, for any reason, the server is unable to automatically set the maximum processes limit to 16,383, it displays an error message.

There are several ways to set the maximum user process limit.

Steps

- Set the limit in `/etc/security/limits.conf`.

  Replace the (*) with the name of the user under which the software will run.

  ```
  * soft nproc 65535
  * hard nproc 65535
  ```
- Set the *NUM_USER_PROCESSES* environment variable to `16383`.
- In the `config/num-user-processes` file, set the *NUM_USER_PROCESSES* to `16383`.

About editing OS-level environment variables
Certain environment variables might affect the Directory Server in unexpected ways. This is particularly true for environment variables that are used by the underlying operating system to control how it uses non-default libraries.

For this reason, the Directory Server explicitly overrides the values of key environment variables like <*PATH*>, <*LD_LIBRARY_PATH*>, and <*LD_PRELOAD*> to ensure that environment settings used to start the server do not inadvertently impact its behavior.

If you need to edit any of these environment variables, set the values of those variables by manually editing the <*set_environment_vars*> function of the `lib/_script-util.sh` script.

You must stop (bin/stop-server) and re-start (bin/start-server) the server for the change to take effect.

Installing sysstat and pstack (Red Hat)
If you plan to run PingDirectory on a Red Hat Linux system, install a couple of packages, **`sysstat`** and **`pstack`**, that are disabled by default, but are useful for troubleshooting.

About this task

The troubleshooting tool **`collect-support-data`** uses the **`iostat`**, **`mpstat`**, and **`pstack`** utilities to collect monitoring, performance, and stack trace information on the server's processes.

Steps

- To install **`systat`** on your Red Hat system, run the following command.

```
$ sudo yum install sysstat gdb dstat -y
```

.

Installing dstat (SUSE Linux)
`dstat` is a system monitoring tool that can help you troubleshoot PingDirectory servers on SUSE distributions.

About this task

The **`collect-support-data`** tool uses the **`dstat`** utility for system monitoring. **`dstat`** can be obtained from the OpenSUSE project website. The following process shows how to install the **`dstat`** utility on SUSE Enterprise Linux 11 SP2:

Steps

1. Sign on as the root user.
2. Add the appropriate repository using the **`zypper`** tool.
3. Install the **`dstat`** utility.

```
$ zypper install dstat
```

Disabling file system swapping
Because file system swapping can interfere with PingDirectory, disable performance tuning tools like **`tuned`**.

About this task

Steps

1. Sign on as the root user.
2. Add the line `vm.swappiness = 0` to the file `/etc/sysctl.conf`.
3. Restart the system to apply the change.
4. Optional: If you need to tune performance after disabling file system swapping, do the following:
   a. Clone the existing performance profile.
   b. Run **`tuned`**.
   c. Add the line `vm.swappiness = 0` to the file `/usr/lib/tuned/profile-name/tuned.conf`.
   d. To select the updated profile, run **`tuned-adm profile customized_profile`**.
   e. Restart the system to apply the changes.

Omitting vm.overcommit_memory
An improperly configured value for the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file might cause the **`setup`** or **`start-server`** tool to fail.

About this task

For Linux systems, the `vm.overcommit_memory` property sets the kernel policy for memory allocations. The default value of 0 indicates that the kernel determines the amount of free memory to grant a `malloc` call from an application. If the property is set to a value other than zero, the operating system might grab too much memory, reducing the amount of available memory for the **`setup`** or **`start-server`** tools.

Steps

Omit the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file to ensure that enough memory is available for these tools.

Managing system entropy
Linux uses entropy to calculate random data that is used by the system in cryptographic operations.

About this task

Some environments with low entropy might have intermittent performance issues with SSL-based communication. This is more typical on virtual machines but can occur in physical instances as well.

Steps

- Monitor the **`kernel.random.entropy_avail`** in **`sysctl`** value for best results.

Setting file system event monitoring (inotify)
An event monitoring tool such as **`inotify`** can be configured for notifying processes about file system events, including file creation, deletion, and updates.

About this task

Linux limits the number of **`inotify`** watches a user can receive.

Steps

- To increase the limit, edit **`etc/sysctl.conf`** to add the following line.

```
fs.inotify.max_user_watches = 524288
```

- Run the following command.

```
$ sudo sysctl -w fs.inotify.max_user_watches=524288
```

Tuning the I/O scheduler
Using the correct I/O scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load.

About this task

For file systems running on an SSD or in a virtualized environment, use the recommended **`noop`** scheduler. For all other systems, use the **`deadline`** scheduler.

The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

Steps

1. To determine which scheduler is configured on your system, run the following command.

```
$ cat /sys/block/<block-device>/queue/scheduler
```

2. To change the scheduler on a running system, run the following command.

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

3. To apply the change, restart the system.

Running as a non-root user (Linux)
You have two options to run as a non-root user but still allow connections on a privileged port.

Use a load balancer or directory proxy server

Many environments can run the server on a non-privileged port but be hidden by a hardware load balancer or LDAP directory proxy server.

Use `netfilter`

Use the **`netfilter`** mechanism, exposed through the **`iptables`** command, to automatically redirect any requests from a privileged port to the unprivileged port on which the server is listening.

Enabling the server to listen on privileged ports (Linux)
For your convenience, enable the server to listen on privileged ports while running as a non-root user.

About this task

Linux systems have a mechanism called capabilities that is used to grant specific commands the ability to do things that are normally only allowed for a root account:

- The **`setcap`** command assigns capabilities to an application.
- The **`cap_net_bind_service`** capability enables a service to bind a socket to privileged ports (port numbers less than 1024).

Steps

1. If Java is installed in **`/ds/java`** (and the Java command to run the server is **`/ds/java/bin/java`**), you can grant the **`cap_net_bind_service`** capability to the Java binary with the following command.

```
$ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
```

2. Create the file **`/etc/ld.so.conf.d/libjli.conf`** with the path to the directory that contains the **`libjli.so`** file.

   The java binary needs an additional shared library (**`libjli.so`**) as part of the Java installation. Because this process imposes stricter limits on where the operating system looks for shared libraries to load for commands that have capabilities assigned, it is also necessary to tell the operating system where to look for this library.

   For example, if the Java installation is in **`/ds/java`**, the contents of that file should be:

```
/ds/java/lib/amd64/jli
```

3. To apply the changes, run the following command.

```
$ sudo ldconfig -v
```

Getting the installation packages

Obtain the latest `.zip` release bundle from Ping Identity and extract it to a folder of your choice to begin the installation process.

About this task

The release bundle contains the Directory Server code, tools, and package documentation.

Complete the following steps to unpack the build distribution.

Steps

1. Download the latest `.zip` distribution of the Directory Server software.
2. Extract the compressed `.zip` archive file to a directory of your choice.

```
$ unzip PingDirectory-<version>.zip
```

You can set up the Directory Server.

Sign on to the Administrative Console

After the server is installed, access the Administrative Console, `https://<host>/console/login`, to verify the configuration and manage the server. The root user DN or the common name of a root user DN is required to log into the Administrative Console. For example, if the DN created when the server was installed is `cn=Directory Manager`, `directory manager`can be used to log into the Administrative Console.

If the Administrative Console needs to run in an external container, such as Tomcat, a separate package can be installed according to that container's documentation. Contact Ping Identity Customer Support for the package location and instructions.

ⓘ **Note:** The session timeout for the console is 24 hours by default. When this duration is exceeded, all inactive users are logged off automatically.

To set a different timeout value, configure the `server.sessionTimeout` application parameter, which specifies the timeout duration in seconds. You can set the value as an init parameter either in the console or on the command line, as shown below.

- Console

  Select **Web Application Extensions**# **Console** and then use the **Init Parameter** field.
- Command line

  The following example uses a value of 1800 seconds (30 minutes).

```
dsconfig set-web-application-extension-prop --no-prompt \
--extension-name Console \
--add init-parameter:server.sessionTimeout=1800
```

For the change to take effect, restart the HTTP(S) Connection Handler or the server itself.

Directory Server folder layout

After extracting the Directory Server distribution file, you see the following folders and command-line utilities.

Layout of the Directory Server Folders

Directories/Files/Tools	Description
`License.txt`	Licensing agreement for the Directory Server.
`README`	`README` file that describes the steps to set up and start the Directory Server.
`bak`	Stores the physical backup files used with the **`backup`** command-line tool.
`bat`	Stores Windows-based command-line tools for the Directory Server.
`bin`	Stores UNIX/Linux-based command-line tools for the Directory Server.
`classes`	Stores any external classes for server extensions.
`collector`	Used by the server to make monitored statistics available to PingDataMetrics Server.
`config`	Stores the configuration files for the backends (admin, config) as well as the directories for messages, schema, tools, and updates .
`db`	Stores the Oracle Berkeley Java Edition database files for the Directory Server.
`docs`	Provides the product documentation.
`import-tmp`	Stores temporary imported items.
`ldif`	Stores any LDIF files that you might have created or imported.
`legal-notices`	Stores any legal notices for dependent software used with the Directory Server.
`lib`	Stores any scripts, jar, and library files needed for the server and its extensions.
`locks`	Stores any lock files in the backends.
`logs`	Stores log files for the Directory Server.
`metrics`	Stores the metrics that can be gathered for this server and surfaced in PingDataMetrics Server.
`resource`	Stores the MIB files for SNMP and can include ldif files, make-ldif templates, schema files, `dsconfig` batch files, and other items for configuring or managing the server .
`revert-update`	The **`revert-update`** tool for UNIX/Linux systems.

Directories/Files/Tools	Description
`revert-update.bat`	The **`revert-update`** tool for Windows systems.
`setup`	The **`setup`** tool for UNIX/Linux systems.
`setup.bat`	The **`setup`** tool for Windows systems.
`scim-data-tmp`	Used to create temporary files containing System for Cross-domain Identity Management (SCIM) request data.
`uninstall`	The **`uninstall`** tool for UNIX/Linux systems.
`uninstall.bat`	The **`uninstall`** tool for Windows systems.
`update`	The **`update`** tool for UNIX/Linux systems.
`update.bat`	The **`update`** tool for Windows systems.
`Velocity`	Stores any customized Velocity templates and other artifacts (CSS, Javascript, images), or Velocity applications hosted by the server.

make-ldif template format

The `make-ldif` template demonstrates the use of all supported tags.

`make-ldif` template

> ⓘ **Note:**
>
> Because this file contains elements that are not defined in the schema, do not import it into a directory.

```
# Copyright 2012-2020 Ping Identity Corporation
# All Rights Reserved.
#
# This file provides a make-ldif template whose primary purpose is to
# demonstrate the use of all variations of all supported tags.  It is not
# intended to result in an LDIF file that should be imported into a
 directory,
# since it includes elements that aren't defined in the schema.
 Nevertheless,
# this file may be useful to individuals looking to create their own
# make-ldif templates or to customize an existing template.

# Any global replacement tokens defined at the top of the template file will
# be replaced with their corresponding value later in the template anywhere
# the token name appears in square brackets.
define basedn=dc=example,dc=com

# A branch is a special kind of entry with a fixed, non-dynamically
 generated
# DN (although the DN may be based partially or entirely on a global
# replacement token).  Some kinds of tags may be used in branch definitions
 (as
# indicated below thorugh the "allowed-in-branch" attribute.  Also, the
# "subordinateTemplate" element specifies the type and number of entries to
# create immediately below each branch.
```

# The template definitions come after the branch definitions, and define
# entries that will be dynamically generated, including their DNs.  Entries
# generated from a template may be either created directly below a branch,
 or
# they may be created below other template-generated entries (i.e., a
 template
# may include a "subordinateTemplate" element indicating that one or more
# entries of a different type should appear below each of the initial
 template
# entries.  In this template file, each template below will demonstrate the
# use of exactly one tag, and exactly one variation of that tag (so tags
 with
```

```
# multiple variations may be illustrated through multiple templates).

template: attribute-value-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: attribute value tag with name
syntax: open-curly-brace attribute-name close-curly-brace
example: {cn}
allowed-in-branch: true
description: This tag will be replaced with the first value of the indicated
 attribute.  The specified attribute must have already been assigned at
 least one value earlier in the template.

template: attribute-value-tag-with-name-and-max-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: attribute value tag with name and max length
syntax: open-curly-brace attribute-name colon max-length close-curly-brace
example: {cn:5}
allowed-in-branch: true
description: This tag will be replaced with at most the specified number
 of characters from the beginning of the first value of the indicated
 attribute.  The specified attribute must have already been assigned at
 least one value earlier in the template.

template: dn-tag-full
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: dn tag with full dn
syntax: less-than "dn" greater-than
example: <dn>
allowed-in-branch: true
description: This tag will be replaced with the full DN of the entry
 currently being generated.  All RDN attributes must be assigned values
 earlier in the template.

template: dn-tag-partial
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: dn tag with partial dn
syntax: less-than "dn" colon num-components greater-than
example: <dn:1>
allowed-in-branch: true
description: This tag will be replaced with at most the specified number of
 components from the entry currently being generated, as counted from left
 to right (e.g., a value of 1 will cause only the RDN to be used, a value
 of 2 will cause both the current entry's RDN and the parent entry's RDN to
 be used, etc.).  All RDN attributes must be assigned values earlier in the
 template.

template: escaped-characters
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: An example of escaping special characters
syntax: backslash-character character-to-escape
example: \{ "this" : "is JSON" \}
allowed-in-branch: true
description: The following characters need to be escaped with a backslash in
 order to be taken literally by make-ldif: \{ \} \< \> \[ \]
```

```
template: file-tag-path
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: file tag with path
syntax: less-than "file" colon file-path greater-than
example: <file:cities>
allowed-in-branch: true
description: This tag will be replaced with a randomly-selected line from
 the specified file.  The file may be specified using a full path, but if no
 path information is provided, then it will be assumed to be in the config/
MakeLDIF directory below the server root.

template: file-tag-path-sequential
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: file tag with path and sequential
syntax: less-than "file" colon file-path colon "sequential" greater-than
example: <file:cities:sequential>
allowed-in-branch: true
description: Each subsequent use of this tag will be replaced with the next
 line from the specified file.  Once all lines of the file have been used,
 then subsequent uses will start over from the beginning of the file.

template: first-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: first tag
syntax: less-than "first" greater-than
example: <first>
allowed-in-branch: false
description: This tag will be replaced with a first name value (taken
 from the first.names file).  The algorithm that the make-ldif tool uses
 guarantees that the combination of the first and last name values will
 always be unique, no matter how many entries are generated (although it may
 need to append a number to the last name value in LDIF files with extremely
 large numbers of values).

template: guid-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: GUID tag
syntax: less-than "guid" greater-than
example: <guid>
allowed-in-branch: true
description: This tag will be replaced with a randomly-generated globally-
unique identifier (GUID), also known as a universally-unique identifier
 (UUID).

template: ifabsent-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifabsent tag with name
syntax: less-than "ifabsent" colon attribute-name greater-than
example: <ifabsent:cn>This value will only appear if the resulting entry
 doesn't have a cn attribute.
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
 always be replaced with the empty string.  However, it may cause any in
```

```
 which this tag is used to be completely suppressed from the resulting entry
 if the specified attribute already exists in the generated entry.  This is
 primarily useful for attributes whose inclusion in generated entries is not
 guaranteed (e.g., randomly determined via the presence tag).

template: ifabsent-tag-with-name-and-value
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifabsent tag with name
syntax: less-than "ifabsent" colon attribute-name colon attribute-value
 greater-than
example: <ifabsent:cn:value>This value will only appear if the resulting
 entry doesn't have a cn attribute with a value of "value".
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
 always be replaced with the empty string.  However, it may cause any in
 which this tag is used to be completely suppressed from the resulting entry
 if the specified attribute value already exists in the generated entry.
  This is primarily useful for attributes whose inclusion in generated
 entries is not guaranteed (e.g., randomly determined via the presence tag).

template: ifpresent-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifpresent tag with name
syntax: less-than "ifpresent" colon attribute-name greater-than
example: <ifpresent:cn>This value will only appear if the resulting entry
 includes a cn attribute.
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
 always be replaced with the empty string.  However, it may cause any in
 which this tag is used to be completely suppressed from the resulting entry
 if the specified attribute is missing from the generated entry.  This is
 primarily useful for attributes whose inclusion in generated entries is not
 guaranteed (e.g., randomly determined via the presence tag).

template: ifpresent-tag-with-name-and-value
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifpresent tag with name
syntax: less-than "ifpresent" colon attribute-name colon attribute-value
 greater-than
example: <ifpresent:cn:value>This value will only appear if the resulting
 entry includes a cn attribute with a value of "value".
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
 always be replaced with the empty string.  However, it may cause any in
 which this tag is used to be completely suppressed from the resulting entry
 if the specified attribute value is missing from the generated entry.  This
 is primarily useful for attributes whose inclusion in generated entries is
 not guaranteed (e.g., randomly determined via the presence tag).

template: last-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: last tag
syntax: less-than "last" greater-than
example: <last>
allowed-in-branch: false
```

```
description: This tag will be replaced with a last name value (taken
 from the last.names file).  The algorithm that the make-ldif tool uses
 guarantees that the combination of the first and last name values will
 always be unique, no matter how many entries are generated (although it may
 need to append a number to the last name value in LDIF files with extremely
 large numbers of values).

template: list-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: list tag
syntax: less-than "list" colon value1 colon value2 ... colon valueN greater-
than
example: <list:first:second:third>
allowed-in-branch: true
description: This tag will be replaced with one of the values in the given
 list.  The value will be selected at random, with each possibility having
 the same chance of being selected.

syntax: less-than "_parentdn" greater-than
example: <_parentdn>
allowed-in-branch: false
description: This tag will be replaced with the full DN of the entry
 immediately superior to the entry being generated, except with commas
 replaced with underscores.
```

Server installation modes

One of the strengths of the PingDirectory Server is the ease with which you can install a server instance using the **`setup`** tool. The **`setup`** tool allows you to quickly install and configure a stand-alone Directory Server instance.

To install a server instance, run the **`setup`** tool in one of the following modes: interactive command-line, or non-interactive command-line mode.

- **Interactive Command-Line Mode**. Interactive command-line mode prompts for information during the installation process. To run the installation in this mode, use the **`setup --cli`** command.
- **Non-Interactive Command-Line Mode**. Non-interactive command-line mode is designed for setup scripts to automate installations or for command-line usage. To run the installation in this mode, **`setup`** must be run with the `--no-prompt` option as well as the other arguments required to define the appropriate initial configuration.

All installation and configuration steps should be performed while logged on to the system as the user or role under which the Directory Server will run.

Before you begin

After you have unzipped the Directory Server ZIP file, you may want to carry out the following functions depending on your deployment requirements:

- **Custom Schema Elements**. If your deployment uses custom schema elements in a custom schema file (for example, `98-schema.ldif`), you may do one of the following:
  - Copy your custom schema file to the `config/schema` directory before running setup.
  - Copy your custom schema file to the `config/schema` directory after setup and re-start the server. If replication is enabled, the restart will result in the schema replicating to other servers in the replication topology.
  - Use the **Schema Editor** after setup. If replication is enabled, schema definitions added through the **Schema Editor** will replicate to all servers in the replication topology without the need for a server restart.
- **Certificates**. If you are setting up a new machine instance, copy your keystore and truststore files to the `<server-root>/config` directory prior to running setup. The keystore and truststore passwords can be placed, in clear text, in corresponding `keystore.pin` and `truststore.pin` files in `<server-root>/config`.
- **Encryption Passphrase**. Encryption for directory data, backups, LDIF exports, and log files can be enabled during setup by providing or generating an encryption key with a passphrase.
- **Locations**. Location names are used to define a grouping of PingDirectory Server products based on physical proximity. For example, a location is most often associated with a single datacenter location. During the installation, assign a location to each server for optimal inter-server behavior. The location assigned to a server within Global Configuration can be referenced by components within the server as well as processes external to the server to satisfy "local" versus "remote" decisions used in replication, load balancing, and failover.
- **Validate ACIs**. Many directory servers allow for less restrictive application of its access control instructions (ACIs), so that they accept invalid ACIs. For example, if a Sun/Oracle server encounters an access control rule that it cannot parse, then it will simply ignore it without any warning, and the server may not offer the intended access protection. Rather than unexpectedly exposing sensitive data, PingDirectory Server rejects any ACIs that it cannot interpret, which ensures data access is properly limited as intended, but it can cause problems when migrating data with existing access control rules to a PingDirectory Server. If you are migrating from a Sun/Oracle deployment to a PingDirectory Server, PingDirectory Server provides a **`validate-acis`** tool in the `bin` directory (UNIX or Linux systems) or `bat` directory (Windows systems) that identifies any ACI syntax problems before migrating data. For more information, see *Validating ACIs Before Migrating Data*.

> ⓘ **Important:**

Each Server Deployment Requires an Execution of Setup - Duplicating a Server-root is not Supported. The installation of the server does not write or require any data outside of the server-root directory. After executing **`setup`**, copying the server-root to another location or system, in order to *duplicate* the installation, is not a supported method of deployment. The server-root can be moved to another host or disk location if a host or file system change is needed.

Ping license keys

License keys are required to install, update, and renew all Ping products.

How to obtain a license

To obtain a license key, contact your account representative or use the *Ping Identity licensing portal*.

When do you need a license

A license is required for setting up a new single server instance and can be used site-wide for all servers in an environment. Additionally, you must obtain a new license when updating a server to a new major version, such as when upgrading from 7.3 to 8.0. When cloning a server instance with a valid license, you do not need a new license.

ⓘ **Note:**

The update process displays a prompt for a new license.

How to specify a license

- Specify a license at setup

  You have these options:

  - Use the `--licenseKeyFile` <*path-to-license*> option with **`setup`**.
  - Copy the license file to the server root directory and then run the **`setup`** tool. The tool discovers the license file.
- Specify a license after setup

  Use the Administrative Console or **`dsconfig`** (in the Topology section, select License).

  ⓘ **Note:** Placing the new license file in the server root directory does not work in this case.

How to view the license status

To view the details of a license, including its expiration, you have these options:

- The server's **`status`** tool
- The Administrative Console's **Status** page (On the **Monitors** tab, search for License.)

License expiration

The server provides a notification as the expiration date approaches.

Before a license expires, obtain a new one and install it by using **`dsconfig`** or the Administrative Console.

ⓘ **Note:**

An expiring license causes alerts and alarms but does not affect the functionality of the product.

Setting up the Directory Server in interactive mode

The **setup** tool also provides an interactive text-based command-line interface to set up a Directory Server instance.

About this task

Complete the following steps to install the Directory Server in interactive mode.

Steps

1. Extract the distribution `.zip` file, review *Before You Begin*, and then go to the server root directory.

   ```
   $ ./setup
   ```

   If the *JAVA_HOME* environment variable is set to an older version of Java, explicitly specify the path to the Java Development Kit (JDK) installation during the setup process. Either set the <*JAVA_HOME*> environment variable with the JDK path or execute the **setup** command in a modified Java environment using the **env** command.

   ```
   $ env JAVA_HOME=/ds/java ./setup
   ```

2. Read the Ping Identity End-User License Agreement, and type `yes` to continue.
3. Enter the fully qualified host name or IP address of the local host, or press Enter to accept the default.
4. Enter the distinguished name (DN) for the initial root user, or press Enter to accept the default (`cn=Directory Manager`).
5. Enter and confirm the root user password.
6. Press Enter to enable the Ping Identity services (Configuration, Consent, Delegated Admin, Documentation, and Directory REST API) and Administrative Console over HTTPS.

   After setup, you can enable or disable individual services and applications by configuring the HTTPS Connection Handler.
7. Enter the port on which the Directory Server will accept connections from HTTPS clients, or press Enter to accept the default.
8. Enter the port on which the Directory Server will accept connections from LDAP clients, or press Enter to accept the default.
9. Enter `no` to use a standard LDAP connection, or accept the default (`yes`) to enable both LDAPS and StartTLS.

   Enabling LDAPS configures the LDAPS Connection Handler to allow SSL over its client connections. Enabling StartTLS configures the LDAP Connection Handler to allow StartTLS.
10. Select the certificate option for this server:
    - Generate a self-signed certificate for testing purposes only.
    - Enter the keystore path and keystore PIN to use an existing certificate using a Java Keystore, .
    - Enter the keystore path and the keystore PIN to use an existing certificate using use a PKCS#12 keystore.
    - Enter only the keystore PIN ro use the PKCS#11 token.

11. Choose the desired encryption for the directory data, backups, and log files from the choices provided:
    - Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments. Use the same encryption passphrase when setting up each server in the topology.
    - Encrypt data with a key generated from a passphrase read from a file.
    - Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
    - Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
    - Do not encrypt server data.
12. Type the base DN for the data, or accept the default base DN of `dc=example,dc=com`.
13. To choose an option to generate and import sample data, type the desired number of entries, or press Enter to accept the default number (10000).

    This option is used for quick evaluation of the Directory Server. See *Initializing Data onto the Server* if you want to use other options to initialize the server.
14. Choose the option to tune the amount of memory that will be consumed by the Directory Server and its tools.
15. Press Enter to prime or preload the database cache at startup prior to accepting client connections.

    Priming the cache can increase the startup time for the Directory Server but provides optimum performance after startup has completed. This option is best used for strict throughput or response time performance requirements, or if other replicas in a replication topology can accept traffic while this Directory Server instance is starting. Priming the cache also helps determine the recommended JVM option, CMSInitiatingOccupancyFraction, when a Java garbage collection pause occurs. See *JVM Garbage Collection Using CMS*.
16. Enter a location name for this server.
17. Enter a unique instance name for this server.

    You cannot change the name after you set it.
18. Press Enter to accept the default (yes) to start the Directory Server after the configuration has completed.

    To configure additional settings or import data, enter `no` to keep the server in shutdown mode.
19. Choose an option to continue server set up.
20. In the **Setup Summary** window, confirm the configuration. , or
    - Press Enter to accept the default (set up with the parameters given), enter the option to repeat the installation process.
    - Enter the option to cancel the setup completely.

Installing the Directory Server in non-interactive mode

Run the **`setup`** command in non-interactive mode to automate the installation process using a script or to run the command directly from the command line.

Non-interactive mode is useful when setting up production or QA servers with specific configuration requirements.

The non-interactive command-line mode requires that all mandatory options be present for each command call. If there are missing or incorrect arguments, the **`setup`** tool fails and aborts the process. You must also use a `--no-prompt` option to suppress interactive output, except for errors, when running in non-interactive mode. Additionally, you must also use the `--acceptLicense` option and specify the port using the `--ldapPort` or `--ldapsPort` option. If neither option is specified, an error message is displayed. To view the license, run the `bin/review-license` command.

To automatically tune the Java virtual machine (JVM) to use maximum memory, use the `--aggressiveJVMTuning` and `--maxHeapSize` {memory} options. To preload the database at startup, use the `--primeDB` option.

To configure a deployment using a truststore, see *Installing the Directory Server in Non-Interactive Mode with a Truststore*.

To see a description of the available command-line options for the **`setup`** tool, use **`setup --help`**.

Installing the Directory Server in non-interactive mode
Install a Directory Server in a production or QA environment with no security enabled.

Steps

- Extract the distribution `.zip` file, review “Before You Begin”, and then use **`setup`** with the `--cli` and `--no-prompt` options for non-interactive mode from the `<server-root>` directory.

  The following command uses the default root user distinguished name (DN) (cn=Directory Manager) with the specified `--rootUserPassword` option. You must include the `--acceptLicense` option or the setup generates an error message. The --instancename option specifies the name for the server instance and should be unique across all instances in the topology. The --location option specifies the name of the location in which the instance will be installed. You should generally configure your topology with a separate location for each data center to allow inter-server communication to prioritize servers in the same location over those in remote locations.

  ```
  $ ./setup --cli --no-prompt --rootUserPassword "password" \
    --baseDN "dc=example,dc=com" --acceptLicense --ldapPort 389 \
    --instancename Instance1 --location Location1
  ```

Installing the Directory Server in non-interactive mode with a truststore

About this task

You can set up the Directory Server using an existing truststore for secure communication. This section assumes that you have an existing keystore and truststore with trusted certificates.

Steps

- Unzip the distribution ZIP file, review *Before You Begin*, and then, from the server root directory, use **`setup`** with the `--cli` and `--no-prompt` options for non-interactive mode. The following example enables security using both SSL and StartTLS. It also specifies a JKS keystore and truststore that define the server certificate and trusted CA. The `userRoot` database contents will remain empty and the base DN entry will not be created.

  ```
  $ ./setup --cli --no-prompt --rootUserPassword "password" \
    --baseDN "dc=example,dc=com" --ldapPort 389 --enableStartTLS \
    --ldapsPort 636 --useJavaKeystore config/keystore.jks \
    --keyStorePasswordFile config/keystore.pin \
    --certNickName server-cert --useJavaTrustStore config/truststore.jks \
    --acceptLicense --instancename Instance1 --location Location1
  ```

  The password to the private key with the keystore is expected to be the same as the password to the keystore. If this is not the case, the private key password can be defined with the Administrative Console or the **`dsconfig`** tool by editing the Trust Manager Provider standard configuration object.

Installing a lightweight server

Users who want to demo or test a lightweight version of the Directory Server on a memory-restricted machine can do so by removing all unused or unneeded configuration objects.

All configuration entries, whether enabled or not, take up some amount of memory to hold the definition and listeners that are notified of changes to those objects.

The configuration framework does not allow you to remove objects that are referenced, and in some cases if you have one configuration object referencing another but really do not need it, then you must first remove the reference to it. If you try to remove a configuration object that is referenced, both **dsconfig** and the administrative console should prevent you from removing it and tell you what still references it.

Depending on your test configuration, some example configuration changes that can be made are as follows:

Reduce the number of worker threads

Each thread has a stack associated with it, and that consumes memory. If you're running a bare-bones server, then you probably do not have enough load to require a lot of worker threads.

```
$ bin/dsconfig set-work-queue-prop \
  --set num-worker-threads:8 \
  --set num-administrative-session-worker-threads:4 \
  --set max-work-queue-capacity:100
```

Reduce the percentage of JVM memory used for the JE database cache

When you have a memory-constrained environment, you want to ensure that as much of the memory that is there is available for use during processing and not tied up caching database contents.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set db-cache-
percent:5
```

Disable the Dictionary Password Validator

The Dictionary Password Validator takes a lot of memory to hold its dictionary. Disabling it frees up some memory. You can delete the other password validators if not needed, such as Attribute Value, Character Set, Length-based, Repeated Characters, Similarity-based, or Unique Characters Password Validator.

```
$ bin/dsconfig delete-password-validator --validator-name Dictionary
```

Remove non-essential schema files

Although not recommended for production deployments, some candidates that you can remove are the following: `03-rfc2713.ldif`, `03-rfc2714.ldif`, `03-rfc2739.ldif`, `03-rfc2926.ldif`, `03-rfc2985.ldif`, `03-rfc3712.ldif`, `03-uddiv3.ldif`.

There are other items that can be removed, depending on your desired configuration. Contact your authorized support provider for assistance.

Uninstalling the Server

The Directory Server provides an **uninstall** command-line utility for quick removal of the code base.

To uninstall a server instance, run the **setup** tool in interactive command-line, or non-interactive command-line mode.

Interactive command-line mode

Interactive command-line mode is a text-based interface that prompts the user for input. To run this mode, use the **bin/uninstall** command with the `--cli` option.

Non-interactive command-line mode

Non-interactive command-line mode suppresses progress information from being written to standard output during processing, except for fatal errors. To run this mode, use the **bin/uninstall** command with the `--no-prompt` option.

ⓘ **Note:**

For standalone installations with a single Directory Server instance, you can also manually remove the Directory Server by stopping the server and recursively deleting the directory and subdirectories, as in the following example.

```
$ rm -rf /ds/PingDirectory
```

Uninstalling the server in interactive mode

Interactive mode uses a text-based, command-line interface to help you remove your instance.

About this task

If **uninstall** cannot remove all of the Directory Server files, the **uninstall** tool generates a message with a list of the files and directories that must be manually deleted. The **uninstall** command must be run as either the root user or the same user (or role) that installed the Directory Server.

Steps

1. From the server root directory, run the **uninstall** command.

   ```
   $ ./uninstall --cli
   ```

2. Select the components to be removed.
   - Remove all components - If you want to remove all components, press **Enter** to accept the default (remove all).
   - Select the components to be removed - If you do not want to remove all components, enter the option to specify the removal of only specific components.

     For each type of server component, press **Enter** to remove it or enter `no` to keep it.
3. If the Directory Server is part of a replication topology, enter `yes` to provide your authentication credentials (Global Administrator ID and password). If you are uninstalling a standalone server, continue to step 7.
4. Enter the Global Administrator ID and password to remove the references to this server in other replicated servers, and then enter or verify the host name or IP address for the server that you are uninstalling.
5. Select how you want to trust the server certificate if you have set up SSL or StartTLS. Press **Enter** to accept the default.

   ```
   How do you want to trust the server certificate for the Directory Server
   on server.example.com:389?

   1) Automatically trust
   2) Use a trust store
   3) Manually validate
   ```

```
Enter choice [3]:
```

6. View the logs for any remaining files and manually remove any remaining files or directories.

   If your Directory Server is running, the server shuts down before continuing the uninstall process. The uninstall action processes the removal requests before completing.

Uninstalling the server in non-interactive mode

The **uninstall** utility provides a non-interactive method to enter the command with the `--no-prompt` option.

About this task
Another useful argument is the `--forceOnError` option that continues the uninstall process when an error is encountered. If an option is incorrectly entered or if a required option is omitted and the `--forceOnError` option is not used, the command fails and aborts.

Steps

1. From the server root directory, run **uninstall** tool with the `--remove-all` option to remove all of the Directory Server's libraries.

   The optional `--quiet` option suppresses output information.

   The following command assumes that the Directory Server is standalone and not part of a replication topology.

   ```
   $ ./uninstall --cli --remove-all --no-prompt --quiet --forceOnError
   ```

2. If any files or directories remain, manually remove them.

Uninstalling selected components in non-interactive mode

Steps

1. From the server root directory, run **uninstall** with the `--backup-files` option to remove the Directory Server's backup files.

   ```
   $ ./uninstall --cli --backup-files --no-prompt --quiet --forceOnError
   ```

2. To view the other options available to remove specific components, use the `--help` or `-H` option.

Upgrading the Server

This section presents multiple update scenarios and their implications to consider when upgrading your server code.

Ping Identity issues software release builds periodically with new features, enhancements, and fixes for improved server performance. Use the Directory Server's update utility to upgrade the current server code version.

Upgrade overview and considerations

The following content provides a brief description of the upgrade process and considerations that might affect your upgrade decisions.

Overview

For the upgrade process, you must download and extract a new version of the Directory Server `.zip` file on the server that will be updated. In addition, you must run the **`update`** utility with the **`--serverRoot`** or **`-R`** option value from the new root server pointing to the installation that will be upgraded.

Considerations

Consider the following when planning for and upgrading replicating servers:

- The upgrading process affects only the server being upgraded. The process does not alter the configuration of other servers.
- The **`update`** tool verifies that the Java version installed meets the new server requirements. Before running the tool, install the Java version that is supported by the new server.
- For precautionary measures, backup the user data `userRoot` before an upgrade. Restoring from a backup might be necessary if all other servers in the replication topology have been upgraded and a database or encoding change in the new server version prevents the database from being used with the older server version. The **`update`** and **`revert-update`** utilities issue a warning when this is the case.
- Temporarily raise the replication purge delay for all servers in the topology to cover the expected downtime for maintenance. This results in a temporary increase in disk usage for the replicationChanges database stored in `<server-root>/changelogDb`.
- Replication does not need to be disabled on a server before an upgrade.
- Make sure upgraded servers are working as expected before upgrading the last server in the topology.
- After all replicating servers are upgraded, enable new features.

> ⓘ **Tip:**
>
> For additional considerations, see the *Planning your upgrade guide*.

Considerations when upgrading to 8.2.0.0

> ⓘ **Important:**
>
> If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

This upgrade moves to Jetty 9.4. As a result, the HTTPS Connection Handler no longer supports TLS_RSA ciphers by default. If you use any legacy HTTPS clients that still require TLS_RSA ciphers, modify the `ssl-cipher-suite` property of the HTTPS Connection Handler to include them.

Upgrading servers in a topology

An update to the current PingDirectory Server release includes the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts.

Before you begin

Before you can update and migrate the admin backend, the following conditions must be satisfied:

- Run the update tool and provide LDAP authentication options to the peer servers of the server being updated. The **`update`** tool connects to the peer servers of the server being updated to obtain the necessary information to populate the topology registry.
- On every server in the topology, configure the encryption protocol requested, either plain, TLS, StartTLS, or SASL, for an LDAP connection.
- Ensure the LDAP credentials are present on every server in the topology.
- Ensure the users related to the LDAP credentials have permissions to read from the admin backend and the config backend of every server in the topology. For example, you can use a root DN user that has `inherit-default-privileges` set to true, such as the `cn=Directory Manager` user, that exists on every server.
- The instance name is set on every server and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server is uniquely identified by its instance name. After the name is set, it cannot be changed.

> ⓘ **Tip:**
>
> If needed, use the following command to set the instance name of a server prior to the update.
>
> ```
> $ bin/dsconfig set-global-configuration-prop \
>   --set instance-name:uniqueName
> ```

> ⓘ **Important:**
>
> This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than a 7.x to a 7.x version and is not applicable to any updates to a server version of 8.x or later.

About this task

Upgrade to a server that uses a topology registry to store network configuration, administrator user accounts, and keys information, as well as migrate the information from the previous server version.

Steps

1. To make clustered configuration changes in a mixed-version cluster, choose one of the following options:
   - Update each server to the same version.
   - Temporarily split up the cluster by changing the `cluster-name` property on the server instance configuration objects.

   > ⓘ **Note:**
   >
   > Changes to clustered configurations are not allowed in mixed-version clusters. This applies to configuration in the `cn=Cluster,cn=config` subtree and only applies to servers with matching cluster names.

2. Make clustered configuration changes again to mirror these changes across the topology.
3. Run the **dsframework** command on the server being updated.

```
$ bin/dsframework set-server-properties \
  --serverID serverID \
  --set ldapport:port \
  --set ldapsport:port \
  --set startTLSEnabled:true
```

> ⓘ **Important:**
>
> To run this command, you must have enabled or fixed the configuration of the LDAP Connection Handlers to support the desired connection security protocol on each server, so that its admin backend has the most up-to-date information.

Before allowing the update, the **update** tool verifies that the following conditions are satisfied on every server in the topology:

- When the first server is being updated, all other servers in the topology are online.
- When updating additional servers, all topology information was obtained from one of the servers that has already been updated.
- The users related to the provided LDAP credentials have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server and is unique across all servers in the topology.

> ⓘ **Note:**
>
> If any of these conditions or those listed in the preceding Before you begin section are not satisfied, the **update** tool lists all of the errors encountered for each server and provides instructions on how to fix them.

When all of these conditions are met, the cluster-wide configuration is synchronized on all servers in the topology.

> ⓘ **Note:**
>
> Older versions have some topology configuration under the **cn=cluster,cn=config** JSON attribute and field constraints. These items do not support mirrored cluster-wide configuration data. In an update, avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree master. If additional configuration steps are needed, see step 4.

4. To synchronize the cluster-wide configuration data across all servers in the topology, run the **config-diff** tool on each pair of servers to determine the differences, and use **dsconfig** to update each instance using the **config-diff** output.

```
$ bin/config-diff --sourceHost hostName \
  --sourcePort port \
  --sourceBindDN bindDN \
  --sourceBindPassword password \
  --targetHost hostName \
  --targetPort port \
  --targetBindDN bindDN \
  --targetBindPassword password
```

Restoring a mixed topology to a clean state
Perform the following steps to restore a mixed-version 6.2 - 7.x topology with replication problems to a clean state with all servers at the same level and with replication functioning normally.

About this task

> ⓘ **Note:**
>
> This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than 7.x to a 7.x version and is not applicable to any updates to server version 8.x or later.

If you are upgrading a Directory Server version prior to 7.3 to 7.3 or later and at least one server was previously removed from the topology, you might receive an error message similar to one of the following:

```
[09/Dec/2019:18:37:56.927 -0700] instanceName="[INSTANCE_NAME]" \
    threadID=438 category=REPLICATION severity=NOTICE msgID=118947975
 msg="The \
    replication total backlog count is 163364"
```

Or:

```
[09/Dec/2019:17:15:10.108 -0700] category=REPLICATION \
   severity=SEVERE_ERROR msgID=14942295 msg="While clearing the database 997
 \
   o=mycompany, the following error happened: (JE 7.5.12) Attempted to
 remove \
   non-existent database 997 o=mycompany DatabaseNotFoundException: (JE
 7.5.12) \
   Attempted to remove non-existent database 997 o=pingone (DbTree.java:922
 \
   DbTree.java:1183 DbTree.java:1235 Environment.java:1001
 Environment.java:1221 \
   Environment.java:1204 Environment.java:1009 ReplicationDbEnv.java:1186 \
   DomainDbEnv.java:995 ReplicationDB.java:1002 DbHandler.java:1324
 DbHandler.java:1064 \
   DbHandler.java:1042 DbHandler.java:798 DbHandler.java:723
 DirectoryThread.java:352 \
   (7.3.0.4-20191127203417.000Z-83a75e2a))"
```

Steps

1. To export a safe copy of the data, run **`bin/export-ldif`** on the primary server.
2. Start the down-level primary server and stop the upgraded replica server.
3. Run **`bin/remove-defunct-server`** on the upgraded replica server and do the following when prompted:
   a. Select the replica server itself.
   b. Supply the credentials for the primary server when prompted.
   c. Select **[c]** to continue.
   d. Enter the path to the local `changelogDB` when prompted.
4. Leave the upgraded replica server stopped and stop the down-level primary server.
5. Run **`bin/dsreplication`** on the primary server and do the following:
   a. Select **2) Manage the topology (add and remove servers)**.
   b. Select **4) Cleanup Server**.
   c. Select **[c]** to continue.
   d. Enter the path to the local `changelogDB` when prompted.

6. Start the down-level primary server and the upgraded replica server.
7. Run **bin/status** on both servers and verify that status of **Replication: disabled** in **Data Sources**.
8. Upgrade the replica server to version 7.3.0.5 or later, which contains fixes for issues 00668265 and DS-40955.
9. Upgrade the primary server to the same level as the replica server.
10. To re-enable replication between the primary and replica server, run the **bin/dsreplication** tool.
11. Re-initialize the replica server data from the primary server.
12. Run **bin/status** on both servers to verify that replication is enabled in **Data Sources** and that both servers show the same number of entries.

Upgrading the Directory Server

Perform an upgrade to the Directory Server with the following steps.

Steps

1. Download and extract the new version of the Directory Server in a location outside the existing server's installation.

   For these steps, assume the existing server installation is located in `/prod/PingDirectory` and the new server version is extracted in the `/home/stage/PingDirectory` location.
2. Run the **update** tool provided with the new server package to update the existing Directory Server.

> ⓘ **Note:**
>
> The update tool might prompt for confirmation of the server configuration changes if it detects customization and display the following code.
>
> ```
> $ /home/staging/PingDirectory/update --serverRoot /prod/PingDirectory
> ```

Reverting an update

After PingDirectory Server has been updated, you can revert to the last version or one level back using the **revert-update** tool.

About this task

The **revert-update** tool accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the **revert-update** tool multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing PingDirectory Server, you can run the **revert-update** command to revert to its previous state, then run the **revert-update** command again to return to its original state. The following steps detail reverting from 7.x to a version prior to 7.0.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server displays warnings about "offline configuration changes," but they are not critical and do not appear on subsequent start ups.

To revert to the most recent server version:

Steps

- Use **revert-update** in the server root directory to revert back to the most recent version of the server.

  ```
  $ PingDirectory-old/revert-update
  ```

Next steps

Reverting from the 7.0 version or later to a version earlier than 7.0 using the **revert-update** command might require extra steps. This is also the case when updating or reverting from a version earlier than 6.2.0.2 to a 6.2.0.2 version or later. These steps are listed when the **update** and **revert-update** tool are run as well. Depending on your installation and configuration, you might need to perform one or more of the following tasks:

- When updating or reverting from 6.2.0.2 or later to a version earlier than 6.2.0.2, indexes might need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and rebuild the indexes using the **rebuild-index** tool. The command for recreating an index is in the `Undo` portion of the `logs/config-audit.log` file. To later revert to an older version, delete and recreate those composite indexes again after the revert process completes.
- When updating to 7.x for the first time, instance names must be set for each server in the topology if they were not previously set. This is done with the following **dsconfig** command.

  ```
  $ bin/dsconfig --bindDN "cn=Directory Manager" \
    --bindPassword secret \
    --no-prompt set-global-configuration-prop \
    --set instance-name:<name>
  ```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the **admin** backend. As long as new servers are not added to the topology after this update, you can use the **revert-update** command to return to the previous version. However, if new servers are added, then the restored **admin** backend of this server does not contain information about the new servers, and the local server cannot communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.
- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a version earlier than 7.x, any servers in the topology using the topology portion of the configuration rather than the **admin** backend must know that the reverted server was downgraded to the **admin** backend. To do this, run the following **dsconfig** command on one of the servers that has not been reverted.

  ```
  $ bin/dsconfig set-server-instance-prop \
    --instance-name <Reverted server instance name> \
    --set server-version:<Version to which server is reverted>
  ```

- If the topology does not have a master server when this command is run, the **revert-update** will not succeed. In this case, you must make one of the remaining updated servers in the topology the master with the following command. This enables the chosen instance to run the **revert-update** command successfully.

  ```
  $ bin/dsconfig set-global-configuration-prop \
    --set force-as-master-for-mirrored-data:true
  ```

- The 7.x server version includes database changes that are not compatible with previous server versions, such as 6.x or earlier. To later revert to an older version, you must export the data to LDIF before performing the reversion. Then, re-import the data after the revert process completes. In addition, you must delete the `changelogDb/` and `db/changelog/` directories in the reverted server root after the revert process completes.

Getting Started with Directory Server

After you have set up your Directory Server instance, you can configure any specific server settings, import your user database, or run initial performance tests to optimize your server's throughput.

> ⓘ **Note:**
>
> The URL is based on the host name and HTTPS port specified during installation, such as https://hostname.com:443/console.

Apply Server Configurations

Apply your server configuration changes individually or using a **dsconfig** batch file. The batch file defines the Directory Server configuration tool, **dsconfig**, commands necessary to configure your server instance. For more information on using batch files, see *Using dsconfig in Batch Mode*.

If you are migrating from a Sun Java System 5.x, 6.x, 7.x directory server, you can use the **bin/migrate-sun-ds-config** command to migrate your configuration settings to this new server instance.

Import Data

Import user data using the **import-ldif** tool. The import serves as an initial test of the schema settings.

```
$ bin/import-ldif --backendID userRoot --ldifFile ../user-data.ldif
```

Install and Configure the Delegated Admin Application

Install a Javascript-based web application for business users to manage identities stored in the Directory Server. The application provides delegated administration of identities for help desk or customer service representatives initiating a password reset and unlock, an employee in HR updating an address stored within another employee profile, or an application administrator updating identity attributes or group membership to allow application single sign-on (SSO) access.

Run Performance Tests

The Directory Server provides two tools for functional performance testing using in-house LDAP clients that access the server directly: **searchrate** to test search performance and **modrate** to test modification performance.

```
$ bin/searchrate --baseDN "dc=example,dc=com" --scope sub \
  --filter "(uid=user.[0-1999])" --attribute givenName --attribute sn
 \
  --attribute mail --numThreads 10

$ bin/modrate --entryDN "uid=user.[0-1999],ou=People,dc=example,dc=com"
 \
  --attribute description --valueLength 12 --numThreads 10
```

Multiple backends

You can create multiple local database backends, each containing one or more different base distinguished names (DNs).

There should be at most one replicating domain on each local database backend. The replication domain should not span multiple local database backends. The typical entry-balancing configuration involves two local database backends: one to serve the global domain data that resides above the entry-

balancing point and another that is defined with the entry-balancing point as the base DN, such as `ou=people,dc=example,dc=com`.

With multiple local database backends configured, the data existing with each backend can be managed independently. In addition, separate index settings are applied to each local database backend.

When creating multiple database backends, consider the following:

- No two backends can have the same base DN.
- If any base DN for a given backend is subordinate to a base DN on another backend, then all base DNs on that backend must be subordinate to the base DN of the other backend.
- The total of all db-cache-percent values should be no more than 65-70% in most cases and should never exceed 100%.

Importing data

After installing the database, such as userRoot, import data into the database.

Steps

- To add a server to a replicating set:
  a. Perform a **`dsreplication enable`** operation.
  b. Import the database through the **`dsreplication initialize`** operation.
- To add a server to a non-replicating set or to add the first server of a future replicating set, import the data with the **`bin/import-ldif`** tool.

  For more information about the **`bin/import-ldif`** tool, see *Importing and Exporting Data* on page 460.

Generating sample data

PingDirectory Server provides LDIF templates to generate sample entries for initializing your server. You can generate the sample data with the **`make-ldif`** utility together with template files that come bundled with the `.zip` build, or you can use template files that you create yourself.

About this task

The templates create sequential entries for testing PingDirectory Server with a range of dataset sizes. The Directory Server templates are located in the `config/MakeLDIF`.

The sample data templates generate a dataset with basic access control privileges that grants anonymous read access to anyone, grants users the ability to modify their own accounts, and grants the admin account full privileges. The templates also include the `uid=admin and ou=People` entries.

Steps

- To generate randomized sample data, use the `--randomSeed` option with the **`make-ldif`** command.

```
$ bin/make-ldif --templateFile config/MakeLDIF/example-10k.template \
  --ldifFile /path/to/data.ldif --randomSeed 0
```

> ⓘ **Note:**
>
> If the `--randomSeed` option is used with the same seed value, the template always generates the same `.ldif` file.

  The command generates 10,000 sample entries and writes them to an output file, `data.ldif`. The random seed generator is set to 0.
- To bypass the **`make-ldif`** command, use the `--templateFile` option with the **`import-ldif`** tool.

Importing data on the Directory Server using offline import

Steps

1. Create a `.ldif` file that contains entries or locate an existing file.

   The **`import-ldif`** tool requires a `.ldif` file, which conforms to standard LDIF syntax without change records. The `changeType` attribute is not allowed in the input LDIF. For information on adding entries to , see *Managing Entries*.
2. Stop the Directory Server.
3. To import data from an LDIF file to the Directory Server, use the **`import-ldif`** command.

   > ⓘ **Tip:**
   >
   > For assistance with the list of options, run **`import-ldif --help`**.

   In the following example, the data is imported from the `data.ldif` file to the `userRoot` backend. Entries rejected due to schema violation are written with the rejection reason to the `rejects.ldif` file. Skipped entries, written to `skipped.ldif`, occur if an entry cannot be placed under a branch node in the directory information tree (DIT) or if exclusion filters, such as `--excludeBranch`, `--excludeAttribute`, or `--excludeFilter` are used. The `--overwrite` option instructs **`import-ldif`** to overwrite existing skipped and rejected files. The `--overwriteExistingEntries` option indicates that any existing data in the backend should be overwritten, and the `--stripTrailingSpaces` option strips trailing spaces on attributes that would otherwise result in an LDIF parsing error.

   ```
   $ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif --
   rejectFile
       rejects.ldif --skipFile skipped.ldif --overwrite --
   overwriteExistingEntries --stripTrailingSpaces
   ```
4. Restart the Directory Server.

Running the server

Run the server as a background or foreground process.

Steps

1. To start the Directory Server, run the bin/start-server command on UNIX or Linux systems.

   An analogous command is in the `bat` folder on Microsoft Windows systems.

   > ⓘ **Note:**
   >
   > The bin/start-server command starts the Directory Server as a background process when no options are specified.
2. Optional: To run the Directory Server as a foreground process, use the bin/start-server command with the `--nodetach` option.

Starting the Directory Server
Start the directory server using the terminal.

Steps

- To start the server, on the terminal run bin/start-server.

```
$ bin/start-server
```

Running the server as a foreground process
Use the terminal to run the PingDirectory service as a foreground process.

Steps

1. To launch the Directory Server as a foreground process, open the terminal and enter bin/start-server with the `--nodetach` option.

```
$ bin/start-server --nodetach
```

2. To stop the Directory Server:
   - Press **CNTRL+C** in the terminal window where the server is running.
   - Run the bin/stop-server command from another terminal window.

Starting the server at boot time
By default,PingDirectory Server does not start automatically when the system is booted. Instead, you must manually start it with the bin/start-server command.

About this task
To configure the Directory Server to start automatically when the system boots, use the **create-systemd-script** utility to create a script, or create the script manually.

Steps

1. Create the service unit configuration file in a temporary location, where "ds" is the user running PingDirectory.

```
$ bin/create-systemd-script \
     --outputFile /tmp/ping-directory.service \
     --userName ds
```

2. As a root user, copy the **ping-directory.service** configuration file into the `/etc/systemd/system` directory.
3. To read the new configuration file, reload **systemd**.

```
$ systemctl daemon-reload
```

4. To start the PingDirectory, run the **start** command.

```
$ systemctl start ping-directory.service
```

5. To configure the PingDirectory to start automatically when the system boots, run the **enable** command.

```
$ systemctl enable ping-directory.service
```

6. Log out as root.

   To perform this task on an RC system, create the startup script with **bin/create-rc-script** and move it to the /etc/init.d directory.

> ⓘ **Note:**
>
> Create symlinks to this script from the /etc/rc3.d directory (starting with an “S” to ensure that the server is started) and /etc/rc0.d directory (starting with a “K” to ensure that the server is stopped).

Signing on to the Administrative Console

After the server is installed, access the administrative console, **https://hostname:HTTPport/console/login**, to verify the configuration and manage the server.

To sign on to the administrative console, use the initial root user DN specified during setup (by default **cn=Directory Manager**).

You can use the **dsconfig** command or the administrative console to create additional root DN users in **cn=Root DNs,cn=config**. These new users require the fully qualified DN as the username, such as **cn=new-admin,cn=Root DNs,cn=config**. To use a simple username (without the **cn=** prefix) for signing on to the administrative console, the root DN user must have the **alternate-bind-dn** attribute configured with an alternate name, such as "admin."

The default link to the administrative console is **https://hostname:HTTPport/console/login**.

If you need to run the administrative console in an external container, such as Tomcat, you can install a separate package (/server-root/resource/admin-console.zip) according to that container's documentation.

> ⓘ **Note:**
>
> The default session timeout for the console is 24 hours. When this duration is exceeded, all inactive users are signed off automatically.
>
> To set a different timeout value, configure the server.sessionTimeout application parameter, which specifies the timeout duration in seconds. You can set the value as an init parameter either in the console or on the command line, as shown below.
>
> For changes to take effect, restart the HTTP(S) Connection Handler or the server.

Console

1. Go to **Web Application Extensions**# **Console**.
2. Use the **Init Parameter** field.

Command line

- The following example uses a value of 1800 seconds (30 minutes).

```
dsconfig set-web-application-extension-prop --no-prompt \
--extension-name Console \
--add init-parameter:server.sessionTimeout=1800
```

Stopping the Directory Server

The Directory Server provides a simple shutdown script, bin/stop-server, to stop the server. Run it manually from the command line or within a script.

About this task

If the Directory Server has been configured to use a large amount of memory, then it might take several seconds for the operating system to fully release the memory and make it available again. If you try to start the server too quickly after shutting it down, then the server might fail because the system does not yet have enough free memory. On UNIX systems, run the **`vmstat`** command and watch the values in the "free" column increase until all memory held by the Directory Server is released back to the system.

You can also set a configuration option that specifies the maximum shutdown time a process might take.

Steps

- Use the bin/stop-server tool to shut down the server.

```
$ bin/stop-server
```

Scheduling a server shutdown

Schedule a server shutdown.

Steps

- To schedule a server shutdown, use the **`bin/stop-server`** tool with the `--stopTime YYYYMMDDhhmmss` option .

  The Directory Server schedules the shutdown and sends a notification to the `server.out` log file. The following example sets up a shutdown task that is scheduled to be processed on June 6, 2012 at 8:45 A.M. CDT. The server uses the UTC time format if the provided timestamp includes a trailing “Z”, for example, 20120606134500Z. The command also uses the `--stopReason` option that writes the reason for the shut down to the logs.

```
$ bin/stop-server --stopTime 20120606134500Z --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --stopReason "Scheduled offline maintenance"
```

Restarting the server

Restart the Directory Server.

About this task

Running the command is equivalent to shutting down the server, exiting the Java Virtual Machine (JVM) session, and then starting up again.

Steps

- Go to the server root directory, and run the bin/stop-server command with the `-R` or `--restart` options.

```
$ bin/stop-server --restart
```

Running the server as a Microsoft Windows service

The server can run as a Windows service on Windows Server 2012 R2 and Windows Server 2016. This enables signing-out of a machine without stopping the server.

Registering the server as a Windows service

Register the server as a Windows service using the Windows command prompt.

About this task

Perform the following steps to register the server as a service:

Steps

1. Stop the server with `bin/stop-server`.

   You cannot register a server while it is running.
2. To register the server as a service, from a Windows command prompt, run `bat/register-windows-service.bat`.
3. After registration, start the server from the Windows Services Control Panel or with the `bat/start-server.bat` command.

   Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

Running multiple service instances

Only one instance of a particular service can run at one time.

About this task

Services are distinguished by the `wrapper.name` property in the `<server-root>/config/wrapper-product.conf` file.

Steps

1. To run additional service instances, change the `wrapper.name` property on each additional instance.
2. Add or change descriptions of the service in the `wrapper-product.conf` file.

Deregistering and uninstalling services

To uninstall a service, you must first deregister it.

About this task

While a server is registered as a service, it cannot run as a non-service process or be uninstalled.

Steps

1. To remove the service from the Windows registry, use the `bat/deregister-windows-service.bat` file.
2. To uninstall the server, run the `uninstall.bat` script.

Configuring log files for services

About this task

The log files are stored in *`<server-root>`*`/logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or the file reaches its maximum size. Only the last three log files are retained.

Steps

These configurations can be changed in the *`<server-root>`*`/config/wrapper.conf` file.

Running the status tool

The Directory Server provides a **`status`** tool that outputs the current state of the server as well as other information, such as server version, java runtime environment statistics, operation processing times, work queue, and administrative alerts.

About this task

The **`status`** tool is located in the `bin` directory for UNIX and Linux or the `bat` directory for Windows.

Steps

1. Run the **`status`** command on the command line.

   The following code displays an example of the current Directory Server status and limits the number of viewable alerts in the last 48 hours. It provides the current state of each connection handler, data sources, JE environment statistics, processing times by operation type, and the current state of the work queue.

```
$ bin/status --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret

          --- Server Status ---
Server Run Status:    Started 28/Mar/2012:10:47:17.000 -0500

 successfully
Info     : 28/Mar/2012 10:47:14 -0500 : The Directory Server is starting
Info     : 28/Mar/2012 10:44:22 -0500 : The Directory Server has started
 successfully
Info     : 28/Mar/2012 10:44:18 -0500 : The Directory Server is starting

Shown are alerts of type [Info,Warning,Error,Fatal] from the past 48 hours
 Use the
--maxAlerts and/or --severity options to filter this list
```

> ⓘ **Note:**
>
> By default, the **`status`** command displays the alerts generated in the last 48 hours. To change this default setting, see step 2.

2. To limit the number of viewable alerts from the default 48 hours, use the `--maxAlerts` option.

Tuning the Server

PingDirectory Server's installation process automatically determines the optimal Java Virtual Machine (JVM) settings based on calculations of the machine running setup.

The default configuration and JVM settings are suitable for most deployments, but it is not uncommon in high-performance environments to make slight changes to the Directory Server's JVM settings as well as performance and resource-related configuration changes with the **`dsconfig`** tool. For these high-performance environments, tuning can achieve optimum throughput performance and disk space usage for PingDirectory Server and its tools.

About minimizing disk access

Minimizing disk access is critical to the directory server performance.

Defining a Java Virtual Machine (JVM) heap size that can contain the entire contents of the database cache in memory minimizes read operations from disk and achieves optimal performance. The database on-disk is comprised of transaction log files, which are only appended to. After an initial database import, the size on-disk will grow by a factor of at least 25% as inactive records accumulate in the transaction logs. During normal operation, the on-disk size of the database transaction logs does not represent the memory needed to cache the database.

Consider minimizing the size of the database based on the known characteristics of your data. Doing so reduces hard disk requirements and the memory requirements for the database cache. An example of this is the Directory Server automatically compacting common parent distinguished names (DN).

Finally, consider the write load on your server and its effect on the database. Write operations will always require an associated write-to-disk, but an environment that sustains a high load of write operations might consider tuning the background database cleaner to minimize the size of the database on disk.

Memory allocation and database cache

Memory allocation and database cache comprise the basic components of the Directory Server footprint and logic behind the automated tuning of the **`setup`** tool.

The Directory Server's optimal performance is dependent on:

- The proper allocation of memory to the Java Virtual Machine (JVM) heap
- The number of processor cores in the system
- The correct combination of JVM options for optimized garbage collection

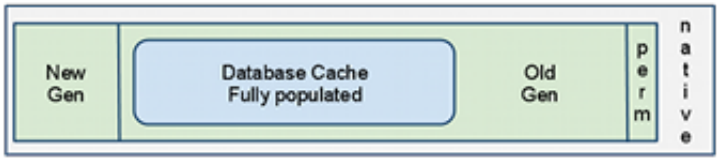
The **`setup`** tool for Directory Server automatically assigns the JVM options and determines the memory allocation based on the total amount of memory on the system; however, in most production deployments, additional tuning might be required to meet the performance objectives for your system.

Often directory server performance tuning can be accomplished by adjusting a few settings. Tuning these settings, which include both JVM and configuration options, require an understanding of the JVM heap structure and the expected database usage.

Directory Server process memory

The Directory Server consists mainly of a Java Virtual Machine (JVM) heap and a marginal amount of memory allocated by the JVM's execution of native code.

While we frequently refer to the JVM Heap as the maximum memory consumed by the Directory Server, the actual process size is slightly larger than the Xmx value because of accumulation of small chunks of native code that Java requires for things, such as SSL sockets.



MY TITLE Java Development Kit (JDK) Heap Structure

Within the JVM Heap, the principal memory components are the new and old generations. The new generation is a smaller area of memory where all data is initially allocated and is cleaned of garbage often. Any data that is present long enough is promoted to the old generation for the longer term. The old generation is where the database cache eventually resides. The old generation size is computed from the leftover heap after defining the `MaxHeapSize` and new generation sizes It is not explicitly stated in the JVM options. A typical set of generation definitions for the JVM is as follows, where mx and ms values represent the heap size.

```
-Xmx16g -Xms16g -XX:MaxNewSize=2g -XX-NewSize=2g
```

> ⓘ **Note:**
>
> The mx and ms values should always be the same, and the MaxNewSize and NewSize values should be the same. This helps avoid negative changes in performance.

The MaxNewSize and NewSize values should never need to exceed 2g. The **`setup`** and **`dsjavaproperties`** tools set MaxNewSize and NewSize values based on the results of extensive performance testing and should not need to be changed.

Determining heap and database cache size

Define proper memory allocation of the directory server components using the Directory Server **`setup`** command.

About this task

To define the proper memory allocation of the directory server components:

Steps

1. Run the Directory Server **`setup`** command.

   > ⓘ **Note:**
   >
   > This must be done on hardware that represents the target production platform, especially with regard to process and memory, and the largest heap size that the **`setup`** tool allows.

2. To define schema and production database settings for the database import, use the **`import-ldif`** tool.

   > ⓘ **Note:**
   >
   > After running **`import-ldif`**, the database is at its most optimized state on-disk with no inactive records. Over time, the on-disk representation of the database grows up to 25-50% as inactive records accumulate before being removed by the server's cleaner thread.

3. After the database is imported, start the server and make any needed configuration changes.
   Set the prime-method to preload on the `userRoot` backend configuration.
4. Restart the Directory Server and watch for a successful preload message.
   - If preloading completes, proceed to step 6.
   - If preloading does not complete, proceed to step 5.
5. If preloading does not complete, troubleshoot with the following steps:
   a. In the **`config/java.properties`** file, in the **`start-server.java-args`** entry, edit the entry to use larger values for **`-Xmx`** and **`-Xms`** arguments.
   b. Run the following command.

      ```
      bin/dsjavaproperties
      ```

   c. Restart the server and proceed to step 6.
6. After preload completes, run the **`status`** command to review the database cache utilization.

   > ⓘ **Note:**
   >
   > A fully loaded database needs at least 10-20% cache headroom available for future growth, as in the following example.

```
             --- JE Environment ---
ID    : Cache Full : Cache  : On-Disk : Alert
---------:------------:--------:---------:------
userRoot : 30%     : 1.1 gb : 868.6mb : None
```

7. Optional: To see the state of the database cache in more detail, run an **`ldapsearch`** on the backend monitor.

> ⓘ **Note:**
>
> In addition to the user configured backends, there might be backends for replication and changelog. The heap is shared among all backends. For information on how the heap amount allocated to each backend is calculated, see*Automatic DB cache percentages* on page 285.

Automatic DB cache percentages
Adjust the allocation of the DB cache percentage when setting up the server.

About this task

The setup process automatically tunes the percentage of the `db-cache-percent` property for the `userRoot` backend based on the maximum configured Java Virtual Machine (JVM) heap size. This is only done for the `userRoot` backend during setup. Other backends created by the user are allocated 10%. Change the allocation if needed. When setting up the server:

Steps

1. Install the server with the necessary memory.

> ⓘ **Note:**
>
> The server autotunes the size of the cache.

2. Set the autotuned cache size to the limit for the combined cache sizes of all of the backends.
3. Divide the server cache based on the expected size of the data in each backend.

Automatic memory allocation
If the Memory Tuning feature is enabled during setup, the **`setup`** algorithm determines the maximum Java Virtual Machine (JVM) heap size based on the total amount of available system memory. Otherwise, the server allocates a maximum JVM heap of 384 MB.

About this task

Directory Server also allows you to specify the maximum heap size during the setup process. For more information, see *JVM Properties for Server and Command-Line Tools*.

Steps

- To enable Memory Tuning during the setup process:
  - Select the feature in interactive command-line mode.
  - Add the `--jvmTuningParameter` option using the **`setup`** tool in non-interactive command-line mode.
  - Regenerate the Java properties file with **`bin/dsjavaproperties`** and the `--jvmTuningParameter` options.

> ⓘ **Note:**
>
> If Memory Tuning is selected, the server allocates the maximum JVM heap depending on the total system memory. The following table displays the automatically allocated maximum JVM heap memory based on available system memory.

Allocated Max JVM Memory if Tuning is Enabled

Available Memory	Allocated JVM Memory
16 GB or more using a 64-bit JVM	The maximum JVM heap size is set to 70% of total system memory. If the maximum JVM heap size is less than or equal to 128GB of memory, which should be the case for systems with up to 160 GB of memory, then the initial heap size is set to equal the maximum heap size.
6 GB#16 GB using a 64-bit JVM	Total system memory - 4 GB
4 GB–6 GB using a 64-bit JVM	2 GB
2 GB–4 GB	512 MB
1 GB–2 GB	384 MB

Automatic memory allocation for the command-line tools
At setup, the Directory Server automatically allocates memory to each command-line utility based on the maximum Java Virtual Machine (JVM) heap size.

The server sets each command-line utility in the `config/java.properties` file with -Xmx/Xms values, depending on the expected memory needs of the tools.

Because some tools can be invoked as a server task while the server is online, there are two definitions of the tool in the `config/java.properties` file:

`.Online`

Typically requires minimal memory because the task is performed within the Directory Server's JVM.

`.Offline`

Can require the same amount of memory needed by the Directory Server. Examples include `import-ldif.offline` and `rebuild-index.offline`.

With large databases, some tools, such as **`ldap-diff`** and **`verify-index`**, might need more than the minimal memory. The following table lists the tools that are expected to have more than the minimal memory needs along with the rules for defining the default heap size.

Default Memory Allocation to the Command-Line Tools

Command-Line Tools	Allocated JVM Memory
start-server, import-ldif (offline), rebuild-index (offline)	MaxHeapSize
backup (offline), dbtest export-ldif (offline), ldap-diff, restore (offline), scramble-ldif, summarize-access-log, verify-index	If Max System Memory is: ▪ Greater than or equal to 16 GB: set heap to 3 GB ▪ Greater than or equal to 8 GB: set heap to 1 GB ▪ Greater than or equal to 4 GB: set heap to 512 MB ▪ Under 4 GB: set heap to 256 MB

Database preloading

The ability to maintain the database contents in the database cache within the Java Virtual Machine (JVM) memory is key to the Directory Server performance.

With a properly sized database cache, a priming method of preload directs the server to load the database contents into memory at server startup before accepting the first client connection. The time needed to preload the database is proportional to the database size. To avoid priming, you can start the server with the **`start-server --skipPrime`** command. If the priming method is `none`, or the **`--skipPrime`** option is specified at startup, the database cache slowly builds as entries are accessed. This can take several days to reach optimal performance.

The preload priming method is suitable for nearly all Directory Server deployments. If the size of the database precludes storing the whole database in memory, there are priming alternatives for optimizing server performance. This type of deployment is considered disk-bound since the disk is accessed when processing most operations. See the section Disk-Bound Deployments for more information. The remaining priming options are applicable to these environments.

The Directory Server database **`prime-method`** property configures how the caches get primed, what gets primed, such as data, internal nodes, system indexes, and where it gets primed, for example a database cache, file system cache, or both. The **`prime-method`** property is a multi-valued option that enables preloading the internal nodes into the database cache before the server starts and then primes the values in the background by cursoring across the database. For more details, see the PingDirectory Server Configuration Reference.

The following is a summary of the priming methods:

Preload All Data

Prime the contents of the backend into the database cache.

Preload Internal Nodes Only

Prime only internal database structure information into the database cache, but do not prime any actual data. This corresponds to the cache-keys-only cache-mode.

Cursor Across Indexes

Use the **`cursor-across-indexes`** property to iterate through backend contents. This is similar to and might be slower than using the preload mechanism, but it enables priming to happen in the background after the server has started. This is used when shorter start up times are desired, and the slower performance of an uncached database is acceptable until the database is primed.

Configuring database preloading
Use the **dsconfig** tool to set the database priming method.

If multiple prime methods are used, the order in which they are specified in the configuration is the order in which they are performed. Changing the preloading option requires restarting the Directory Server. The following procedures shows how to configure database preloading.

Configuring database preloading
Configure database preloading.

Steps

1. To load the database contents from disk into memory when the server starts up, set the prime method to preload.

   This eliminates the need for the server to gradually prime the database cache using client traffic and ensures that the server has optimal performance when it starts to receive client connections.

   ```
   $ bin/dsconfig set-backend-prop \
     --backend-name userRoot \
     --set prime-method:preload
   ```

2. To apply the changes, restart the Directory Server.
   a. Run **bin/stop-server**.
   b. Run **bin/start-server**.

Configuring multiple preloading methods
Configure multiple preloading methods.

Steps

1. To achieve the benefits of preloading without delaying server startup, set **prime-method** to **preload-internal-nodes-only**, which caches all of the keys within the database, but not the values.

   The database values themselves can be cached in the background once the server has been started with the **cursor-across-indexes** option.

   ```
   $ bin/dsconfig set-backend-prop \
     --backend-name userRoot \
     --add prime-method:preload-internal-nodes-only \
     --add prime-method:cursor-across-indexes \
     --set background-prime:true
   ```

2. To apply the changes, restart the Directory Server.
   a. Run **bin/stop-server**.
   b. Run **bin/start-server**.

Configuring system index preloading
Configure system index preloading.

About this task
Some environments have many indexes configured though only a few are used for performance-sensitive traffic.

Steps

1. To reduce server start up time, preload only the necessary indexes into the database at startup.

   ```
   $ bin/dsconfig set-backend-prop --backend-name userRoot \
     --set prime-method:preload \
   ```

```
  --set prime-all-indexes:false \
  --set system-index-to-prime:dn2id \
  --set system-index-to-prime:id2entry
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name mail \
  --set prime-index:true
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name uid \
  --set prime-index:true
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name entryUUID \
  --set prime-index:true
```

2. To apply the changes, restart the Directory Server.
   a. Run **`bin/stop-server`**.
   b. Run **`bin/start-server`**.

Databases on storage area networks, network-attached storage, or running in virtualized environments

There are several considerations when using network-based storage or storage abstracted by virtualization that are not issues when databases are stored on local disks.

A data durability problem occurs when remote storage or the virtualization environment experiences service interruptions, ranging from connectivity loss to total failure from power loss. Data corruption can occur when the storage layer accepts data for writing that is not made durable before a crash occurs. In these cases, a database property can be set that reduces the likelihood of data loss and data corruption. The database property **`database-on-virtualized-or-network-storage`** can be set on a per-backend environment basis to request all database writes to be written durably to the underlying storage.

There is a performance penalty when enabling this property and, in most cases, is not recommended except where network storage is unreliable. For network file systems, the benefits of faster recovery and less likelihood of data loss from unplanned events might outweigh the penalty. The exact overhead of enabling **`database-on-virtualized-or-network-storage`** depends on the characteristics of the database, the host file system, storage array configuration, and network and virtualization input and output parameters. The write overhead penalty might be substantial for SAN environments. Incremental and full backup strategies should be used instead if performance is unacceptable.

To enable **`database-on-virtualized-or-network-storage`** for each applicable backend, use the following command as an example, which references the configuration for the userRoot backend.

```
$ bin/dsconfig set-global-configuration-prop \
  --set database-on-virtualized-or-network-storage:true
```

This should be set to `false` if the database is on a local disk.

Database cleaner

Production environments that have a high volume of write operations might require cleaner thread tuning to control the on-disk database size as log files with inactive nodes wait to be cleaned and deleted.

The Directory Server stores its Oracle Berkeley DB Java Edition (JE) database files on-disk in the `db` directory. Each JE database log file is labeled `nnnnnnnn.jdb`, where `nnnnnnnn` is an 8-digit hexadecimal number that starts at 00000000 and is increased by 1 for each file written to disk. JE only appends data to the end of each file and does not overwrite any existing data. JE uses one or more cleaner threads that run in the background to compact the number of JE database (db) files.

The cleaner threads begin by scanning the records in each db file, starting with the file that contains the smallest number of active records. Next, the cleaner threads append any active records to the most recent database file. If a record is no longer active due to modifications or deletions, the cleaner threads leave it untouched. After the db file no longer has active records, the cleaner threads can either delete the file or rename the discarded file.

> ⓘ **Note:**
>
> Because of this approach to cleaning, the database size on-disk can temporarily increase when cleaning is being performed and files are waiting to be removed.

The local DB backend configuration object has two properties that control database cleaning: `db-cleaner-min-utilization` and `db-num-cleaner-threads`. The `db-cleaner-min-utilization` property determines, by percentage, when to begin cleaning out inactive records from the database files. By default, the property is set to 75, which indicates that database cleaning ensures that at least 75% of the total log file space is devoted to live data.

> ⓘ **Note:**
>
> This property only affects the on-disk representation of the database and not the in-memory database cache—only live data is ever cached in memory.

The `db-num-cleaner-threads` property determines how many threads are configured for db cleaning. The default single cleaner thread is normally sufficient. However, environments with a high volume of write traffic might need to increase this value to ensure that database cleaning can keep up.

If the number of database files grow beyond your expected guidelines or if the Directory Server is experiencing an increased number of update requests, you can increase the number of cleaner threads using the **`dsconfig`** tool by going to **Backend**# **Select Advanced Properties**# **db-num-cleaner-threads**.

Compacting common parent DNs

PingDirectory Server compacts entry distinguished names (DNs) by tokenizing common parent DNs.

About this task

Tokenizing the common parent DNs allows you to increase space usage efficiency when encoding entries for storage. The Directory Server automatically defines tokens for base DNs for the backend, such as `dc=example,dc=com`. You can also define additional common base DNs you want to tokenize.

Steps

- Use the following configuration to tokenize two branches: `ou=people,dc=example,dc=com` and `ou=customers,dc=example,dc=com`.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --add "compact-common-parent-dn:ou=people,dc=example,dc=com" \
  --add "compact-common-parent-dn:ou=customers,dc=example,dc=com"
```

Setting the import thread count

For most systems, the default setting of 16 threads is sufficient and provides good import performance. On some systems, increasing the import thread count can lead to improved import performance while selecting a value that is too large can actually cause import performance to degrade.

About this task

If minimizing LDIF import time is crucial to your deployment, you must determine the optimal number of import threads for your system, which is dependent on both the underlying system and the data set being imported.

Steps

- Use the **dsconfig** command to set the number of import threads.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set import-
thread-count:24
```

JVM properties for server and command-line tools

The Directory Server and tools refer to the `config/java.properties` file for Java Virtual Machine (JVM) options that include important memory settings.

The `java.properties` file sets the default Java arguments for the Directory Server and each command-line utility includes the default *<JAVA_HOME>* path.

The `java.properties` is generated at server setup time and defines memory-related JVM settings based on the user-provided value for max heap size if you selected the aggressive memory tuning option at setup. Most of the JVM options specified for both server and tools do not need customization after setup. The exception is the `-Xmx/Xms` options, which specify the maximum and initial JVM heap size. See the section on *Memory Allocation and Database Cache* for advice on tailoring the `-Xmx/Xms` values.

Other than altering the heap size of the server process (**start-server**) or command-line tools, the most common change required to `java.properties` is when you want to update the JVM version. A single edit applies the new JVM to all server and tool use.

Applying changes using dsjavaproperties

To apply the changes to the `config/java.properties` file, edit the file manually, and then run the **bin/dsjavaproperties** utility.

The **dsjavaproperties** tool uses the information contained in the `config/java.properties` file to generate a `lib/set-java-home` script, or `lib\set-java-home.bat` on Microsoft Windows systems, which is used by the Directory Server and all of its supporting tools to identify the Java environment and its JVM settings. During the process, **dsjavaproperties** calculates an MD5 digest of the contents of the `config/java.properties` file and stores the digest in the generated **set-java-home** script.

The **dsjavaproperties** utility also performs some minimal validation whenever the property references a valid Java installation by verifying that `$(java-home)/bin/java` exists and is executable.

If you make any changes to the `config/java.properties` file but forget to run `bin/dsjavaproperties`, the Directory Server compares the MD5 digest with the version stored in **set-java-home** and sends a message to standard error if the digests differ.

```
WARNING -- File /ds/PingDirectory
            /config/java.properties has been edited without
running dsjavaproperties to apply the changes
```

Updating the Java version in the properties file
To change the version of Java that is used by the server and tools, edit the `config/java.properties` file and apply the change by invoking **`bin/dsjavaproperties`** with no command line options.

About this task

You must restart the server for the change to take affect.

Steps

- Inside **`config/java.properties`**, alter the value of **`default.java-home`** to point to the Java correct Java Runtime Environment (JRE).

  Any time the **`config/java.properties`** file is updated, the **`bin/dsjavaproperties`** tool must be run to apply the new configuration.

```
$ bin/dsjavaproperties
```

Regenerating the Java properties file
The **`dsjavaproperties`** command provides an `--initialize` option that allows you to regenerate the Java properties file specifically if you set up the Directory Server using standard memory usage but opt for aggressive memory tuning after setup.

About this task

Rather than reconfigure the Java properties file by re-running **`setup`** or manually editing the `java.properties` file, you can regenerate the properties file for aggressive memory tuning. Any existing file is renamed with a `.old` suffix.

Steps

- Run the **`dsjavaproperties`** command to regenerate the java properties file for aggressive memory tuning.

```
$ bin/dsjavaproperties --initialize --jvmTuningParameter AGGRESSIVE
```

Tuning for disk-bound deployments

Configure the server for a disk-bound configuration.

About this task

For best performance, configure the Directory Server to fully cache the DIT in the backend database cache. Directory Server configuration assumes this scenario. For databases too large to fit in memory, other options are available:

- Configure the server for a disk-bound data set. When the database is stored on an SSD, this configuration yields server performance that is comparable to a fully-cached scenario.
- Use uncached attributes or entries as described in the following section.
- Use a Directory Proxy Server in an entry-balancing deployment, which allows all data to be cached in a partitioned environment.

Steps

1. When installing the server, choose the **Aggressive** option for JVM memory configuration and to preload the data when the server starts.
2. Set the `default-cache-mode` of the `userRoot` backend to `cache-keys-only`.

3. Set operating system `vm.swappiness` to 0 to protect the Directory Server JVM process from an overly aggressive file system cache.
4. When the data set is imported with the above settings, verify in the `import-ldif` output that the cached portions of the data set fit comfortably within the database cache.

Uncached attributes and entries

Although achieving optimal Directory Server performance requires that the entire data set be fully cached, there can be deployments in which fully caching the data set is not possible due to hardware or financial constraints, or in which acceptable performance can be achieved by only caching a portion of the data.

The Directory Server already provides support for controlling caching on a per-database basis, such as to cache only certain indexes and system databases, but these features might not provide sufficient control over how memory is used, particularly with regard to which entries are included in the cache, and they do not provide any degree of control over caching only a portion of attributes.

To better address the needs of environments that require partial caching, the Directory Server provides two new options: the ability to exclude certain entries from the cache, and the ability to exclude certain attributes from the cache. The Directory Server uses an `uncached-id2entry` database container, which is similar to the `id2entry` database that maps an entry's unique identifier and its encoded representation. The `uncached-id2entry` database contains either complete or partial representations of entries that are intended to receive less memory for caching. For example, if an entry has a large attribute and the system has hardware constraints on memory, then you can configure the system to not cache this particular attribute or entry. This functionality is only available for the local DB backend, which uses the Berkeley DB Java Edition database.

The `uncached-id2entry` database can be included in the set of databases to prime, but if priming is to be performed, it only includes internal nodes and not leaf nodes. For example, the internal nodes of the `uncached-id2entry` database are included in the preload if the `prime-all-indexes` option is set to "true," or if the `system-index-to-prime-internal-nodes-only` option has a value of `uncached-id2entry`.

Backup and Restore

There are no special considerations for backup and restore with regard to uncached entries and attributes. Backup successfully saves your database contents, including uncached entries and attributes. Because of the way the server deals with changes to uncached entry and uncached attribute configuration, there is no problem with restoring a backup that was taken with a different uncached entry configuration than is currently in place for the server. Any entries encoded in a manner that is inconsistent with the current uncached entry or uncached attribute configuration are properly re-encoded whenever they are updated, or whenever the re-encode entries task is invoked.

Replication

Replication does not propagate information about which portions of entries might have been cached or uncached, nor does it require that different replicas have the same uncached attribute or uncached entry configuration.

LDIF Import and Export

When LDIF content is imported into the server, the uncached attribute and uncached entry configuration is used to determine on a per-entry basis whether some or all of the content for that entry should be written into the `uncached-id2entry` database. The determination is based on the current configuration and is completely independent of and unaware of the configuration that might have been in place when the LDIF data was initially exported. Neither the LDIF import nor export tools provide any options that specifically target only cached or only uncached content, but these tools do provide the ability to include or exclude entries using search filters or to include or exclude specific attributes.

Server Access Log

Server access log messages can include `uncachedDataAcessed=true` in the result message for any operation in which it was necessary to access uncached data in the course of processing the associated request. For add, delete, modify, or modify DN result messages, `uncachedDataAcessed=true` indicates that at least a portion of the new or updated entry was written into the `uncached-id2entry` database or that at least a portion of the updated entry was formerly contained in the `uncached-id2entry` database. For compare result messages, it indicates that at least a portion of the target entry was contained in the `uncached-id2entry` database and that data from the uncached portion of the entry was required to evaluate the assertion. For search result messages, it indicates that one or more of the entries evaluated as potential matches contained uncached data and that data from the uncached portion of at least one entry was needed in determining what data should be returned to the client.

Uncached Entry and Attribute Properties

The Directory Server provides three new advanced properties on the local DB backend to control the caching mode for the `uncached-id2entry` database:

uncached-id2entry-cache-mode

Specifies the cache mode that is used when accessing the records in the `uncached-id2entry` database. If the system has enough memory available to fully cache the internal nodes for this database, then `cache-keys-only` is recommended. Otherwise it is better to select `no-caching` to minimize the amount of memory required for interacting with the `uncached-id2entry` database. For more information, see the PingDirectory Server Configuration Reference.

uncached-attribute-criteria

Specifies the criteria used to identify attributes that are written into the `uncached-id2entry` database, rather than the `id2entry` database. This property is only used for entries in which the associated `uncached-entry-criteria` does not indicate that the entire entry should be uncached. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all attributes are written into the `id2entry` database.

uncached-entry-criteria

Specifies the criteria used to identify entries that are written into the `uncached-id2entry` database, rather than the `id2entry` database. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all entries are written into the `id2entry` database.

Configuring uncached attributes and entries
Configure uncached attributes and entries.

About this task
The following procedure assumes that the `uncached-id2entry-cache-mode` property is set to the default value, `cache-keys-only`. For more information on the `uncached-id2entry` cache modes, see the PingDirectory Server Configuration Reference.

Steps

1. Run **`dsconfig`** to uncache entries that match the criteria.

```
$ bin/dsconfig create-uncached-entry-criteria \
  --criteria-name "Fully Uncached l=austin" --type filter-based \
```

```
  --set enabled:true --set "filter:(l=austin)"
```

The filter uncaches all entries that have its location set to "austin", such as `l=austin`.

2. Run **`dsconfig`** to uncache attributes that match the criteria.

   The `--type simple` option indicates that the simple uncached attribute criteria be used to specify the attribute-type that should be uncached. For those entries that are fully stored in the `uncached-id2entry` database container, the uncached attribute is ignored.

   In this example, the attribute-type criteria that should be uncached is `jpegPhoto`.

```
$ bin/dsconfig create-uncached-attribute-criteria \
  --criteria-name "Uncached jpegPhoto" --type simple \
  --set enabled:true --set attribute-type:jpegPhoto
```

3. Set the uncached properties for the `userRoot` backend.

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set "uncached-entry-criteria:Fully Uncached l=austin" \
  --set "uncached-attribute-criteria:Uncached jpegPhoto"
```

4. Run the **`re-encode-entries`** tool to initiate a task that causes a local DB `userRoot` backend to re-encode all or a specified subset of the entries that it contains.

   The tool does not alter the entries themselves but provides a useful mechanism for applying significant changes to the way that entries are stored in the backend.

   The following example initiates a task that re-encodes all fully-cached entries in the `userRoot` backend, rate-limited to no more than 100 entries per second.

```
$ bin/re-encode-entries --hostname directory.example.com --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --backendID userRoot --skipFullyUncachedEntries \
  --skipPartiallyUncachedEntries --ratePerSecond 100
```

JVM garbage collection using CMS

To ensure reliable server performance with Java, the Directory Server depends on Java's Concurrent Mark and Sweep process (CMS) for background garbage collection.

Out of several garbage collection options, CMS is the ideal choice for consistent system availability. For the most part, the CMS collector runs as one or more background threads within the Java virtual machine (JVM), freeing up space in JVM Heap from an area called the old generation. One of the criteria used by CMS to determine when to start background garbage collection is a parameter called CMSInitiatingOccupancyFraction. This percentage value, which applies to the Old Generation, is recommended for the JVM to initiate CMS when data occupancy in Old Generation reaches the threshold.

Ideally, the database cache takes less than 70% of the space available in the Old Generation, and the `CMSInitiatingOccupancyFraction` value of 80 leaves plenty of headroom to prevent the JVM from running out of space in Old Generation because of an inability for CMS to keep up. Because CMS takes processing resources away from the Directory Server, do not set the CMSInitiatingOccupancyFraction at or below the expected database cache size, which would result in the constant running of CMS in the background. For a description of determining Old Generation size, see the section on *Memory Footprint and Database Cache*.

When the CMS collection process cannot keep pace with memory demands in the Old Generation, the JVM resorts to pausing all application processing to allow a full garbage collection. This event, called a "stop-the-world pause", does not break existing TCP connections or alter the execution of the Directory Server requests. The goal in tuning CMS is to prevent the occurrence of these pauses. When one does occur, the Directory Server generates an alert after the pause and records the pause time in the error log.

Because determining an ideal `CMSInitiatingOccupancyFraction` can be difficult,we warn if the Directory Server detects a garbage collection pause by generating a recommended value for the occupancy threshold based on the current amount of memory being consumed by the backend caches. Unfortunately, an administrator cannot determine the ideal occupancy threshold value in advance. To warn of any impending garbage collection pauses, the Directory Server calculates a recommended value for the `CMSInitiatingOccupancyFraction` property and exposes it in the JVM Memory Usage monitor entry in the following attribute:

```
recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

Also, when you start the server, an administrative alert indicates the current state of the CMSInitiatingOccupancyFraction and its recommended value.

```
$ bin/start-server [20/April/2012:10:35:25 -0500] category=CORE
 severity=NOTICE msgID=458886
msg="PingDirectory Server
            8.1.0.0 (build 20120418135933Z, R6226) starting up"

... (more output) ...

[20/April/2012:10:35:53 -0500] category=UBID_EXTENSIONS severity=NOTICE
msgID=1880555580 msg="Memory-intensive Directory Server
components are configured to consume 71750382 bytes of memory:
['userRoot local DB backend' currently consumes 26991632 bytes and
can grow to a maximum of 64323584 bytes, 'changelog cn=changelog backend'
currently consumes 232204 bytes and can grow to a maximum of 2426798 bytes,
'Replication Changelog Database' currently consumes 376661 bytes and can
grow to a maximum of 5000000 bytes]. The configured value of
CMSInitiatingOccupancyFraction is 36 which is less than the minimum
recommended value (43) for the server's current configuration. Having
this value too low can cause the Concurrent Mark and Sweep garbage
collector to run too often, which can cause a degradation of throughput
and response time. Consider increasing the CMSInitiatingOccupancyFraction
value to at least the minimum value, preferably setting it to the
recommended value of 43 by editing the config/java.properties file,
running dsjavaproperties, and restarting the Directory Server.
If the server later detects that this setting actually leads to a
performance degradation, a separate warning message will be logged.
If this server has not yet been fully loaded with data, then you
can disregard this message"

[20/April/2012:10:35:53 -0500] category=CORE severity=NOTICE msgID=458887
msg="The Directory Server has started successfully"
```

The Directory Server only makes a recommendation if all of the backends are preloaded and the CMSInitiatingOccupancyFraction JVM property is explicitly set, which is done automatically. For example, if you installed the Directory Server and specified that the database be preloaded (or "primed") at startup, then the Directory Server can make a good recommendation for the Directory Server when a pause occurs. If the backend database cache is not full and has not been preloaded, then the recommended value might be an inaccurately low value.

> ⓘ **Note:**
>
> The generated value for the Directory Server property could change over time with each Directory Server build, Java release, or changes in data set. If the current value is close to the recommended value, then you do not need to change the property unless the server experiences a JVM pause.

If the Directory Server experiences a JVM garbage collection pause, you can retrieve the recommended value from the server, reset the Directory Server property, run **dsjavaproperties**, and restart the server.

Determining the CMSInitiatingOccupancyFraction
Use the terminal to determine the CMSInitiatingOccupancyFraction value.

Steps

1. Retrieve the `prime-method` property for the backend.

```
$ bin/dsconfig get-backend-prop --backend-name userRoot \
  --property prime-method
```

> **Note:**
>
> If you set the `Preload Database at startup` option during the installation, then skip to step 3.

2. If the `prime-method` property was not configured, run **bin/dsconfig** to set the property to PRELOAD, and then restart the Directory Server to preload the database cache.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --set prime-method:preload

$ bin/stop-server
$ bin/start-server
```

At startup, you see an administrative message if the current CMSInitiatingOccupancyFraction property is below the recommended value.

> **Note:**
>
> You can get the recommended value from this message and change it in the `config/java.properties` file in step 5.

3. If you were unable to see the recommended CMSInitiatingOccupancyFraction property at startup presented in the previous step, pre-tune the value of the CMSInitiatingOccupancyFraction property to ensure that all of the data is imported into the server and preloading is enabled in the backend.
   a. Retrieve the recommended CMSInitiatingOccupancyFraction value by issuing the following search.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectclass=ds-memory-usage-monitor-entry)" \
  cms-initiating-occupancy-fraction \
  recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

> **Note:**
>
> If the `recommended-cms-initiating-occupancy-fraction-for-current-data-set` is not present, then make sure that the server has been restarted since enabling preload for the backends.

```
dn: cn=JVM Memory Usage,cn=monitor
cms-initiating-occupancy-fraction:80
recommended-cms-initiating-occupancy-fraction-for-current-data-set:55
```

4. Open the `config/java.properties` file using a text editor and manually edit the CMSInitiatingOccupancyFraction (or any other property) to its recommended value in the `start-server.java-args` property.
5. Save the file.

   The following arguments are recommended for a Sun 5440 server. Contact your authorized support provider for specific assistance.

   ```
   start-server.java-args=-d64 -server -Xmx20g -Xms20g -XX:MaxNewSize=1g
   -XX:NewSize=1g -XXParallelGCThreads=16 -XX:+UseConcMarkSweepGC
   -XX:+CMSConcurrentMTEnabled -XX:+CMSParallelRemarkEnabled
   -XX:+CMSParallelSurvivorRemarkEnabled -XX:ParallelCMSThreads=8
   -XX:CMSMaxAbortablePrecleanTime=3600000
   -XX:+CMSScavengeBeforeRemark -XX:RefDiscoveryPolicy=1
   -XX:CMSInitiatingOccupancyFraction=55 -XX:+UseParNewGC
   -XX:+UseBiasedLocking -XX:+UseLargePages
   -XX:+HeapDumpOnOutOfMemoryError
   ```

   The `-XX:ParallelGCThreads` should be limited to 16 (default) or to 8 for smaller systems. The `-XX:ParallelCMSThreads` should be limited to 8.
6. To apply the changes, run the **`bin/dsjavaproperties`** command.

   ```
   $ bin/dsjavaproperties
   ```
7. Restart the Directory Server.

Configuring the Server

Configure the server to meet the performance, hardware, operating system, and memory requirements for your production environment.

The out-of-the-box, initial configuration settings for the PingDirectory Server provide an excellent starting point for most general-purpose Directory Server applications. However, additional tuning might be necessary to meet the needs of your production environment.

The Directory Server stores its configuration settings in an LDIF file, `config/config.ldif`. Rather than editing the file directly, the Directory Server provides command-line options and an administrative console to configure the server. The Directory Server also includes tools to create server groups to apply configuration changes to multiple servers at one time

About the configuration tools

Use the administrative console or the `dsconfig` command-line tool to modify the PingDirectory Server.

You can access and modify the PingDirectory Server configuration in the following ways:

- Use the Administrative Console. The PingDirectory Server provides an administrative console for graphical server management and monitoring. The console provides equivalent functionality to the **`dsconfig`** command for viewing or editing configurations. All configuration changes using this tool are recorded in `logs/config-audit.log`, which also has the equivalent reversion commands that let you back out of a configuration.
- Use the `dsconfig` command-line tool. The **`dsconfig`** tool is a text-based menu-driven interface to the underlying configuration. The tool runs the configuration using three operational modes: interactive command-line mode, non-interactive command-line mode, and batch mode. All configuration changes made using this tool are recorded in `logs/config-audit.log`.

About the dsconfig configuration tool

The **dsconfig** tool is the text-based management tool used to configure the underlying Directory Server configuration.

The `dsconfig` tool has three operational modes: interactive mode, non-interactive mode, and batch mode.

The **dsconfig** tool offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, you should keep the server running when you access the configuration for the server to give the user feedback about the validity of the configuration.

Using dsconfig in interactive command-line mode

In interactive mode, the **dsconfig** tool offers a filtering mechanism that only displays the most common configuration elements.

About this task

The user can specify that more expert level objects and configuration properties be shown using the menu system.

Running **dsconfig** in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the PingDirectory Server.

Steps

1. To start `dsconfig` in interactive command-line mode, invoke the `dsconfig` script without any arguments.
   You are prompted for connection and authentication information to the Directory Server, and then a menu displays the available operation types.
2. To accept the default values, press **Enter**.

> ⓘ **Note:**
>
> In some cases, a default value is provided in square brackets. For example, [389] indicates that the default value for that field is port 389.

3. To skip the connection and authentication prompts, provide the connection and authentication information using the command-line options of `dsconfig`.

Configuring the Server using dsconfig interactive mode
Configure the PingDirectory Server using the `dsconfig` command-line tool in interactive mode.

Steps

1. Launch the **dsconfig** tool in interactive command-line mode.

```
$ bin/dsconfig
```

2. Enter the LDAP connection parameters.
   - Enter the Directory Server host name or IP address.
   - Press **Enter** to accept the default.
3. Enter the number corresponding to the type of LDAP connection that you are using on the Directory Server, or press **Enter** to accept the default.

   The numbers for the LDAP connection type are 1 for LDAP, 2 for SSL, and 3 for StartTLS. The default entry is 1.

4. Enter the LDAP listener port number, or accept the default port.

   The default port is the port number of the server local to the tool.
5. Enter the user bind DN and the bind DN password.

   The default is `cn=Directory Manager`.
6. On the **Directory Server Configuration Console** main menu, enter a number corresponding to the configuration that you want to change.

   > ⓘ **Note:**
   >
   > The number might change between releases or within the same release, depending on the options selected, such as in cases where more expert level objects and properties are displayed.
7. In this example, select the number for Backend.
8. Set the `db-cache-percent` to 40%.

   The optimal cache percentage depends on your system performance objectives and must be tuned as determined through analysis. In many cases, the default value chosen by the **`setup`** utility is sufficient.
9. On the **Backend management** menu, enter the number corresponding to view and edit an existing backend.
10. Select the backend to work with or press **Enter** to accept the default.

    In this example, using the basic object menu, only one backend that can be viewed in the directory, `userRoot`.
11. From the **Local DB Backend** properties menu, type the number corresponding to the `db-cache-percent` property.
12. Enter the option to change the value, and then type the value for the `db-cache-percent` property.

    In this example, type `40` for 40 %.
13. To apply the changes, enter `f`.

    > ⓘ **Note:**
    >
    > Before you apply the change, the **`dsconfig`** interactive command-line mode provides an option to view the equivalent non-interactive command based on your menu selections. This is useful in building **`dsconfig`** script files for configuring servers in non-interactive or batch mode. If you want to view the equivalent **`dsconfig`** non-interactive command, type `d`. For more information, see *Getting the Equivalent dsconfig Non-Interactive Mode Command*.
14. In the **Backend management** menu, to quit the `dsconfig` tool, enter `q`.

Viewing dsconfig advanced properties

Configure **`dsconfig`** interactive mode to hide or display additional advanced properties.

About this task

> ⓘ **Note:**
>
> For most configuration settings, some properties are more likely to be modified than others.

Steps

1. Repeat steps 1–9 in *Configuring the Server using dsconfig interactive mode* on page 299.
2. To display the advanced properties, from the **Local DB Backend properties** menu, enter `a`.
   This toggles any hidden properties.

Changing the dsconfig object menu

The purpose of object levels is topresent only those properties that an administrator will likely use.

About this task

Because some configuration objects are more likely to be modified than others, the PingDirectory Server provides four different object menus that hide or expose configuration objects to the user. The `object` type is a convenience feature designed to improve menu readability.

The following object menus are available:

Basic

Only includes the components that are configured most frequently.

Standard

Includes all components in the Basic menu plus other components that might occasionally need to be altered in many environments.

Advanced

Includes all components in the Basic and Standard menus plus other components that might require configuration under special circumstances or that might be harmful if configured incorrectly.

Expert

Includes all components in the Basic, Standard, and Advanced menus plus other components that almost never require configuration, or that could seriously impact the functionality of the server if not properly configured.

To change the `dsconfig` object menu:

Steps

1. Using `dsconfig`, repeat steps 1–6 in *To Install the in Interactive Mode*.
2. On the **PingDirectory Server configuration** main menu, enter the letter `o` to change the object level.

   Basic objects are displayed by default.
3. Enter a number corresponding to an object level of your choice.
   - Enter `1` for Basic.
   - Enter `2` for Standard.
   - Enter `3` for Advanced.
   - Enter `4` for Expert.
4. Review the menu at the new object level.

   Additional configuration options for the Directory Server components are displayed.

dsconfig interactive administrative alerts

The **`dsconfig`** tool and the administrative console provide a feature that displays notifications for certain operations that require further administrative action to complete the process.

If you change a certain backend configuration property, the admin action appears in two places during a **`dsconfig`** interactive session:

- When configuring the property
- Before you apply the change

For example, if you change the `db-directory` property on the userRoot backend, such as specifying the path to the file system path that holds the Oracle Berkeley DB Java Edition backend files, an admin action reminder displays during one of the steps.

The admin action alert also appears as a final confirmation step. The alert allows you to continue and apply the change or back out of the configuration if the resulting action cannot be conducted at the present time. For example, after you type the letter `f` to apply the `db-directory` property change, the admin alert message appears:

```
Enter choice [b]: f One or more configuration property changes require
 administrative action or confirmation/notification. Those properties include:
 * db-directory: Modification requires that the Directory Server be stopped,
 the database directory manually relocated, and then the Directory Server
 restarted. While the Directory Server is stopped, the directory and files
 pertaining to this backend in the old database directory must be manually
 moved or copied to the new location. Continue? Choose 'no' to return to the
 previous step (yes / no) [yes]:
```

```
Enter choice [b]: f One or more configuration property changes require
administrative action or confirmation/notification. Those properties include:
* db-directory: Modification requires that the Directory Server be stopped,
the database directory manually relocated, and then the Directory Server
restarted. While the Directory Server is stopped, the directory and files
pertaining to this backend in the old database directory must be manually
moved or copied to the new location. Continue? Choose 'no' to return to the
previous step (yes / no) [yes]:
```

Currently, only a small set of properties that display an admin action alert appear in **dsconfig** interactive mode and the administrative console. For more information on the properties, see the *PingDirectory Server Configuration Reference*, located in the server's `docs/config-guide` directory.

Using dsconfig in non-interactive mode

The **dsconfig** non-interactive command-line mode provides a simple way to make arbitrary changes to the Directory Server by invoking it from the command line.

Steps

1. To use administrative scripts to automate configuration changes, run the **dsconfig** command in non-interactive mode.

   Non-interactive mode is convenient for scripting applications.

   > ⓘ **Note:**
   >
   > If you plan to make changes to multiple configuration objects at the same time, then the batch mode might be more appropriate.

2. Use the **dsconfig** tool to update a single configuration object using command-line arguments to provide all of the necessary information.

   The following shows the general format for the non-interactive command line.

   ```
   $ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
   ```

   > ⓘ **Note:**
   >
   > The `--no-prompt` argument indicates that you want to use non-interactive mode. The `{sub-command}` is used to indicate which general action to perform. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the Directory Server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending

on your setup. For example, using standard LDAP connections, you can invoke the **dsconfig** tool, as shown.

```
$ bin/dsconfig --no-prompt list-backends \
  --hostname server.example.com \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --bindPassword password
```

3. If your system uses SASL GSSAPI (Kerberos), invoke **dsconfig** as shown.

```
$ bin/dsconfig --no-prompt list-backends \
  --saslOption mech=GSSAPI \
  --saslOption authid=admin@example.com \
  --saslOption ticketcache=/tmp/krb5cc_1313 \
  --saslOption useticketcache=true
```

4. To always display the advanced properties, use the `--advanced` command-line option.

> ⓘ **Note:**
>
> The `{subcommandArgs}` argument contains a set of arguments specific to the particular subcommand that you want to invoke.
>
> Global arguments can appear anywhere on the command line, including before the subcommand and after or intermingled with subcommand-specific arguments. The subcommand-specific arguments can appear anywhere after the subcommand.

Configuring the Server using dsconfig non-interactive mode

Use `dsconfig` non-interactive mode to modify memory and specify parent distinguished names (DNs).

Steps

- To change the amount of memory used for caching database contents and to specify common parent DNs that should be compacted in the underlying database, use the **dsconfig** command in non-interactive mode.

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set db-cache-percent:40 \
  --add "compact-common-parent-dn:ou=accts,dc=example,dc=com" \
  --add "compact-common-parent-dn:ou=subs,dc=example,dc=com"
```

Viewing a list of dsconfig properties

Run `dsconfig` commands to view a list of properties, objects, property descriptions, and property information.

Steps

1. To view the list of all `dsconfig` properties, run the **dsconfig** command with the `list-properties` option.

> ⓘ **Note:**
>
> Remember to add the LDAP connection parameters.

```
$ bin/dsconfig list-properties
```

2. To view objects at and below the menu object level, use the **dsconfig** command with the `list-properties` option and the `--complexity <menu level>` option.

```
$ bin/dsconfig list-properties --complexity advanced --includeDescription
```

> ⓘ **Note:**
>
> You can also add the `--includeDescription` argument that includes a synopsis and description of each property in the output. Remember to add the LDAP connection parameters.

3. If the server is offline, you can run the command with the `--offline` option without needing to enter the LDAP connection parameters.

```
$ bin/dsconfig list-properties --offline --complexity advanced --
includeDescription
```

4. To review the property information provided with the server, view the *<server-root>*`/docs/config-properties.txt` file.

Getting the equivalent dsconfig non-interactive mode command

Although the **dsconfig** non-interactive command-line mode is convenient for scripting and automating processes, obtaining the correct arguments and properties for each configuration change can be time-consuming.

About this task

For quick and easy configuration, use an option to display the equivalent non-interactive command using **dsconfig** interactive mode. The command displays the equivalent **dsconfig** command to recreate the configuration in a scripted configuration or to enter any pending changes on the command line for another server instance more quickly.

> ⓘ **Note:**
>
> There are two other ways to get the equivalent **dsconfig** command. One way is by looking at the `logs/config-audit.log` file. It might be more convenient to configure the Directory Server the way you want and then get the **dsconfig** arguments from the log. Another way is to configure an option using the Administrative Console. The console shows the equivalent **dsconfig** command prior to applying the change.

To get the equivalent `dsconfig` non-interactive mode command:

Steps

1. Use **dsconfig** in interactive mode to make changes to a configuration, but do not apply the changes (that is, do not enter the letter `f`).
2. To view the equivalent non-interactive command, enter `d`.
3. View the equivalent command, and then press **Enter** to continue.

   Based on an example in the previous section, changes made to the `db-cache-percent` returns the following.

   ```
   Command line to apply pending changes to this Local DB Backend: dsconfig
   set-backend-prop --backend-name userRoot --set db-cache-percent:40
   ```

   The command does not contain the LDAP connection parameters required for the tool to connect to the host because it is presumed that the command would be used to connect to a different remote host.

Using dsconfig batch mode

Configure the Directory Proxy Server in `dsconfig` batch mode.

About this task

The PingDirectoryProxy Server provides a **dsconfig** batching mechanism that reads multiple **dsconfig** invocations from a file and executes them sequentially.

The batch file provides advantages over standard scripting by minimizing LDAP connections and Java virtual machine (JVM) invocations that normally occur with each **dsconfig** call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment or from a test environment to a production environment. The `--no-prompt` option is required with **dsconfig** in batch mode.

If a **dsconfig** command has a missing or incorrect argument, the command fails and aborts the batch process without applying any changes to the Directory Proxy Server. The **dsconfig** command supports a **--batch-continue-on-error** option that instructs **dsconfig** to apply all changes and skip any errors.

You can view the `logs/config-audit.log` file to review the configuration changes made to the Directory Proxy Server and use them in the batch file. The batch file can have blank lines for spacing and lines starting with a pound sign (#) for comments. The batch file also supports a `\` line continuation character for long commands that require multiple lines.

The Directory Proxy Server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Oracle to PingDirectoryProxy Server machines.

Steps

1. Create a text file that lists each **dsconfig** command with the complete set of properties that you want to apply to the Directory Proxy Server.

> ⓘ **Note:**
>
> The items in this file should be in the same format as those accepted by the **dsconfig** command.
>
> The batch file can have blank lines for spacing and lines starting with a pound sign (#) for comments.
>
> The batch file also supports a "\" line continuation character for long commands that require multiple lines.

```
# This dsconfig operation creates the exAccountNumber global attribute
 index.
dsconfig create-global-attribute-index
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--index-name exAccountNumber --set prime-index:true

# Here we create the entry-count placement algorithm with the
# default behavior of adding entries to the smallest backend
# dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name example_com_entry_count
--type entry-counter
--set enabled:true
--set "poll-interval:1 m"

# Note that once the entry-count placement algorithm is created
# and enabled, we can delete the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then delete the
```

```
# original round-robin algorithm created during the setup
# procedure.

dsconfig delete-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin
```

2. To read and execute the commands, run **dsconfig** with the `--batch-file` option.

Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth tokens

Configure an access token validator to use PingFederate OAuth tokens with PingDirectory.

Before you begin

You need the following information:

- The runtime engine service port of the PingFederate server, usually 9031
- The client ID of an OAuth 2.0 client configured on the PingFederate server
- The client secret of the OAuth 2.0 client
- The IP address of the PingFederate server

About this task

After you configure a PingFederate server to issue OAuth 2 tokens, you must make these tokens compatible with SCIM 2.0 operations on PingDirectory Server or PingDirectoryProxy Server.

This section explains how to set up an access token validator to handle this task.

Steps

1. Register the PingFederate server using the following command.

```
dsconfig create-external-server \
  --server-name PingFederateInstance \
  --type http \
  --set base-url:https://<PingFed IP address>:<PingFed port> \
  --set hostname-verification-method:allow-all \
  --set "trust-manager-provider:Blind Trust"
```

> ⓘ **Note:**
>
> In this example, the hostname verification method is set to allow-all and the Blind Trust manager provider is used for the sake of simplicity. You should not use these settings for production environments.

2. Create the access token validator using the following command.

```
dsconfig create-access-token-validator \
  --validator-name PingFederateValidator \
  --type ping-federate \
  --set enabled:true \
  --set authorization-server:PingFederateInstance \
  --set client-id:client-id \
```

```
  --set client-secret:client-secret
```

> ⓘ **Note:**
>
> Take the *client-id* and *client-secret* values from the PingFederate OAuth 2 client that will be used with the PingDirectory Server or PingDirectoryProxy Server.

3. Add the access token validator to the SCIM 2 HTTP Servlet configuration with the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set access-token-validator:PingFederateValidator
```

4. Test the validator by sending a GET request to `/scim/v2/ServiceProviderConfig`.

   This endpoint does not require any scopes to access, just a valid bearer token. The sever should return a response similar to the following.

```
{
    "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ServiceProviderConfig"
    ],
    "patch": {
        "supported": true
    },
    "bulk": {
        "supported": false,
        "maxOperations": 0,
        "maxPayloadSize": 0
    },
    "filter": {
        "supported": true,
        "maxResults": 0
    },
    "changePassword": {
        "supported": true
    },
    "sort": {
        "supported": false
    },
    "etag": {
        "supported": false
    },
    "authenticationSchemes": [
        {
            "name": "OAuth 2.0 Bearer Token",
            "description": "The OAuth 2.0 Bearer Token Authentication
 scheme. OAuth enables clients to access protected resources by obtaining
 an access token, which is defined in RFC 6750 as \"a string representing
 an access authorization issued to the client\", rather than using the
 resource owner's credentials directly.",
            "specUri": "http://tools.ietf.org/html/rfc6750",
            "type": "oauthbearertoken",
            "primary": true
        }
    ],
    "meta": {
        "resourceType": "ServiceProviderConfig",
        "location": "https://localhost:8443/scim/v2/ServiceProviderConfig"
    }
}
```

About recurring tasks and task chains

You can use the **dsconfig create-recurring-task** command to create recurring tasks and task chains to perform regular maintenance tasks for PingDirectory Server. These tasks can perform regular backups, LDIF exports, enter and exit lockdown mode, or other static operations.

Because this process is owned by the server, tasks do not require special privileges or credentials, and they can be run when the server is offline.

Create tasks and then add them to a recurring task chain for scheduling. The task chain ensures that invocations of a task or set of tasks run in a specified order and do not overlap.

A recurring task includes:

- The task-specific object classes to include in the task entry
- The task-specific attributes to include in the task entry, if any
- Whether to alert on task start, success, or failure
- Any addresses to email on task start, success, or failure
- Whether to cancel an instance of the task if it is dependent upon another task and that task does not complete successfully

After you create a task, add one or more tasks to a task chain and schedule the chain using the **dsconfig create-recurring-task-chain** command.

A recurring task chain includes:

- An ordered list of the tasks to invoke
- The months, days, times, and time zones in which each task can be scheduled to start
- The behavior to exhibit if any of the tasks are interrupted by a server shutdown
- The behavior to exhibit if the server is offline when the start time occurs

> ⓘ **Note:**
>
> Changing the schedule for an existing recurring task chain only takes effect the next time an instance of the chain needs to be scheduled. It does not affect any existing instances of the chain that are already scheduled. Existing scheduled instances still run at the originally scheduled time. When that run is complete, the server schedules the next iteration according to the then-current schedule logic.
>
> Also, you cannot simply cancel the existing scheduled instance to make the next instance run earlier. When you cancel an instance of a recurring task chain, the server automatically schedules the next instance for the next time that matches the scheduling criteria. It never schedules a new instance for earlier than or the same time as one that you manually canceled.

Creating a recurring task and task chain

Use **dsconfig** to create one or more tasks and then add them to a task chain for scheduling.

Steps

1. To create a task, use **dsconfig create-recurring-task**.

   The following creates a backup task.

```
$ bin/dsconfig create-recurring-task \
  --task-name backup-1 \
  --type backup \
  --set 'email-on-failure:admin1@company.com' \
  --set 'email-on-failure:admin2@company.com' \
  --set compress:true \
  --set encrypt:true \
  --set "retain-previous-full-backup-age:4 w" \
  --set retain-previous-full-backup-count:10
```

2. To create a task chain to schedule and run recurring tasks, use **`dsconfig create-recurring-task-chain`**.

```
$ bin/dsconfig create-recurring-task-chain \
  --chain-name "backup chain" \
  --set recurring-task:backup-1 \
  --set scheduled-date-selection-type:selected-days-of-the-month \
  --set scheduled-day-of-the-month:last-day-of-the-month \
  --set scheduled-time-of-day:02:00
```

LDIF export as a recurring task
You can create a recurring task to schedule the export of LDIF data.

For new installations, the server exports LDIF data by default every day at 1:05 a.m. in the default time zone for the Java virtual machine (JVM), which is generally the time zone configured for the underlying system. At the scheduled time, the server exports the contents of each public backend to a file in the server root `ldif` directory.

> ⓘ **Note:**
>
> Public backends are non-administrative backends containing user-supplied data.

The server compresses and encrypts the LDIF exports if the global configuration is set to encrypt LDIF exports by default, which is enabled if encryption is configured during setup. The LDIF exports are rate limited to ten megabytes per second to minimize the impact on server performance, and exports are retained for seven days.

The recurring task chain is created in instances that are updated to this release. However, the task chain is not enabled by default.

LDIF export can export multiple backends in the same recurring task. You can use the **`backend-id`** property to include multiple backends. You can use the **`exclude-backend-id`** property to exclude one or more backends. These optional properties are mutually exclusive:

- If the **`backend-id`** property has one or more values, only the backends with those IDs are exported.
- If the **`exclude-backend-id`** property has one or more values, all public backends except those listed are exported.
- If neither the **`backend-id`** property nor the **`exclude-backend-id`** property supply values, all public backends are exported.

Lockdown mode as a recurring task
You can create recurring tasks to move a server in and out of lockdown mode. Moving a server in and out of lockdown mode is useful for scheduling other tasks while the server is mostly idle and not accepting connections from clients.

While in lockdown mode, the server reports itself as unavailable and also rejects requests from any user that doesn't have the **`lockdown-mode`** privilege.

The recommended flow for a recurring task chain that uses lockdown mode would be:

1. Enter lockdown mode task.
2. Delay task that waits for the work queue to report that the server is idle.
3. Run desired tasks to perform while the server is in lockdown mode.
4. Leave lockdown mode task.

The enter lockdown mode and leave lockdown mode tasks each allow one optional property that you can use to supply a description for why that the server is being moved into this mode.

File retention recurring task
You can configure a recurring task to remove files in a specified directory that match a given pattern.

You can exclude files that match count-based, time-based, or space-based retention criteria. If any files are to be removed, the oldest files are removed before the most recent file.

If the file name pattern includes a "`${timestamp}`" element, the timestamp is used to identify the file's age. If the file name pattern does not include a timestamp, then the file's age is determined by using the file's creation time, if available, or the last modified time, if the creation time is not available. If a file's age cannot be determined, the file is not removed.

If multiple files have the same age, the server uses lexicographic ordering to differentiate between them. Lexicographic ordering is applicable only for files with no **`retain-file-age`** property configured or for files that are older than that age. If multiple files do not share the same age, but that age is younger than the **`retain-file-age`** value, then those files are retained.

When configuring a file removal task, you must specify at least one of the following properties:

- **`retain-file-count`**
- **`retain-file-age`**
- **`retain-aggregate-file-size`**

Using exec tasks

Exec tasks allow administrators and external users to execute a specified command on the server once or as recurring tasks.

About this task

The server restricts the kinds of commands that can be executed, and the access level of users who can execute them.

These safeguards and requirements include:

- The absolute path to the command to execute must be listed in the *<server-root>*`/config/exec-command-whitelist.txt` file.
- The global configuration must be updated to allow the exec task. The server does not permit it by default. The following command enables this.

```
$ bin/dsconfig set-global-configuration-prop \
  --add allowed-task:com.unboundid.directory.server.tasks.ExecTask
```

- The user scheduling the task must have the **`exec-task`** privilege. The server does not grant permission to run this task to any user by default, including root users.

The following configuration changes grant the **`exec-task`** privilege to a single root user, all root users, or a single non-root user:

Steps

- To grant the **`exec-task`** privilege to a single root user, run the following.

```
$ bin/dsconfig set-root-dn-user-prop --user-name "<username>" \
  --add privilege:exec-task
```

- To grant the **`exec-task`** privilege to all root users, run the following.

```
$ bin/dsconfig set-root-dn-prop \
  --add default-root-privilege-name:exec-task
```

- To grant the **`exec-task`** privilege to a single non-root user, run the following.

```
dn: <userdn>
```

```
changetype: modify
add: ds-privilege-name
ds-privilege-name: exec-task
```

- Use the **schedule-exec-task** tool to create an exec task from the command line.

  The following command schedules an exec task to run the **verify-index** tool to check the integrity of the **cn** index in the backend that hosts **"dc=example,dc=com"**, assuming that the server is installed in **/ds**.

```
$ bin/schedule-exec-task --hostname directory.example.com \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --promptForBindPassword \
  --waitForCompletion \
  --logCommandOutput \
  /ds/bin/verify-index --baseDN dc=example,dc=com --index cn
```

Topology configuration

Topology configuration enables automatic server grouping and configuration change mirroring. It uses a master and slave architecture for mirroring shared data across the topology.

All writes and updates are forwarded to the master, which forwards them to all other servers. Reads can be served by any server in the group, and servers can be added to an existing topology at installation.

> ⓘ **Note:**
>
> To remove a server from the topology, you must uninstall it with the uninstall tool.

Topology master requirements and selection

A topology master server receives configuration changes from other servers in the topology, verifies the changes, and then makes the changes available to all connected servers.

When updating, the master sends a digest of its subtree contents. If the node's digest differs from the master's, the server node knows it is not synchronized. The servers pull the entire subtree from the master if they detect that they are not synchronized.

A server detects it is not synchronized with the master under the following conditions:

- The server's subtree digest differs from the master's digest at the end of its periodic polling interval.
- One or more servers have been added to or removed from the topology.

The master of the topology is selected by prioritizing servers based on:

- Minimum supported product version
- Availability
- Server version
- Earliest start time
- Startup UUID (smaller is preferred)

After determining a master, the topology data is reviewed from all available servers, every five seconds by default, to determine if any new information identifies a better server master. If a new server can be the master and no other servers have indicated that they should be the master, it will communicate its eligibility to the other servers. This ensures that all servers accept the same master at approximately the same time, within a few milliseconds of each other. If there is no better master, the initial master maintains the role.

After the best master has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that master.

  The master server itself is considered while determining this majority.

- There is only a single master in the entire topology.

If either of these conditions is not met, the topology is without a master and the peer polling frequency is reduced to 100 milliseconds to find a new master as quickly as possible. If there is no master in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as master with the `force-as-master-for-mirrored-data` option in the Global Configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as masters, then a `multiple-servers-forced-as-masters` alarm is raised.

Topology components
When you install a server , you can add it to an existing topology, cloning the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

Server configuration settings

Configuration settings for the topology are configured in the global configuration and in the config file handler backend. They are topology settings, but they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The global configuration object contains a single topology setting, force-as-master-for-mirrored-data. This should be set to `true` on only one of the servers in the topology, and is used only if the topology cannot determine a master because most of the servers are not available. A server with this setting enabled is assigned the role of master if no suitable master can be determined.

The config file handler backend defines three topology **`mirrored-subtree`** settings:

mirrored-subtree-peer-polling-interval

Specifies the frequency at which the server polls its topology peers to identify any changes warranting a new master selection. A lower value ensures a faster failover, but it also causes more traffic among the peers. The default value is 5 seconds. If no suitable master is found, the polling frequency adjusts to 100 milliseconds until a new master is selected.

mirrored-subtree-entry-update-timeout

Specifies the maximum length of time to wait for an entry update operation, such as add, delete, modify or modify-dn, to be applied by the master on all of the servers in the topology. The default is 10 seconds, but updates can take up to twice as long if master selection is in progress at the time the update operation is received.

mirrored-subtree-search-timeout

Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

Topology settings

Topology metadata is stored under the cn=topology,cn=config subtree and cluster data is stored under the cn=cluster,cn=config subtree. The only setting that can be changed is the cluster name.

Monitor data for the topology
Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to identify changes in the topology.

Topology data includes the following:

- The server ID of the current master, if the master is not known
- The instance name of the current master or if a master is not set, a description stating why a master is not set
- A flag indicating which server thinks that it should be the master

- A flag indicating which server is the current master
- A flag indicating a server that was forced as master
- The total number of configured peers in the topology group
- The peers connected to this server
- The current availability of this server
- A flag indicating that a server is not synchronized with its master or another node in the topology if the master is unknown
- The amount of time in milliseconds that multiple masters were detected by this server
- The amount of time in milliseconds that no suitable server is found to act as master
- A SHA-256 digest encoded as a base-64 string for the current subtree contents

The following metrics are included if this server has processed any operations as master:

- The number of operations processed by this server as master
- The number of successful operations processed by this server as master
- The number of operations processed by this server as master that failed to validate
- The number of operations processed by this server as master that failed to apply
- The average amount of time taken in milliseconds by this server to process operations as the master
- The maximum amount of time taken in milliseconds by this server to process an operation as the master

Servers and certificates

The following provides a detailed description of PingDirectory Server certificate types.

PingDirectory Server uses two main types of certificates:

Listener certificates

Used to secure communication through TLS.

Inter-server certificates

Used to authenticate between server instances in a topology.

Listener certificates

When a client initiates TLS negotiation with the server, the server presents a certificate chain to the client and the certificate at the head of the chain functions as a listener certificate.

Because the client decides whether to trust the certificate chain, it is recommended that the chain be signed by an issuer whom the client is likely to trust or that the client can be easily configured to trust.

You can create self-signed certificates with long lifespans, but a certificate that a certification authority signs is likely to have a relatively short lifespan. Commercial authorities typically issue certificates that are valid for only one or two years, but some authorities use shorter validity windows.

Short certificate lifespans offer some security benefits. In particular, because most clients do not verify whether a certificate has been revoked, a shorter validity window minimizes the timeframe that a compromised certificate can be used. If the process for replacing certificates is streamlined or automated, administrative inconvenience can be kept to a minimum.

Listener certificates are stored in key stores that are referenced by key manager providers, which in turn provide the logic and configuration for accessing the key stores. If a server component, like a connection handler, requires access to a certificate that it presents to a peer during the TLS negotiation process, that component must reference the key manager provider that points to the key store containing the appropriate certificate. If the key store contains multiple certificates, and if the component referencing the key store includes a property specifying the certificate's nickname, the certificate with that alias is selected. Otherwise, the server lets the Java virtual machine (JVM) select a certificate that might not be well-defined.

The server also provides trust manager providers, which determine whether to trust the certificate chains with which it is presented. A trust manager provider can reference a specified trust store file, but other

options include the JVM default trust store, which uses the Java installation's default set of trusted issuers, and the blind trust manager provider, which automatically trusts every certificate chain that is presented to it.

> ⓘ **Note:**
>
> Never use a blind trust manager in a production environment because it leaves the server vulnerable to impersonation and man-in-the-middle attacks. However, a blind trust manager can be convenient in test environments when troubleshooting certain types of problems.

Replacing listener certificates

Certificate authorities typically restrict the lifespans of the certificates that they sign. If you use a certification authority to issue listener certificates, you are likely replacing the certificates on a regular basis.

About this task

The **`replace-certificate`** tool performs the following steps:

1. Obtain a new certificate chain.
2. Make necessary updates to the key manager provider and the connection handler configurations
3. Update the server instance listener configuration with the new certificate.

The **`replace-certificate`** tool offers the following modes of operation:

Interactive mode

Walks you through the process of obtaining a new certificate and installing it in the server. Interactive mode also displays the non-interactive commands that are required to achieve the same result.

Non-interactive mode

Useful when scripting the process of replacing a certificate.

Steps

- To replace a listener certificate, run the **`replace-listener-certificate`** subcommand of the **`replace-certificate`** tool.

> ⓘ **Note:**
>
> You can replace certificates manually, but the **`replace-certificate`** tool automates the process. The **`replace-certificate`** tool provides information about multiple listener certificates during the transitional phase that occurs when you install them.
>
> The **`replace-listener-certificate`** subcommand takes arguments that provide the following information:
>
> - Arguments required to authenticate to PingDirectory Server, such as --bindDN and --bindPasswordFile
> - Details about the key store that contains the new certificate
> - Updates that must be made to the key and trust manager providers
> - Whether to signal the HTTP connection handler to reload its certificates after the update is complete

The following arguments are available:

Argument	Description
--source-key-store-file {path}	Path to the Java KeyStore (JKS) or PKCS #12 file that contains the private key entry with the new certificate chain. This argument is required.
--source-key-store-password {password}	Clear-text password that is needed to access the contents of the source key store.
--source-key-store-password-file {path}	Path to the file that contains the password necessary to access the contents of the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database.
--source-certificate-alias {alias}	Password that is required to access the appropriate private key in the source key store. If neither the --source-private-key-password nor the --source-private-key-password-file argument is provided, the key store password is used as the private key password.
--source-private-key-password-file {path}	Path to the file that contains the password needed to access the appropriate private key in the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database. If neither the --source-private-key-password nor the --source-private-key-password-file argument is provided, the key store password is used as the private key password.
--key-manager-provider {name}	Name of the key manager provider that is updated to use the new certificate chain. The value must identify a file-based key manager provider, and the new certificate chain must be enabled. Defaults to JKS if a value is not specified.

Argument	Description
--trust-manager-provider {name}	Name of the trust manager provider that is updated with the information required to trust the new certificate chain. The value must identify a file-based trust manager provider, and the new certificate chain must be enabled. If neither this argument nor the --use-jvm-default-trust-manager-provider argument is provided, the tool assumes that the name of the trust manager provider is identical to the name of the key manager provider.
--use-jvm-default-trust-manager-provider	Indicates that the server must be configured to use the JVM-default trust manager provider, which trusts certificates signed by issuers in the `cacerts` trust store provided with the Java virtual machine (JVM), rather than updating an existing trust manager provider.
--target-certificate-alias {alias}	Alias to use for the new certificate in the key manager provider's key store, and for appropriate updates in the trust manager provider's trust store. Defaults to an alias of server-cert if a value is not specified. ⓘ **Note:** If the key manager provider's key store, or the trust manager provider's trust store, already contains an entry with the given alias, the existing entry is renamed.
--reload-http-connection-handler-certificates	Indicates that the tool is requesting that the server cause any HTTPS-based connection handlers to reload their certificates, so that the connection handlers can use the updated certificate. LDAP connection handlers react to the change immediately and start presenting the new certificate chain during subsequent TLS negotiations. HTTPS connection handlers continue using the former certificate until the connection handler is restarted or until the connection handler is asked specifically to reload its certificates. ⓘ **Note:** This option might prevent clients with existing TLS sessions that were negotiated with the former certificate from being resumed.

- To remove earlier certificates from the server instance listener configuration, run the purge-retired-listener-certificates subcommand.

> ⓘ **Note:**
>
> The purge-retired-listener-certificates subcommand does not take arguments other than the ones that are required to authenticate to the server.
>
> By default, the **`replace-certificate`** tool updates the server instance listener configuration object to include the new listener certificate, and it merges the old and new certificates residing in the configuration object.

Inter-server certificates
Each server instance in a topology has an inter-server certificate that is generated during the setup process.

The inter-server certificate is not exposed to clients, so a trusted issuer does not need to sign it. Instead, the topology registry, representing a mirrored portion of the configuration with information about every PingDirectory Server instance in the environment, contains the information that each instance needs to trust the inter-server certificates for all other instances.

Inter-server certificates can be used to protect certain secrets that are shared among servers within the topology, like the secrets that are used to digitally sign log files, backups, and LDIF exports. Inter-server certificates include the encryption keys that reversible password-storage schemes use.

The inter-server certificate is generated with a long lifespan. Replace it only when you suspect that its private key is compromised.

Replacing the inter-server certificate
During the installation process, the inter-server certificate is generated with a long lifespan and does not require replacement under normal circumstances. You should replace the inter-server certificate only if you suspect that its private key is compromised.

About this task

The inter-server certificate is intended for use only between server instances within the same topology. Because it is not exposed to regular clients, the inter-server certificate does not need to be trusted.

The **`replace-certificate replace-inter-server-certificate`** command performs the following steps:

- Acquires the new inter-server certificate from a provided Java KeyStore (JKS) or PKCS #12 key store
- Makes the necessary updates to the `config/ads-truststore` file in the server key store
- Updates the server instance configuration object to include the new inter-server certificate

> ⓘ **Note:**
>
> To avoid the need to replace the inter-server certificate on a regular basis,use a self-signed certificate with a long lifespan. Each server instance must possess its own, unique inter-server certificate that satisfies the following conditions:
>
> - Uses an RSA key pair
> - Has a minimum key size of 2048 bits
>
> The following types of certificates are not allowed:
>
> - Certificates with an elliptic curve key pair
> - Certificates with an RSA key that is smaller than 2048 bits

Steps

- To replace the inter-server certificate, run the **`replace-inter-server-certificate`** subcommand of the **`replace-certificate`**.

  The **`replace-inter-server-certificate`** subcommand takes a subset of the arguments that are used with the **`replace-listener-certificate`** subcommand, including the following arguments:

  - --source-key-store-file {path}--source-key-store-password {password}
  - --source-key-store-password-file {path}
  - --source-certificate-alias {alias}
  - --source-private-key-password {password}
  - --source-private-key-password-file {path}
- To delete earlier values that are no longer needed, run the **`purge-retired-inter-server-certificates`** subcommand.

> ⓘ **Note:**
>
> By default, the new inter-server certificate is merged with the existing values in the server instance configuration entry.

X.509 certificates
PingDirectory Server supports X.509 certificates, the most common type of certificates. *RFC 5280* describes X.509v3, which provides the current version of the specification.

An X.509v3 certificate includes the following components:

X.509 encoding version

Enables the differentiation between an X.509v3 certificate and one that conforms to an earlier or later version of the specification.

Serial number of the certificate

Integer value that uniquely identifies a certificate as issued by a certification authority.

Subject DN

Distinguished name for the certificate, which often provides details about the context in which the certificate is to be used. For more information, see *Certificate subject DNs* on page 319.

Issuer DN

Distinguished name for the issuer certificate, which is the certificate used to sign the certificate. For a self-signed certificate, this value matches the subject DN.

Validity window

Indicates the timeframe during which the certificate is considered valid. This component includes the following elements:

- notBefore

  Specifies the earliest time at which the certificate is considered valid.
- notAfter

  Specifies the latest time at which the certificate is considered valid.

Public key

Public portion of a pair of cryptographically linked keys. For more information, see *Certificate key pairs* on page 320.

Signature

A type of cryptographic proof that the certificate truly was sent from the issuer and has remained unaltered. A self-signed certificate is signed with its own private key. Otherwise, it is signed with the issuer's private key.

An X.509v3 certificate might also include the following optional components:

Subject unique ID

Uniquely identifies the certificate. This component has been deprecated in favor of the subject key identifier extension, so it is generally omitted from X.509v3 certificates.

Issuer unique ID

Subject unique ID of the issuer certificate, if available. This component has been deprecated in favor of the authority key identifier extension.

Set of extensions

Provides additional context for the certificate and the manner in which it is used. For more information, see *Certificate extensions* on page 320.

Certificate subject DNs

A certificate's subject distinguished name (DN) provides information about how the certificate should be used.

Like an LDAP DN, a certificate's subject DN consists of a comma-delimited series of attribute-value pairs. However, unlike an LDAP DN, the attribute names in a certificate subject DN are typically written in all uppercase characters.

A certificate's subject DN is also referred to as its subject. The following attributes commonly appear in a certificate subject.

Attribute name	Attribute description
`CN`	Common name **Note:** For a listener certificate, the `CN` attribute typically identifies the host name that clients use to access the certificate. However, the subject alternative name extension is recommended more highly for accomplishing the same task. Most certificate subject DNs include at least the `CN` attribute.
`E`	Email address
`OU`	Name of the organizational unit, such as the relevant department
`O`	Name of the organization or company
`L`	Name of the locality, such as the appropriate city
`ST`	Full name of the state or province
`C`	ISO 3166 country code

A certificate subject includes at least one attribute-value pair, and the `CN` attribute is typically present. Other attributes can be omitted, although the `O` and `C` attributes are also common. For example, a listener certificate for a server with an address of `ldap.example.com`, which is run by the US-based company Example Corp, might have a subject of `CN=ldap.example.com,O=Example Corp,C=US`.

Certificate key pairs
Each certificate contains a key pair that consists of two keys that are linked cryptographically. If you encrypt data with one key, the data can be only decrypted with the other key.

Although a key pair can be created easily when both keys are generated simultaneously, the process of deriving one key from the other is extremely difficult, a process categorized in cryptographic terms as computationally infeasible.

When generating a key pair, one key is designated as the public key, and the other key is designated the private key. The public key can be made widely available, but the private key must be kept secret and not shared with anyone.

As long as the secrecy of the private key is maintained, the key pair can be used to perform the following functions:

- Encryption, sometimes referred to as confidentiality

  If someone wants to send you a secret message without anyone else viewing it, the message can be encrypted with your public key. Only you possess the private key, so only you can decrypt the message.
- Digital signatures

  If you encrypt data with your private key, it can be decrypted only with your public key. Because your public key can be made widely available, this encryption method does not actually protect the content. However, digital signatures prove that a message came from you because only your private key could have generated it.

> ⓘ **Note:**
>
> When generating a digital signature, the entire message is generally not encrypted. Only a hash of the message is encrypted, typically by using a digest algorithm like SHA-256.
>
> This approach protects the integrity of a message. A decrypted signature that matches the digest of the original message guarantees that the message came from you and that it has remained unaltered since you signed it.

The following public key algorithms are used primarily in certificates that facilitate TLS communication:

- RSA, which is based on the multiplication of large prime numbers
- EC, which is based on computations that involve special types of elliptical curves

Although RSA is supported more widely than EC, it is slower and requires larger keys to achieve the same level of security. To support legacy clients, you should use an RSA certificate and choose a key size of at least 2,048 bits.

If all of your clients support EC certificates, you should use an EC certificate with a key size of at least 256 bits.

Certificate extensions
Extensions provide additional context for a certificate.

Some of the more common extension types include the following:

Subject key identifier

Holds a unique identifier for the certificate, which is generally derived from the certificate's public key.

Authority key identifier

Holds the subject key identifier for the issuer certificate. This extension type helps to identify the issuer certificate, especially when presented with an incomplete certificate chain.

Subject alternative name

Holds a list of ways that clients are expected to reference a server when establishing a connection to it.

> ⓘ **Note:**
>
> Clients must take this information into account when deciding whether to trust a server's certificate.
>
> The most common types of values include DNS names, IP addresses, and URIs. DNS names must be fully qualified, but can optionally use an asterisk in the leftmost component to match any single name in that component. For example, `*.example.com` could match `www.example.com` or `ldap.example.com`, but would not match `ldap.east.example.com` or `example.com`.

Key usage

Provides information about the manner in which the certificate is expected to be used. The following key usages are allowed:

`digitalSignature`

Indicates that the certificate can be used for digitally signing data, excluding certificates and certificate revocation lists (CRL).

`nonRepudiation`

Indicates that the certificate can be used to prevent denying the authenticity of a message. `nonRepudiation` is also known as `contentCommitment`.

`keyEncipherment`

Indicates that the certificate can be used to protect encryption keys, such as symmetric keys that are derived during TLS key agreement.

`dataEncipherment`

Indicates that the certificate can be used for encrypting data directly.

`keyAgreement`

Indicates that the certificate's public key can be used for key agreement, such as deriving the symmetric key that protects TLS communication.

`keyCertSign`

Indicates that the certificate can act as a certification authority and be used for signing other certificates.

`cRLSign`

Indicates that the certificate can be used to sign CRLs.

`encipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for encrypting data during key agreement.

`decipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for decrypting data during key agreement.

Extended key usage

Acts as an alternative to the key usage extension and provides additional high-level functionality. The following extended key usages are allowed:

`serverAuth`

Indicates that the server can present the certificate to the client during TLS negotiation.

`clientAuth`

Indicates that the client can present the certificate to the server during TLS negotiation.

`codeSigning`

Indicates that the certificate can be used to sign source and compiled code.

`emailProtection`

Indicates that the certificate can be used to sign or encrypt email messages.

`timeStamping`

Indicates that the certificate can be used to assert the time that an event occurred.

`ocspSigning`

Indicates that the certificate can be used to sign an online certificate status protocol (OCSP) response.

Basic constraints

Indicates whether the certificate can act as a certification authority and, if so, the maximum number of intermediate certificates that can follow it in a certificate chain.

Certificate chains

A certificate chain is an ordered list of one or more certificates. In such a chain, each subsequent certificate is the issuer of the previous certificate.

During TLS negotiation, the server presents a certificate chain to the client, which determines whether to trust the chain and continue with the negotiation. The client can also present its own certificate chain to the server.

If a certificate is self-signed, its chain contains only that single certificate. If a certificate is signed by a self-signed certificate authority (CA) certificate, such as a root CA, the chain contains two certificates: the server certificate and the CA certificate that follows it. If a single intermediate CA (a CA certificate that is signed by a root CA) is present, the chain contains the server certificate, followed by the intermediate CA, and then the root CA.

Intermediate certificate authorities are useful for security purposes, especially in commercial authorities. If a client trusts a root CA certificate, it is likely to trust anything with that root CA certificate at the base of its chain. Consequently, the root CA certificate must be kept secure.

ⓘ **Note:**

If the root CA certificate is compromised, any certificate that is directly or indirectly signed by it can no longer be trusted.

With intermediate CA certificates, the root certificate can be kept offline in secure storage and used only when a new intermediate CA certificate must be signed. The intermediate CA certificates can be used to sign end-entity certificates, but must be protected to avoid compromising any of the certificates. A compromised certificate must be revoked along with all of the certificates that it signed. In such a scenario, the root CA can be used to sign a new certificate.

ⓘ **Note:**

The certificate chain that the server presents to the client, or that the client presents to the server, during TLS negotiation does not always need to be the complete chain. If the root CA at the end of the chain is widely trusted, the server can assume that the client already has that root CA in its default set of trusted certificates. The server can leave that root CA off the chain with the assumption that the client will retrieve

it from its default trust store. While the same assumption could theoretically be true for intermediate CA certificates, only the root CA certificate is commonly omitted. When a client receives an incomplete chain, the client looks in its default trust store to determine whether the trust store contains the issuer certificate, which it can identify by using properties like the issuer distinguished name (DN) or an authority key identifier extension.

The certificate at the head of a certificate chain, which appears as the first one in the list, is often called the end-entity certificate. If this certificate appears at the head of the chain that a server presents during TLS negotiation, it is referred to as the server certificate. If the certificate appears at the head of a chain that a client presents, it is referred to as a client certificate. The certificate at the end of a complete chain must be a root CA certificate. In the case of a self-signed certificate, the chain contains only a single certificate that serves both roles.

About representing certificates, private keys, and certificate signing requests
X.509 is an encoding format that uses the ASN.1 distinguished encoding rules (DER), which exist in binary format. When writing a certificate to a file, either a raw DER format or a plaintext format called PEM can be used.

PEM encoding consists of a line that contains the text `-----BEGIN CERTIFICATE-----`, followed by a set of lines that contains the base64-encoded representation of the raw DER bytes (typically with no more than 64 characters per line), followed by a line that contains the text `-----END CERTIFICATE-----`.

The X.509 encoding contains a certificate's public key, but not its private key. The PKCS #8 specification in *RFC 5958* describes the encoding for private keys. This approach uses a DER encoding with a PEM variant that instead uses the following header and footer, respectively.

```
 -----BEGIN PRIVATE KEY-----
-----END PRIVATE KEY-----
```

RFC 5958 also describes an encrypted representation of the private key, but that format is currently unsupported.

The PKCS #10 specification in *RFC 2986* describes the CSR format. This format uses a DER encoding with a PEM variant that uses the following header and footer, respectively.

```
-----BEGIN CERTIFICATE REQUEST-----
-----END CERTIFICATE REQUEST-----
```

Some implementations use the following alternate, nonstandard forms.

```
-----BEGIN NEW CERTIFICATE REQUEST-----
-----END NEW CERTIFICATE REQUEST-----
```

Certificate trust
When a server presents its certificate chain to a client during TLS negotiation, the client decides whether to trust the certificate chain and concludes whether it is communicating with a legitimate server instead of an impostor.

If a client is tricked through DNS hijacking into communicating with a rogue application instead of with a legitimate server, the application can steal the client's credentials, or can fool the client into concluding that it has performed an action that it has not performed. If a rogue application acts as a broker between the client and the legitimate server, the client might be unable to detect the change, and the malicious application might be capable of stealing data or altering the communication. Consequently, you should avoid `trust all` or `blind trust` options in a production environment.

When determining whether to trust a server certificate chain, a client performs the following steps.

Processing steps

1. Verifies that it has received the complete certificate chain.

   If a server presents an incomplete chain, the client must ensure that it can complete the chain with information in an explicitly provided trust store or default trust store. If the client cannot complete the certificate chain, the chain is not trusted.
2. Verifies that each subsequent certificate in the chain is the issuer certificate for, and that its private key was used to sign, the certificate that precedes it.

   > ⓘ **Note:**
   >
   > If a certificate chain contains extraneous certificates, or if a subsequent certificate did not issue the certificate that precedes it, the chain is not trusted.
3. Confirms that it has a reason to trust the certificate at the root of the chain.

   > ⓘ **Note:**
   >
   > This step is generally performed by ensuring that the root certificate authority (CA) certificate can be found in either a default trust store or a trust store that is configured for use by the client. If the client has no prior knowledge of the root CA certificate, the chain is not trusted.
4. Verifies that the current time lies within the validity window for each certificate in the chain.

   > ⓘ **Note:**
   >
   > The chain is not trusted under the following conditions:
   >
   > - When the `notBefore` value of any certificate in the chain is later than the current time.
   > - When the `notAfter` value of any certificate in the chain is earlier than the current time.
5. Verifies that the server certificate at the head of the chain is suitable for the server with which the client thinks it is communicating.

   > ⓘ **Note:**
   >
   > The client must verify that the address used to connect to the server matches one of the following values:
   >
   > - The `CN` attribute of the certificate's subject.
   > - One of the values of any subject alternative name extension.

These steps represent a starting point. If necessary, the client can perform additional types of validation. For example, if a root or intermediate certification authority maintains a certificate revocation list (CRL) or supports the online certificate status protocol (OCSP), the client must verify that none of the certificates in the chain has been revoked. The client can also verify that the CA certificates include the basic constraints extension, and that the server certificate does not contain too many levels. Other checks, like those that use certificate policy extensions, can also be performed.

Keystores and truststores

A keystore is a type of database that holds certificates.

The following examples represent the most common forms of keystores:

- File that uses the Java-specific Java KeyStore (JKS) format
- File that uses the standard PKCS #12 format
- Collection of files that holds certificates and private keys, typically in PEM or DER format
- Hardware security module (HSM) that makes the certificate information available through an interface like PKCS #11

PingDirectory Server supports file-based keystores by using the JKS and PKCS #12 formats and by using hardware security modules that are accessible through PKCS #11. The server does not currently support a keystore format that consists of individual certificate and private key files. To import these files into a JKS or PKCS #12 keystore, use the **`manage-certificates`** tool.

A keystore also represents a collection of entries, each of which is identified by a name that an alias calls. Keystores can have the following entry types:

Private key entries

Contain a certificate chain and a private key. When a server accepts a TLS-based connection, it uses a private key entry to obtain the certificate chain that it presents to the client. The server can also use the private key from the same entry to process its key agreement. Similarly, a client uses a private key entry when presenting its own certificate chain to a server.

Trusted certificate entries

Contain a single certificate without a private key. As the name implies, a trusted certificate entry is intended primarily for use when determining whether to trust a certificate chain that is presented during TLS negotiation.

Secret key entries

Contain a secret key only, without an associated certificate. These types of entries are not used for TLS processing. Instead, they hold symmetric encryption keys or other types of secrets.

A password, sometimes called a PIN, protects the contents of a keystore. In some cases, like with JKS keystores, some content might be accessible without a password, and a password might be required only when trying to access private keys or secret keys. In other cases, like with PKCS #12 keystores, you might need a password for any interaction with the keystore.

Additional passwords can further protect private keys. This approach is often the same as with the keystore password, but the password can be different. This tactic is useful when a single keystore is shared for multiple purposes, for example, and when merely having access to the keystore does not guarantee access to all of the data that it contains.

> ⓘ **Note:**
>
> A truststore is another name for a keystore that is intended primarily for use when determining whether to trust a certificate chain that has been presented. Truststores generally contain primarily trusted certificate entries, but that case is not required.

Java runtime environments typically include a default truststore, often `jre/lib/security/cacerts` or `lib/security/cacerts`, that is prepopulated with several widely trusted certification authority certificates. When presented with a certificate that one of these authorities has signed, the default truststore can allow the certificate to be trusted without any additional configuration. When presented with a self-signed certificate, or when presented with a certificate that is signed by an issuer not in the default truststore, such as a private corporate certification authority, a separate truststore is required.

Transport Layer Security (TLS)
TLS describes a mechanism for securely communicating between two parties that might have no prior knowledge of each other.

TLS is the successor to SSL, and the two terms are often used interchangeably, even though such usage might not technically be correct.

> ⓘ **Note:**
>
> SSL remains the more widely recognized term. The abbreviation TLS occasionally generates confusion with the StartTLS extended operation, particularly in LDAP.

TLS provides security in the form of the following main components:

Certificate trust

Is about reassuring a connection-initiating client that it is communicating with the server to which it intended to connect. To ensure that the server shares the same degree of confidence in the identity and legitimacy of the client, it can ask the client to present its own certificate chain. For more information, see *Certificate Trust*.

Cipher selection

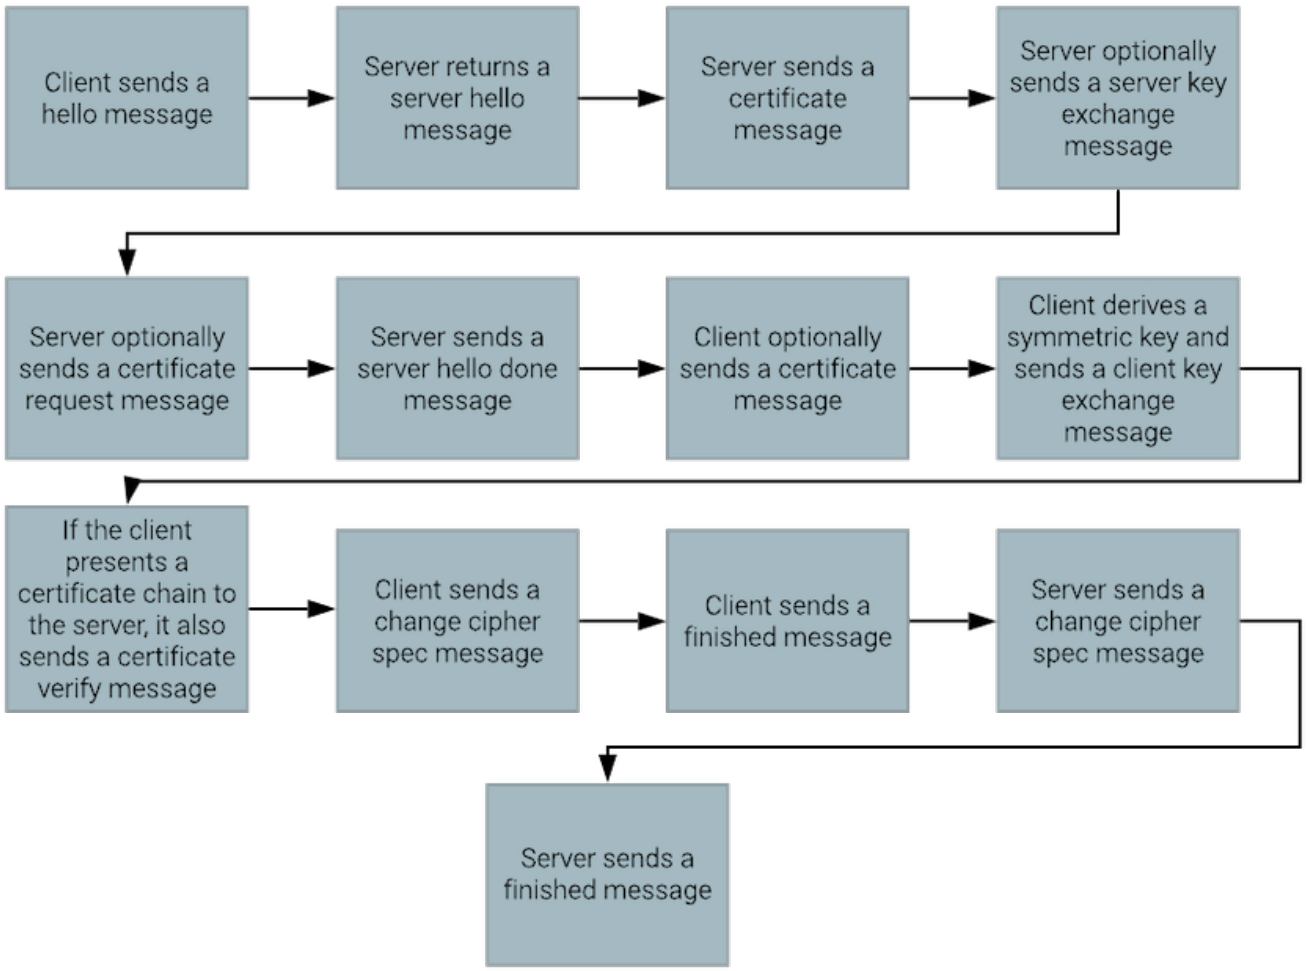
Involves choosing the cipher and the key to protect the bulk of the communication. Although a client can use a server certificate's public key to encrypt data before sending it, this approach can lead to the following issues:

- Unless the client presents its own certificate chain to the server, the server cannot encrypt the data that it sends back to the client.
- Public key encryption is considerably slower than symmetric encryption, in which the same key is used for both encryption and decryption. Public key encryption is also called asymmetric encryption because different keys are used to encrypt and decrypt data.
- If you rely entirely on the security of a private key to ensure the secrecy of a communication, and if the private key becomes compromised, data that has been encrypted with the private key must also be considered compromised.

Rather than relying solely on public key encryption to protect communication between a client and server, the TLS negotiation process allows a client and server to agree on the type of encryption and the secret key to use after completing the negotiation process.

TLS handshakes
The process of negotiating the TLS is referred to as the handshake.

Although the exact process depends on the TLS version that is ultimately chosen, the following steps represent the basic components of a TLS 1.2 handshake:



TLS processing steps

1. The client sends a `hello` message that provides the server with the following information:
   - Highest supported version of the TLS protocol
   - The cipher suites that the client uses
   - Set of extensions with additional information:
     - The address that the client uses to communicate with the server
     - The signature algorithms and elliptic curves that the client supports
     - Whether the client supports secure renegotiation
2. The server returns a `server hello` message that provides the client with the following information:
   - The TLS protocol version that the server uses
   - The cipher suite that the server selects

   The server can also provide its own extensions to the client.
3. The server sends a `certificate` message that provides its certificate chain to the client.
4. The server can optionally send a `server key exchange` message with additional information that the client might need to securely derive the same symmetric encryption key that the server generates.
5. The server can optionally send a `certificate request` message that asks the client to present its own certificate chain to the server.

6. The server sends a `server hello done` message to inform the client that it has completed its `hello` sequence.
7. The client can optionally send a `certificate` message to the server with its own certificate chain.

> ⓘ **Note:**
>
> The client sends a `certificate` message only when the server initially sends a certificate request. If the client receives such a request, it can refuse to, and probably will not, send a certificate chain. The server decides whether to require a client certificate chain. In LDAP, the server commonly asks the client to present a certificate, but continues with TLS negotiation even if the client does not present one. This approach supports authentication methods like SASL EXTERNAL, in which a client uses the certificate chain that it presents during TLS negotiation as proof of its identity.

8. The client derives a symmetric key to use for the remainder of the encrypted processing, and sends a `client key exchange` message to the server. The `client key exchange` message includes the information that the server needs to generate the same key. Only the client and server know the value of the key, even if another entity can observe the communication that passes between the client and the server.
9. If the client presents a certificate chain to the server, it also sends a `certificate verify` message to prove that the private key for the certificate is included at the head of the chain.
10. The client sends a `change cipher spec` message to the server, which informs the server that the client will use the agreed-upon symmetric key to encrypt everything else that it sends to the server.
11. The client sends a `finished` message to the server to indicate that it has completed its portion of the handshake.
12. The server sends a `change cipher spec` message to the client, which informs the client that the server will use the agreed-upon symmetric key to encrypt everything else that it sends to the client.
13. The server sends a `finished` message to the client to indicate that it has completed its portion of the handshake.

TLS 1.3 uses a different handshake sequence that can require only a single round-trip to exchange the necessary information between the client and the server. TLS 1.2 requires two round-trips. To accomplish this task, TLS 1.3 tries to guess the type of key agreement that the server wants to use, and sends the relevant information to the server up front instead of waiting to hear from the server.

Because an extra round of communication between the client and server is eliminated, the server finishes its portion of the negotiation before the client. The server must assume that the client trusts its certificate chain. Because the server might log a successful negotiation only to discover late, through a TLS alert, that the client rejected the certificate, this approach might complicate certain types of troubleshooting.

Key agreement

Key agreement processing provides a critical component of TLS negotiation.

It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

RSA key exchange

The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.

Diffie-Hellman (DH) key exchange

The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE

versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, use ECHDE over DHE, and either of those options over RSA. The DH algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. The use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

LDAP StartTLS extended operation
In most scenarios, a client that uses TLS establishes a connection to a port that is dedicated to its use, like 636 (LDAPS) or 443 (HTTPS).

The client begins the TLS-negotiation process by sending a `client hello` message over the connection. In some scenarios, the client establishes a non-secure connection and later converts it to a secure one. In LDAP, this task is accomplished by using the **`StartTLS`** extended operation.

The **`StartTLS`** extended operation provides the following advantages over a dedicated LDAPS connection:

- To enable secure as well as insecure communication, only one port needs to be opened through a firewall.
- A client can use opportunistic encryption, in which the client performs the following steps:

  1. Queries the root DSE to determine whether the server supports StartTLS.
  2. Secures the connection, if possible.

  Opportunistic encryption is useful in scenarios like following referrals because LDAP URLs do not officially support LDAPS as a scheme.

To ensure that a communication is always secure, use LDAPS instead of establishing an insecure connection that you secure later with the **`StartTLS`** extended operation. If you enable support for unencrypted LDAP communication, as **`StartTLS`** requires, a client might send a password-containing bind request or other sensitive data over an unencrypted connection. A server can be configured to reject unencrypted communication, but it cannot prevent a client from sending an unencrypted request.

> ⓘ **Note:**
>
> Although you can use **`StartTLS`** to temporarily secure a connection before falling back on an unencrypted LDAP communication, PingDirectory Server does not support this strategy.

About the manage-certificates tool
PingDirectory Server offers a **`manage-certificates`** tool that enables interaction with Java KeyStore (JKS) and PKCS #12 key stores.

Although it behaves similarly to the **`keytool`** utility that accompanies most Java distributions, **`manage-certificates`** is easier to use, provides improved usage information, and offers additional functionality.

Available subcommands

The **`manage-certificates`** tool uses the following subcommands to indicate which function to invoke:

Subcommand	Function
`list-certificates`	Lists the certificates in a keystore.

Subcommand	Function
import-certificate	Imports a certificate into a trusted certificate entry or imports a certificate chain and private key into a private key entry.
export-certificate	Exports a certificate from a keystore.
export-private-key	Exports a private key from a keystore.
generate-self-signed-certificate	Generates a self-signed certificate.
generate-certificate-signing-request	Generates a certificate-signing request that can be provided to a certification authority.
sign-certificate-signing-request	Signs a certificate-signing request with a specified issuer certificate.
check-certificate-usability	Checks a specified certificate in a keystore to verify whether it is suitable for use as a listener certificate.
trust-server-certificate	Initiates the TLS-negotiation process with a specified server to obtain its certificate chain so that a truststore can be updated with the necessary information to trust the chain.
display-certificate-file	Displays the contents of a file that contains one or more PEM-encoded or DER-encoded X.509 certificates.
display-certificate-signing-request-file	Displays the contents of a file that contains a PEM-encoded or DER-encoded PKCS #10 certificate-signing request (CSR).
change-certificate-alias	Changes the alias for an entry in a keystore.
change-keystore-password	Changes the password for a keystore.
change-private-key-password	Changes the password that protects the private key for a specified entry in a keystore.

Common arguments

Most of the **manage-certificates** subcommands require access to a Java KeyStore (JKS) or PKCS #12 keystore. In such instances, use the --keystore argument to specify the path to the keystore.

If the keystore already exists, the tool detects automatically whether it is a JKS or PKCS #12 keystore. If the operation creates a new keystore, you can specify the type explicitly by using the --keystore-type argument, followed by a value of JKS or PKCS12. If you do not specify the keystore type, a default value of JKS is used.

Some situations require you to provide the password that is needed to access the keystore. For a JKS keystore, you might need to provide a keystore password only for operations that involve creating a keystore or accessing a private key. However, you will likely need to provide the password for all operations that involve a PKCS #12 keystore.

To provide a keystore password, use one of the following arguments:

- --keystore-password, followed by the clear-text password for the keystore.

- --keystore-password-file, followed by the path to a file that contains the password for the keystore. The file might contain the password in the clear, or it might be encrypted with a definition from the server's encryption-settings database.
- --prompt-for-keystore-password. If this argument is provided, the tool prompts you interactively to provide the password.

If a private key is protected with a different password than the keystore itself, specify one of the following arguments to provide the private key password:

- --private-key-password, followed by the plaintext password.
- --private-key-password-file, followed by the path to a file that contains the clear-text or encrypted password.
- --prompt-for-private-key-password, which causes the tool to prompt interactively for the password.

Several operations require you to specify the keystore entry to target. In such scenarios, provide the --alias argument, followed by the name of the alias for that entry.

Listing the certificates in a keystore
List the certificates available in a keystore.

Steps

- To list the certificates in a keystore, use the **`list-certificates`** subcommand.

  This subcommand requires you to specify the path to the keystore file, and possibly the password that is needed to access the keystore. The following options are also available:

Option	Description
--alias {alias}	Specifies the alias of the certificate to display. If this value is not provided, all certificates are displayed. To list more than one specific certificate, specify this value multiple times.
--display-pem-certificate	Includes a PEM-encoded representation of each certificate as part of the output.
--verbose	Includes details about each certificate.

  The following command demonstrates the basic listing of a keystore that contains a single certificate chain.

```
$ bin/manage-certificates list-certificates \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin

Alias:  server-cert (Certificate 1 of 2 in a chain)

Generating self-signed certificates

The process of creating a self-signed certificate is straightforward because a self-signed certificate claims itself as its own issuer.

Although self-signed certificates are convenient for testing environments, clients do not trust them by default. Consequently, you should not use them as listener certificates in production environments.

The **`manage-certificates`** tool offers a **`generate-self-signed-certificate`** subcommand that can create a self-signed certificate. In addition to the arguments that provide information about the keystore, certificate alias, and optional private key password, the following arguments are available.

Argument	Description
`--subject-dn {subject}`	Subject DN for the certificate to create. This value is required.
`--days-valid {number}`	Number of days that the certificate remains valid. Defaults to 365 if no value is specified.
`--validity-start-time {timestamp}`	Indicates the time at which the certificate begins its validity window. This value is assumed to reflect the local time zone, and must be expressed in the form YYYYMMDDhhmmss, where a value of 20190102030405 indicates January 2, 2019, at 3:04:05 AM. Defaults to the current time if no value is specified.
`--key-algorithm {name}`	Name of the algorithm to use when generating the key pair. For a listener certificate, this value is typically RSA or EC. Defaults to RSA if no value is specified. **Note:** This argument cannot be used in conjunction with the `--replace-existing-certificate` argument.

Argument	Description
`--key-size-bits {number}`	Length of the key, in bits, to generate. If the `--key-algorithm` argument is given, then `--key-size-bits {number}` must also be specified. Conversely, if the `--replace-existing-certificate` argument is given, then `--key-size-bits {number}` must not be specified. Typical key sizes are: ▪ RSA key – 2048 or 4096 bits If a default RSA key is used but this argument is not provided, a default key size of 2048 bits is used. ▪ Elliptic curve key – 256 or 384 bits
`--signature-algorithm {name}`	Name of the algorithm to use to sign the certificate. If the `--key-algorithm` argument is used to specify an algorithm other than RSA, then `--signature-algorithm {name}` must also be specified. If the `--replace-existing-certificate` argument is used, then `--signature-algorithm {name}` must not be specified. Typical signature algorithms include SHA256withRSA for certificates with RSA keys, and SHA256withECDSA for certificates with elliptic curve keys. If a default key algorithm is used but the `--signature-algorithm {name}` argument is not provided, a default value of SHA256withRSA is used.
`--replace-existing-certificate`	Uses the new certificate to replace an existing certificate in the key store (within the same alias), and reuses the key for that certificate.
`--inherit-extensions`	Indicates that, when replacing an existing certificate, the new certificate contains the same set of extensions as the existing certificate. If the `--replace-existing-certificate` argument is provided, but the `--inherit-extensions` argument is omitted, the new certificate contains only arguments that are provided explicitly.
`--subject-alternative-name-dns {name}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided DNS name. The given name must be fully qualified, although it can contain an asterisk (*) as a wildcard in the leftmost component. To include multiple DNS names in the subject alternative name extension, specify the `--subject-alternative-name-dns {name}` argument multiple times.

Argument	Description
`--subject-alternative-name-ip-address {address}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided IP address. The given address must be a valid IPv4 or IPv6 address. No wildcards are allowed. To include multiple IP addresses in the subject alternative name extension, specify the `--subject-alternative-name-ip-address {address}` argument multiple times.
`--subject-alternative-name-email-address {address}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided email address. To include multiple email addresses in the subject alternative name extension, specify the `--subject-alternative-name-email-address {address}` argument multiple times.
`--subject-alternative-name-uri {uri}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided URI. To include multiple URIs in the subject alternative name extension, specify the `--subject-alternative-name-uri {uri}` argument multiple times.
`--subject-alternative-name-oid {oid}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided object identifier (OID). The given value must be a valid OID. To include multiple OIDs in the subject alternative name extension, specify the `--subject-alternative-name-oid {oid}` argument multiple times.
`--basic-constraints-is-ca {value}`	Indicates that the certificate is expected to have a basic constraints extension, with a specified value of true or false, for the flag indicating whether to consider the certificate a certification authority that can be used to sign other certificates. ▪ For root and intermediate certificate authority (CA) certificates, the `--basic-constraints-is-ca {value}` argument must be present with a value of true. ▪ For end-entity certificates, the `--basic-constraints-is-ca {value}` argument can optionally be present with a value of false. ▪ For a self-signed certificate, specify the `--basic-constraints-is-ca {value}` argument with a value of false to indicate that the certificate is not considered a CA certificate.

Argument	Description
`--basic-constraints-maximum-path-length {number}`	Indicates that the basic constraints extension is expected to include a path length constraint element with the specified value. Use this argument only if `--basic-constraints-is-ca` is provided with a value of true. A path length constraint value of 0 indicates that the certificate can be used to issue only end-entity certificates. A path length constraint value of 1 indicates that the certificate can be used to sign end-entity certificates or intermediate CA certificates, the latter of which can be used to sign only end-entity certificates. A value greater than 1 indicates the presence of several intermediate CA certificates between it and the end-entity certificate at the head of the chain.
`--key-usage {value}`	Indicates that the certificate is expected to have a key usage extension with the specified value. The following values are allowed: ▪ digital-signature ▪ non-repudiation ▪ key-encipherment ▪ data-encipherment ▪ key-agreement ▪ key-cert-sign ▪ crl-sign ▪ encipher-only ▪ decipher-only To include multiple key usages, specify the `--key-usage {value}` argument multiple times.
`--extended-key-usage {value}`	Indicates that the certificate is expected to have an extended key usage extension with the specified value. The following values are allowed: ▪ server-auth ▪ client-auth ▪ code-signing ▪ email-protection ▪ time-stamping ▪ ocsp-signing

For example, the following command can be used to generate a self-signed server certificate.

```
bin/manage-certificates generate-self-signed-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --keystore-type JKS \
     --alias server-cert \
```

```
     --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
     --key-algorithm EC \
     --key-length-bits 256 \
     --signature-algorithm SHA256withECDSA \
     --subject-alternative-name-dns ds.example.com \
     --subject-alternative-name-dns ds1.example.com \
     --subject-alternative-name-dns localhost \
     --subject-alternative-name-ip-address 1.2.3.4 \

Generating certificate signing requests

A certificate signing request (CSR) contains all of the information that a certification authority requires to issue a certificate.

RFC 2986 defines the request format, also known as PKCS #10, and includes the following elements:

- Certificate signing request version
- Requested subject distinguished name (DN) for the certificate
- Public key for the requested certificate
- Requested set of extensions for the certificate
- Signature that proves the requester has the private key for the given public key

To create a certificate signing request, use the **`manage-certificates generate-certificate-signing-request`** command, which performs the following steps:

1. Generated a public and private key pair.
2. Stores the key pair in a key store with a given alias.
3. Outputs the certificate signing request to the terminal.
4. Optionally writes the certificate signing request to a file.

Because a certificate signing request contains many of the same elements as a certificate, the command to generate one takes most of the same arguments as for generating a self-signed certificate. The following arguments are unavailable when generating a CSR:

- `--replace-existing-certificate`
- `--days-valid {number}`
- `--validity-start-time {timestamp}`

The following arguments are available when generating a certificate signing request but not when generating a self-signed certificate:

`--output-file {path}`

Path to a file to which the certificate signing request is written. If this value is not provided, the request is written only to the terminal in PEM form.

`--output-format {value}`

Format to use when writing the certificate signing request. This value can be PEM or DER, but the DER format is used only in conjunction with the `--output-file` argument. Defaults to PEM if the `--output-format {value}` argument is not provided.

`--use-existing-key-pair`

Indicates that the CSR uses a key pair that already exists in the key store with the given alias, rather than generating a new key pair, in which case the specified alias must not already be in use in the key store.

The following example command creates a CSR.

```
bin/manage-certificates generate-certificate-signing-request \
     --output-file ds1-cert.csr \
     --output-format PEM \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --keystore-type JKS \
     --alias server-cert \
     --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
     --key-algorithm EC \
     --key-length-bits 256 \
     --signature-algorithm SHA256withECDSA \
     --subject-alternative-name-dns ds.example.com \
     --subject-alternative-name-dns ds1.example.com \
     --subject-alternative-name-dns localhost \
     --subject-alternative-name-ip-address 1.2.3.4 \
     --subject-alternative-name-ip-address 127.0.0.1 \
     --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
     --key-usage digital-signature \
     --key-usage key-encipherment \
     --key-usage key-agreement \
     --extended-key-usage server-auth \
     --extended-key-usage client-auth

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing
request.

Successfully wrote the certificate signing request to file
'/ds/build/package/PingDirectory/ds1-cert.csr'.
```

If the contents of the resulting CSR file are made available to a certification authority to be signed, the resulting signed certificate can be imported into the key store.

To print the contents of a certificate signing request file, use the **`display-certificate-signing-request-file`** subcommand, which supports the following arguments:

--certificate-signing-request-file {path}

Path to the file that contains the certificate signing request to display.

--verbose

Indicates that the command is expected to display verbose information about the request, rather than a basic information set.

The following example demonstrates the basic output from the command.

```
$ bin/manage-certificates display-certificate-signing-request-file \
    --certificate-signing-request-file ds1-cert.csr

    PKCS #10 Certificate Signing Request Version:  v1
    Subject DN:  CN=ds.example.com,O=Example Corp,C=US
    Signature Algorithm:  SHA-256 with ECDSA
    Public Key Algorithm:  EC (secP256r1)
```

The following example demonstrates the verbose output.

```
$ bin/manage-certificates display-certificate-signing-request-file \
     --certificate-signing-request-file ds1-cert.csr \
     --verbose

PKCS #10 Certificate Signing Request Version:  v1

```

Importing signed and trusted certificates

Use the **`manage-certificates import-certificate`** command to import certificates into a keystore.

This command is used to accomplish the following tasks:

- Import a certificate that a certification authority has signed into the keystore in which the key pair was generated. In this scenario, the certificate is imported into a private key entry and must be imported as a certificate chain rather than an end-entity certificate.
- Import a trusted issuer certificate into a trust store. In this scenario, the certificate is imported into a trusted certificate entry as a single certificate instead of as a chain.
- Import a certificate chain, along with the private key for the end-entity certificate. This approach imports certificates that were generated through another library, like OpenSSL.

In addition to the arguments that provide information about the key store and the alias into which the certificate or certificate chain is imported, the **`manage-certificates import-certificate`** command accepts the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to import. The certificate can be in PEM or DER format and can be a single certificate or a certificate chain. If the certificates in the chain reside in separate files, specify the --certificate-file {path} argument multiple times when you import a certificate chain.

`--private-key-file {path}`

Path to the file containing the private key that corresponds to the certificate at the head of the imported chain. The private key can be in PEM or DER format.

`--no-prompt`

Indicates that the certificate is to be imported without prompting for confirmation. By default, a summary of the certificate is displayed, and you must confirm that you want to import it.

The following example command imports a signed certificate into the key store that generates the certificate signing request.

```
$ bin/manage-certificates import-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --certificate-file ds1-cert.pem \
     --certificate-file ca-cert.pem

The following certificate chain will be imported into the keystore into
 alias
'server-cert', preserving the existing private key associated with that
 alias:

Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US

Do you want to import this certificate chain into the keystore? yes

Successfully imported the certificate chain.
```

If you do not provide the `--no-prompt` argument, the **`manage-certificates import-certificate`** tool still displays information about the certificates to import. To view additional information about a certificate before you import it, use the **`display-certificate-file`** subcommand, which supports the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to view.

`--verbose`

Displays verbose information about the certificate.

The output of the **`display-certificate-file`** subcommand has the same format and content as the **`list-certificates`** subcommand.

Exporting certificates

Use the **`export-certificate`** subcommand to export a single certificate or a certificate chain from a key store to a file in PEM or DER format.

The **`export-certificate`** subcommand supports the normal arguments about the key store and certificate alias, in addition to the following arguments:

`--output-file {path}`

Path to the file to which exported certificates are written. If this value is not provided, the certificates are written to standard output rather than a file.

`--output-format {format}`

Format in which exported certificates are written. The value can be PEM or DER, but the DER format can be used only if the output is written to a file. Defaults to PEM if no value is specified.

`--export-certificate-chain`

Indicates that a certificate chain, rather than the end-entity certificate only, is to be exported.

`--separate-file-per-certificate`

Indicates the use of separate output files for each exported certificate, rather than placing all of the certificates in a single file. If this argument is provided and multiple certificates are to be exported, then .1 is appended to the path for the indicated output file for the first certificate in the chain, .2 is appended for the second certificate, and so on.

The following example exports a certificate chain.

```
$ bin/manage-certificates export-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --output-file server-cert.pem \
     --output-format PEM \
     --export-certificate-chain \
     --separate-file-per-certificate

Successfully exported the following certificate to '/ds/server-cert.pem.1':
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
                     (3 hours, 26 minutes, 23 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
                           (364 days, 20 hours, 33 minutes, 36 seconds from
 now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint:
 02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb

1d:b5:eb:3c:f5:ff:bf:79:a2:a5:86:b8:e4:33:76:4d:d7:50:dc:a4:34:95:37:be:89:45:
86:1f:5d:79:c3:93

Successfully exported the following certificate to '/ds/server-cert.pem.2':
Subject DN:  CN=Example Root CA,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:00:07 PM CST
                     (3 hours, 35 minutes, 39 seconds ago)
Validity End Time: Saturday, November 5, 2039 at 10:00:07 PM CDT
                   (7299 days, 20 hours, 24 minutes, 20 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP384r1)
SHA-1 Fingerprint:
 0e:5c:21:c9:a5:36:0a:24:eb:aa:55:b6:a5:94:0e:e0:56:03:22:e6
SHA-256 Fingerprint:
   77:cf:66:d7:3c:8a:fd:67:2d:b7:36:fd:60:1d:ca:eb:1b:03:b1:12:7b:10:1f:26:
   05:b7:b9:0d:02:e0:38:3e
```

The **`export-certificate`** subcommand exports only the public portion of a certificate. Its private key is not included. To export the private key, use the **`export-private-key`** subcommand, which supports the following arguments, in addition to the usual key store and alias arguments:

`--output-file {path}`

Path to the file to which the exported private key is written. If this value is not provided, the key is written to standard output rather than a file.

`--output-format {format}`

Format in which the exported private key is written. The value can be PEM or DER, but the DER format is used only if the output is written to a file. Defaults to PEM if no value is specified.

The following code provides an example of the **`export-private-key`** subcommand .

```
$ bin/manage-certificates export-private-key \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --output-file server-cert-key.pem \
     --output-format PEM

Successfully exported the private key.
```

Using manage-certificates as a simple certification authority

If your PingDirectory Server instances need to support an arbitrary or unknown set of clients, configure them with certificates from a trusted issuer, such as a commercial authority or the free Let's Encrypt service.

About this task

If you control every client that accesses the servers, you might want to create your own internal certification authority so that you have a common issuer for all servers. In such a scenario, the clients need to trust only the certificates that the issuer signs. Commercial and open-source software packages provide full-featured certification authority functionality, but you can use the **`manage-certificates`** tool to create a certificate authority (CA) certificate that you can use to sign certificate-signing requests.

Steps

1. Create a CA certificate.

   A CA certificate is a self-signed certificate that possesses the following extensions:

   - A key usage extension that includes at least the keyCertSign usage
   - A basic constraints extension that identifies the certificate as a CA certificate

   If you do not plan to use an intermediate CA certificate, the basic constraints extension must have a path length constraint of 0. If you plan to use an intermediate CA certificate, the path length constraint must be 1. Because certificates that the CA certificate signs are valid only for as long as all certificates in the chain remain valid, we recommend that you specify a long lifespan for the CA certificate.

   The following example creates a new root CA certificate.

   ```
   $ bin/manage-certificates generate-self-signed-certificate \
        --keystore /ca/root-ca-keystore \
        --keystore-password-file /ca/root-ca-keystore.pin \
        --keystore-type JKS \
        --alias root-ca-cert \
        --subject-dn "CN=Example Root CA,O=Example Corp,C=US" \
        --days-valid 7300 \
        --key-algorithm RSA \
        --key-size-bits 4096 \
        --signature-algorithm SHA256withRSA \
        --basic-constraints-is-ca true \
        --basic-constraints-maximum-path-length 1 \
        --key-usage key-cert-sign \
        --key-usage crl-sign

   Successfully created a new JKS keystore.

   Successfully generated the following self-signed certificate:
   Subject DN:  CN=Example Root CA,O=Example Corp,C=US
   Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
   Validity Start Time: Monday, January 27, 2020 at 03:47:29 PM CST (0
    seconds ago)
   ```

```
Validity End Time: Sunday, January 22, 2040 at 03:47:29 PM CST
                   (7299 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
SHA-1 Fingerprint:
 bc:8e:5b:30:52:ec:03:63:b4:9a:aa:1a:45:a0:fc:84:49:dd:e8:64
SHA-256 Fingerprint:

 d5:47:06:cd:a2:95:42:61:1f:c7:aa:04:16:1e:c1:70:41:c4:44:48:bf:74:20:5f:1c:
   61:e2:aa:40:08:3a:ff
```

2. Export the public portion of the root CA certificate for future reference.

   When you import a signed certificate, you can import the public portion of the root CA certificate as a standalone certificate into trust stores as well as into part of a certificate chain.

3. Create a new certificate signing request to create an intermediate CA certificate,

   The certificate signing request uses essentially the same settings as the root CA. If you anticipate only a single intermediate CA, its basic constraints extension must have a path length constraint of 0, rather than 1, to indicate that it is used only to sign end-entity certificates and that it cannot create subordinate CA certificates by itself.

   The following example command creates a certificate signing request.

```
$ bin/manage-certificates generate-certificate-signing-request \
     --keystore /ca/intermediate-ca-keystore \
     --keystore-password-file /ca/intermediate-ca-keystore.pin \
     --keystore-type JKS \
     --alias intermediate-ca-cert \
     --subject-dn "CN=Example Intermediate CA,O=Example Corp,C=US" \
     --key-algorithm RSA \
     --key-size-bits 4096 \
     --signature-algorithm SHA256withRSA \
     --basic-constraints-is-ca true \
     --basic-constraints-maximum-path-length 0 \
     --key-usage key-cert-sign \
     --key-usage crl-sign \
     --output-file /ca/intermediate-ca-cert.csr \
     --output-format PEM

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing
request.

Successfully wrote the certificate signing request to file
'/ca/intermediate-ca-cert.csr'.
```

4. Use the root CA certificate to sign the certificate signing request for the intermediate CA certificate with the **`sign-certificate-signing-request`** subcommand.

   The **`sign-certificate-signing-request`** subcommand takes most of the same arguments as generating a self-signed certificate. The primary differences between the argument sets are as follows:

   - The key store that contains the certificate uses the provided key store arguments to sign the request. To specify the name of the certificate to use when signing the request, use the `--signing-certificate-alias` argument.
   - To specify the path to the file that contains the certificate signing request file to generate, provide a `--request-input-file` argument.
   - To specify the path to the file to which the signed certificate is written, provide a `--certificate-output-file` argument. If this argument is omitted, the PEM representation of the certificate is written to standard output.
   - To specify the format, PEM or DER, in which the certificate is written to the output file, provide an `--output-format` argument.
   - To specify the subject to use for the signed certificate, use the `--subject-dn` argument. To use the subject DN from the certificate signing request, omit this argument.
   - To specify the name of the signature algorithm, use the `--signature-algorithm` argument.

     > ⓘ **Note:**
     >
     > Because the requester generated the key, you cannot specify the key algorithm or the key length.

   - To indicate that the signed certificate includes every extension that is listed in the certificate signing request, use the `--include-requested-extensions` argument. If this argument is not provided, explicitly specify the set of extensions to include.

   The following example command signs the certificate signing request for an intermediate CA certificate.

   ```
   $ bin/manage-certificates sign-certificate-signing-request \
        --keystore /ca/root-ca-keystore \
        --keystore-password-file /ca/root-ca-keystore.pin \
        --signing-certificate-alias root-ca-cert \
        --days-valid 7300 \
        --include-requested-extensions \
        --request-input-file /ca/intermediate-ca-cert.csr \
        --certificate-output-file /ca/intermediate-ca-cert.pem \
        --output-format PEM

   Read the following certificate signing request:

   PKCS #10 Certificate Signing Request Version:  v1
   Subject DN:  CN=Example Intermediate CA,O=Example Corp,C=US
   Signature Algorithm:  SHA-256 with RSA
   Public Key Algorithm:  RSA (4096-bit)

   Do you really want to sign this request? yes

   Successfully wrote the signed certificate to file
   '/ca/intermediate-ca-cert.pem'.
   ```

5. After you obtain the intermediate CA certificate, create secure, offline backups of the root CA certificate.

6. Remove the root CA certificate, or at least its private key, from all systems.

> ⓘ **Note:**
>
> Make certain that all end-entity certificates are signed with the intermediate CA certificate, and that the process is identical to the previous example. Restore the root CA certificate only if you need to sign another intermediate CA certificate.

Enabling TLS support during setup
Enable TLS support in the server.

To enable TLS support in the server, you should complete one of the following tasks during the setup procedure:

- Provide a key store that contains the certificate to use.
- Make the installer generate a self-signed certificate.

When using the **`setup`** tool in interactive mode, it prompts you for the information that it needs to configure secure communication, as shown in the following example.

```
Do you want to enable the Directory Server services (Available State,
Available or Degraded State, Configuration, Consent, Directory REST API,
Documentation, SCIM2, and Swagger UI) and Administrative Console over
HTTPS?  After setup, you can selectively enable or disable individual
services and applications by configuring the HTTPS Connection Handler
(yes / no) [yes]: yes

On which port should the Directory Server accept connections from HTTPS
clients? [443]: 443

On which port should the Directory Server accept connections from LDAP
clients? [389]: 389

Do you want to enable LDAPS? (yes / no) [yes]: yes
On which port should the Directory Server accept connections from LDAPS
clients? [636]: 636

Do you want to enable StartTLS? (yes / no) [yes]: yes

Certificate server options:

    1)  Generate self-signed certificate (recommended for testing purposes
        only)
    2)  Use an existing certificate located on a Java Keystore (JKS)
    3)  Use an existing certificate located on a PKCS12 keystore
    4)  Use an existing certificate on a PKCS11 token

Enter option [1]: 2

Java Keystore (JKS) path: /ca/ds1-keystore
Keystore PIN: {password}

Truststore options:

    1)  Generate a default JKS truststore
    2)  Use an existing JKS truststore
    3)  Use an existing PKCS12 truststore

Enter option [1]: 2

JKS truststore path: /ca/truststore
```

```
Truststore password (can be blank): {password}
```

When using **setup** in non-interactive mode, use the following arguments to configure TLS support.

Argument	Description
`--ldapsPort {port}`	Server enables support for LDAPS (LDAP over TLS) on the specified TCP port.
`--httpsPort {port}`	Server enables support for HTTPS for SCIM, the Directory REST API, and the web-based administration console on the specified TCP port.
`--enableStartTLS`	LDAP connection handler enables support for the StartTLS extended operation.
`--generateSelfSignedCertificate`	**setup** generates a self-signed certificate that is presented to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--useJavaKeyStore {path}`	Server uses the specified Java KeyStore (JKS) key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--usePKCS12KeyStore {path}`	Server uses the specified PKCS #12 key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--usePKCS11KeyStore`	Server uses a PKCS #11 key store, like a hardware security module, to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation. The Java Virtual Machine (JVM) must already be configured to access the appropriate key store through PKCS #11.
`--keyStorePassword {password}`	Password that is needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store. The **setup** tool assumes that the private key password matches the key store password.
`--keyStorePasswordFile {path}`	Path to the file that contains the password needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store.
`--certNickname {alias}`	Alias of the private key entry in the specified key store that contains the certificate chain to present to clients during TLS negotiation. This argument is optional but recommended if the key store contains multiple certificates.
`--useJavaTrustStore {path}`	Server uses the specified JKS trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation.

Argument	Description
`--usePKCS12TrustStore {path}`	Server uses the specified PKCS #12 trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation
`--trustStorePassword {password}`	Password that is needed to interact with the specified JKS or PKCS #11 trust store.
`--trustStorePasswordFile {path}`	Path to the file that contains the password needed to interact with the specified JKS or PKCS #11 trust store.

The following example command sets up PingDirectory Server in non-interactive mode with an existing certificate.

```
$ ./setup \
     --no-prompt \
     --acceptLicense \
     --ldapPort 389 \
     --ldapsPort 636 \
     --httpsPort 443 \
     --enableStartTLS \
     --useJavaKeyStore config/keystore \
     --keyStorePasswordFile config/keystore.pin \
     --certNickname server-cert \
     --useJavaTrustStore config/truststore \
     --trustStorePasswordFile config/truststore.pin \
     --baseDN dc=example,dc=com \
     --rootUserDN "cn=Directory Manager" \
     --rootUserPasswordFile root-pw.txt \
     --maxHeapSize 10g \
     --encryptDataWithPassphraseFromFile encryption-settings-password.txt \
     --instanceName ds1 \
     --location Austin \
     --noPropertiesFile

Ping Identity Directory Server 8.0.0.0

Enabling TLS support after setup

If the server has been set up without support for TLS, enable TLS support later by completing the following tasks.

Steps

1. Obtain a certificate chain.

   For more information about obtaining a certificate chain, see *Certificate chains* on page 322. To prepare a Java KeyStore JKS or PKCS #12 key store with an appropriate certificate chain and private key, use the **`manage-certificates`** tool. We also recommend that you create a trust store that the server can use.

2. Configure the key and trust manager providers.

   For more information, see *Configuring key and trust manager providers* on page 350.
3. Configure connection handlers.

   For more information, see *Configuring connection handlers* on page 350.

Configuring key and trust manager providers
After you have a key store, configure a key manager provider to access it.

The server is preconfigured with key manager providers, `JKS` and `PKCS12`, that you can use with JKS or PKCS #12 key stores, respectively. You can update the appropriate key manager provider in most cases to reference the key store that you plan to use. The following code provides an example.

```
dsconfig set-key-manager-provider-prop \
     --provider-name JKS \
     --set enabled:true \
     --set key-store-file:config/keystore \
     --set key-store-pin-file:config/keystore.pin
```

A similar change configures a trust manager provider to reference the appropriate trust store. The following code provides an example.

```
dsconfig set-trust-manager-provider-prop \
     --provider-name JKS \
     --set enabled:true \
     --set include-jvm-default-issuers:true \
     --set trust-store-file:config/truststore
     --set trust-store-pin-file:config/truststore.pin
```

ⓘ **Note:**

If all clients and servers use certificates that are signed by issuers and are included in the JVM's default trust store, you can use the `JVM-Default` trust manager provider to accomplish this task.

Configuring connection handlers
After you configure the key and trust manager providers, update the connection handlers to use the key and trust manager providers.

Steps

- For the LDAP connection handler, use the following command to enable StartTLS with a configuration change. By default, the LDAP connection handler accepts non-secure connections.

  ```
  dsconfig set-connection-handler-prop \
    --handler-name "LDAP Connection Handler" \
    --set allow-start-tls:true \
    --set key-manager-provider:JKS \
    --set trust-manager-provider:JKS \
    --set ssl-cert-nickname:server-cert \
    --set ssl-client-auth-policy:optional
  ```
- If you did not configure secure communication during setup, the LDAPS connection handler is disabled. To configure LDAPS support in this scenario, enable the connection handler and configure most of the same settings. You must set allow-start-tls to `false` and use-ssl to `true`. See the following code for an example configuration.

  ```
  dsconfig set-connection-handler-prop \
    --handler-name "LDAPS Connection Handler" \
    --set enabled:true \
  ```

```
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert \
  --set ssl-client-auth-policy:optional
```

The following example uses a similar configuration change to enable the HTTPS connection handler.

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true \
  --set listen-port:443 \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert
```

Updating the topology registry

After the server connection handlers are updated to enable TLS, update the topology registry to provide information about the new configuration.

The topology registry holds information about server instances that are part of the environment, and it helps to facilitate inter-server communication, such as replication, mirroring portions of the configuration, and PingDirectory Server's automatic backend server-discovery functionality.

The following table details the two types of entries that require updating.

Configuration types and their update descriptions

Configuration Type	Update description

Server instance listener configuration	▪ Provides information that is needed to trust the TLS certificates that instances in the topology present.
	▪ The server instance listener configuration must include the server certificate, which is defined as the certificate at the head of the chain. This version must be the multi-line, PEM-formatted representation of the certificate. You can use **`dsconfig`** to import the certificate from a file, as shown in the following example.
	`bin/dsconfig set-server-instance-listener-prop \`
	`  --instance-name ds1 \`
	`  --listener-name ldap-listener-mirrored-config \`
	`  --set server-ldap-port:636 \`
	`  --set connection-security:ssl \`
	`  --set 'listener-certificate>/ca/ds1-cert.pem'`
	Note:
	The less-than operator > in the final line indicates that the value is read from a file rather than provided directly. In addition, you might not need to enclose the property name and path within single straight quotes to prevent the shell from interpreting the less-than symbol as an attempt to redirect input.

Server instance configuration	▪ Provides information about options for communicating with those instances.
	▪ Update the server instance configuration object to reflect the new methods that are available for communication with the instance. For example, the `preferred-security` property identifies the mechanism by which other instances in the topology attempt to communicate with the instance.
	The following example code sets the LDAPS and HTTPS ports, indicates that StartTLS support is enabled, and instructs other instances to use SSL (LDAPS) when communicating with the instance.
	`dsconfig set-server-instance-prop \`
	`  --instance-name ds1 \`
	`  --set ldaps-port:636 \`
	`  --set https-port:443 \`
	`  --set preferred-security:ssl \`
	`  --set start-tls-enabled:true`

Troubleshooting TLS-related issues

Use this section for troubleshooting problems that might arise during TLS configuration, including communication and security issues that affect clients as well as PingDirectory Server.

- *Log messages*
- *manage-certificates check-certificate-usability*
- *ldapsearch*
- *Using low-level TLS debugging*

Log messages

The following describes how to use the server's log messages to troubleshoot TLS-related issues.

To troubleshoot TLS-related issues, start by checking the server's access log. If the client can establish a TCP connection to the server, which must occur before TLS negotiation can start, the access log shows a `CONNECT` message with the following information:

- Source and destination address and port for the connection
- Protocol
- Selected client connection policy

The `CONNECT` message does not appear

If the `CONNECT` does not appear, the client might be unable to communicate with the server. The culprit can be a network problem, a firewall that is blocking attempts to communicate, or the client is trying to use an incorrect address or port.

The `CONNECT` message does appear

If the `CONNECT` message appears in the access log, it typically includes a `conn` element that specifies the connection ID. To view additional log messages for the client connection, use the **`search-logs`** tool. For example, if the connection ID is `12345`, the following command displays the complete set of associated log messages.

```
$ bin/search-logs --logFile logs/access conn=12345
```

If you are using LDAPS

If you are attempting to use LDAPS, one of the following log messages appears next:

- `SECURITY-NEGOTIATION` message – Indicates that the client and server successfully completed the negotiation process and that the issue likely occurred after the TLS session was established. This message also includes details about the negotiation, including the TLS protocol and the selected cipher suite.
- `DISCONNECT` message – The issue might involve a failure in the TLS-negotiation process. In such scenarios, the message usually includes a `reason` element that provides additional information about the reason for the disconnect.

  If the failure occurred during TLS negotiation, the usefulness of the `DISCONNECT` message depends in part on whether the failure occurred on the client or the server. For example, if the server decided to abort the negotiation, the message ideally contains the specific reason. If the problem occurred on the client, the log message likely contains only the general category for the failure.

> ⓘ **Note:**
>
> The TLS protocol does not provide a mechanism for conveying detailed error messages. Instead, it offers only a basic alert mechanism with a fixed set of alert types. For example, if a client does not trust the certificate chain that the server presents to it, the server might receive a generic alert like `certificate_unknown`, even if the client knows the precise reason for rejecting the chain. In such

instances, you might need to determine whether the client can provide additional details about the issue.

If the access log does not provide useful information

If the access log does not provide useful information, check the server error log. Although the error log does not normally include information about issues that relate to client communication, it provides helpful information in certain circumstances, like when an internal error within the server interferes with communication attempts.

manage-certificates check-certificate-usability
The **`manage-certificates`** tool offers a **`check-certificate-usability`** subcommand to examine a specified entry in a key store and to identify potential issues that might interfere with secure communication.

The **`check-certificate-usability`** tool completes the following tasks:

- Ensures that a specified entry in the key store includes a private key and a complete certificate chain
- Checks whether the certificate at the root of the chain is found in the Java virtual machine's (JVM's) default set of trusted certificates
- Ensures that the current time lies is within the validity window for all certificates in the chain
- Validates the signatures for all certificates in the chain
- Warns if the end-entity certificate is self-signed
- Warns if the end-entity certificate does not contain an extended key usage extension with the `serverAuth` usage
- Warns if the issuer certificates do not have a key usage extension with the `keyCertSign` usage
- Warns if the issuer certificates do not have a basic constraints extension indicating that it can operate as a certification authority

  If the chain violates a path length constraint, the **`check-certificate-usability`** tool reports an error.
- Ensures that the signature algorithm uses a strong message digest algorithm, like SHA-256

  The **`check-certificate-usability`** tool reports an error for weak digest algorithms like MD5 or SHA-1, and reports a warning for unrecognized digest algorithms.
- Ensures that none of the certificates that use an RSA key pair have a key size less than 2048 bits

The following example demonstrates the usage for the **`manage-certificates check-certificate-usability`** command and its output when no problems are identified.

```
$ bin/manage-certificates check-certificate-usability \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert

Successfully retrieved the certificate chain for alias 'server-cert':

Subject DN:  CN=ds1.example.com,O=Example Corp,C=US

OK:  The certificate chain is complete.  Each subsequent certificate is
the issuer for the previous certificate in the chain, and the chain ends
with a self-signed certificate.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' has a valid
signature.

OK:  Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a
valid signature.

OK:  Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a valid
signature.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' will expire at
Wednesday, November 11, 2020 at 03:52:44 PM CST (364 days, 23 hours, 54
minutes, 14 seconds from now), which is not in the near future.

OK:  Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US'
will expire at Monday, November 7, 2039 at 03:52:42 PM CST (7299 days, 23
hours, 54 minutes, 12 seconds from now), which is not in the near future.

OK:  Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' will
expire at Monday, November 7, 2039 at 03:52:38 PM CST (7299 days, 23
hours, 54 minutes, 8 seconds from now), which is not in the near future.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' at the head of
the chain includes an extended key usage extension, and that extension
includes the serverAuth usage.

OK:  Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US'
includes a basic constraints extension, and the certificate chain
```

```
satisfies those constraints.

OK:  Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US'
includes a key usage extension with the keyCertSign usage flag set to
true.

OK:  Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes
a basic constraints extension, and the certificate chain satisfies those
constraints.

OK:  Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes
a key usage extension with the keyCertSign usage flag set to true.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' uses a signature
algorithm of 'SHA-256 with RSA', which is is considered strong.

OK:  Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' uses a
signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK:  Certificate 'CN=Example Root CA,O=Example Corp,C=US' uses a signature
algorithm of 'SHA-256 with RSA', which is is considered strong.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' has a 2048-bit
RSA public key, which is considered strong.

OK:  Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a
4096-bit RSA public key, which is considered strong.

OK:  Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a 4096-bit
RSA public key, which is considered strong.

No usability errors or warnings were identified while validating the
certificate chain.
```

If any usability issues are identified, they might be responsible for communication problems.

ldapsearch

The **`ldapsearch`** command-line utility is a powerful tool for issuing searches against an LDAP directory server. It also provides a convenient method for troubleshooting a variety of issues, including problems that are relevant to TLS communication.

The following table details arguments that are the most useful for TLS-related communication.

TLS-related communication arguments and their descriptions

Argument	Description
--hostname {address}	Address of the server to which the connection is established
--port {port}	TCP port of the server to which the connection is established. The standard port for non-secure LDAP, or LDAP to be secured with StartTLS, is 389, and the standard port for secure LDAPS is 636. Many deployments use alternate ports, especially non-privileged ports above 1024.
--useSSL	The tool establishes an initially insecure LDAP connection, which is secured later with the StartTLS extended operation.

Argument	Description
--trustStorePath {path}	Path to the trust store that is used when determining whether to trust the certificate chain that the server presents during TLS negotiation. If neither this argument nor the --trustAll argument is provided, the tool prompts you interactively whether to trust server certificates that are not signed by an issuer in the Java virtual machine's (JVM's) default trust store.
--trustStoreFormat {format}	Format for the trust store, which is typically JKS or PKCS12.
--trustStorePassword {password}	Password that is required to access the contents of the trust store.
--trustStorePasswordFile {path}	Path to the file that contains the password that is required to access the contents of the trust store.
--trustAll	The tool blindly trusts all TLS certificate chains that are presented to it. Although this argument can prove useful for troubleshooting purposes, it is not recommended for general use.
--keyStorePath {path}	Path to the key store to use if a client certificate chain is presented to the server. ⓘ **Note:** Use this argument only when one of the following conditions is satisfied: ▪ The server is configured to require clients to present a certificate. ▪ You intend to use the certificate to authenticate through SASL EXTERNAL.
--keyStoreFormat {format}	Format for the key store, which is typically JKS or PKCS12.
--keyStorePassword {password}	Password to access the key store.
--keyStorePasswordFile {path}	Path to the file that contains the password necessary to access the key store.
--certNickname {alias}	Alias of the private key entry in the key store. Use when obtaining the certificate chain to present to the server.
--useSASLExternal	The client authenticates with the EXTERNAL SASL mechanism, which typically identifies the client using the certificate chain that is presented during TLS negotiation.

Argument	Description
--enableSSLDebugging	The tool activates the low-level TLS-debugging feature that the JVM provides.

The following command provides an example of the simplest method for testing TLS communication with PingDirectory Server.

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
The server presented the following certificate chain:

     Subject: CN=ds1.example.com,O=Example Corp,C=US
     Valid From: Tuesday, November 12, 2019 at 08:28:08 PM CST
     Valid Until: Wednesday, November 11, 2020 at 08:28:08 PM
 CST

```

Trust stores and trust-related arguments

If no trust-related arguments are provided, the tool uses the JVM's default trust store to verify whether to trust the certificate chain, based on the information that it contains. If a trusted authority has signed the server certificate, the negotiation process continues without further interaction.

If the chain cannot be trusted, based on the information in the JVM-default trust store, **ldapsearch** prompts you interactively about whether to trust the certificate. If you accept the chain, the client and server complete the negotiation process, and the client sends the search request to the server. If the search succeeds, the server can communicate over TLS.

To test with a trust store instead of being prompted interactively, use the --trustStorePath argument that points to the appropriate trust store. If you are using a Java Keystore (JKS) trust store, you might not need to provide the trust store password. If you are using a PKCS #12 trust store, you need to provide the trust store password. The following code provides an example.

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore.p12 \
     --trustStorePasswordFile config/truststore.pin \
     --trustStoreFormat PKCS12 \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

Client certificate chains and key stores

To present a client certificate chain to the server, either because the server's connection handler is configured with an ssl-client-auth-policy value of required or because you plan to use the certificate to authenticate by way of the SASL EXTERNAL mechanism, provide at least the key store and its corresponding password. You can also specify the alias of the certificate chain to present, which is recommended if your client key store contains multiple certificates. The following code provides an example.

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore.p12 \
     --trustStorePasswordFile config/truststore.pin \
     --trustStoreFormat PKCS12 \
     --keyStorePath client-keystore \
     --keyStorePasswordFile client-keystore.pin \
     --certNickname client-cert \
     --useSASLExternal \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
```

```
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

If you need to further troubleshoot a TLS-related issue

If you encounter a TLS-related issue that you cannot resolve by examining the **`ldapsearch`** output or the server logs, use the --enableSSLDebugging option to enable the JVM's support for low-level debugging of TLS processing. For more information, see *Using low-level TLS debugging* on page 360.

Using low-level TLS debugging
Use tools other than the command-line tools that are provided with PingDirectory Server for performing low-level TLS debugging.

Before you begin

> ⓘ **Note:**
>
> If you need to use low-level debugging options, enable the Java Virtual Machine (JVM)'s support for TLS debugging. Many of the command-line tools that are provided with PingDirectory Server, such as **`ldapsearch`**, offer an --enableSSLDebugging argument that simplifies this process.

Steps

1. In the `config/java.properties` file, add the following line to the set of properties for the appropriate tool.

   ```
   -Djavax.net.debug=all
   ```

2. For the changes to take effect, run the **`bin/dsjavaproperties`** command.

Next steps

The next time the tool is run, an output is generated detailing the TLS-related processing that the JVM is performing. You and the support team can use the output to identify the issue.

Using the Configuration API

PingDirectory Server provides a Configuration API when updating the server configuration with LDAP is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers allow the application/json content type.

About this task
The server includes a servlet extension that provides read and write access to the server's configuration over HTTP.

Steps

- To add the extension to one of the server's HTTP Connection Handlers, run the following code.

  ```
  $ bin/dsconfig set-connection-handler-prop \
  ```

```
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:Configuration
```

> ⓘ **Note:**
>
> By default, the extension is enabled for new installations. You can enable the extension for existing deployments.

The API is made available on the HTTPS Connection Handler's host:port in the `/config` context. Due to the potentially sensitive nature of the server's configuration, use the HTTPS Connection Handler for hosting the configuration extension.

Authentication and authorization with the Configuration API
Use this topic for how to make changes for customizing authentication and authorization access with the Configuration API.

Authentication

Clients must use HTTP basic authentication to authenticate to the Configuration API. If the username value is not a distinguished name (DN), then it resolves to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a username. To customize this behavior, either customize the default identity mapper or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. The following code provides an example.

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Configuration \
  --set "identity-mapper:Alternative Identity Mapper”
```

Authorization

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACI.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

The Configuration API and the dsconfig tool relationship
The Configuration API is designed to mirror the **`dsconfig`** tool, using the same names for properties and object types.

Property names are presented as hyphen case in **`dsconfig`** and as camel-case attributes in the API. In API requests that specify property names, case is not important. `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the **`dsconfig list-connection-handlers`** command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a local database backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the **`dsconfig`** tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the System for Cross-domain Identity Management (SCIM) specification. Request specific attributes using the attributes query parameter, whose value must be a comma-delimited list of properties to be returned, such as `attributes=baseDN,description`. You can exclude attributes from responses by specifying the excludedAttributes parameter.

Configuration API operations supported in REST APIs

HTTP Method	Description	Related dsconfig Example
GET	Lists the properties of an object when used with a path representing an object, such as `/config/global-configuration` or `/config/backends/userRoot`. Can also list objects when used with a path representing a parent relation, such as `/config/backends`.	▪ **`get-backend-prop`** ▪ **`list-backends`** ▪ **`get-global-configuration-prop`**
POST	Creates a new instance of an object when used with a relation parent path, such as `/config/backends`.	**`create-backend`**
PUT	Replaces the existing properties of an object. A PUT operation is similar to a PATCH operation, except that the PATCH identifies the difference between an existing target object and a supplied source object. Only those properties in the source object are modified in the target object. The target object is specified using a path, such as `/config/backends/userRoot`.	▪ **`set-backend-prop`** ▪ **`set-global-configuration-prop`**
PATCH	Updates the properties of an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	▪ **`set-backend-prop`** ▪ **`set-global-configuration-prop`**
DELETE	Deletes an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	**`delete-backend`**

ⓘ **Note:**

The `OPTIONS` method can also be used to determine the operations permitted for a particular path.

Object names, such as userRoot in the description column, must be URL-encoded for use in the path segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent, %, character. The following URL is for accessing the HTTP Connection Handler object.

```
/config/connection-handlers/http%20connection%20handler
```

GET example

This topic provides an example of a GET request and response concerning the userRoot backend for reference.

GET request

The following code example is a GET request for information about the **`userRoot`** backend.

```
GET /config/backends/userRoot
```

```
Host: example.com:5033
Accept: application/scim+json
```

GET response

The following code example is the response.

```

      ],
      "id": "alarms",
      "meta": {
        "resourceType": "Alarm Backend",
        "location": "http://localhost:5033/config/backends/alarms"
      },
  ...
```

PATCH example

Modify the Configuration API using the HTTP PATCH method.

The PATCH request body is a JSON object formatted according to the System for Cross-domain Identity Management (SCIM) patch request. The Configuration API supports a subset of possible values for the path attribute that indicates the configuration attribute to modify.

Modify the configuration object's attributes according to the information in the following table, which details the comparable `dsconfig modify-[object]` options to each PATCH request.

Operations and PATCH requests to modify the configuration object's attributes

Operation	PATCH request	Comparable `dsconfig modify-[object]` options
Set the single-valued `description` attribute to a new value.	`{ "op" : "replace", "path" : "description", "value" : "A new backend." }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --set "description:A new backend"`
Add a new value to the multi-valued `jeProperty` attribute.	`{ "op" : "add", "path" : "jeProperty", "value" : "je.env.backgroundReadLi`	`$ dsconfig set-backend-prop --backend-name userRoot \ --add je-property:je.env.backgroundReadLimi`
Remove a value from a multi-valued property. In this case, path specifies a SCIM filter identifying the value to remove.	`{ "op" : "remove", "path" : "[jeProperty eq \"je.cleaner.adjustUtili \"]" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --remove je-property:je.cleaner.adjustUtilizat`
Second operation to remove a value from a multi-valued property, where the `path` specifies both an attribute to modify and a SCIM filter whose attribute is the following value.	`{ "op" : "remove", "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]`	`$ dsconfig set-backend-prop --backend-name userRoot \ --remove je-property:je.nodeMaxEntries=32`
Option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value.	`{ "op" : "remove", "path" : "id2childrenIndexEntryLi }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --reset id2childrenIndexEntryLimit`

The following is the full example request.

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json

{
  "schemas" :
 [ "urn:ietf:params:scim:api:messages:2.0:PatchOp" ],
  "Operations" : [ {
    "op" : "replace",
    "path" : "description",
    "value" : "A new backend."
```

```
  }, {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }, {
    "op" : "remove",
    "path" : "[jeProperty eq
 \"je.cleaner.adjustUtilization=false\"]"
  }, {
    "op" : "remove",
    "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
  }, {
    "op" : "remove",
    "path" : "id2childrenIndexEntryLimit"
  } ]
}
```

The API responds with the entire modified configuration object, which can include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions. The following is an example response.

```
{
 "schemas": [
   "urn:unboundid:schemas:configuration:2.0:backend:local-db"
 ],
 "id": "userRoot2",
 "meta": {
   "resourceType": "Local DB Backend",

          of the backend must be exported to LDIF and re-imported
 to
          allow the new limit to be used for any id2children keys
          that had already hit the previous limit."
     }
   ]
 }
```

```
}
```

Configuration API paths

The Configuration API and supported sub-paths are available under the `/config` path.

A full listing of supported sub-paths is available when you access the base `/config/ResourceTypes` endpoint.

```
GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json
```

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted or created. These paths can be differentiated from others by their singular, rather than plural, relation name, such as `global-configuration`.

The following sample response is abbreviated.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],

        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/
ResourceTypes/access-control-handler"
      }
    },
    {
 ...
```

The response's `endpoint` elements enumerate all available sub-paths. You can use the path `/config/access-control-handler` in the example to get a list of existing access control handlers and create new ones. You can use a path containing an object name, such as `/config/backends/{backendName}` (where `{backendName}` corresponds to an existing backend like `userRoot`) to obtain an object's properties, update the properties, or delete the object.

Sort and filter objects

The Configuration API supports System for Cross-domain Identity Management (SCIM) parameters for filter, sorting, and pagination.

Search operations can specify a SCIM filter to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters, or paging parameters. Include or exclude attributes can be specified in both GET and list operations.

GET Parameter	Description
filter	Values can be simple SCIM filters, such as `id eq "userRoot"`, or compound filters like `meta.resourceType eq "Local DB Backend"` and `baseDn co "dc=exmple,dc=com"`.
sortBy	Specifies a property value by which to sort.
sortOrder	Specifies either `ascending` or `descending` alphabetical order.
startIndex	1-based index of the first result to return.
count	Indicates the number of results per page.

Update properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH.

With PUT, the server computes the differences between the object in the request with the current version in the server and performs modifications where necessary. The server never removes attributes that are not specified in the request. The API responds with the entire modified object.

Sample request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
  "description" : "A new description."
```

```
}
```

Sample response:

```
{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],
  "id": "userRoot",
  "meta": {

  "writabilityMode": "enabled"
}
```

Administrative actions

Updating a property might require an administrative action before changes can take effect.

If you need administrative actions to update a property, the server returns `200 Success`. Any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

For example, changing the `jeProperty` of a backend results in the following:

```
"urn:unboundid:schemas:configuration:messages:2.0": {
    "required-actions": [
      {
       "property": "baseContextPath",
       "type": ""componentRestart",
       "synopsis": "In order for this modification to take
 effect, the component
                   must be restarted, either by disabling and re-
enabling it, or
                   by restarting the server"
      },
      {
        "property": {
        "type": "other",
        "synopsis": "If this limit is increased, then the
                  contents of the backend must be exported to
 LDIF
                  and re-imported to allow the new limit to be
 used
                  for any id2children keys that had already hit
 the
                  previous limit."
      }
    ]
```

```
  }
```

Updating servers and server groups
You can configure servers as part of a server group so that configuration changes applied to a single server are applied to all servers in a group.

When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query attribute. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `single-server` or `server-group` can be specified.

```
http://localhost:8082/config/backends/userRoot?
applyChangeTo=single-server
```

Configuration API responses
Clients of the API should examine the HTTP response code to determine the success or failure of a request.

The following are response codes and their meanings.

Response Code	Description	Response Body
200 Success	The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the `urn:unboundid:schemas:configuration:messages:2.0` object.	List of objects, object properties, or administrative actions
204 No Content	The requested operation succeeded and no further information has been provided, as in the case of a DELETE operation.	None
400 Bad Request	The request contents are incorrectly formatted or a request is made for an invalid API version.	Error summary and optional message
401 Unauthorized	User authentication is required. Some user agents, such as browsers, might respond by prompting for credentials. If the request specified credentials in an Authorization header, they are invalid.	None
403 Forbidden	The requested operation is forbidden, either because the user does not have sufficient privileges or some other constraint, such as an object is edit-only and cannot be deleted.	None
404 Not Found	The requested path does not refer to an existing object or object relation.	Error summary and optional message

Response Code	Description	Response Body
409 Conflict	The requested operation could not be performed due to the current state of the configuration. For example, an attempt was made to create an object that already exists, or an attempt was made to delete an object that is referenced by another object.	Error summary and optional message
415 Unsupported Media Type	The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.	None
500 Server Error	The server encountered an unexpected error. Report server errors to Customer Support.	Error summary and optional message

ⓘ **Note:**

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages can change, and their presence can depend on server configuration. Use the HTTP return code and the context of the request to create a client error message.

The following is an example encoded error message.

```
{
 "schemas": [
   "urn:ietf:params:scim:api:messages:2.0:Error"
 ],
 "status": 404,
 "scimType": null,
 "detail": "The Local DB Index does not exist."
}
```

Working with the Directory REST API

The Directory REST API is the native interface for client access to the PingDirectory Server. Instead of trying to manage directory hierarchy or require attribute mapping, the Directory REST API provides direct access to directory data in a way that is dynamic, discoverable, and efficient.

Before you begin

The Directory REST API gives developers who are more comfortable with REST than LDAP access to arbitrary directory data in a way that ensures directory data remains consistent regardless of whether it is accessed from LDAP or REST. The Directory API is enabled during server setup. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.

While both the Directory REST API and System for Cross-domain Identity Management (SCIM) provide REST access to directory data, the goals of the two protocols are different. SCIM is useful to generic, external clients that require simple, narrow access to identity data, but because it is a less common standard for identity stores, it might not offer as much functionality or be as user-friendly as the Directory REST API.

The Directory REST API can be used for the following operations.

HTTP operation	Resource endpoint	Description	Allowed query parameters
DELETE	**/directory/v1/{dn}**	Delete an entry.	
GET	**/directory/v1**	Get metadata about the API and server.	
GET	**/directory/v1/{dn}**	Retrieve a single entry.	▪ expand ▪ includeAttributes ▪ excludeAttributes
GET	**/directory/v1/{dn}/subtree**	Search an entry's descendants.	▪ filter ▪ searchScope ▪ cursor ▪ limit ▪ includeAttributes ▪ excludeAttributes
GET	**/directory/v1/schemas**	Retrieve the schemas of all available object classes.	
GET	**/directory/v1/schemas/{objectclass}**	Retrieve schema for a specific object class.	
GET	**/directory/v1/schemas/_operationalAttributes**	Retrieve schema for operational attributes.	
GET	**/directory/v1/me**	Alias for retrieving the current user.	
PATCH	**/directory/v1/{dn}**	Modify an entry (add or delete values).	expand
POST	**/directory/v1**	Create a new entry.	expand
PUT	**/directory/v1/{dn}**	Modify or rename an entry.	expand

Steps

- Configure the Directory REST API with any of the following properties using **dsconfig**:

Command	Description
basic-auth-enabled	Specifies whether users can connect to the service with HTTP Basic authentication. If disabled, users need a bearer token. If changed, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled. Basic authentication is enabled by default.
identity-mapper	If HTTP Basic authentication is enabled, the identity mapper referenced by this distinguished name (DN) must be used to map the

Command	Description
	user names provided to user entries. By default, an identity mapper is provided, which maps a fully-qualified DN to an entry. For changes to take effect, the server must be restarted, or any HTTP connection handlers referencing this service disabled and re-enabled.
access-token-validator	Specifies the subset of this server's Access Token Validators (by DN), which can validate Bearer authentication tokens. By default, if no validators are specified, then any of the validators on the server can be used. For changes to take effect, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled.
access-token-scope	The scope that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, Bearer token authentication is disabled, and only Basic authentication is used. By default, no value is provided. Changes to this value take effect immediately.
audience	A string or URI audience that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, any audience is acceptable. By default, no value is provided. Changes to this value take effect immediately.
max-page-size	The maximum number of entries to be returned in one page from the search endpoint. Actual results returned might be lower due to the limit query parameter on the request and the actual number of available results. The value must be an integer between 1 and 1000. The default value is 100. Changes to this value take effect immediately.
schemas-endpoint-objectclass	The list of object classes that will be returned by the **/schemas/** endpoint in the REST API. By default, no schemas are returned. Changes to this value take effect immediately.

The following example uses **dsconfig** to configure an **objectClass** entity.

```
dsconfig set-http-servlet-extension-props --extension-name "Directory REST
 API" \
  --add schemas-endpoint-objectclass:ubidPerson
```

Configuring the Server using the Administrative Console

The PingDirectory Server provides an administrative console for server configuration and monitoring that has the same functionality as the **dsconfig** command.

When signing on to the Administrative Console, the console does not persistently store any credentials for authenticating to the Directory Server. Instead, the console uses the credentials provided by the user when signing on.

When managing multiple directory server instances, the provided credentials must be valid for each instance.

Signing on to the Administrative Console

About this task

To sign on to the console, enter a fully qualified distinguished name (DN), for example, `cn=admin2,cn=Topology Admin Users,cn=Topology,cn=config`. For more information, see *Configuring a global administrator* on page 387.

Steps

1. Start the Directory Server.

   ```
   $ bin/start-server
   ```

2. In a browser, go to *http://server-name:389/console/login*.
3. In the **Username** and **Password** fields, enter the root user DN credentials.

4. Click **Sign In**.

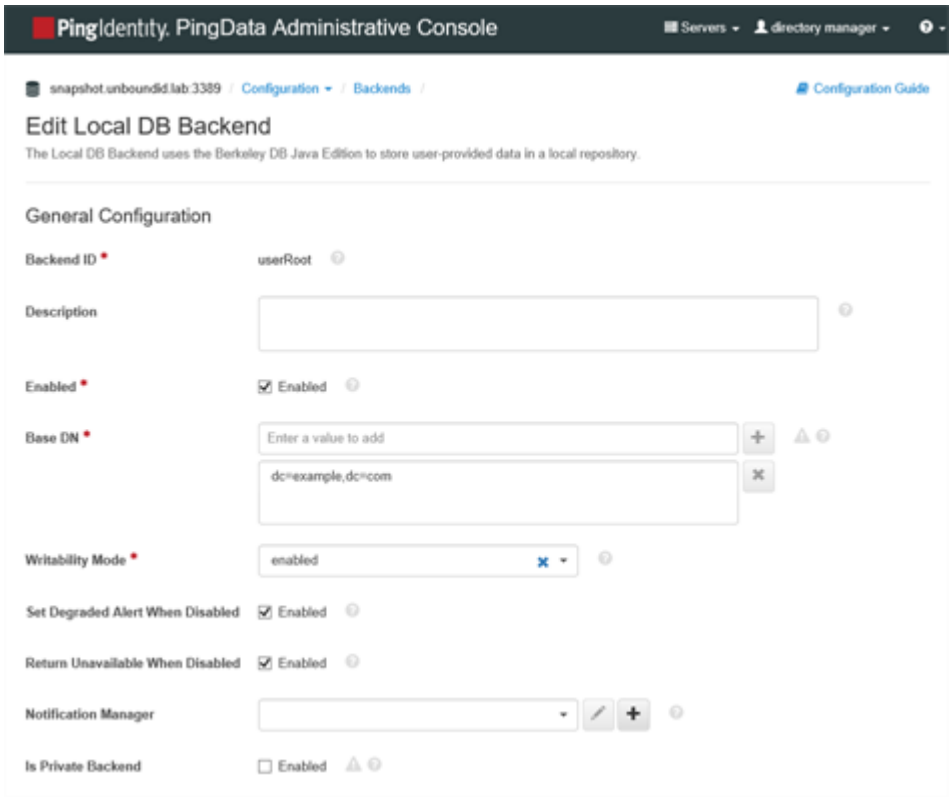
Configuring the Server using the Console

Steps

1. From the Administrative Console, go to **Configuration**#

   Backends.
2. At the top of the **Administrative Console** page, select the **Show Advanced Properties** check box.
3. Click the name of the backend you want to configure.

4. Change or enter values in the server configuration.



5. To apply your changes, click **Save**.

Generating a summary of configuration components

The `config-diff` toolgenerates a summary of the configuration in a local or remote directory server instance.

About this task

The `config-diff` tool is useful for comparing configuration settings on the directory server instance when troubleshooting issues or when verifying configuration settings on newly-added servers. The tool can interact with the local configuration regardless of whether the server is running.

Steps

- To generate a summary of configuration components, run `config-diff`
  `$ bin/config-diff` generates a summary of a local online server.
- To generate a comparison of the current configuration with the pre-installation configuration, run the following.

```
$ bin/config-diff --sourceLocal \
  --sourceBaseline \
  --targetLocal \
  --exclude differs-after-install \
  --outputFile configuration-steps.dsconfig
```

  This comparison ignores any changes that could be made by the installer and writes the output to a file called `configuration-steps.dsconfig`.

  You can use this file as the basis for a script to configure a new server identical to the local server.
- To view other available tool options, run `config-diff --help`.

Administrator account classes

Directory Server provides three different classes of administrator accounts: root user, administrator, and global administrator.

Root user

The root user is the LDAP-equivalent of a UNIX super-user account and inherits its privileges from the default root user privilege set. For more information on default root privileges, see *Default root privileges*. The root user account is an entry that is stored in the server's configuration under `cn=Root DNs,cn=config` and bypasses access control evaluation. It can be created manually or with the `dsconfig` tool. This account has full access to the entire set of data in the directory information tree (DIT) and to the server configuration and its operations. One important difference between other vendors' servers and Directory Server's implementation is that the root user's rights are granted through a set of privileges. This allows Directory Server to have multiple root users on its system, but the normal practice is to set up administrator user entries. The root user has no resource limits by default.

Administrator

The administrator user can have a full set of root user privileges but often has a subset of these privileges to limit the accessible functions that can be performed. The administrators' entries typically have limited access to the entire set of data in the DIT, which is controlled by access control instructions. These entries reside in the backend configuration, for example, `uid=admin,dc=example,dc=com`, and are replicated between servers in a replication topology. In some cases, administrator user accounts might be unavailable when the server enters lockdown mode unless the administrator is given the lockdown mode privilege.

Global administrator

A global administrator is primarily responsible for managing configuration server groups. A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology where configuration changes to one server can be applied to all of the servers at one time. Global administrator entries are stored in the `cn=Topology Admin Users,cn=Topology,cn=config` backend and are always mirrored across servers in a replication topology. These users can be assigned privileges like other administrator users but are typically used to manage the data under `cn=Topology,cn=config`.

Managing root user accounts

PingDirectoryProxy Server provides a default root user, `cn=Directory Manager`, that is stored in the server's configuration file, such as under `cn=Root DNs,cn=config`.

About this task

The root user is the LDAP-equivalent of a UNIX superuser account and inherits its read-write privileges from the default root privilege set.

Steps

- To create or update root users, use the `dscconfig` tool.

```
bin/dsconfig create-root-dn-user --user-name "Joanne Smith" \
  --set last-name:Smith \
  --set first-name:Joanne \
  --set user-id:jsmith \
  --set 'email-address:jsmith@example.com' \
  --set mobile-telephone-number:8889997777 \
  --set home-telephone-number:5556667777 \
  --set work-telephone-number:4445556666
```

> ⓘ **Note:**
>
> Root user entries are stored in the server's configuration.

- To limit full access to all of Directory Proxy Server, create separate administrator accounts with limited privileges so that you can identify the administrator responsible for a particular change.

> ⓘ **Note:**
>
> Separate user accounts for each administrator make it possible to enable password policy functionality, such as password expiration, password history, and requiring secure authentication, for each administrator.

Default root privileges

The PingDirectoryProxy Server contains a privilege subsystem that allows for a more fine-grained control of privilege assignments.

> ⓘ **Note:** Creating restricted root user accounts requires assigning privileges and necessary access controls for actions on specific data or backends. Access controls are determined by how the directory is configured and the structure of your data. See Chapter 16: Managing Access Controls for more information.

The following set of root privileges are available to each root user DN:

Default Root Privileges

Privilege	Description
audit-data-security	Allows the associated user to execute data security auditing tasks.
backend-backup	Allows the user to perform backend backup operations.
backend-restore	Allows the user to perform backend restore operations.
bypass-acl	Allows the user to bypass access control evaluation.
config-read	Allows the user to read the server configuration.
config-write	Allows the user to update the server configuration.
disconnect-client	Allows the user to terminate arbitrary client connections.
ldif-export	Allows the user to perform LDIF export operations.
ldif-import	Allows the user to perform LDIF import operations.
lockdown-mode	Allows the user to request a server lockdown.
manage-topology	Allows the user to modify topology setting.
metrics-read	Allows the user to read server metrics.
modify-acl	Allows the user to modify access control rules.
password-reset	Allows the user to reset user passwords but not their own. The user must also have privileges granted by access control to write the user password to the target entry.

Privilege	Description
permit-get-password-policy-state-issues	Allows the user to access password policy state issues.
privilege-change	Allows the user to change the set of privileges for a specific user, or to change the set of privileges automatically assigned to a root user.
server-restart	Allows the user to request a server restart.
server-shutdown	Allows the user to request a server shutdown.
soft-delete-read	Allows the user access to soft-deleted entries.
stream-values	Allows the user to perform a stream values extended operation that obtains all entry DNs and/or all values for one or more attributes for a specified portion of the DIT.
third-party-task	Allows the associated user to invoke tasks created by third-party developers.
unindexed-search	Allows the user to perform an unindexed search in the Oracle Berkeley DB Java Edition backend.
update-schema	Allows the user to update the server schema.
use-admin-session	Allows the associated user to use an administrative session to request that operations be processed using a dedicated pool of worker threads.

The Directory Proxy Server provides other privileges that are not assigned to the root user DN by default but can be added using the **`ldapmodify`** tool (see Modifying Individual Root User Privileges) for more information.

Other Available Privileges

Privilege	Description
bypass-pw-policy	Allows the associated user bypass password policy rules and restrictions.
bypass-read-aci	Allows the associated user to bypass access control checks performed by the server for bind, compare, and search operations. Access control evaluation may still be enforced for other types of operations.
jmx-notify	Allows the associated user to subscribe to receive JMX notifications.
jmx-read	Allows the associated user to perform JMX read operations.
jmx-write	Allows the associated user to perform JMX write operations.
permit-externally-processed-authentication	Allows the associated user accept externally processed authentication.
permit-proxied-mschapv2-details	Allows the associated user to permit MS-CHAP V2 handshake protocol.
proxied-auth	Allows the associated user to accept proxied authorization.

Configuring administrator accounts

An administrator account is any account in the user backend that is assigned one or more privileges or is given access to read and write operations beyond that of a normal user entry.

The privilege mechanism is the same as that used for root distinguished name (DN) accounts and allows individual privileges to be assigned to an administrator entry.

Typically, administrator user entries are controlled by access control evaluation to limit access to the entire set of data in the directory information tree (DIT). You can grant fine-grained read and write access using the access control definitions available through the `aci` attribute. Administrator entries reside in the backend configuration, for example, `uid=admin,dc=example,dc=com`, and are replicated between servers in a replication topology.

The following examples show how to configure administrator accounts:

- The first procedure shows how to set up a single, generic `uid=admin,dc=example,dc=com` account with limited privileges.

  > ⓘ **Note:**
  >
  > If you generated sample data at install, you can view an example `uid=admin` entry using **`ldapsearch`**.

- The second example shows a more realistic example where the user is part of the administrators group.

> ⓘ **Note:**
>
> Both examples are based on a simple DIT. Actual deployment cases depend on your schema.

Setting up a single administrator account

About this task

To create an example of a single, generic administrator account:

Steps

1. Create an LDIF file with an example administrator entry.

```
dn: uid=admin,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
givenName: Admin
uid: admin
cn: Admin User
sn: User
userPassword: password
```

2. To add the entry, use the **`ldapmodify`** tool.

```
$ bin/ldapmodify --defaultAdd --filename admin.ldif
```

3. To add the access control instruction (ACI) to the root suffix or base DN to give full access to the new administrator, create another LDIF file.

   > ⓘ **Note:**
   >
   > The ACI grants full access to all user attributes, but not to operational attributes. To grant access to operational attributes as well as user attributes, use `(targetattr = "*||+")` in the access control instruction.

   ```
   dn: dc=example,dc=com
   changetype: modify
   add: aci
   aci: (targetattr = "*")
     (version 3.0; acl "Grant full access for the admin user";
       allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
   ```

4. To add the entry, use the **`ldapmodify`** tool.

   ```
   $ bin/ldapmodify --filename admin.ldif
   ```

5. To verify the additions, use the **`ldapsearch`** tool.

   In the following example, the first command searches for the entry that contains `uid=Admin` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including ACIs, associated with the entry.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com "(uid=admin)"

   $ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base
    "(objectclass=*)" "+"
   ```

6. Add specific privileges to the administrator account, then to process the modify operation press **CTRL-D**.

   For this example, add the `password-reset` privilege to the administrator account from the command line.

   ```
   $ bin/ldapmodify
   dn: uid=admin,dc=example,dc=com
   changetype: modify
   add: ds-privilege-name
   ds-privilege-name: password-reset
   ```

   ```
   Processing MODIFY request for uid=admin,dc=example,dc=com
   MODIFY operation successful for DN uid=admin,dc=example,dc=com
   ```

7. Assign a password policy for the administrator account.

   Create an `Admin Password Policy`, then add the password policy to the account.

   ```
   $ bin/dsconfig create-password-policy \
     --policy-name "Admin Password Policy" \
     --set "description:Password policy for administrators" \
     --set password-attribute:userpassword \
     --set "default-password-storage-scheme:Salted SHA-256" \
     --set password-change-requires-current-password:true \
     --set force-change-on-reset:true \
     --set "max-password-age:25w 5d" \
     --set grace-login-count:3 \
     --no-prompt
   ```

8. To apply the password policy to the account, run the **`ldapmodify`** command.

   Execute the **`ldapmodify`** command with a bind DN that has sufficient rights, such as a root DN, as in the following example.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password
 Policies,cn=config
```

Changing the administrator password

About this task

Root users are governed by the root password policy and by default, their passwords never expire. To change a root user password, use the `ldappasswordmodify` tool.

Steps

1. Open a text editor and create a text file containing the new password.

   For this example, name the file `rootuser.txt`.

```
$ echo password > rootuser.txt
```

2. To change the root user's password, run **`ldappasswordmodify`**.

```
$ bin/ldappasswordmodify --port 1389 --bindDN "cn=Directory Manager"\
  --bindPassword secret --newPasswordFile rootuser.txt
```

3. Remove the text file.

```
$ rm rootuser.txt
```

Setting up an administrator group

About this task

The following example shows how to set up a group of administrators that have access rights to the whole Directory Server.

> ⓘ **Note:**
>
> The example uses a static group using the `GroupOfUniqueNames` object class.

Steps

1. Create an LDIF file with an example administrator group.

   For this example, name the file `admin-group.ldif`

```
dn: ou=Groups,dc=example,dc=com
objectClass: organizationalunit
objectClass: top
ou: Groups

dn: cn=Dir Admins,ou=Groups,dc=example,dc=com
objectClass: groupofuniquenames
```

```
objectClass: top
uniqueMember: uid=user.0, ou=People, dc=example,dc=com
uniqueMember: uid=user.1, ou=People, dc=example,dc=com
cn: Dir Admins
ou: Groups
```

2. To add the entries, use the **ldapmodify** tool.

```
$ bin/ldapmodify --defaultAdd --filename admin-group.ldif
```

3. To add the ACI to the root suffix or base DN to provide full access to the Directory Server to the new administrator, create another LDIF file.

   For this example, name the file `admin-aci.ldif`.

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (target="ldap:///dc=example,dc=com")
  (targetattr != "aci")
  (version 3.0; acl "allow all Admin group";
    allow(all) groupdn = "ldap:///cn=Dir
 Admins,ou=Groups,dc=example,dc=com";)
```

4. To add the ACI, use the **ldapmodify** tool.

```
$ bin/ldapmodify --filename admin-aci.ldif
```

5. To verify the additions, use the **ldapsearch** tool.

   In the following example, the first command searches for the entry that contains `cn=Dir Admins` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including ACIs, associated with the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(cn=Dir Admins)"

$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base \
  "(objectclass=*)" "+"
```

6. To add specific privileges to each administrator account, use an LDIF file.

   For this example, name the file `admin-priv.ldif`.

   For this example, add the `password-reset` privilege to the `user.0` administrator account from the command line. To add the privilege, use the **ldapmodify** tool. Repeat the process for the other administrators configured in the administrator group.

```
dn: uid=user.0,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset

$ bin/ldapmodify --filename admin-priv.ldif
```

```
Processing MODIFY request for uid=user.0,dc=example,dc=com
MODIFY operation successful for DN uid=user.0,dc=example,dc=com
```

7. To assign a password policy for the administrator account, use an LDIF file. Save the file as `admin-pwd-policy.ldif`.

   For example, create an `Admin Password Policy`, then add the password policy to the account. To apply the password policy to the account, use the **`ldapmodify`** tool.

```
dn: uid=user.0,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password
 Policies,cn=config

$ bin/ldapmodify --filename admin-pwd-policy.ldif
```

Configuring a global administrator

A global administrator is created when replication is enabled and is responsible for managing configuration server groups.

A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology where configuration changes to one server can be applied to all of the servers at a time.

Global administrators are stored in the topology registry. These entries are always mirrored between servers in a topology. Global administrators can be assigned privileges like other administrator users but are typically used to manage the data under `cn=topology,cn=config` and `cn=config`. You can create new or remove global administrators using the **`dsconfig`** tool. The global administrator entries are located in the `cn=Topology Admin User, cn=topology,cn=config` branch.

Creating a global administrator

Steps

1. To create a new global administrator, use the `create-topology-admin-user` option with **`dsconfig`**.

```
$ bin/dsconfig create-topology-admin-user \
  --user-name admin2 \
  --set alternate-bind-dn:cn=admin2 \
  --set password:rootPassword
```

2. To verify the creation of the new administrator, use the `list-topology-admin-users` option with **`dsconfig`**.

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
____________________:_______
admin               : generic
admin2              : generic
```

Removing a global administrator

Steps

1. To delete a global administrator, use the `delete-topology-admin-user` option with **`dsconfig`**.

```
$ bin/dsconfig delete-topology-admin-user --user-name admin2
```

2. To verify the deletion of the global administrator, use the `list-topology-admin-users` option with **`dsconfig`**.

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
____________________:______
admin               : generic
```

Configuring server groups

The PingDirectory Server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group.

About this task

After you have set up a server group, you can make an update on one server using **`dsconfig`**, then apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the **`dsconfig`** non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using **`dsconfig`** in interactive command-line mode, you are asked if you want to apply the change to a single server or to all servers in the server group.

You can create an administrative server group using the **`dsconfig`** tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group, as outlined in *Replication Configuration*.

The following example procedure adds three Directory Proxy Server instances into the server group labeled "group-one".

Steps

1. Create a group called “group-one” using **`dsconfig`**.

```
$ bin/dsconfig create-server-group --group-name group-one
```

2. Add any directory server to the server group.

   If you have set up replication between a set of servers, these server entries are created by the **`dsreplication`** `enable` command.

```
$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server1

$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server2

$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server3
```

3. Set a global configuration property for each of the servers that should share changes in this group.

```
$ bin/dsconfig set-global-configuration-prop \
  --set configuration-server-group:group-one
```

4. Test the server group.

   In this example, enable the log publisher for each directory server in the group "server-group" by using the `--applyChangeTo server-group` option.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
```

```
  --applyChangeTo server-group
```

5. View the property on the first directory server instance.

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

```
Property : Value(s)
---------:---------
enabled : true
```

6. Repeat step 5 on the second and third directory server instances.
7. Test the server group by disabling the log publisher on the first directory server instance by using the `--applyChangeTo single-server`.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:disabled \
  --applyChangeTo single-server
```

8. View the property on the first directory server instance.

   The first directory server instance should be disabled.

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

```
Property : Value(s)
---------:---------
enabled : false
```

9. View the property on the second directory server instance.

   Repeat this step on the third directory server instance to verify that the property is still enabled on that server.

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

```
Property : Value(s)
---------:---------
enabled : true
```

Client connection policy configuration

Client connection policies help distinguish what portions of the DIT the client can access.

They enforce restrictions on what clients can do in the server. A client connection policy specifies criteria for membership based on information about the client connection, including client address, protocol, communication security, and authentication state and identity. The client connection policy, however, does not control membership based on the type of request being made.

Every client connection is associated with exactly one client connection policy at any given time, which is assigned to the client when the connection is established. The choice of which client connection policy to use is reevaluated when the client attempts a bind to change its authentication state or uses the StartTLS extended operation to convert an insecure connection to a secure one. Any changes you make to the client connection policy do not apply to existing connections. The changes only apply to new connections.

Client connections are always unauthenticated when they are first established. If you plan to configure a policy based on authentication, you must define at least one client connection policy with criteria that match unauthenticated connections.

When a client has been assigned to a policy, you can determine what operations they can perform. For example, your policy might allow only SASL bind operations. Client connection policies are associated with one or more subtree views, which determine the portions of the DIT a particular client can access. For example, you might configure a policy that prevents users connecting over the extranet from accessing configuration information. The client connection policy is evaluated in addition to access control, so even a root user connecting over the extranet would not have access to the configuration information.

About the client connection policy

Client connection policies are based on two factors.

Connection criteria

The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can be used in other instances when the server needs to perform matching based on connection-level properties, such as filtered logging. A single connection can match multiple connection criteria definitions.

Evaluation order index

If multiple client connection policies are defined in the server, then each of them must have a unique value for the `evaluation-order-index` property. The client connection policies are evaluated in order of ascending evaluation order index. If a client connection does not match the criteria for any defined client connection policy, then that connection will be terminated.

If the connection policy matches a connection, then the connection is assigned to that policy and no further evaluation occurs. If, after evaluating all of the defined client connection policies, no match is found, the connection is terminated.

When a client connection policy is assigned

A client connection policy can be associated with a client connection at the following times.

- When the connection is initially established. This association occurs exactly once for each client connection.
- After completing processing for a StartTLS operation. This association occurs once at most for a client connection because StartTLS cannot be used more than once on a particular connection. You can not stop using StartTLS while keeping the connection active.
- After completing processing for a bind operation. This association occurs zero or more times for a client connection because the bind request can be processed many times on a given connection.

StartTLS and bind requests are subject to whatever constraints are defined for the client connection policy that is associated with the client connection at the time that the request is received. When they have completed, then subsequent operations are subject to the constraints of the new client connection policy assigned to that client connection. This policy might not be the same client connection policy that was associated with the connection before the operation was processed. That is, any policy changes do not apply to existing connections and only apply when the client reconnects.

All other types of operations are subject to whatever constraints are defined for the client connection policy used by the client connection at the time that the request is received. The client connection policy assigned to a connection never changes as a result of processing any operation other than a bind or StartTLS. The server does not re-evaluate the client connection policy for the connection in the course of processing an operation. For example, the client connection policy is never re-evaluated for a search operation.

Restricting the type of search filter used by clients

You can restrict the types of search filters that a given client might be allowed to use to prevent the use of potentially expensive filters, like range or substring searches.

You can use the `allowed-filter-type` property to provide a list of filter types that can be included in the search requests from clients associated with the client connection policy. This setting is only used if search is included in the set of allowed operation types. This restriction only applies to searches with a scope other than `baseObject`, such as searches with a scope of `singleLevel`, `wholeSubtree`, or `subordinateSubtree`.

You can use the `minimum-substring-length` property to specify the minimum number of non-wildcard characters in a substring filter. Any attempt to use a substring search with an element containing fewer than this number of bytes is rejected. For example, you can configure the server to reject filters like "`(cn=a*)`" and "`(cn=ab*)`", but to allow "`(cn=abcde*)`". This property setting is only used if search is included in the set of allowed operation types and at least one of `sub-initial`, `sub-any`, or `sub-final` is included in the set of allowed filter types.

There are two primary benefits to enforcing a minimum substring length:

- Allowing short substrings can require the server to perform more expensive processing. The search requires more server effort to assemble a candidate entry list for short substrings because the server has to examine more index keys.
- Allowing short substrings makes it easier for a client to put together a series of requests to retrieve all the data from the server, a process known as "trawling". If a malicious user wants to obtain all the data from the server, then it is easier to issue 26 requests like "`(cn=a*)`", "`(cn=b*)`", "`(cn=c*)`", ..., "`(cn=z*)`" than if the user is required to do something like "`(cn=aaaaa*)`", "`(cn=aaaab*)`", "`(cn=aaaac*)`", ..., "`(cn=zzzzz*)`".

Resource limits

Client connection policies can specify resource limits, helping to ensure that no single client monopolizes server resources.

You can limit the total number of connections to a server from a particular client or from clients that match specified criteria. You can also limit the duration of the connection.

A client connection policy can only be used to enforce additional restrictions on a client connection. You cannot use it to grant a client capabilities that it would not otherwise have.

Any change to any of these new configuration properties only impacts client connections that are assigned to the client connection policy after the change is made. Any connection associated with the client connection policy before the configuration change was made continues to be subject to the configuration that was in place at the time it was associated with that policy.

Resource Limiting Properties

Property	Description
`maximum-concurrent-connections`	Specifies the maximum number of client connections that can be associated with that client connection policy at any given time. The default value of zero indicates that no limit is enforced. If the server already has the maximum number of connections associated with a client connection policy, then any attempt to associate another connection with that policy, such as newly-established connections or an existing connection that has done something to change its client connection policy, such as perform a bind or StartTLS operation, causes that connection to be terminated.

Property	Description
`terminate-connection`	Specifies that any client connection for which the client connection policy is selected, such as whether it is a new connection or an existing connection that is assigned to the client connection policy after performing a bind or StartTLS operation, is immediately terminated. This property can be used to define criteria for connections that you do not want to be allowed to communicate with the Directory Server.
`maximum-connection-duration`	Specifies the maximum length of time that a connection associated with the client connection policy can remain established to the Directory Server, regardless of the amount of activity on that connection. A value of "0 seconds" (default) indicates that no limit is enforced. If a connection associated with the client connection policy has been established for longer than this time, then it is terminated.
`maximum-idle-connection-duration`	Specifies the maximum length of time that a connection associated with the client connection policy can remain established with the Directory Server without any requests in progress. A value of "0 seconds" (default) indicates that no additional limit is enforced on top of whatever idle time limit might already be in effect for an associated connection. If a nonzero value is provided, then the effective idle time limit for any client connection is the smaller of the `maximum-idle-connection-duration` from the client connection policy and the idle time limit that would otherwise be in effect for that client. This property can be used to apply a further restriction on top of any value that might be enforced by the `idle-time-limit` global configuration property which defines a default idle time limit for client connections, or the `ds-rlim-idle-time-limit` operational attribute which might be included in a user entry to override the default idle time limit for that user.
`maximum-operation-count-per-connection`	Specifies the maximum number of operations that a client associated with the client connection policy is allowed to request. A value of zero (default) indicates that no limit is enforced. If a client attempts to request more than this number of operations on the same connection, then that connection will be terminated.
`maximum-concurrent-operations-per-connection`	Specifies the maximum number of operations that might be active at any time from the same client. This limit only applies to clients that use asynchronous operations with multiple outstanding requests at any given time. A value of zero (default) indicates that no limit is enforced. If a client already has the maximum number of outstanding requests in progress and issues a new request, then that request is delayed or rejected based on the value of the `maximum-concurrent-operation-wait-time-before-rejecting` property.

Property	Description
`maximum-concurrent-operation-wait-time-before-rejecting`	Specifies the maximum length of time that a client connection should allow an outstanding operation to complete if the maximum number of concurrent operations for a connection are already in progress when a new request is received on that connection. A value of “0 seconds” (default) indicates that any new requests received while the maximum number of outstanding requests are already in progress for that connection are immediately rejected. If an outstanding operation completes before this time expires, then the server might be allowed to process that operation. If the time expires, the new request is rejected.
`maximum-ldap-join-size-limit`	Specifies the maximum number of entries that can be directly joined with any individual search result entry. A value of zero indicates that no LDAP join size limit is enforced. The limit can be overridden on a per-user basis using the **`ds-rlim-ldap-join-size-limit`** operational attribute. The LDAP join size limit is also restricted by the search operation size limit. If a search result entry is joined with more entries than allowed, the join result control has a "size limit exceeded" (integer value 4) result code.
`allowed-request-control`	Specifies the OIDs of the request controls that clients associated with the client connection policy are allowed to use. If any allowed-request-control OIDs are specified, then any request that includes a control not in that set is rejected. If no `allowed-request-control` values are specified (default), then any control whose OID is not included in the set of denied-request-control values is allowed.
`denied-request-control`	Specifies the OIDs of the request controls that clients associated with the client connection policy are not allowed to use. If there are any `denied-request-control` values, then any request containing a control whose OID is included in that set is rejected. If there are no `denied-request-control` values (default), then any request control is allowed if the `allowed-request-control` property is also empty, or only those controls whose OIDs are included in the set of `allowed-request-control` values are allowed if at least one `allowed-request-control` value is provided.

Property	Description
`allowed-filter-type`	Specifies the types of components that might be used in filters included in search operations with a non-base scope that are requested by clients associated with the client connection policy. Any non-base scoped search request whose filter contains a component not included in this set is rejected. The set of possible filter types include: ▪ and ▪ or ▪ not ▪ equality ▪ sub-initial ▪ sub-any ▪ sub-final ▪ greater-or-equal ▪ less-or-equal ▪ approximate-match ▪ extensible-match By default, all filter types are allowed. ⓘ **Note:** No restriction is placed on the types of filters that might be used in searches with a base scope.
`allow-unindexed-searches`	Specifies whether clients associated with the client connection policy are allowed to request searches that cannot be efficiently processed using the configured set of indexes. ⓘ **Note:** Clients must still have the `unindexed-search` privilege, so this option does not grant the ability to perform unindexed searches to clients that would not have otherwise had that ability, but it might be used to prevent clients associated with the client connection policy from requesting unindexed searches when they might have otherwise been allowed to do so. By default, this has a value of "true", indicating that any client associated with the client connection policy that has the `unindexed-search` privilege is allowed to request unindexed searches.
`minimum-substring-length`	Specifies the minimum number of bytes, which might be present in any sub- Initial, subAny, or subFinal element of a substring search filter component in a search with a non-baseObject scope. A value of one (which is the default) indicates that no limit is enforced. This property might be used to prevent clients from issuing overly-vague substring searches that might require installing the Directory Server to examine too many entries over the course of processing the request.

Property	Description
`maximum-search-size-limit`	Specifies the maximum number of entries that might be returned from any single search operation requested by a client associated with this client connection policy. **Note:** This property only specifies a maximum limit and never increases any limit that might already be in effect for the client thought the `size-limit` global configuration property or the `ds-rlim-size-limit` operational attribute. A value of zero (default) indicates that no additional limit is enforced on top of whatever size limit might already be in effect for an associated connection. If a nonzero value is provided, then the effective maximum size limit for any search operation requested by the client is the smaller of the size limit from that search request, the `maximum-search-size-limit` from the client connection policy, and the size limit that would otherwise be in effect for that client.

Defining the operation rate

Configure the maximum operation rate for individual client connections and collectively for all connections associated with a client connection policy.

If the operation rate limit is exceeded, the Directory Server can either reject the operation or terminate the connection. You can define multiple rate limit values, making it possible to fine tune limits for both a long term average operation rate and short term operation bursts. For example, you can define a limit of one thousand operations per second and one million operations per day, which works out to an average of fewer than twelve operations per second, but with bursts of up to one thousand operations per second.

Specify rate limit strings as a maximum count, followed by a slash and a duration. The count portion must contain an integer and can be followed by the following multipliers:

- k (to indicate that the integer should be interpreted as thousands)
- m (to indicate that the integer should be interpreted as millions)
- g (to indicate that the integer should be interpreted as billions)

The duration portion must contain a time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w) and can be preceded by an integer to specify a quantity for that unit.

For example, the following are valid rate limit strings:

- 1/s (no more than one operation over a one-second interval)
- 10K/5h (no more than ten thousand operations over a five-hour interval)
- 5m/2d (no more than five million operations over a two-day interval)

You can provide time units in many different formats. For example, a unit of seconds can be signified using s, sec, sect, second, and seconds.

Client connection policy deployment example

In this example scenario, we assume the following:

1. Two external LDAP clients are allowed to bind to the Directory Server.
2. Client 1 should be allowed to open only one connection to the server.
3. Client 2 should be allowed to open up to five connections to the server.

For more information on this client connection policy deployment example, see the following topics:

Define the connection policies
Set a per-client connection policy limit on the number of connections that can be associated with a particular client connection policy

Define at least two client connection policies, one for each of the two clients. Each policy must have different connection criteria for selecting the policy with which a given client connection should be associated.

Because the criteria is based on authentication, you must create a third client connection policy that applies to unauthenticated clients because client connections are always unauthenticated as soon as they are established and before they have sent a bind request. Clients are not required to send a bind request as their first operation.

Define the following three client connection policies:

- Client 1 Connection Policy, which only allows client 1, with an evaluation order index of 1
- Client 2 Connection Policy, which only allows client 2, with an evaluation order index of 2
- Unauthenticated Connection Policy, which allows unauthenticated clients, with an evaluation order index of 3

Define simple connection criteria for the Client 1 Connection Policy and the Client 2 Connection Policy with the following properties:

- The `user-auth-type` must not include none so that it only applies to authenticated client connections.
- The `included-user-base-dn` should match the bind DN for the target user. This distinguished name (DN) can be full DN for the target user, or it can be the base DN for a branch that contains a number of users that you want treated in the same way.

> ⓘ **Tip:**
>
> To create more generic criteria that match more than one user, you could list the DNs of each of the users explicitly in the `included-user-base-dn` property. If there is a group that contains all of the pertinent users, then you could instead use the `[all|any|not-all|not-any]-included-user-group-dn` property to apply to all members of that group. If the entries for all of the users match a particular filter, then you could use the `[all|any|not-all|not-any]-included-user-filter` property to match them.

How the policy is evaluated
Whenever a connection is established, the server associates the connection with exactly one client connection policy.

The server does this by iterating over all of the defined client connection policies in ascending order of the evaluation order index. Policies with a lower evaluation order index value are examined before those with a higher evaluation order index value. The first policy that the server finds whose criteria match the client connection is associated with that connection. If no client connection policy is found with criteria matching the connection, then the connection is terminated.

So, in this example, when a new connection is established, the server first checks the connection criteria associated with the Client 1 Connection Policy because it has the lowest evaluation order index value. If it finds that the criteria do not match the new connection, the server then checks the connection criteria associated with the Client 2 Connection Policy because it has the second lowest evaluation order

index. If these criteria do not match, the server finally checks the connection criteria associated with the Unauthenticated Connection Policy because it has the third lowest evaluation order index. It finds a match, so the client connection is associated with the Unauthenticated Connection Policy.

After the client performs a bind operation to authenticate to the server, then the client connection policies are re-evaluated. If Client 2 performs the bind, then the Client 1 Connection Policy does not match, but the Client 2 Connection Policy does, so the connection is re-associated with that client connection policy. Whenever a connection is associated with a client connection policy, the server checks to see if the maximum number of client connections have already been associated with that policy. If so, then the newly-associated connection is terminated.

For example, Client 1 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. Client 1 then sends a bind request. The determination of whether the bind operation is allowed is made based on the constraints defined in the Unauthenticated Connection Policy because it is the client connection policy already assigned to the client connection. When the bind has completed, the server re-evaluates the client connection policy against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to the Client 1 Connection Policy.

Next, Client 2 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. When Client 2 sends a bind request, the operation is allowed based on the constraints defined in the Unauthenticated Connection Policy. When the bind is complete, the client connection is evaluated against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria do not match, so the Client 2 connection is evaluated against the connection criteria associated with Client 2 Connection Policy because it has the next lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to Client 2 Connection Policy.

Client 1 sends a search request. The Client 1 Connection Policy is used to determine whether the search operation should be allowed because this is the client connection policy assigned to the client connection for Client 1. The connection is not re-evaluated before or after processing the search operation.

Configuring a client connection policy using the console
Configure a client connection policy using the PingDirectory Administrative Console.

Steps

1. From the Administrative Console, in the **Core Server** section, click **Client Connection Policies**.

   > ⓘ **Tip:**
   >
   > If you do not see **Client Connection Policies** on the menu, change the **Object Types** filter to **Standard**.

2. To add a new policy, click **Add New**.
3. Enter a **Policy ID**.

   If you want to base your new client connection policy on an existing policy, select it from the **Template** menu.
4. Configure the properties of the client connection policy, then to enable the policy, select **Enabled**.
5. Enter the order in which you want the new policy to be evaluated in the **Evaluation Order Index** box, and then click **Continue**.

   A policy with a lower index is evaluated before a policy with a higher index. The Directory Server uses the first evaluated policy that applies to a client connection.

6. Select the connection criteria that match the client connection for this policy.
   a. To change the criteria, click **View** and **Edit**.
   b. To add new criteria, click **Select New**.
   c. Select the operations allowed for clients that are members of this connection group.
   d. To make operations available to clients, use the **Add** and **Remove** buttons.
   e. Specify the extended operations that clients are allowed and denied to use.
7. Enter the type of authorization allowed and the SASL mechanisms that are allowed and denied in response to client requests.
8. Select the **Include Backend Subtree Views** check box if you want to automatically include the subtree views of backends configured in the Directory Server.

   You can also choose to include and exclude specific base DNs using the appropriate fields.
9. Save your changes.
   - To review the **`dsconfig`** command equivalent and save your changes, click **Confirm then Save**.
   - To save your changes without first reviewing the **`dsconfig`** output, click **Save Now**.

Configuring a client connection policy using dsconfig
Configure a client connection policy using the **`dsconfig`** tool.

About this task

Configure a client connection policy using the **`dsconfig`** tool in interactive mode from the command line. You can access the **Client Connection Policy** menu on the **Standard objects** menu.

Steps

1. Use the **`dsconfig`** tool to create and configure a client connection policy.

   Specify the host name, connection method, port number, and bind distinguished names (DNs) described in previous procedures.
2. To change to the **Standard objects** menu, from the Directory Server main menu, enter `o`, and then enter the number for the **Standard** menu.
3. From the Directory Server main menu, enter the number associated with **Client Connection Policy**.
4. From the **Client Connection Policy management** menu, enter the number corresponding to **Create a new connection policy**.
5. To create a new client connection policy from scratch, enter `n`.
6. Enter a name for the new client connection policy.
7. To enable the connection policy, from the **Enabled Property** menu, select **True**.
8. To set the evaluation order for the policy, from the **Evaluation-Order Property** menu, enter a value between 0 and 2147483647.

   A client connection policy with a lower evaluation-order is evaluated before one with a higher number. For this example, enter `9999`.
9. From the **Client Connection Policy** menu, review the configuration.
   a. If you want to make any further modifications, enter the number corresponding to the property.
   b. To finish the creation of the client connection policy, enter `f`.

   Any changes that you make to the client connection policy do not apply to existing connections. They only apply to new connections.

Restricting server access based on client IP address
Two methods are available to limit client access to the Directory Server.

Connection Handlers

You can limit the IP addresses using the LDAP or LDAPS connection handlers. The connection handlers provide an `allowed-client` property and a `denied-client` property. The `allowed-client` property specifies the set of allowable address masks that can establish connections to the handler. The `denied-client` property specifies the set of address masks that are not allowed to establish connections to the handler.

Client Connection Policies

For a more fine-grained approach, restrict access by configuring a new client connection policy. Then, create a new connection criteria and associate it with the connection policy. A connection criteria defines sets of criteria for grouping and describing client connections based on a number of properties, including the protocol, client address, connection security, and authentication state for the connection. Each client connection policy can be associated with zero or more connection criteria. Server components can use connection criteria to indicate which connections to process and what kind of processing to perform, such as to select connections and operations for filtered logging or to classify connections for network groups.

Restricting server access using the connection handlers
Use **`dsconfig`** to set the `allowed-client` property for the LDAP connection handler.

Steps

- Set the `allowed-client` property for the LDAP connection handler using **`dsconfig`**.
- Specify the address mask for the range of allowable IP addresses that can establish connections to the Directory Server.
- To configure the server using the **`dsconfig`** tool on the local host, specify the loopback address to 127.0.0.1.

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --set "allowed-client:10.6.1.*" \
  --set allowed-client:127.0.0.1
```

Restricting server access using client connection policies
A client-established connection to the PingDirectory server is associated with a client connection policy. Use client connection policies to restrict the kinds of requests that the client can issue and impose resource limits for that connection.

Steps

1. Create a simple connection criteria.

   The following example uses the **`dsconfig`** tool in non-interactive mode. It allows only the Directory Server's IP address and loopback to have access.

   ```
   $ bin/dsconfig set-connection-criteria-prop \
     --criteria-name allowed-ip-addrs \
     --add included-client-address:10.6.1.80 \
     --add included-client-address:127.0.0.1
   ```

2. Assign the criteria to the client connection policy.

   ```
   $ bin/dsconfig set-client-connection-policy-prop \
     --policy-name new-policy \
   ```

```
  --set connection-criteria:allowed-ip-addrs
```

After you have run the command, access is denied to remote IP addresses. The Directory Server does not require a restart.

3. Add a remote IP range to the criteria.

> ⓘ **Note:**
>
> For the following example, add `10.6.1.*`.

```
$ bin/dsconfig set-connection-criteria-prop \
  --criteria-name allowed-ip-addrs \
  --add "included-client-address:10.6.1.*"
```

Access from any remote servers is allowed. The Directory Server does not require a restart.

4. To restore default behavior, remove the criteria from the connection policy.

> ⓘ **Tip:**
>
> Include the LDAP or LDAPS connection parameters, such as host name, port, bindDN, bindPassword, with the **`dsconfig`** command.

```
$ bin/dsconfig set-client-connection-policy-prop \
  --policy-name new-policy --remove connection-criteria:allowed-ip-addrs
```

The Directory Server does not require a restart.

Automatically authenticating clients that have a secure communication channel

The Directory Server provides the option to automatically authenticate clients that have a secure communication channel, either SSL or StartTLS, and to present their own certificate.

About this task

By default, this option is disabled. When enabled, the net effect is as if the client issued a SASL EXTERNAL bind request on that connection.

> ⓘ **Note:**
>
> This option is ignored if the client connection is already authenticated, such as when using StartTLS, but the client had already performed a bind before the StartTLS request. If the bind attempt fails, the connection remains unauthenticated but usable. If the client subsequently sends a bind request on the connection, it's processed as normal, and any automatic authentication is destroyed.

Steps

- Run the following **`dsconfig`** command.

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAPS Connection Handler" \
  --set "auto-authenticate-using-client-certificate:true"
```

Securing the Server with lockdown mode

The Directory Server provides tools to enter and leave lockdown mode if the server requires a security lockdown.

About this task

In lockdown mode, only users with the `lockdown-mode` privilege can perform operations Users who do not have the privilege are rejected. By default, root users have this privilege. You can give other administrators this privilege. Users with this privilege can configure lockdown mode as a recurring task.

Some configuration problems can lead to inadvertent exposure of sensitive information, such as an access control rule that cannot be properly parsed, and cause the server to place itself in lockdown mode. This ensures that an administrator can manually correct the problem. Lockdown mode does not persist across restarts.

Steps

- To perform some administrative operations and ensure that other client requests are not allowed to access any data in the server, manually place the Directory Server into lockdown mode.

  Any client request to the Directory Server in lockdown mode receives an `Unavailable` response.
- To take the directory server out of lockdown mode, use either of the following options:
  - Use the **`leave-lockdown-mode`** command.
  - Restart the server.
- To start a server in lockdown mode, use the **`start-server`** `--lockdownMode` option.

Entering lockdown mode manually

Steps

- To enter lockdown mode, run **`enter-lockdown-mode`**.

```
$ bin/enter-lockdown-mode
```

Leaving lockdown mode

Steps

- To leave lockdown mode, run **`leave-lockdown-mode`**.

```
$ bin/leave-lockdown-mode
```

Starting a server in lockdown mode

Steps

- To start a server in lockdown mode, run the **`start-server`** command with the `--lockdownMode` option.

```
$ bin/start-server --lockdownMode
```

Configuring maximum shutdown time

The Directory Server provides an option for administrators to set a maximum time for a shutdown process to take.

Before you begin

During shutdown, some database checkpointing and cleaning threads might remain active even after the default time period on systems with large or busy database backends. If checkpointing or cleaning is aborted prematurely, it can lead to significantly longer startup times for the Directory Server. When a shutdown process is initiated, the server begins stopping all of its internal components and waits up to 5 minutes for all threads to complete before exiting.

About this task

Use the **`dsconfig`** tool to configure the maximum shutdown time to allow database operations to complete.

Steps

- To increase the maximum shutdown time for your system, choose from one of the following options.
  - Run the **`dsconfig`** tool.

    ⓘ **Note:**

    The following command increases the maximum shutdown time from 5 minutes to 6 minutes. The command allows time values of w (weeks), d (days), h (hours), m (minutes), s (seconds), ms (milliseconds).

    Include the LDAP or LDAPS connection parameters, such as host name, port, bindDN, and bindDN password, with the **`dsconfig`** command.

    ```
    $ bin/dsconfig set-global-configuration-prop --set "maximum-shutdown-
    time:6 m"
    ```

  - Change the `maximum-shutdown-time` property using the **`dsconfig`** tool in interactive mode. From the main menu, select **Global Configuration**, and then select the option to display advanced properties.

About working with referrals

A referral is a redirection mechanism that tells client applications that a requested entry or set of entries is not present on the Directory Server but can be accessed on another server.

Use referrals when entries are located on another server. The Directory Server implements two types of referrals depending on the requirement:

Referral on Update plugin

The Directory Server provides a Referral on Update plugin to create any referrals for update requests, such as `add`, `delete`, `modify`, or `moddn` operations, on read-only servers. For example, given two replicated directory servers where one server is a master with read-write capabilities, and the other is a read-only server. You can configure a referral for any client update requests on the second directory server to point to the master server. For example, if a client application sends an add request on the second directory server, the directory server responds with a referral that indicates any updates should be made on the master server. All read requests on the read-only server process normally.

Smart referrals

The Directory Server supports smart referrals that map an entry or a specific branch of a directory information tree (DIT) to an LDAP URL. Any client requests (reads or writes) targeting at or below the branch of the DIT send a referral to the server designated in the LDAP URL.

Specifying LDAP URLs

Referrals use LDAP URLs to redirect a client application's request to another server.

LDAP URLs have a specific format, described in RFC 4516 and require that all special characters be properly escaped and any spaces indicated as "%20". LDAP URLs have the following syntax.

```
ldap[s]://hostname:port/base-dn?attributes?scope?filter
```

`ldap[s]`

Indicates the type of LDAP connection to the Directory Server. If the Directory Server connects over a standard, non-encrypted connection, then LDAP is used. If it connects over SSL, then LDAPS is used.

> ⓘ **Note:**
>
> Any search request initiated by means of an LDAP URL is anonymous by default unless an LDAP client provides authentication.

`hostname`

Specifies the host name or IP address of the Directory Server.

`port`

Specifies the port number of the Directory Server. If no port number is provided, the default LDAP port (389) or LDAPS port (636) is used.

`base-dn`

Specifies the distinguished name (DN) of an entry in the directory information tree (DIT). The Directory Server uses the base DN as the starting point entry for its searches. If no base DN is provided, the search begins at the root of the DIT.

`attributes`

Specifies those attributes for which the Directory Server should search and return. You can indicate more than one attribute by providing a comma-separated list of attributes. If no attributes are provided, the search returns all attributes.

`scope`

Specifies the scope of the search, which could be one of the following:

`base`

Only searches the specified base DN entry.

`one`

Only search one level below the specified base DN.

`sub`

Searches the base entry and all entries below the specified base DN.

If no scope is provided, the server performs a base search.

`filter`

Specifies the search filter to apply to entries within the scope of the search. If no filter is provided, the server uses `+`.

Creating referrals
Create a smart referral by adding an entry with the referral and `extensibleObject` object classes or adding the object classes to a specific entry.

About this task

The referral object class designates the entry as a referral object. The `extensibleObject` object class allows you to match the target entry by matching any schema attribute. The following example shows how to set up a smart referral if a portion of a directory information tree (DIT) is located on another server.

To create a referral:

Steps

1. Create an LDIF file with an entry that contains the `referral` and `extensibleObject` object classes.

```
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
objectClass: top
objectClass: referral
objectClass: extensibleObject
ou: Engineering Team1
ref: ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

2. On the first server, add the referral entry using the **`ldapmodify`** command.

```
$ bin/ldapmodify --defaultAdd --fileName referral-entry.ldif
```

3. To verify the addition, search for a user.

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com "(uid=user.4)"
```

```
SearchReference(referralURLs={ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com??sub?})
```

Modifying a referral
Run a modify command to modify a referral.

Steps

- To modify the `ref` attribute on the referral entry, run **`ldapmodify`** with the `manageDSAIT` control.

```
$ bin/ldapmodify --control manageDSAIT
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
changetype: modify
replace: ref
ref: ldap://server3.example.com/
ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

Deleting a referral
Run `ldapdelete` to delete a referral.

Steps

- To delete the referral entry, run **`ldapdelete`** with the `manageDSAIT` control.

```
$ bin/ldapdelete \
  --control manageDSAIT "ou=EngineeringTeam1,ou=People,dc=example,dc=com"
```

Configuring a read-only server

The PingDirectory Server provides a means to configure a hub-like, read-only directory server for legacy systems that require it.

About this task

The read-only directory server participates in replication but cannot respond to any update requests from an external client. You can configure the Directory Server by setting the writability mode to internal-only, which makes the server operate in read-only mode. Read-only mode directory servers can process update operations from internal operations but reject any write requests from external clients. Because the Directory Server cannot accept write requests, you can configure the server to send a referral, which redirects a client's request to a master server. The client must perform the operation again on the server named in the referral.

> ⓘ **Note:**
>
> For Implementers of third party extensions, many Server SDK extensions use the `InternalConnection` interface to process operations in the server, rather than issuing LDAP requests over the network. If an extension does so in response to an external update request, then any Directory Server using that extension will effectively respond to external update requests, even though the Directory Server is configured to operate in read-only mode, as described previously. One possible workaround is to split the extension into two extensions, one for reads and one for writes, and then to disable (or not to deploy) the write-only extension when configuring a Directory Server in read-only mode.

Steps

1. Install two replicating directory servers.

   For more information on various ways to set up your servers, see *Enabling Replication*.
2. On the second server, run the **`dsconfig`** command to set the writability mode of the server to internal-only.

```
$ bin/dsconfig set-global-configuration-prop \
  --set writability-mode:internal-only
```

3. On the second server, run the **`dsconfig`** command to create a referral that instructs the server to redirect client write requests under `dc=example,dc=com` to server1.example.com:1389.

   The referral itself is defined as a plugin of type `referral-on-update`. This command sets up the server to process read operations but redirects all write operations under `dc=example,dc=com` to another server.

```
$ bin/dsconfig create-plugin --plugin-name "Refer Updates" \
  --type referral-on-update \
  --set enabled:true \
  --set referral-base-url:ldap://server1.example.com:1389/ \
  --set "base-dn:dc=example,dc=com"
```

4. To test the referral, attempt to modify an entry and confirm that the server responds with the result code of 10.

   The resulting message is available in the server's access log.

```
$ bin/ldapmodify -p 2389 -D "cn=Directory Manager" -w password
dn: uid=user.12,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 408 555 1155
```

```
[06/Aug/2012:15:28:21.468 -0400] MODIFY
RESULT conn=86 op=1 msgID=1 requesterIP="127.0.0.1"
dn="uid=user.12,ou=People,dc=example,dc=com" resultCode=10
referralURLs="ldap://server1.example.com:1389/uid=user.12,
ou=People,dc=example,dc=com" etime=0.223
```

Configuring HTTP access for the Directory Server

Although most clients communicate with the PingDirectory Server using LDAP, the server also provides support for an HTTP connection handler that uses Java servlets to serve content to clients over HTTP.

Ping Identity offers an extension that uses this HTTP connection handler to add support for the System for Cross-domain Identity Management (SCIM) protocol. Third-party developers can also use the Server SDK to write extensions that leverage this HTTP support.

The following sections describe how to configure HTTP servlet extensions and how to configure an HTTP connection handler.

For more information, see the following topics:

- *Configuring HTTP Servlet Extensions* on page 406
- *Configuring HTTP operation loggers* on page 407
- *Example HTTP log publishers* on page 408
- *Configuring HTTP connection handlers* on page 410

Configuring HTTP Servlet Extensions

You must first configure one or more servlet extensions to use the HTTP connection handler.

Servlet extensions are responsible for obtaining Java servlets, using the Java Servlet 3.0 specification as described in JSR 315, and registering them to be invoked using one or more context paths. If you plan to deploy the System for Cross-domain Identity Management (SCIM) extension, follow the instructions in *Managing the SCIM 2.0 Servlet Extension* on page 1195. For custom servlet extensions created using the Server SDK, the process varies based on whether you are using a Java-based or Groovy-scripted extension.

Configuring web application servlet extensions

About this task

A web application can be deployed either as a WAR file that has been packaged according to the standard layout and containing a `web.xml` deployment descriptor, or from a directory containing the application's source components arranged in the standard layout.

Steps

- When deploying a web application from a directory, specify the location of the `web.xml` deployment descriptor if it is not in the standard location.
- Specify the directory used by the server for temporary files.

Results
At runtime, the web application has access to the server classes.

Configuring Java-based servlet extensions

About this task

For Java-based extensions, first use the Server SDK to create and build the extension bundle as described in the Server SDK documentation.

Steps

- Use the **`manage-extension`** tool to install it.

  ```
  $ bin/manage-extension --install/path/to/extension.zip
  ```

  The Java-based extension can then be configured for use in the server using **`dsconfig`** or the Administrative Console. Create a new Third Party HTTP Servlet Extension, specifying the fully-qualified name for the `HTTPServletExtension` subclass in the `extension-class` property, and providing any appropriate arguments in the `extension-argument` property.

> ⓘ **Note:**
>
> Web application and Servlet extensions run in a shared embedded web application server environment. Incompatibilities or conflicts might arise from use of different versions of commonly used JARs or including frameworks such as loggers, Spring components, JAX-RS implementations or other resources that might require a dedicated Java virtual machine (JVM) environment. After introducing a custom extension, check the server error log for an indication that the extension loaded successfully. The error log might also contain debug information if the extension failed to load with an initialization exception or did not complete initialization.

Configuring Groovy-scripted extensions

Steps

1. For Groovy-scripted extensions, place the necessary Groovy scripts in the appropriate directory based on the package for those scripts after the `lib/groovy-scripted-extensions` directory.
2. Create a new Groovy Scripted HTTP Servlet extension, specifying the fully-qualified Groovy class name for the `script-class` property, and providing any appropriate arguments in the `script-argument` property.

Configuring HTTP operation loggers
Interactions between servlet extensions and HTTP clients are generally not recorded in the server access log unless a servlet extension performs internal operations to interact with data held in the directory server.

About this task

To capture information about communication with HTTP clients, you must configure one or more HTTP operations loggers.

By default, the server comes with a single HTTP operation logger implementation, which uses the standard W3C common log format. It records messages in the following format.

```
127.0.0.1 - - [01/Jan/2012:00:00:00 -0600]"GET/hello HTTP/1.1" 200 113
```

The log message contains the following elements:

- The IP address of the client that issued the request

- The RFC 1413 (ident) identity of the client

  Because the ident protocol is not typically provided by HTTP clients, the HTTP connection handler never requests this information. This identity is always represented as a dash to indicate that information is not available.
- The authenticated identity determined for the request by HTTP authentication or a dash to indicate that the request was not authenticated
- The time that the request was received
- The request issued by the client, including the HTTP method, path and optional query string, and the HTTP protocol version used
- The integer representation of the HTTP status code for the response to the client
- The number of bytes included in the body of the response to the client

Steps

- To configure an HTTP operation logger to use this common log format, create a new instance of a Common Log File HTTP Operation Log Publisher object.
  a. Specify the path and name for the active log file.
  b. Specify the rotation and retention policies to manage the log files.

  > ⓘ **Note:**
  >
  > Properties for Common Log File HTTP Operation Log Publisher objects generally have the same meaning and use as they do for other kinds of loggers.
- To create custom Java-based or Groovy-scripted HTTP operation loggers using the Third Party HTTP Operation Log Publisher and Groovy Scripted HTTP Operation Log Publisher object types, use the Server SDK.

Example HTTP log publishers
When troubleshooting HTTP connection handler issues, start with the logs to determine any potential problems.

About this task

The following examples walk you through how to use various **`dsconfig`** commands and their associated options to configure log files to use for troubleshooting connection handler issues.

The following section shows some **`dsconfig`** commands and their corresponding log files.

Steps

- To configure a default detailed HTTP Log Publisher with default log rotation and retention policies, use the `create-log-publisher` option with **`dsconfig`**.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Detailed Access Logger" \
  --type detailed-http-operation \
  --set enabled:true \
  --set log-file:logs/http-detailed-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
```

```
  --set "retention-policy:Size Limit Retention Policy"
```

The corresponding log file provides access information below. The log message contains the following elements:

- The time that the request was received
- The request ID issued by the client, including the IP address, port, HTTP method, and URL
- The authorization type, request content type, and status code
- The response content length
- The redirect URI
- The response content type

The HTTP log file shows the following.

```
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300604
 from="10.5.1.10:53269"
method="GET" url="https://10.5.1.129:443/Gimel/Users/
uid=user.402914,ou=People,
dc=gimel" authorizationType="Basic" requestContentType="application/json"
statusCode=200 etime=4.145 responseContentLength=1530 redirectURI="https://
x2270-11.example.lab:443/Gimel/Users/uid=user.402914,ou=people,dc=gimel"
responseContentType="application/json"
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300605
 from="10.5.1.10:53269"
method="PUT" url="https://10.5.1.129:443/Gimel/Users/
uid=user.207585,ou=people,
dc=gimel" authorizationType="Basic" requestContentType="application/json"
statusCode=200 etime=4.872 responseContentLength=1532 redirectURI="https://
x2270-11.example.lab:443/Gimel/Users/uid=user.207585,ou=people,dc=gimel"
responseContentType="application/json"
[23/Feb/2012:11:31:18 -0600] RESULT requestID=4309872 from="10.5.1.10:3
```

- To configure a detailed HTTP Log Publisher with request and response header names and values, including the `Content-Type` request header, use the `set-log-publisher-prop` option with **`dsconfig`**.

> ⓘ **Note:**
>
> The `Content-Type` request header is suppressed by default.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "HTTP Detailed Access Logger" \
  --set log-request-headers:header-names-and-values \
  --remove suppressed-request-header-name:Content-Type \
  --set log-response-headers:header-names-and-values
```

The following is a log example of a query request by a SCIM Server using the property, `scim-query-rate`. The log message contains the basic log elements shown in the first example plus the following additional information:

- The request header for the host, HTTP method, content type, connection, user agent
- The response header for the access-control credentials

```
[23/Oct/2012:11:39:41-0600] RESULT requestID=4665307 from="10.5.0.20:56044"
method="GET" url="https://10.5.1.129:443/Beth/Users?
attributes=userName,title,
emails,urn:scim:schemas:extension:custom:1.0:descriptions,urn:scim:schemas:
extension:enterprise:1.0:manager,groups,urn:scim:schemas:extension:custom:1.0:

nection: keep-alive" requestHeader="User-Agent: DataSync-6.0.0.0 (Build
20121022173845Z, Revision 11281)" authorizationType="Basic"
 requestContentType="appli-
cation/json" statusCode=200 etime=10.615 responseContentLength=0
```

Configuring HTTP connection handlers

HTTP connection handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. HTTP connection handlers can be used to host web applications on the server.

Each HTTP connection handler should be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this does not prevent the entire Directory Server from starting. Directory Server's **`start-server`** tool outputs any errors to the error log. This allows Directory Server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with an HTTP connection handler include the following:

listen-address

Specifies the address on which the connection handler listens for requests from clients. If not specified, then requests are accepted on all addresses bound to the system.

listen-port

Specifies the port on which the connection handler listens for requests from clients. Required.

use-ssl

Indicates whether the connection handler uses SSL/TLS to secure communications with clients, such as whether it uses HTTPS rather than HTTP. If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.

http-servlet-extension

Specifies the set of servlet extensions that are enabled for use with the connection handler. You can have multiple HTTP connection handlers listening on different address/port combinations with identical or different sets of servlet extensions. You must configure at least one servlet extension.

http-operation-log-publisher

Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers are used.

key-manager-provider

Specifies the key manager provider that is used to obtain the certificate presented to clients if SSL is enabled.

trust-manager-provider

Specifies the trust manager provider that is used to determine whether to accept any client certificates presented to the server.

num-request-handlers

Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads are automatically selected based on the number of CPUs available to the Java virtual machine (JVM).

web-application-extension

Specifies the web applications hosted by the server.

Configuring an HTTP connection handler

About this task

An HTTP connection handler has two dependent configuration objects:

- One or more HTTP servlet extensions
- An HTTP log publisher

  The log publisher is optional, but in most cases, you should configure one or more logs to troubleshoot any issues with your HTTP connection.

> ⓘ **Note:**
>
> You must configure the HTTP servlet extension and log publisher before configuring the HTTP connection handler.

Steps

1. To configure your HTTP servlet extensions, use the `create-http-servlet-extension` option with **`dsconfig`**.

   This example uses the `ExampleHTTPServletExtension` example in the Server SDK.

   ```
   $ bin/dsconfig create-http-servlet-extension \
     --extension-name "Hello World Servlet" \
     --type third-party \
   ```

```
  --set "extension-
class:com.unboundid.directory.sdk.examples.ExampleHTTPServletExtension" \
  --set "extension-argument:path=/" \
  --set "extension-argument:name=example-servlet"
```

2. To configure one or more HTTP log publishers, use the `create-log-publisher` option with **`dsconfig`**.

   This example configures two log publishers: one for common access and one for detailed access. Both log publishers use the default configuration settings for log rotation and retention.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access Logger" \
  --type common-log-file-http-operation \
  --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Detailed Access Logger" \
  --type detailed-http-operation \
  --set enabled:true \
  --set log-file:logs/http-detailed-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

3. To configure the HTTP connection handler, specify the HTTP servlet extension and log publishers using the `create-connection-handler` option with **`dsconfig`**.

   > ⓘ **Note:**
   >
   > You can update some configuration properties later as needed, but for others, like `listen-port`, you must disable and then re-enable the HTTP Connection Handler for the change to take effect.

```
$ bin/dsconfig create-connection-handler \
  --handler-name "Hello World HTTP Connection Handler" \
  --type http \
  --set enabled:true \
  --set listen-port:8443 \
  --set use-ssl:true \
  --set "http-servlet-extension:Hello World Servlet" \
  --set "http-operation-log-publisher:HTTP Common Access Logger" \
  --set "http-operation-log-publisher:HTTP Detailed Access Logger" \
  --set "key-manager-provider:JKS" \
  --set "trust-manager-provider:JKS"
```

4. To monitor the connection handler, use the **`ldapsearch`** tool.

   > ⓘ **Note:**
   >
   > By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE` by default.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

Configuring an HTTP connection handler for web applications

About this task

To host web applications on the server, use HTTP connection handlers.

Steps

1. To create the web application servlet extension, use the `create-web-application-extension` option with **`dsconfig`**.

```
$ bin/dsconfig create-web-application-extension \
  --extension-name "Hello Web Application" \
  --set "base-context-path:/hello-app" \
  --set "document-root-directory:/opt/hello-web-app"
```

2. To monitor the connection handler, use the **`ldapsearch`** tool.

> ⓘ **Note:**
>
> By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE`.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

HTTP correlation IDs
Correlation IDs make it easier to track log messages across a software system request that passes through multiple subsystems.

Scattered and intermingled log messages create challenges for tracing the request flow on distributed systems. A correlation ID can be assigned to a request and added to all associated operations as the request is processed. A correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP or HTTPS Connection Handler.

When an HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID might also be passed to the LDAP subsystem.

The correlation ID appears with associated requests in LDAP logs in the **`correlationID`** key for the following REST APIs:

- SCIM 1
- Delegated admin
- Consent
- Directory

The correlation ID is used as the default client request ID value in intermediate client request controls used by the following REST APIs:

- SCIM 2
- Consent
- Directory

Values related to the intermediate client request control appear in the LDAP logs in the **`via`** key and are forwarded to downstream LDAP servers when received by PingDirectoryProxy Server. The correlation ID header is also added to requests forwarded by the PingDataGovernance gateway.

For Server SDK extensions that have access to the current `HttpServletRequest`, the current correlation ID can be retrieved as a string through the `HttpServletRequest` **`com.pingidentity.pingdata.correlation_id`** attribute, as shown.

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

Configuring HTTP correlation ID support

About this task

Correlation ID support is enabled by default for each HTTP Connection Handler.

Steps

- To enable or disable correlation ID support for the HTTPS Connection Handler, use the `set-connection-handler-prop` option with **`dsconfig`**.

  This example shows how to enable correlation ID support.

  ```
  $ dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set use-correlation-id-header:true
  ```

  This example shows how to disable correlation ID support.

  ```
  $ dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set use-correlation-id-header:false
  ```

- To customize the response header name for the correlation ID, use the `set-connection-handler-prop` option with **`dsconfig`**.

  > ⓘ **Note:**
  >
  > The server generates a correlation ID for every HTTP request and sends it in the response through the **`Correlation-Id`** response header.

  This example changes the **`correlation-id-response-header`** property value to `X-Request-Id`.

  ```
  $ dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --set correlation-id-response-header:X-Request-Id
  ```

- To designate the names of one or more HTTP request headers that contain an existing correlation ID value, use the `set-connection-handler-prop` option with **`dsconfig`**.

  > ⓘ **Note:**
  >
  > This enables the server to integrate with a larger system consisting of every servers using correlation IDs.
  >
  > By default, the server generates a new, unique correlation ID for each HTTP request and ignores any correlation ID that might be set on the request.

  ```
  $ dsconfig set-connection-handler-prop --handler-name "HTTPS Connection
   Handler" \
    --set correlation-id-request-header:X-Request-Id \
    --set correlation-id-request-header:X-Correlation-Id \
    --set correlation-id-request-header:Correlation-Id \
  ```

```
   --set correlation-id-request-header:X-Amzn-Trace-Id
```

HTTP correlation ID example

In this example, a request to the Directory REST API is made and the correlation ID enables finding HTTP-specific log messages with LDAP-specific log messages. The response to the API call includes a Correlation-Id header with the value **`a54aee33-c6c6-4467-be25-efd1db7a8b76`**.

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
 Accept: */*
 Accept-Encoding: gzip, deflate
 Authorization: Bearer ...
 Connection: keep-alive
 Host: localhost:1443
 User-Agent: HTTPie/0.9.9

 HTTP/1.1 200 OK
 Content-Length: 266
 Content-Type: application/hal+json
 Correlation-Id: ee919049-6710-4594-9c66-28b4ada4b127
 Date: Fri, 02 Nov 2018 15:16:50 GMT
 Request-Id: 369

 {
      "_dn": "uid=user.86,ou=People,dc=example,dc=com",
      "_links": {
         "schemas": [
            {
              "href": "https://localhost:1443/directory/v1/schemas/
inetOrgPerson"
            }
         ],
         "self": {
              "href": "https://localhost:1443/directory/v1/
uid=user.86,ou=People,dc=example,dc=com"
         }
     },
     "mail": [
         "user.86@example.com"
     ]
 }
```

This correlation ID can be used to search the HTTP trace log for matching log records, as follows:

```
$  grep 'correlationID="ee919049-6710-4594-9c66-28b4ada4b127"'

DNS caching

You can use two global configuration properties to control the caching of host name-to-numeric IP address or DNS lookup results returned from the name resolution services of the underlying operating system.

About this task

Steps

1. To configure these properties, use the **`dsconfig`** tool.

   Global configuration properties and their descriptions

Global configuration property	Description
network-address-cache-ttl	Sets the Java system property **`networkaddress.cache.ttl`**, and controls the length of time in seconds that a host name-to-IP address mapping can be cached. By default, it keeps resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.
network-address-outage-cache-enabled	Caches host name-to-IP address results in the event of a DNS outage. By default, this is set to true, meaning name resolution results are cached. Unexpected service interruptions might occur during planned or unplanned maintenance, network outages, or an infrastructure attack. This cache can allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

2. To reduce delays due to unnecessary DNS lookups, follow these recommendations:
   a. Maintain a connection pool in the client app rather than opening new connections for each bind.
   b. Add appropriate records to DNS, including PTR records.
   c. Add `options timeout:1` or `options single-request` in the `/etc/resolv.conf` file.
   d. If IPv6 requests are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory Server's `config/java.properties` file, so that running `bin/dsjavaproperties` and restarting the server no longer issues IPv6 PTR requests.

IP address reverse name lookups

The PingDirectory Server performs numeric IP address-to-host name lookups.

Numeric IP address-to-host name lookups

The following are some of the numeric IP address-to-host name lookups:

- Binding to the Directory: Decoding, examining, or evaluating a DNS bind rule
- Logging: Logging information to certain monitors or writing to the error log
- Java Management Extension (JMX): Creating a server socket
- Key Management: Generating a trust store
- Replication Server: Creating an SSL socket
- Replication Session Management: Obtaining a session or performing a handshake with a replication server
- Simple Authentication and Security Layer (SASL) Authentication: Applying configuration changes
- SMTP Alert Handler: Initializing or sending an alert notification

Configuring address masks

Address masks configured in Access control instructions (ACIs), connection handlers, connection criteria, and certificate handshake processing might trigger implicit reverse name lookups.

For more information about how address masks are configured in the server, see the following information for each server:

- ACI DNS: bind rules in *Managing Access Control* on page 566 for Directory Server and Directory Proxy Server
- `ds-auth-allowed-address`: *Restricting access through operational attributes in user entities* for Directory Server
- Connection Criteria: *Restricting server access based on client IP address* on page 399 for Directory Server and Directory Proxy Server
- Connection Handlers: *Restricting server access using the connection handlers* on page 399 for a configuration reference guide for all servers

Configuring traffic through a load balancer

Configure the PingDirectory Server to get traffic through a load balancer and to record the actual client's IP address.

Before you begin

By default, when a PingDirectory Server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, it logs incoming requests as originating with the intermediate HTTP server instead of the client that sent the request.

Steps

1. To record the actual client's IP address to the trace log, enable **`X-Forwarded-*`** handling in both the intermediate HTTP server and the PingDirectory Server.
2. Edit the appropriate connection handler object, HTTPS or HTTP, and set **`use-forwarded-headers`** to **`true`**.

   > ⓘ **Note:**
   >
   > When **`use-forwarded-headers`** is set to **`true`**, the server uses the client IP address and port information in the **`X-Forwarded-*`** headers instead of the address and port of the entity that's sending the request, the load balancer. This client address information shows up in logs, such as in the **`from`** field of the HTTP REQUEST and HTTP RESPONSE messages.

3. On the load balancer, configure settings to provide the **`X-Forwarded-*`** information, such as **`X-Forwarded-Host:`**.

Working with the Referential Integrity plugin

Referential Integrity is a plugin mechanism that maintains the distinguished name (DN) references between an entry and a group member attribute. If you have a group entry consisting of member attributes specifying the DNs of printers, you can enable the referential integrity plugin to ensure that the group entry is automatically removed if a printer entry is removed from the Directory Server.

Before you begin

By default, the Referential Integrity plugin is disabled. When enabled, the plugin performs integrity updates on the specified attributes, such as `member` or `uniquemember`, after a delete, modify DN, or a rename, such as subordinate `modifyDN`, operation is logged to the `logs/ referint` file. If an entry is deleted, the plugin checks the log file and makes the corresponding change to the associated group entry.

Important points about the Referential Integrity plugin:

- Index all specified attributes that are configured for Referential Integrity.
- On replicated servers, the Referential Integrity plugin configuration is not propagated to other replicas. You must manually enable the plugin on each replica.

- The plugin settings must be identical on all machines.
- If the Referential Integrity plugin is enabled and configured to operate in synchronous mode, subtree delete operations are not allowed. You must configure the plugin to operate in asynchronous mode by specifying a nonzero update interval for subtree delete operations to perform.

About this task

Enable the Referential Integrity plugin.

Steps

1. Determine the attributes needed for your system.

   By default, the `member` and the `uniquemember` attributes are set for the plugin.
2. To enable the Referential Integrity plugin, run the **`dsconfig`** tool.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
  --set enabled:true
```

Working with the Unique Attribute plugin

The Unique Attribute plugin enforces uniqueness constraints on the values of one or more attributes across a portion of the Directory Server. The plugin checks for uniqueness prior to an add, modify, or modify distinguished name (DN) request and instructs the server to reject the request if a constraint violation is found.

About this task

By default, the plugin is disabled because it can affect performance in heavy write load environments. After the plugin is enabled, it does not check for attribute uniqueness on existing entries, only on new `ADD`, `MODIFY`, or `MODDN` operations. To ensure that no such conflicts exist in the data, administrators can use the **`identify-unique-attribute-conflicts`** command.

> ⓘ **Important:**
>
> Ensure all attributes to enforce for uniqueness are indexed for equality in all backends.
> Use the LDAP SDK uniqueness request control for enforcing uniqueness on a per-request basis. For more information on the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control, see *Use the server SDK and LDAP SDK*. See the ASN.1 specification to implement support for it in other APIs.

You can enforce attribute uniqueness in replicated environments in which each replica contains the complete set of data for which to provide uniqueness, regardless of whether clients communicate directly with the server or interact with it through a Directory Proxy Server. In such environments, all servers have identical uniqueness configurations.

> ⓘ **Note:**
>
> It is not possible to prevent conflicts that arise from simultaneous writes on separate replicas. However, such conflicts are detected after the changes have been replicated and then triggers administrative alert notifications.

For proxied environments that do not have the complete set of data on all servers, such as environments that use entry balancing or that store different portions of the DIT on different servers, implement the Global Uniqueness Attribute plugin on the Directory Proxy Server instead of enabling the attribute

uniqueness plugin on the PingDirectory Server Admin Guide. For more information, see the *PingDirectory Server Admin Guide* and the *PingDirectoryProxy Server Admin Guide*.

To enable the Unique Attribute plugin:

Steps

1. Determine which attributes must be unique in your data.
2. To enable the plugin, run the **dsconfig** tool.

   By default, the plugin type property is set to `postsynchronizationadd`, `postsynchronizationmodify`, `postsynchronizationmodifydn`, `preoperationadd`, `preoperationmodify`, and `preopertionmodifydn`.

   The following example checks for attribute uniqueness prior to `ADD` operation using the `--set plugin-type:preoperationadd` option.

   ```
   $ bin/dsconfig set-plugin-prop --plugin-name "UID Unique Attribute" \
     --set enabled:true
   ```

   a. If you want to set one plugin type, use the `--set plugin-type:<operation-type>` option.

Working with the Purge Expired Data plugin

Use the Purge Expired Data plugin to delete expired entries or attribute values and cleanup expired PingFederate Persistent Access Grants.

When the plugin is enabled, a background thread in the plugin periodically searches for and purges expired data. For optimal performance, enable the Purge Expired Data plugin on multiple servers in a topology. For example, you can configure one server to delete data while others are searching for expired data.

Create and configure the Purge Expired Data plugin with the **dsconfig** tool. Configuration options include the base distinguished name (DN) and filter, the items to be purged, how to identify expired data, and the frequency for polling and purging. You must index the search for expired data. An alarm is raised if the server purging data falls behind the configured **max-updates-per-second**. Monitoring information is available in the Admin Console, or **cn=monitor**.

Configuring the Purge Expired Data plugin for expired entries

About this task

Use the Purge Expired Data plugin to delete all unverified account entries that have not been accessed in the past eight weeks. The is useful for the following scenarios:

- Accounts that potential customers started to create through an application's registration process but then did not complete.
- The phone number or email address that was provided during registration was not verified and should be allowed to be used by another account.

Steps

1. If necessary, enable the Last Access Time plugin:

   The server can track the last access time automatically in the `ds-last-access-time` attribute by enabling the Last Access Time plugin.

   ```
   $ bin/dsconfig set-plugin-prop \
     --plugin-name "Last Access Time" \
     --set enabled:true
   ```

2. To determine expiration order, create an index on the date attribute.

   The Purge Expired Data plugin requires the date attribute that is used to determine expiration to be indexed for ordering.

```
$ bin/dsconfig create-local-db-index \
  --backend-name userRoot \
  --index-name ds-last-access-time \
  --set index-type:ordering
```

3. If there is data present in the directory, rebuild the index.

```
$ bin/rebuild-index \
  --baseDN dc=example,dc=com \
  --index ds-last-access-time
```

4. Create the plugin that purges account entries **`objectclass=account`** that are not verified.

   The following example purges account entries **`verified=false`** after eight weeks of inactivity.

```
$ bin/dsconfig create-plugin \
  --plugin-name "Purge Old Unvalidated Accounts" \
  --type purge-expired-data \
  --set enabled:true \
  --set datetime-attribute:ds-last-access-time \
  --set "expiration-offset:8 w" \
  --set "filter:(&(objectClass=account)(verified=false))"
```

Configuring the Purge Expired Data plugin for expired attribute values

About this task

Use the Purge Expired Data plugin to delete values of an attribute that have expired. For example, an application can track information about an employee's session and then expire the session after 24 hours. There can be multiple active sessions tracked across different devices with session information as shown in the following example.

In this example, the LDAP attribute is `sessioninfo` and the JSON field that stores the timestamp is `creationTime`. These are used to configure the Purge Expired Data plugin.

```
sessionInfo: { "sessionId" : "E85FAC04E331FFCA55549B10B7C7A4FA",
"ipAddress": "10.0.0.00", "userAgent": "Mozilla/5.0 (iPad; U; CPU OS 3_2
 like Mac OS X; en-us)
AppleWebKit/531.21.10 (KHTML, like Gecko) Version/4.0.4 Mobile/7B367
 Safari/531.21.10",
"creationTime" : "2018-03-31T13:10:15Z" }
```

Create the plugin to purge the JSON attribute values after 24 hours, rather than the entire session entry.

Steps

1. Create an index on the `creationTime` field of the `sessioninfo` attribute.

```
$ bin/dsconfig create-json-attribute-constraints \
  --attribute-type sessioninfo \
  --set enabled:true
```

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type sessioninfo \
  --json-field creationTime \
  --set index-values:true \
```

```
  --set value-type:string
```

2. Create and enable the plugin.

```
$ bin/dsconfig create-plugin \
  --plugin-name "Purge Old Session Data Plugin" \
  --type purge-expired-data \
  --set enabled:true \
  --set "custom-datetime-format:yyyy-MM-dd'T'HH:mm:ss'Z'" \
  --set datetime-attribute:sessioninfo \
  --set datetime-format:custom \
  --set datetime-json-field:creationTime \
  --set "expiration-offset:1 d" \
  --set purge-behavior:delete-json-attribute-values
```

Configuring uniqueness across attribute sets

Configure attribute uniqueness across a set of attributes using the `multiple-attribute-behavior` property.

About this task

To enable uniqueness across attribute sets:

Steps

- To configure the UID unique attribute plugin to apply across multiple attributes, use the `dsconfig` tool.

  The following table details the `multiple-attribute-behavior` property and the values it can take.

  The `multiple-attribute-behavior` property values, descriptions, and examples

Value	Description	Example
`unique-within-each-attribute`	If multiple attributes are specified, then uniqueness is enforced for all values of each attribute, but the same value might appear in different attributes in the same entry or in different entries.	For example, assume you have an existing entry that has attributes `telephoneNumber=123-456-7890` and `mobile=123-456-7891`. If you set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-within-each-attribute"` and add: ▪ An entry with a `telephoneNumber` value that matches the `telephoneNumber` attribute in the existing entry, then the add request fails. ▪ An entry with a `mobile` value that matches the `mobile` attribute in the existing entry, then the request fails. ▪ An entry with the same `telephoneNumber` and `mobile` attribute values, such as 123-456-7893, but differs from the values in the existing entry, then the add request succeeds.

Value	Description	Example
`unique-across-all-attributes-including-in-same-entry`	If multiple attributes are specified, then uniqueness is enforced across all of those attributes. If a value appears in one of those attributes that value might not be present in any other of the listed attributes in the same entry, nor in any of the listed attributes in other entries.	For example, assume you have an existing entry that has attributes, `telephoneNumber=123-456-7890` and `mobile=123-456-7891`. If you set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-across-all-attributes-including-in-same-entry"` and add: ▪ An entry with a `telephoneNumber` value, such as 123-456-7890, that matches the `telephoneNumber` attribute in an existing entry, then the add request fails. ▪ An entry with a `mobile` value that matches the `mobile` attribute in an existing entry, then the request fails. ▪ An entry with a `mobile` value, such as 123-456-7890, that matches the `telephoneNumber` attribute in an existing entry, then that fails. ▪ An entry with the same `telephoneNumber` and `mobile` attribute values, such as 123-456-7893, but differ from the values in an existing entry, then the add request fails.

Value	Description	Example
`unique-across-all-attributes-except-in-same-entry`	If multiple attributes are specified, then uniqueness is enforced across all of those attributes. So, if a value appears in one of those attributes, that value might not be present in any of the listed attributes in other entries. However, the same value might appear in multiple attributes in the same entry.	For example, assume you have an existing entry that has attributes, `telephoneNumber=123-456-7890` and `mobile=123-456-7891`. You set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-across-all-attributes-except-in-same-entry"` and add: ▪ An entry with a `telephoneNumber` value, such as 123-456-7890, that matches the `telephoneNumber` attribute in an existing entry, then the add request fails. ▪ An entry with a `mobile` value that matches the `mobile` attribute in the existing entry, then the request fails. ▪ An entry with a `mobile` value, such as 123-456-7890, that matches the `telephoneNumber` attribute in an existing entry, then the request fails. ▪ An entry with a `telephoneNumber` value, such as 123-456-7891, that matches the `mobile` attribute in an existing entry, then the request fails. ▪ An entry with the same `telephoneNumber` and `mobile` attribute values, such as 123-456-7893, but that differs from the values in an existing entry, then the add request succeeds.

The `multiple-attribute-behavior` property is set to `unique-within-each-attribute`, which indicates that uniqueness is enforced for all values of each attribute, such as `telephoneNumber=123-456-7890` and `mobile=123-456-7891`, but the same value, such as either 123-456-7890 or 123-456-7891 might appear in different attributes in the same entry or in different entries.

```
$ dsconfig create-plugin \
  --plug-in "Unique telephoneNumber and mobile" \
  --type "unique-attribute" \
  --set "enabled:true" \
  --set "type:telephoneNumber" \
```

```
  --set "type:mobile" \
  --set "multiple-attribute-behavior:unique-within-each-attribute" \
  --no-prompt
```

Working with the Last Access Time plugin

Use the Last Access Time plugin to record the timestamp of the last activity targeting an entry. The plugin updates the **ds-last-access-time** attribute of the entry when accessing it using an `ADD`, `BIND`, `COMPARE`, `MODIFY`, `MODIFY DN`, or `SEARCH` operation.

Before you begin

Consider the following before using this plugin:

- An updated **ds-last-access-time** attribute value is replicated like any other change to an entry.
- The **ds-last-access-time** attribute is not returned from a search, unless included in the attributes list explicitly, or given the "+" specification for operational attributes.
- The **ds-last-access-time** value format is **yyyyMMddHHmmss.SSS'Z'**, which provides millisecond-level accuracy, such as **20131207144135.821Z**.
- The **ds-last-access-time** attribute can be indexed with a local database index. The ordering index type is the most relevant, but might require a higher index entry limit (default is 4000) to accommodate searches for entries that are not accessed for a long period of time. The ordering index type with a short time range or high index entry limit results in indexed search results for requests, such as **(ds-last-access-time>=20131207144135.821Z)**.

About this task

Use the plugin with the Directory Server Uncached Attribute Criteria or any application that needs to determine the last access time of an entry. The plugin also enables defining request criteria to limit the scope of tracking the last access time. The **max-search-result-entries-to-update** property also prevents mass updates of **ds-last-access-time** when searches contain many results, but might not reflect end-user access.

Steps

- Enable the plugin on all servers that have the same configuration.

> ⓘ **Important:**
>
> For deployments earlier than version 4.5 that use the Last Access Time plugin, disable the plugin before upgrading, and then re-enable it after the update is complete. If servers are running different versions, the `last-access-time` updates might occur with a higher frequency than intended.

Working with the Pass-Through Authentication plugin

Use the Pass-Through Authentication plugin to delegate bind operations to remote LDAP servers by forwarding simple bind requests to an external LDAP server, including Active Directory.

Before you begin

Consider the following points before using the Pass-Through Authentication plugin:

- Configure the plugin to attempt a local bind, to set or update a local password, and to bypass local password policies to ensure remote passwords are migrated.
- Remote servers that accept a forwarded bind request might require connection security, such as a secure StartTLS or LDAPS TLS connection.
- Updating a password in PingDirectory Server might result in divergent passwords between the local and remote server. If necessary, use PingDataSync Server to synchronize passwords between servers.

The following table identifies and describes the configuration properties associated with the Pass-Through Authentication plugin.

The Pass-Through Authentication plugin properties and their descriptions

Property	Description
server-access-mode	Determines whether the servers are accessed in **round-robin**, **failover-on-unavailable**, or **failover-on-any-failure** mode. The default server access mode is **round-robin**.
update-local-password	Indicates whether the local password value requires updating to the value used in the bind request in the event that the local bind fails but the forwarded bind succeeds. To update passwords, a local entry must previously exist.
allow-lax-pass-through-authentication-passwords	Indicates whether updates to the local password value accept passwords that do not meet local password policy requirements.
connection-criteria	Specifies a set of connection criteria that must match the client associated with the local bind request for the bind to be forwarded to the remote server.
request-criteria	Specifies a set of request criteria that must match the local bind request or a local target entry for the bind to be forwarded to the remote server.
dn-map	Specifies one or more distinguished name (DN) mappings that can transform bind DNs before attempting to forward the bind to remote servers.
search-base-dn	Use when searching for a remote user entry by using a filter constructed from the pattern that the **search-filter-pattern** property defines. A DN map and search filter pattern cannot both be configured. If neither a DN map nor a search filter pattern is defined, user entries are expected to have the same DN in the local server and the remote servers.

Steps

- Enable the plugin on all servers that use the same configuration.

The Pass-Through Authentication plugin for the PingOne for Customers service
Although PingDataSync Server supports bidirectional synchronization between PingDirectory Server and the PingOne for Customers service, using the Pass-Through Authentication plugin for PingOne

for Customers Service can propagate password changes from the PingOne for Customers service into PingDirectory Server.

This plugin features a mandatory **try-local-bind** configuration property that enables one of the following modes of operation:

- When **try-local-bind** is `true`, the plugin attempts to authenticate locally first. It sends a request to the PingOne for Customers service only if the local bind attempt fails.
- When **try-local-bind** is `false`, the plugin attempts to authenticate with the PingOne for Customers service first.

The following table identifies and describes the configuration properties associated with the Pass-Through Authentication plugin for PingOne for Customers Service.

Pass-Through Authentication plugin properties and their descriptions for PingOne for Customers Service

Property	Description	Required	Default
api-url	URL that PingDirectory Server uses to communicate with the PingOne for Customers service.	Yes	N/A
auth-url	URL that PingDirectory Server uses to authenticate to the PingOne for Customers service.	Yes	N/A
oauth-client-id	OAuth client ID that PingDirectory Server uses to authenticate to the PingOne for Customers service.	Yes	N/A
oauth-client-secret	OAuth client secret that PingDirectory Server uses to authenticate to the PingOne for Customers service.	Yes	N/A
environment-id	Identifier for the PingOne for Customers environment that contains the users for whom pass-through authentication is attempted.	Yes	N/A
included-local-entry-base-dn	If this value is set, authentication attempts are passed to the PingOne for Customers service only for users in a specified DN. If this value is set, only users who exist within a specified base DN allow their authentication attempts to be passed through to the PingOne for Customers service.	No	All public naming contexts (if not set)
connection-criteria	Reference to a connection criteria object to use to identify the bind requests to pass-through to the PingOne for Customers service based on the server's knowledge of the client expected to be the address, protocol, and security level. If this property is defined, only client connections that match the criteria are included. If this property is not defined, all clients are included.	No	N/A

Property	Description	Required	Default
request-criteria	Reference to a request criteria object to use to identify the bind requests to pass through to the PingOne for Customers service, based on the contents of the request. If this property is defined, only bind requests that match the criteria are included. If this property is not defined, all bind requests are included.	No	N/A
try-local-bind	Indicates whether PingDirectory Server tries to process the bind locally before forwarding the bind request to the PingOne for Customers service. If this value is set to `true` and the bind succeeds locally, PingDirectory Server does not make a request to the PingOne for Customers service. If this value is set to `false`, PingDirectory Server ignores local credentials and attempts to authenticate only to the PingOne for Customers service.	Yes	`True`
override-local-password	Indicates whether PingDirectory Server attempts to bind to the PingOne for Customers service if the local account has a password. This property is used if **try-local-bind** is `true`. If it has a value of `false`, the plugin attempts to authenticate to the PingOne for Customers service only if the local user account does not have a password. If the local bind attempt fails while this value is set to `true`, the server tries to authenticate to the PingOne for Customers service even if the local account has a password.	Yes	`True`

Property	Description	Required	Default
update-local-password	Indicates whether PingDirectory Server attempts to set the password for the local user account, regardless of whether one is already set, when the local authentication attempt fails but the attempt to authenticate with the PingOne for Customers service succeeds. This property is used only if **try-local-bind** is `true`. If the on-premise PingDirectory Server is the authoritative source for passwords, set this property to `false` and configure PingDataSync Server to synchronize password changes from PingDirectory Server into the PingOne for Customers service. If the passwords differ, either the local password or the password for the PingOne for Customers service allows the user to authenticate. If the PingOne for Customers service is the authoritative source for passwords, set this property to `true`. To ensure that a pass-through attempt to the PingOne for Customers service does not override local changes, make all password changes in the PingOne for Customers service.	Yes	`False`
allow-lax-pass-through-authentication-passwords	Indicates whether PingDirectory Server bypasses the normal password-validation process when setting the local password from the PingOne for Customers service. This property is used only when both **try-local-bind** and **update-local-password** are `true`. If this value is `true` when a local bind attempt fails but the authentication attempt with the PingOne for Customers service succeeds, the user's password is updated locally even if a local attempt to change the password to the same value is rejected because the password is considered too weak. If this value is `false`, pass-through authentication succeeds if the authentication with PingOne for Customers service succeeds. However, the password for the PingOne for Customers service does not replace the local password.	Yes	`True`
ignored-password-policy-state-error-condition	Set of zero or more password policy state error conditions that are ignored for pass-through authentication. For a list of values and their descriptions, see the following table.	No	N/A

Property	Description	Required	Default
user-mapping-local-attribute	Name of an LDAP attribute that is used to map local user entries to the corresponding PingOne for Customers account. This property must include the same number of values as the **user-mapping-remote-json-field** property, and the order of their values is correlated. If multiple values are specified, all attributes must be present in the local entry, and the plugin performs an `AND` search in the PingOne for Customers service to locate the user account with all the values in the corresponding fields. The `entryDN` attribute can be used to represent the DN of the local entry.	Yes	N/A
user-mapping-remote-json-field	The name of a PingOne for Customers field used to map local user entries to the corresponding PingOne for Customers account. This property must include the same number and order of values as the `user-mapping-local-attribute` property.	Yes	N/A
additional-user-mapping-scim-filter	The System for Cross-domain Identity Management (SCIM) filter included in the search and used to identify the PingOne for Customers account that corresponds to the local user entry. If a value is provided for this property, it is used with the SCIM filter that was created to map the local user entry to a PingOne for Customers account. If a value is not provided for this property, no additional filter is used.	No	N/A

The following table identifies the values to use with the optional configuration property **ignored-password-policy-state-error-condition** and describes the scenarios in which a user is permitted to bind when using pass-through authentication.

Optional configuration property and the scenarios for use when using pass-through authentication

Property	Scenario in which a user can still bind by using pass-through authentication
temporarily-locked-due-to-failures	The account is locked temporarily because of too many failed attempts.
permanently-locked-due-to-failures	The account is locked permanently because of too many failed attempts.
locked-due-to-idle-interval	The account is locked because the user has not authenticated recently.

Property	Scenario in which a user can still bind by using pass-through authentication
locked-due-to-maximum-reset-age	The account is locked because an administrator recently reset the password, and the user failed to specify a new password within the allotted time frame.
password-is-expired	The password is expired.

Troubleshooting server performance issues

The following are the most common reasons that customers encounter performance issues and some suggestions for diagnosing and addressing these issues.

Slow password storage schemes

Slow password storage schemes are configurable schemes designed to use a lot of CPU and memory to thwart attackers, but they can affect legitimate operations like password validation and authentication.

The following password storage schemes are intentionally expensive:

- PBKDF2
- bcrypt
- scrypt
- Argon2
- The MD5, SHA-2-256 and SHA-2-512 variants of the crypt scheme

These schemes are designed to consume a significant amount of CPU, and memory in some cases, to increase the amount of resources an attacker must expend to crack a password if they happen to get access to the password's encoded representation. This same cost is also incurred for legitimate operations involving the password, including encoding clear-text passwords during account creation and password changes and when validating passwords during authentication. You can configure these schemes to adjust the amount of resources they consume, and you should configure them so that the resource consumption under expected peak load does not exceed the capacity of the topology.

Additionally, if you are initially populating the server using an LDIF import that contains clear-text passwords, using one of these schemes can cause the LDIF import to proceed at a small fraction of the rate that could be achieved with a faster storage scheme, such as one that uses a 256-bit or 512-bit salted SHA-2 digest. In such cases, you might import the data using a faster scheme and then change the configuration to make the desired scheme the new default, and mark the scheme used for import as deprecated. As a result, accounts with passwords encoded using the import scheme are automatically re-encoded with the new scheme the first time that the user successfully authenticates using that password.

Database size versus memory capacity

Best performance is achieved when the contents of the database can be fully cached in memory.

If possible, the amount of memory allocated to PingDirectory Server should be large enough so that all of the data can fit in the database cache. Memory sizing estimates appear at the end of the output when you run the `import-ldif` tool.

If the amount of data that needs to be stored exceeds the available memory capacity of the individual systems on which the server runs, there are a couple options:

- Break up the data into segments that are small enough to be fully cached on their own, and use PingDirectoryProxy Server's entry balancing functionality to make them appear as a single logical set.
- Tune the server so that the most frequently accessed information can be served from memory while disk access might be required for other data. In disk-bound deployments, you can use backend

configuration options such as cache mode, uncached attribute criteria, and uncached entry criteria to help prioritize what data should remain in memory versus what can be retrieved from disk.

Large number of access control rules
As the number of access control rules increases, so does the potential costs of determining whether a client is allowed to request a given operation and of paring down search result entries based on the data that the client is permitted to access.

The server might need to re-evaluate all access control rules after certain update operations, including modify DN operations, to determine whether these are affected by the change.

In many cases, deployments with an extremely large number of access control rules, especially those with large numbers of branches in which the same structure might be repeated across each of these branches, might be able to leverage parameterized access control instructions (ACIs) to dramatically reduce the number of access control rules that need to be defined and evaluated. In other cases, it is possible to refactor the access control configuration to achieve the same effect but with far fewer rules.

Large static groups
PingDirectory Server supports large static groups with hundreds of thousands of members or more, but these can have a significant impact on performance. Consider replacing large static groups with dynamic groups.

It can be expensive in terms of system resources to update the large static group to add or remove members because each update requires rewriting the entire entry. It can also be expensive to decode the entry when retrieving it from the database, even if it is held in the database cache, and to return the list of members to a client in search results.

If possible, consider replacing large static groups with dynamic groups. Dynamic groups automatically determine their membership based on criteria defined in LDAP URLs. A dynamic group consumes little memory and disk space and does not need to be altered as entries are created, updated, and removed. In some cases, it is possible to use virtual static groups in conjunction with dynamic groups to create entries that behave like static groups for read operations. This lets you maintain compatibility with applications that only understand static groups but use dynamic groups behind the scenes to determine membership.

If it is not possible to eliminate large static groups, you can enable the static group entry cache. While this does not reduce the performance impact of updating large static groups, it can make it much more efficient to access those groups for read operations.

Large index ID sets
Indexes store data that make it possible to quickly retrieve matching entries during a search. As the size of an ID set increases, so does the potential resource cost of accessing the ID set.

Each index record maps an index key to a list of the entry IDs for the entries that match that key. If you have an equality index for a given attribute, there is a key for each unique value for that attribute and the values for each key of the IDs of the entries that contain that value. For substring indexes, there can be multiple keys for the same attribute value (one for each unique six-character substring within the value), and the same substring can apply to many different values of the same attribute.

For an attribute index, you can store ID sets in one of two ways that each affect performance differently:

- In the regular (non-exploded) case, each index key occurs once, and the value of this key is the entire list of IDs for entries that match the key. The ID set for a non-exploded index key can be retrieved quickly because only a single database read is required. However, as the size of the ID set grows, the cost of updating it grows because it is necessary to replace the entire set, which requires larger amounts of disk I/O and can place an increased burden on the database cleaner.
- In the exploded case, the same key can be stored multiple times (one for each entry that matches that key), with each instance of the key associated with a different entry ID. Updating the ID set for an exploded key is always fast because the writes are small, but the cost of reading the ID set increases with the number of IDs.

You can also use composite indexes. These offer many advantages over attribute indexes and when they can be used. Some of these advantages, such as the ability to configure a base DN or combinations of attributes, do not have any effect on performance with regard to large ID sets. They use a hybrid of the exploded and non-exploded approaches to maintaining the ID set, such that a large set can be split into multiple pieces, but each piece can have up to 5000 IDs rather than just one. This means that retrieving a large ID set from a composite index can be thousands of times cheaper than retrieving the same ID set from an exploded attribute index. Updating a large ID set in a composite index should be cheaper in terms of systems resources than updating the same ID set in a non-exploded attribute index because the write is much smaller.

In environments with performance problems related to very large index ID sets, you might consider the following options as a way to help improve performance:

- Consider reducing the index entry limit for that index. The index entry limit specifies the maximum number of IDs that an ID set can have for an index key.
  - If a key matches more entries than this limit, the server stops maintaining the index for that key, and attempts to access it behave as if it were unindexed, while the index continues to be maintained for keys matching smaller numbers of entries. If you don't have searches that depend only on those keys, then this is an excellent way of eliminating the cost of maintaining large ID sets. It isn't logical to set the index entry limit to a value that is a large percentage of the total number of entries in the server. In such cases, there might not be a significant performance difference between indexed and unindexed search performance, but there would be no need to maintain the associated large ID sets.
- If there are cases in which you need a large index entry limit, then consider increasing the limit only for that index, rather than increasing the default limit for all indexes in the backend.
  - The `index-entry-limit` property in the backend applies to all indexes that don't specify their own limit, but each index also offers an `index-entry-limit` property that, if set, overrides the index entry limit configured for the backend. As such, if you need a higher index entry limit for a particular index, set a higher limit just for that one index instead of raising the default limit for all indexes in the backend.
- For attribute indexes with keys matching a large number of entries, consider converting it to a composite index when possible.
  - Composite indexes can completely replace equality and ordering attribute indexes, and they can support "starts with" substring searches, regardless of whether they have "contains" or "ends with" components. Composite indexes can't currently replace approximate match indexes or substring searches that don't have a "starts with" component.
- Consider eliminating any unnecessary substring indexes.
  - As previously noted, substring indexes are more likely to have large ID sets than equality, ordering, or approximate match indexes because substring keys are generally smaller and any given substring key can apply to multiple attribute values. It's also not commonly understood that equality attribute indexes and equality composite indexes are used for substring searches with a "starts with" component. As such, a substring index is not used for substring searches with a "starts with" unless there isn't an equality index for that attribute.
  - If a substring index is defined for an attribute that isn't targeted by substring searches, or that is only targeted by substring searches that contain a "starts with" component (regardless of whether it also includes "contains" or "ends with" components), then that substring index is not necessary and can be removed. You can use access logs to determine the types of searches that clients are performing, and the `summarize-access-log` and `search-logs` tools might help with that.
- If a substring index is needed for a given attribute, then consider increasing the substring length for that index.
  - By default, the server creates a separate substring key for each unique six-character substring in an attribute value, and there might be cases in which the same six-character substring appears in several different values. If that occurs and causes substring keys to have large ID sets, then increasing the substring length for that index reduces the number of values that might share the any given key and can reduce the number of IDs associated with that key.

- As a last resort, consider tuning the exploded index threshold for an index (the number of entries that an ID set needs to have for a given key before it will transition from a non-exploded set to an exploded one) based on the expected usage for that index.
  - If search performance is more important than update performance for an attribute with large ID sets, then raising the exploded index threshold helps keep the ID set stored as a monolithic block of IDs. On the other hand, if update performance is more important than search performance, then lowering the exploded index threshold might help.

Missing indexes
Maintain indexes to determine if an index is missing.

Maintaining unneeded indexes can have a detrimental effect on performance, but it can also be detrimental if a needed index is missing.

The best way to identify expensive searches processed in the server is to examine the access logs for search operations with a high `etime` (elapsed processing time) value. After you identify these search operations, you can filter out any of these operations that do not need to be fast. For example, you might have applications that generate reports by performing inefficient searches, such as searches to retrieve all entries, and it is usually more acceptable for those searches to be slow.

For any remaining searches that are slow or that should be faster, the best way to understand why the search is expensive is to issue a search with the same base DN, scope, and filter, but request only the `debugsearchindex` attribute.

> ⓘ **Note:**
>
> `debugsearchindex` is a special attribute that makes the server return debug information about the index processing that is being performed in the course of evaluating the search, and how long it took to complete each step of the evaluation.

From this output, you can see which indexes were used and which could not be used because there was either no applicable index or the index entry limit had been exceeded for the target key. You can see expensive accesses to exploded indexes and identify indexes you want to add, indexes that can benefit from being converted to composite indexes, or indexes where you might need to increase the index entry limit. Alternatively, you can determine a different way to perform the search so that it does not depend on components that are unindexed or that match a large number of entries.

Configuring the Directory Server for Oracle compatibility

Configure the Directory Server for Oracle compatibility.

About this task

For companies that are migrating from an Oracle server to the PingDirectory Server, the PingDirectory Server provides a **`dsconfig`** batch file, `sun-ds-compatibility.dsconfig`, which describes the various components that can be configured to make the server exhibit behavior closer to an Oracle configuration.

Administrators can use the `sun-ds-compatibility.dsconfig` batch file to apply the Directory Server's configuration with the necessary **`dsconfig`** commands by uncommenting the example commands listed in the file and then running the **`dsconfig`** command specifying the batch file.

> ⓘ **Note:**
>
> This batch file is not comprehensive and must be used together with the **`migrate-sun-ds-config`** tool, located in the `bin` folder, or `bat` folder for Windows systems, during the migration process. Both the tool and the batch file overlap in some areas but provide good initial migration support from the Oracle server to a Ping Identity server.

Another useful tool is the **migrate-ldap-schema** tool in the `bin` folder, or `bat` folder for Windows systems, which migrates schema information from an existing LDAP server onto this instance. All attribute type and object class definitions that are contained in the source LDAP server are added to the targeted instance or written to a schema file.

Steps

1. From the Directory Server server root directory, open the `sun-ds-compatibility.dsconfig` file in the `docs` folder.

   You can use a text editor to view the file.
2. Read the file completely.
3. Apply any changes to the file by removing the comment symbol at any **dsconfig** command example, and then applying the **dsconfig** command specifying the batch file.

```
$ bin/dsconfig --no-prompt --bindDN "cn=Directory Manager" \
  --bindPassword "password" --batch-file /path/to/dsconfig/file
```

4. Run the **migrate-ldap-schema** tool to move the schema definitions on the source server to the destination Ping Identity server.

```
$ bin/migrate-ldap-schema
```

5. Run the **migrate-sun-ds-config** tool to see what differences exist in the Ping Identity configuration versus the Oracle configuration.
6. On the PingDirectory Server, run the following command.

```
$ bin/migrate-sun-ds-config
```

7. Test the server instance for further settings that might not have been set with the batch file, the **migrate-ldap-schema** tool, or the **migrate-sun-ds-config** tool.
8. If you notice continued variances in your configuration, contact your authorized support provider.

Supporting unindexed search requests

By default, the Directory Server denies all unindexed search requests, except for those issued by the bind distinguished names (DNs) that have the `unindexed-search` privilege.

About this task

This default behavior keeps the server from tying up worker threads on time-consuming, unindexed searches. However, you can turn off the enforcement of the `unindexed-search` privilege to allow any client to perform an unindexed search.

Steps

1. Set the `disabled-privilege` global configuration property to `unindexed-search` as follows.

```
$ bin/dsconfig set-global-configuration-prop \
  --set disabled-privilege:unindexed-search
```

2. If you choose to allow unindexed searches, cap the maximum number of concurrent unindexed search requests using the `maximum-concurrent-unindexed-searches` global configuration property.

```
$ bin/dsconfig set-global-configuration-prop \
  --set maximum-concurrent-unindexed-searches:2
```

3. Limit unindexed search privileges for particular clients using the `allow-unindexedsearches` property of the client connection policy.

   For more information about configuring client connection policies, see *Client connection policy configuration*.

Syncing passwords to PingOne

Create a direct attribute mapping to sync passwords from PingDirectory Server to PingOne.

About this task

PingDirectory Server maps the userPassword attribute to thepassword attribute to sync passwords with PingOne.

Steps

- To create a direct attribute mapping, run the following.

```
dsconfig create-attribute-mapping \
--map-name PingDirectory_to_PingOne_User_Map \
--mapping-name password \
--type direct \
--set from-attribute:userPassword
```

  PingDataSync Server can synchronize passwords that have been encrypted by PingDirectory Server or a hashed version of the password, depending on how an administrator chooses to store passwords on PingDirectory Server.
- To sync passwords from a generic relational database management system (RDBMS), create a direct attribute mapping with the from-attribute being whichever attribute the RDBMS uses to store the password.

  In the following example, the RDBMS uses the `dbPassword` attribute to store the password.

```
dsconfig create-attribute-mapping \
--map-name Generic_RDBMS_to_PingOne_User_Map \
--mapping-name password \
--type direct \
--set from-attribute:dbPassword
```

  RDBMS passwords cannot be encrypted and should be hashed with a scheme that PingDirectory Server recognizes.

  PingDataSync Server cannot synchronize passwords between PingOne systems because PingDataSync Server cannot retrieve passwords from PingOne.

Configuring PingOne to use SSO for the PingData Administrative Console

Allow administrative users to single sign-on (SSO) to the PingData admin console from PingOne.

Before you begin

You need the following to complete this process:

- A configured PingData server. This server will host the the PingOne administration console console that is being configured for SSO.
- A PingOne for Customers account. For more information, see *Getting started with PingOne for Customers*.
- Access to the the PingOne administration console console. For more information, see *Using the beta version of My Ping*.

Steps

1. In the PingOne administration console, add a link to the PingOne solutions home page.
   a. In the the PingOne administration console admin console, click **Add Environment**.

      If you're adding PingDirectory Server or PingDataGovernance Server to an existing environment, click the name of an environment, click the **Plus** icon and click **Add** to add PingDirectory.
   b. To create an environment, on the **Create Environment** page, select from **Customers**, **Workforce**, or **Custom**.
   c. Select **PingDirectory** and **PingOne for Customers**.
   d. Click **Next**.
   e. Select `It's already been deployed`.
   f. In the **Enter Admin URL** field, enter `https://<hostname>:<port>/console/login`, replacing the bracketed variables with the PingData server's hostname and HTTP port.
   g. Click **Next**.
   h. In the **Environment Name** field, enter a name for this environment.
   i. Optional: In the **Description** field, enter a description for the environment.
   j. From the **Region** list, select your data center region.
   k. From the **License** list, select the license for this environment.
   l. Click **Finish**.
2. To configure the matching administrator accounts for PingOne and the PingData server, go to the PingOne dashboard for the environment that will be used with the PingData server and repeat the following steps for each PingOne user for whom you want to enable SSO.
   a. In the PingOne administration console, on your environment line, click the **PingOne** icon.
   b. In PingOne, go to **Identities**.
   c. On the line of the administrative user you want to configure, click the **Expand** icon.
   d. Run the following **`dsconfig`** command against the PingData server, replacing the bracketed fields with the values of the administrative user.

      ```
      dsconfig create-root-dn-user --user-name <Username> \
        --set first-name:<Given Name> \
        --set last-name:<Family Name>
      ```
3. Register the Administrative Console with PingOne.
   a. Go to *Add an application - Web application* and follow the instructions in the **Add an OIDC application** subsection.
   b. Enter the application properties as shown in the following table.

Property	Value
Application Name	PingData Administrative Console
Description	Application for the PingData Administrative Console
Redirect URLs	`https://<hostname>:<port>/console/oidc/cb`
Attribute Mapping	'Username' = 'sub'

> ⓘ **Note:**
>
> Fill in the bracketed values in **Redirect URLs** with your PingData server's hostname and HTTP port.

4. Edit the listed properties for the newly created application so that the properties have the values show in the following table, following the instructions in *Edit an application - OIDC* in the PingOne Administration Guide.

Property	Value
Response Type	Code
Grant Type	Authorization Code
Token Endpoint Authentication Method	Client Secret Basic

5. Record the values for the following application properties to use in later steps:
   - Issuer
   - Client ID
   - Client Secret
6. Create a copy of the `PingDirectory/config/sample-dsconfig-batch-files/enable-pingone-admin-console-sso.dsconfig` file, leaving the source file as-is.
7. Open the copy of the file and replace the bracketed values with the values from step 5.
8. Run the file using the following command.

```
dsconfig --batch-file \
    enable-pingone-admin-console-sso-copy.dsconfig \
    --no-prompt
```

9. Click the link to the PingData server from the PingOne solutions home page.
   A PingOne sign on page displays.
10. Sign on using the administrative user credentials.
    The Administrative console index page displays.

Configuring Soft Deletes

PingDirectory Server 3.2.4 and later supports a soft-delete feature.

This feature preserves a deleted entry's attribute and uniqueness characteristics so it can be undeleted or permanently removed at a later date.

About soft deletes

Soft deletes preserve a deleted entry's attribute and uniqueness characteristics so it can be undeleted or permanently removed at a later date.

The standard implementation of an LDAP server allows adding, renaming, modifying, searching, comparing, and deleting one or more entries. By specification, the `delete` operation permanently removes an entry and its attributes in a Directory Information Tree (DIT) but records the changes in access, and optionally, audit and change logs. The `delete` operation severs any associations such as references and group memberships. Meta attributes, such as operational attributes, which can be unique to an entry like `entryUUID`, are lost or different if the same entry is re-added to the Directory Server.

There are cases where a company might want to preserve their deleted entries to allow for possible undeletion at a later date. For example, a company might want to retain account and subscriber entries for their users who leave but later rejoin. Artifacts that a user creates such as account histories, web pages, notes, can be tracked and recovered while a user is deleted or when the user returns as an active customer. Soft deletes facilitate this use-case.

A delete request can result in a soft delete either by the client explicitly requesting a soft delete or by the request matching criteria defined in an active soft delete policy. The soft-deleted entries are renamed by prefixing an `entryUUID` operational attribute to the DN and adding an auxiliary object class to the entry, `ds-soft-delete-entry`, which saves the entry in a hidden state. All active references and group memberships are then removed. While in this hidden state, clients cannot access soft-deleted entries under normal operating conditions. Only clients with the `soft-delete-read` privilege can interact with soft-deleted entries.

To allow soft deletes, the Directory Server's attribute uniqueness function has been relaxed to allow for the co-existence of a soft-deleted entry and an active entry with identical naming attributes, such as `uid`. For example, if a user John Smith was soft deleted, but a different John Smith was added to the user accounts system, both entries can reside in the DIT without conflict. One entry would exist in a soft-deleted state and the other in an active state. The Directory Server extends this capability by allowing multiple users with the same DN, who would normally conflict if active, to reside in the soft-deleted state.

Soft-deleted entries can be restored with an `undelete` operation. The same uniqueness constraints that apply when adding a new user to the Directory Server are enforced when a soft-deleted entry is undeleted. In the previous example, John Smith was soft-deleted, but a different John Smith with the same `uid` as the original John Smith was later added to the system. If the original John Smith was undeleted from its soft-deleted state, it would result in a conflict with the active John Smith entry. Administrators must modify the DN of the soft-deleted entry to avoid such conflicts.

Administrators can permanently remove a soft-deleted entry by performing a regular `delete` operation on it. This operation, called a hard delete, permanently removes a soft-deleted entry from the server. You can also permanently remove a regular non-soft-deleted entry using a hard delete. This is useful when the server is configured with a soft-delete policy that would otherwise turn a regular delete request into a soft delete.

The Directory Server provides tool arguments that can use the soft delete request control, the hard delete request control, and other controls necessary to process these operations. Procedures to show how to use these options are presented later in this section.

For replicated topologies, when a participating directory server soft deletes an entry, it notifies the other replicas in the topology to soft delete the same entry on its respective machine. The changelog backend also records these entries by annotating them using an attribute that indicates its soft-deleted state. Modification and hard deletes of soft-deleted entries are not recorded by default in the changelog but can be enabled in the server. For maximum compatibility, make sure all servers in the replication cluster support soft deletes and have identical soft delete configurations.

General tips on soft deletes

Administrators should be aware of the following tips about soft deletes:

- The LDAP SDK and Server SDK both fully support soft-deletes.
- There is little performance difference between retrieving a regular entry and a soft-deleted entry. However, there might be a performance impact when a search operation has to match criteria, such as `uid=john.smith`, for both active entries and soft-deleted entries. For example, if there is one active `uid=john.smith` entry and two soft-deleted `uid=john.smith` entries, it might take the server more time to retrieve and try to match the criteria before it can return the results.
- The soft delete feature fully supports uncached attributes and uncached entries. For more information, see *Uncached Attributes and Entries*.
- Soft-deletion is allowed for leaf nodes only. Soft-deletion of any parent entry is not allowed. Likewise, soft-deleted entries that have soft-deleted sub-entries are not allowed.
- There are two available state options for soft-deletes:
  - Administrators can permanently delete a soft-deleted entry or undelete the entry.
  - Administrators cannot soft-delete an already soft-deleted entry, which returns an `UNWILLING_TO_PERFORM` result code.

- Soft-deleted users have no privileges. Soft-deleted users do not have the ability to bind to the Directory Server or have authentication access. They cannot change their passwords and cannot undelete themselves. Soft-deleted entries also cannot be used as an authorization identity using the proxied authorization or immediate client control. The soft-delete process does not destroy privilege assignment. If a soft-deleted entry is undeleted, the restored entry retains the same privileges it originally had before being soft deleted. One possible exception to this are privileges assigned by virtual attributes that no longer match the newly-undeleted entry. Those entries do not retain their original privileges.
- Soft-deleted entries might not be accessible from alternate access methods like SCIM.
- Soft-deleted entries can be modified but not renamed. Administrators can search for all soft-deleted entries and the original source entry attributes can be updated as long as the administrator has modify privileges and access to the `soft-delete-read` privilege. Any attempt to rename a soft-deleted entry using a `modify DN` operation results in an `UNWILLING_TO_PERFORM` result code.
- Replication has access to the LDAP operations with soft delete controls. These operations are transmitted, processed, and replayed as high-level requests, which are re-played on remote replicated servers. The replication conflict-resolution mechanism handles soft-deleted entries like any regular entries. For example, if a soft delete is executed independently on two servers and is then replicated, this results in a replication conflict. For maximum compatibility, all servers in a replication cluster should support soft deletes and have identical soft delete configuration.
- Soft-deletes are supported in transactions. The processing workflow uses the transactions mechanism and maintains the context information necessary to rollback failures to soft delete or undelete.
- There are no special configuration steps to configure soft deletes on the Directory Proxy Server. The soft-deleted entry is routed directly to the underlying Directory Server. There is one exception: in an entry-balancing deployment, the Directory Proxy Server is responsible for routing the soft-deleted entry to the Directory Server containing the originally soft-deleted item. As with standard entry-balanced deployments, it is not possible to use `moddn` to undelete an entry to a different Directory Server.
- The default behavior includes soft-deleted entries as part of the **`export-ldif`** operation. If soft-deleted entries are to be excluded from export, administrators can use the `--excludeSoftDeleteEntries` option to filter out the entries.
- The soft delete feature can be used with users who have proxied authorization privileges.
- For customers using the PingDataSync Server, soft-deleted entries are not synchronized by the server. Modifications or deletes of a soft-deleted entry are ignored by the Data Sync Server, and do not appear in the changelog by default. An actual soft delete operation appears to the changelog as a regular `delete` operation, and an actual undelete operation appears in the changelog as a regular `add` operation.
- References to a deleted DN are not restored by the referential integrity plugin when you undelete a soft-deleted entry. For example, if you have referential integrity enabled and you soft-delete a DN that is a member of a static group, the referential integrity plugin removes this DN from the group's list of members. When you undelete the soft-deleted entry, the plugin does not add the entry back to the group.
- The soft delete policy configuration supports two new properties, `soft-delete-retention-time` and `soft-delete-retain-number-of-entries`, that perform the purging of soft-deleted entries. For more information, see *Configuring Soft-Delete Automatic Purging*.
- The root user account, such as `cn=Directory Manager`, has access to all of the controls needed to run the soft delete operations by default. For non-root users, you must grant access to these soft delete controls using access control rules. An example is shown in step 1 of *To Configure Soft Deletes as a Global Configuration*. The following soft delete controls are available to non-root users:

  Soft delete request control

  Allows the user to perform a soft delete operation. The object identifier (OID) for the control is 1.3.6.1.4.1.30221.2.5.20.

  Soft delete response control

Allows the server to hold the DN of the soft-deleted entry that results from a soft delete request. The OID for the control is 1.3.6.1.4.1.30221.2.5.21.

Hard delete request control

Allows the user to run a hard delete operation on the entry, regardless if it is a regular or soft-deleted entry. The OID for the control is 1.3.6.1.4.1.30221.2.5.22.

Undelete request control

Allows the user to undelete a soft-deleted entry using an ADD request. The OID for this control is 1.3.6.1.4.1.30221.2.5.23.

Soft-deleted entry access request control

Allows the user to search for any soft-deleted entries. The OID for this control is 1.3.6.1.4.1.30221.2.5.24.

> ⓘ **Note:**
>
> A bind DN with the `stream-values` privilege can perform operations that can reveal soft-deleted entries, even if that bind DN does not have permission to use the soft-deleted entry access request control. For example, if a user can successfully run **`dump-dns`** or **`ldap-diff`**, then that user can get a list of soft-deleted entry DNs or soft-deleted entry contents through the output of one of those tools.

Configuring soft deletes on the Server

Use any of the following methods to configure soft deletes on the Directory Server.

Method	Description
Using a soft-delete policy and global configuration property	Configure soft deletes by creating a soft-delete policy and a global configuration property. The soft-delete policy enables the feature on the server, while the global configuration property sets the controls used for the soft-delete requests. To enter a soft delete request, the **`ldapmodify`** or **`ldapdelete`** command requires the `--useSoftDelete` option. A delete request that does not have the `--useSoftDelete` option is treated as a hard delete, which permanently removes the entry.
Using connection criteria	Configure soft deletes by defining connection criteria within a client connection policy. Any clients that meet the criteria have their deletes processed as soft deletes.
Using request criteria	Configure soft deletes by defining request criteria within a client connection policy. Any client requests that meet the criteria have their deletes processed as soft deletes. ⓘ **Note:** You can define both connection criteria and request criteria. Both criteria can exist within a soft-delete

Method	Description
	policy. In this case, the connection criteria is processed first, then the request criteria.

Configuring soft deletes as a global configuration
Configure the soft delete feature by creating a soft delete policy and then setting the configuration property on the server. The presence of the soft-delete policy enables the feature on the server and allows the global configuration property to send the necessary soft delete requests.

About this task

For this configuration, use the `--useSoftDelete` option used with the **`ldapmodify`** or **`ldapdelete`** commands to send the delete using the soft delete request control. Without the `--useSoftDelete` option, any delete is processed as a hard delete.

To configure soft deletes as a global configuration:

Steps

1. Configure a soft delete policy using the **`dsconfig`** command.

   The soft delete configuration requires a soft delete policy, which enables the feature on the server.

   ```
   $ bin/dsconfig create-soft-delete-policy \
     --policy-name default-soft-delete-policy
   ```

2. Configure the soft delete as a global configuration property using the **`dsconfig`** command.

   This command sets up the soft delete controls necessary to send them as a request.

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --set soft-delete-policy:default-soft-delete-policy
   ```

Configuring a user to use soft or hard delete controls
To use soft deletes, a user must have access to the appropriate controls. By default, only the Directory Manager has access to these controls.

About this task

The user must also have the **`soft-delete-read`** privilege. Access control instructions (ACIs) allow the user to:

- Modify target entries
- Use the soft delete and undelete controls
- Use the soft-deleted entry access control to modify soft-deleted entries
- Use the hard delete request control to permanently delete an soft-deleted entry

The **`uid=admin,dc=example,dc=com`** user that is installed with the sample data during setup already has an ACI giving it access to user entries as follows.

```
(targetattr="*")(version 3.0; acl "Grant full access for the admin user";
allow (all) userdn="ldap:///uid=admin,dc=example,dc=com”;)
```

Steps

1. To restrict the scope, add the following ACIs to the base suffix or other point in the directory information tree (DIT) as required.

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.21")
(version 3.0; acl "Allow admins to use the Soft Delete Request Control and
 Soft Delete Response Control";
allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.22") (version 3.0; acl "Allow admins
 to use the Hard Delete
Request Control";allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.23") (version 3.0; acl "Allow admins
 to use the Undelete
Request Control";allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.24") (version 3.0; acl "Allow admins
 to use the Soft-Deleted
Entry Access RequestControl"; allow (read) userdn="ldap:///
uid=admin,dc=example,dc=com”;)
```

2. Add the **`ds-privilege-name`** attribute to the user with the value **`soft-delete-read`**.

```
$ ./bin/ldapmodify -s -p 1389 -D uid=admin,dc=example,dc=com -w password
# Successfully connected to localhost:1389.

dn: uid=user.10,ou=people,dc=example,dc=com
changetype: delete

# Deleting entry uid=user.10,ou=people,dc=example,dc=com ...
# Result Code:  0 (success)
# Soft Delete Response Control:
#      OID:  1.3.6.1.4.1.30221.2.5.21
#      Soft-Deleted Entry DN:  entryUUID=8dbe8cb4-1aa3-41c5-88ec-
a6280eeff918+uid=user.10,ou=People,dc=example,dc=com
```

Searching for soft deletes

Soft-deleted entries are excluded from normal LDAP searches because they represent deleted entries. The updated **`ldapsearch`** tool supports these types of searches.

About this task

There are three different ways to search for soft-deleted entries.

Steps

- To perform a base-level search on a soft-deleted entry by distinguished name (DN), run the **`ldapsearch`** command and specify the base DN of the specific soft-deleted entry that you are searching for.
- To filter your search by `ds-soft-delete-entry` object class, run a search for all soft-deleted entries with the **`ldapsearch`** command with a filter on the `ds-soft-delete-entry` object class.

- To return soft-deleted entries, use the soft-delete-entry-access-control with the LDAP search.

  The **ldapsearch** tool provides a shortcut option, `--includeSoftDeletedEntries`, that sends the control to the server for processing. The control allows for the following search possibilities:

  - Return only soft-deleted entries.
  - Return non-deleted entries along with soft-deleted entries.
  - Return only soft-deleted entries in undeleted form.

Running a base-level search on a soft-deleted entry
Use the command line to run a base-level search on a soft-deleted entry.

Steps

- Run the **ldapsearch** command using the base distinguished name (DN) of the specified soft-deleted entry.

```
$ bin/ldapsearch \
  --baseDN entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com \
  --searchScope base "(objectClass=*)"
```

```
# Soft-deleted entry DN:
# entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-soft-delete-entry
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239

st: TN
```

Running a filtered search by soft-delete-entry object class
Retrieve all soft-deleted entries using the `ds-soft-delete-entry` object class.

Steps

- Run the **ldapsearch** command to retrieve all soft-deleted entries using the `ds-soft-delete-entry` object class.

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
```

```
  "(objectclass=ds-soft-delete-entry)"
```

Running a search using the soft delete entry access control

The following examples use the `--includeSoftDeleteEntries {with-non-deleted-entries | without-non-deleted-entries | deleted-entries-in-undeleted-form}` option, which uses the soft delete entry access control.

About this task

You can use the `--control` option with the soft delete entry access control symbolic name, `softdeleteentryaccess`, or the `--control` option with the actual soft delete entry access control OID, `1.3.6.1.4.1.30221.2.5.24`.

Steps

1. To return only soft-deleted entries, run **`ldapsearch`** using the `--includeSoftDeletedEntries` option with the value of `without-non-deleted-entries`.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com \
     --includeSoftDeletedEntries without-non-deleted-entries \
     --searchScope sub "(objectclass=*)"
   ```

2. To return non-deleted entries along with soft-deleted entries, run **`ldapsearch`** using the `--includeSoftDeletedEntries` option with the value of `with-non-deleted-entries`.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com \
     --includeSoftDeletedEntries with-non-deleted-entries \
     --searchScope sub "(objectclass=*)"
   ```

3. To return only soft-deleted entries in undeleted form, run **`ldapsearch`** using the `--includeSoftDeletedEntries` option with the value of `deleted-entries-in-undeleted-form`.

   Some applications require access to all entries in the server, including both active and soft-deleted entries.

   The following command returns all entries that were soft-deleted but presents it in a form that is similar to a regular entry with the soft-delete DN in comments. This regular entry format does not show the actual soft-deleted DN but displays it in an "undeleted" form even though it is not actually "undeleted". The object class, `ds-soft-delete-entry`, is also not displayed.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com \
     --includeSoftDeletedEntries deleted-entries-in-undeleted-form \
     --searchScope sub "(ds-soft-delete-from-dn=*)"

   # Soft-deleted entry DN:
   # entryUUID=2b5511e2-7616-389b-ab0c-025c805ad32c
   +uid=user.14,ou=People,dc=exam-
   ple,dc=com
   dn: uid=user.14,ou=People,dc=example,dc=com
   objectClass: top
   objectClass: person
   objectClass: organizationalPerson

```

Undeleting a soft-deleted entry using the same RDN

When you decide to undelete a soft-deleted entry, if the original Relative Distinguished Name (RDN), such as `uid=user.1`, is still available, you can perform the undelete using that same RDN.

About this task

To undelete a soft-deleted entry, use **`ldapmodify`** with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore. In an LDIF file or from the command line, specify the `dn:<target entry>` attribute, which is the distinguished name (DN) that the entry is undeleted to, and the `ds-undelete-from-dn` attribute, which is the entry that is undeleted from. An undelete requires the `add` changetype so that the entry can be re-added to the server.

Steps

- To undelete a soft-deleted entry using the same RDN, run the command **`ldapmodify`** with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore.

  The first DN is the entry to undelete to and the `ds-undelete-from-dn` is the soft-delete entry to undelete from.

  ```
  $ bin/ldapmodify --allowUndelete
  dn: uid=user.1,ou=People,dc=example,dc=com
  changetype:add
  ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-b11b-
  7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
  ```

  The `--allowUndelete` option sends the soft undelete request control to the server.

Undeleting a soft-deleted entry using a new RDN

In some cases, you can allocate the original Relative Distinguished Name (RDN), `uid=user.1`, to a new user. This is permitted when the entry is in a soft-deleted state. To properly undelete this entry, you must specify a new RDN value you can use to restore the entry.

About this task

In this case, specifying the RDN of `uid=user.5` undeletes the original entry, but with the new distinguished name (DN) in the following example, and the `uid` attribute on the entry is updated with the new value of `user.5`. All other attributes of the users entry, including the `entryUUID`, remain unchanged.

To undelete a soft-deleted-entry using a new RDN:

Steps

1. Run the command **`ldapmodify`** to undelete a soft-deleted entry that has an original RDN, `uid=user.1`, to a new RDN, `uid=user.5`.

   > ⓘ **Note:**
   >
   > If you specify a DN that already exists in the Directory Server as a normal entry, this leads to an `entry already exists` error. Ensure the DN that you are undeleting the entry to does not already exist.

   ```
   $ bin/ldapmodify --allowUndelete
   dn: uid=user.5,ou=People,dc=example,dc=com
   changetype:add
   ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-
   b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
   ```

2. To view the results, run **`ldapsearch`**.

   ```
   dn: uid=user.5,ou=People,dc=example,dc=com
   objectClass: top
   objectClass: person
   objectClass: organizationalPerson
   objectClass: inetOrgPerson
   postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239
   postalCode: 66239
   description: This is the description for Aartjan Aalders.
   uid: user.5
   userPassword: {SSHA}RdBCwQ2kIw57LukRthjrFBS/oFylJARnmTnorA==
   employeeNumber: 1
   initials: AKA
   givenName: Aartjan
   pager: +1 197 025 3730
   mobile: +1 890 430 9077
   cn: Aartjan Aalders
   sn: Aalders
   telephoneNumber: +1 094 100 7524
   street: 59748 Willow Street
   homePhone: +1 332 432 4295
   l: Green Bay
   mail: user.3@maildomain.net
   st: TN
   entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4
   ```

   The RDN and the `uid` attribute has changed.

Modifying a soft-deleted entry

Modify a soft-deleted entry the same as a regular entry using the **`ldapmodify`** tool. The entry remains hidden in its soft-deleted state after the change.

About this task

Soft-deleted entries can be modified like any regular entry. The only restriction is that you cannot change the distinguished name (DN) or run a `moddn` operation. To move a soft-deleted entry from one machine to another, use the **`move-subtree`** command and specify the DN of the soft-deleted entry. For more information, see *To Move an Entry from One Machine to Another*.

> ⓘ **Note:**

To modify a soft-deleted entry, the user needs the `soft-delete-read` privilege to access the soft-deleted entry.

Steps

- To modify a soft-deleted entry, run the **`ldapmodify`** command and specify the soft-deleted DN.

```
$ bin/ldapmodify
dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 390 103 6918
# Processing MODIFY request for entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
# MODIFY operation successful for DN entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

Hard deleting a soft-deleted entry

Use this section for instructions on hard deleting a soft-deleted entry from the server when soft-deleted entries are configured as global configuration for requests or configured using a connection or request criteria.

About this task

Consider the following when hard deleting a soft-deleted entry:

Steps

- To permanently remove a soft-deleted entry from the server, run **`ldapdelete`** on the soft-deleted entry for soft-deleted entries.
- To hard delete a soft-deleted entry, use **`ldapdelete`** with the `--useHardDelete` option.

  The Hard Delete Request Control works with soft deletes. It applies when soft delete policies are in place as a means to override soft deletes requests. If soft deletes are configured, running **`ldapdelete`** with the Hard Delete Request Control, such as using the `--useHardDelete` option, guarantees that any entry permanently deletes.

Hard deleting a soft-deleted entry (global configuration)

About this task
Permanently remove a soft-deleted entry from the Directory Server.

Steps

- To permanently remove a soft-deleted entry, run **`ldapdelete`** on the soft-deleted entry.

  The following example assumes that you configured soft deletes as a global configuration for requests.

```
$ bin/ldapdelete \
  entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com

Processing DELETE request for entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
DELETE operation successful for DN entryUUID=4e9b7847-edcb-3791-b11b-
```

```
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

> **Note:**
>
> You cannot soft-delete an already soft-deleted entry. If you use the **`--useSoftDelete`** subcommand with the **`ldapdelete`** operation on a soft-deleted entry, an error message generates.
>
> ```
> DELETE operation failed. Result Code: 53 (Unwilling to Perform) Diagnostic
> Message: DELETE operation failed.
> ```

Hard deleting a soft-deleted entry (connection or request criteria)

About this task
Permanently remove a soft-deleted entry from the Directory Server.

Steps

- To permanently remove a soft-deleted entry run **`ldapdelete`** with the **`--useHardDelete`** subcommand on the soft-deleted entry.

  The following example assumes that you configured soft deletes using a connection or request criteria.

  ```
  $ bin/ldapdelete --useHardDelete \
    entryUUID=4e9b7847-edcb-3791-
  b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
  ```

Configuring soft deletes by connection criteria

Use this section for instructions on enabling and disabling soft deletes with connection criteria.

The Directory Server supports soft deletes where any delete operation is treated as a soft-delete request as long as the LDAP client meets the connection criteria.

To configure soft deletes:

- Define the connection criteria used in a client connection policy.
- Configure the soft delete connection criteria in the soft-delete policy.

Enabling soft deletes by connection criteria

Before you begin
Configure a soft-delete policy and global configuration, as shown in *Configuring Soft Deletes as a Global Configuration*.

Steps

1. Create a connection criteria using **`dsconfig`** and name it `Internal Applications`.

   In the following example the soft delete connection criteria is configured for a member of a line of business (LOB) applications group connecting from the 10.8.1.0 network.

   ```
   $ bin/dsconfig create-connection-criteria \
     --criteria-name "Internal Applications" \
     --type simple \
     --set included-client-address:10.8.1.0/8 \
     --set "all-included-user-group-dn:cn=LOB
    Applications,ou=Groups,dc=example,dc=com"
   ```

2. Set the `auto-soft-delete-connection-criteria` property to the soft-delete connection criteria you created in step 1.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set "auto-soft-delete-connection-criteria:Internal Applications"
```

Disabling soft deletes by connection criteria

About this task
Disable soft deletes by connection criteria.

Steps

- Reset the `auto-soft-delete-connection-criteria` property on the soft-delete policy.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset auto-soft-delete-connection-criteria
```

Configuring soft deletes by request criteria

Soft deletes can be configured using request criteria within a client connection policy. All delete requests that meet the request criteria is treated as a soft delete. The presence of a soft delete by connection criteria is exclusive of the soft delete by request criteria. Both can be present in a soft-delete policy.

Enabling soft deletes by request criteria

Steps

1. Configure a soft-delete policy and global configuration as shown in “Configuring Soft Deletes as a Global Configuration”.
2. Configure request criteria for soft deletes. The soft delete request criteria is configured for an external delete request from a member of the Internal Applications group matching an entry with object class "inetorgperson" with the request excluding the Soft Delete Request Control and the Hard Delete Request Control.

```
$ bin/dsconfig create-request-criteria \
  --criteria-name "Soft Deletes" \
  --type simple \
  --set "description:Requests for soft delete" \
  --set operation-type:delete \
  --set operation-origin:external-request \
  --set "connection-criteria:Internal Applications" \
  --set not-all-included-request-control:1.3.6.1.4.1.30221.2.5.20 \
  --set "all-included-target-entry-filter:(objectClass=inetorgperson)"
```

3. In the soft delete policy created in step 1, set the `auto-soft-delete-connection-criteria` property to the simple criteria created in the previous step.

```
$ bin/dsconfig create-soft-delete-policy \
  --policy-name default-soft-delete-policy \
  --set "auto-soft-delete-request-criteria:Soft Deletes"
```

Disabling soft deletes by request criteria

Steps

- To disable soft deletes by request criteria, reset the soft-delete policy.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset auto-soft-delete-request-criteria
```

Configuring soft delete automatic purging

By default, the Directory Server retains soft-deleted entries indefinitely. For companies that want to set up automatic purging of soft-deleted entries, the server provides two properties on the Soft Delete Policy that can be configured for either the maximum retention time for all soft-deleted entries and/or the retained number of soft-deleted entries. These changes take effect without requiring a server restart.

Configuring soft-delete automatic purging

About this task

You can change either the retention time or the retained number of entries to enable automatic purging. By default, both are set to an indefinite retention time and number of entries. The time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w), may be preceded by an integer to specify a quantity for that unit, such as "1 d", "52 w", etc. Once you configure the properties, the changes take effect immediately without the need for a server restart.

Note that the server will delete all of the soft-deleted entries according to the policy in effect. If the policy is changed while entries are in the process of being deleted, the new policy takes effect after the in-process batch of entries is deleted and applies to any remaining soft-deleted entries going forward according to the new policy.

Steps

1. Retrieve the name of the Soft Delete Policy in effect using the **`dsconfig`** command. For this example, the Soft Delete Policy is called `default-soft-delete-policy`.

```
$ bin/dsconfig get-global-configuration-prop \
  --property soft-delete-policy
```

2. Do one or both of the following:
   - Run **`dsconfig`** to set the retention time for soft-deleted entries.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set "soft-delete-retention-time:52 w"
```

   - Run **`dsconfig`** to set the retained number of soft-deleted entries.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set soft-delete-retain-number-of-entries:1000000
```

3. The Soft Delete Policy must be assigned to the global configuration if it has not been assigned yet.

```
$ bin/dsconfig set-global-configuration-prop \
  --set soft-delete-policy:default-soft-delete-policy
```

Disabling soft-delete automatic purging

About this task

You can disable Soft-Delete automatic purging using the **dsconfig** command. The change takes effect immediately without the need of a server restart. However, if the server is in the middle of an automatic soft-delete purging, it may continue to purge entries until the next time it evaluates the Soft Delete Policy.

Steps

- Run `dsconfig` to reset the Soft-Delete Policy properties that control automatic purging: `soft-delete-retention-time` and `soft-delete-retain-number-of-entries`.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset soft-delete-retention-time \
  --reset soft-delete-retain-number-of-entries
```

Soft and hard delete processes

See the following tables for the results of actions taken during the soft and hard delete processes.

If no automatic soft delete criteria is configured

The following table summarizes the resulting actions of a `DELETE` operation for soft deletes.

Action	Result
Delete	Performs a hard delete on the entry.
Delete with the Soft Delete Request Control	Performs a soft delete on the entry.
Delete of a soft-deleted entry	Performs a hard delete on the entry.
Delete of a soft-deleted entry with the Soft Delete Request Control	Not allowed. Generates an `UNWILLING_TO_PERFORM` error.
Delete with a Hard Delete Request Control	Performs a hard delete on the entry.
Delete of a soft-deleted entry with the Hard Delete Request Control.	Performs a hard delete on the entry.

If soft delete connection or request criteria is configured

The following table summarizes the resulting actions of a `DELETE` operation for soft deletes configured by connection criteria or request criteria.

Action	Result
Delete not matching criteria	Performs a hard delete on the entry.
Delete matching criteria	Performs a soft delete on the entry.

Action	Result
Delete of a soft-deleted entry not matching criteria	Performs a hard delete on the entry.
Delete of a soft-deleted entry matching criteria	Performs a hard delete on the entry.
Delete not matching criteria with the Hard Delete Request Control	Performs a hard delete on the entry.
Delete matching criteria with the Hard Delete Request Control	Performs a hard delete on the entry.
Delete with Soft and Hard Delete Request Controls	Not allowed. Generates an `UNWILLING_TO_PERFORM` error.

Soft delete controls and tool options

See the following tables for summaries of soft delete controls and tools.

Soft delete OIDs

The following table shows the OpenIDs (OIDs) for each soft delete control. The soft delete OIDs are defined in the LDAP SDK generated API documentation.

OID Type	OID
Soft Delete Request Control	1.3.6.1.4.1.30221.2.5.20
Soft Delete Response Control	1.3.6.1.4.1.30221.2.5.21
Hard Delete Request Control	1.3.6.1.4.1.30221.2.5.22
Soft Undelete Request Control	1.3.6.1.4.1.30221.2.5.23
Soft Delete Entry Access Control	1.3.6.1.4.1.30221.2.5.24

Soft delete tool options

The following table shows the new tool options available for the soft delete operations.

Operation	Options
`ldapdelete` / `ldapmodify`	`--useSoftDelete/-s`. Process `DELETE` operations with the Soft Delete Request Control, whereby entries are renamed and hidden instead of being permanently deleted. The Directory Server must be configured to allow soft deletes. ⓘ **Note:** Any entries in the LDIF file with the changetype of `delete` are processed as a soft-delete request.
`ldapdelet`	`--useHardDelete`. Process `DELETE` operations with the Hard Delete Request Control, which bypasses any soft delete policies and processes the delete request immediately without retaining the entry as a soft-deleted entry. The Directory Server must be configured to allow soft deletes.
`ldapsearch`	`--includeSoftDeletedEntries {with-non-deleted-entries | without-non-deleted-entries | deleted-entries-in-undeleted-form}`. Process search operations with the soft delete entry access control. Soft delete search options are as follows: **with-non-deleted-entries** Returns all entries matching the search criteria with the results, including non-deleted and soft-deleted entries. **without-non-deleted-entries** Returns only soft-deleted entries matching the search criteria. **deleted-entries-in-undeleted-form** Returns only soft-deleted entries matching the search criteria with the results returned in their undeleted entry form. Users must have access to the Soft Delete Entry Access Control to search for soft-deleted entries.
`ldapmodify`	`--allowUndelete`. Process `ADD` operations, which include the `ds-undelete-from-dn` attribute as undelete requests. Undelete requests re-add previously soft-deleted entries back to the server as non-deleted entries by providing the Undelete Request Control with the `ADD` operation. The Directory Server must be configured to allow soft deletes to process any undelete requests and the client user must have the `soft-delete-read` privilege.

Soft delete OID symbolic names using with the --control/-J option

The following table shows the symbolic names that can be used with the server's LDAP commands using the `--control/-J` option.

Control	Symbolic Name
Soft Delete Request Control	softdelete

Control	Symbolic Name
Hard Delete Request Control	harddelete
Soft Undelete Request Control	undelete
Soft Delete Entry Access Control	softdeleteentryaccess

Monitoring soft deletes

The Directory Server provides monitoring entries and logs to track all soft delete operations. The access and debug logs do not have any options specific for soft deletes.

New monitor entries
Two new monitor entries are present for a backend monitor entry.

Administrators see the following additional monitor entries on `cn=userRoot Backend,cn=monitor`:

`ds-soft-delete-entry-operations-count`

Displays the number of soft deletes performed on the backend since server startup.

`ds-undelete-operations-count`

Displays the number of undeletes performed on the backend since server startup.

`ds-backend-soft-deleted-entry-count`

Displays the current number of soft-deleted entries in the database.

`ds-auto-purged-soft-deleted-entry-count`

Displays the current number of soft-deleted entries purged since the backend or server was restarted.

Monitoring soft deletes
Monitor soft deletes using the **`ldapsearch`** command.

Steps

- Run **`ldapsearch`** on the `cn=userRoot Backend,cn=monitor` branch using a search criteria targeting the `ds-backend-monitor-entry` object class.

```
$ bin/ldapsearch --baseDN "cn=userRoot Backend,cn=monitor" \
  --searchScope sub "(objectclass=ds-backend-monitor-entry)"
```

```
dn: cn=userRoot Backend,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-backend-monitor-entry
objectClass: extensibleObject
cn: userRoot Backend
ds-backend-id: userRoot
ds-backend-base-dn: dc=example,dc=com
ds-backend-is-private: FALSE
ds-backend-entry-count: 200001
ds-backend-soft-deleted-entry-count: 1000
ds-soft-delete-operations-count: 40
ds-undelete-operations-count: 20
```

```
ds-auto-purged-soft-deleted-entry-count: 0
ds-base-dn-entry-count: 200001 dc=example,dc=com
ds-backend-writability-mode: enabled
```

Access logs

The access log records the LDAP operations corresponding to soft delete and undelete for `DELETE`, `SEARCH`, `MODIFY`, and `ADD` operations with the related soft-deleted values.

The access log does not require any configuration for soft delete.

`DELETE` (soft-delete) operations

The access log displays the following.

```
[14/May/2012:09:40:16.942 -0500] DELETE RESULT conn=18 op=1 msgID=2
dn="uid=user.1,ou=People,dc=example,dc=com" resultCode=0 etime=30.367
softDeleteEntryDN="entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,
ou=People,dc=example,dc=com"
```

`SEARCH` operations for soft-deleted entries

The access log displays the following.

```
[14/May/2012:09:40:52.320 -0500] SEARCH RESULT conn=19 op=1 msgID=2
base="dc=example,dc=com" scope=2 filter="(objectclass=ds-soft-delete-
entry)"
attrs="ALL" resultCode=0 etime=1.631 entriesReturned=1
```

`MODIFY` operations of soft-deleted entries

The access log displays the following.

```
[14/May/2012:09:42:43.679 -0500] MODIFY RESULT conn=20 op=1 msgID=1
dn="entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=exam-
ple,dc=com" resultCode=0 etime=2.639 changeToSoftDeletedEntry=true
```

`ADD` (soft-undelete) operations

The access log displays the following.

```
[14/May/2012:09:58:16.728 -0500] ADD RESULT conn=25 op=1 msgID=1
dn="uid=user.0,ou=People,dc=example,dc=com" resultCode=0 etime=22.700
undeleteFromDN="entryUUID=ad55a34a-763f-358f-93f9-
da86f9ecd9e4+uid=user.0,
ou=People,dc=example,dc=com"
```

Audit logs

The audit log captures any `MODIFY` and `DELETE` operations of soft-deleted entries.

These changes are recorded as fully commented-out audit log entries. The audit log does not require any configuration for soft deletes.

For any soft-deleted entry, the audit log entry displays the `ds-soft-delete-entry-dn` property and its soft-deleted entry distinguished name (DN).

```
# 14/May/2012:10:57:09.054 -0500; conn=30; op=1
# ds-soft-delete-entry-dn: entryUUID=68147342-1f61-3465-8489-
3de58c532130+uid=user.2,ou=People,dc=example,dc=com
dn: uid=user.2,ou=People,dc=example,dc=com
```

```
changetype: delete
```

For any `MODIFY` changes made, the log displays the LDIF, the modifier's name, and update time.

```
# 14/May/2012:10:58:33.566 -0500; conn=33; op=1
# dn:
 entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
ple,dc=com
# changetype: modify
# replace: homePhone
# homePhone: +1 003 428 0966
#-
# replace: modifiersName
# modifiersName: uid=admin,dc=example,dc=com
#-
# replace: modifyTimestamp
# modifyTimestamp: 20131010020345.546Z
```

For any undelete of a soft-deleted entry, the log displays the `ds-undelete-from-dn` attribute plus the entry unique ID, create time, and creator's name.

```
# 14/May/2012:10:59:21.754 -0500; conn=34; op=1
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: add
uid: user.2
ds-undelete-from-dn:
 entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=Peo-
ple,dc=example,dc=com
ds-entry-unique-id:: vw1jg801S7GWrTiS3UE5DA==
createTimestamp:: 20131010181148.630Z
creatorsName: uid=admin,dc=example,dc=com
```

For hard (permanent) deletes of a soft-deleted entry, the log displays the soft-deleted entry DN that was removed.

```
# 14/May/2012:11:00:14.055 -0500; conn=36; op=1
# dn:
 entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
ple,dc=com
# changetype: delete
```

Configuring the file-based audit log for soft deletes
Configure the file-based audit log for soft deletes.

Steps

1. Enable the audit log if it is disabled.

   ```
   $ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
    Logger" \
   --set enabled:true
   ```

2. View the audit log.

   The `soft-delete-entry-audit-behavior` property is set to `commented` by default and provides additional information in comments about the soft-deleted entry that was either created or undeleted.

   ```
   # 11/May/2012:15:33:17.552 -0500; conn=13; op=1
   # ds-soft-delete-entry-dn:entryUUID=54716bfd-fbc4-3108-ac37-
   bf6b1b166e37+uid=user.15,ou=People,dc=example,dc=com
   dn: uid=user.15,ou=People,dc=example,dc=com
   ```

```
changetype: delete
```

Changelog

You can configure the changelog to capture soft-delete changes to entries so that external clients, such as PingDataSync Server, can access these changes.

The `ds-soft-delete-entry` attribute represents an entry that has been soft-deleted and is part of the source entry passed into the changelog to indicate the entry has been soft-deleted.

All soft-delete operations appear in the changelog as regular DELETE operations. When a soft delete occurs, the resulting changelog entry includes a `ds-soft-delete-entry-dn` operational attribute with the value of the soft-deleted entry DN. PingDataSync Server recognizes the `ds-soft-delete-entry-dn` attribute and does nothing with it.

The changelog backend `soft-delete-entry-included-operation` property determines whether MODIFY or DELETE operations of soft-deleted entries appear in the changelog. This property is disabled by default.

Configuring soft deletes on the changelog backend

Steps

1. To configure soft deletes on the changelog backend, run the following.

```
$ bin/dsconfig set-backend-prop \
--backend-name changelog \
--set soft-delete-entry-included-operation:delete \
--set soft-delete-entry-included-operation:modify
```

2. Run a soft-delete operation on an entry.
3. To review the changelog for the soft-deleted entry, run the following.

```
$ bin/ldapsearch --baseDN cn=changelog \
  "(objectclass=*)" "+"
```

```
dn: cn=changelog
subschemaSubentry: cn=schema
entryUUID: 9920f7e9-5a04-392a-82a8-32662d7d3863
ds-entry-checksum: 304022441
dn: changeNumber=1,cn=changelog

Disabling soft deletes as a global configuration

To disable soft deletes on your Directory Server, reset the global configuration property and the remove the soft-delete policy.

About this task

From that point, PingDirectory processes all deletes as hard deletes by default. Any use of the soft-deleted options with the LDAP tools results in an error. Any existing soft-deleted entries that are present disabling after the global configuration remain in the server as latent entries.

> ⓘ **Note:**
>
> Be sure to include the LDAP bind parameters for your system when running each of these commands.

Steps

1. To reset the global configuration property, run the following **`dsconfig`** command.

```
$ bin/dsconfig set-global-configuration-prop --reset soft-delete-policy
```

2. To reset the global configuration property, run the following **`dsconfig`** command.

```
$ bin/dsconfig delete-soft-delete-policy --policy-name default-soft-delete-
policy
```

Importing and Exporting Data

The PingDirectory Server supports import or export of the database backends in LDAP Data Interchange Format (LDIF). The **`bin/import-ldif`** and **`bin/export-ldif`** tools can be used to create or export database backends for online of offline servers. The tools support options that can restrict the input or output to a subset of the entries or a subset of the attributes within entries. The tools also provide features to compress, encrypt or digitally sign the data.

Importing data

The PingDirectory Server provides initialization mechanisms to import database files. The **`import-ldif`** command-line tool imports data from an LDAP Data Interchange Format (LDIF) file. The data imported by the **`import-ldif`** command can include all or a portion of the entries (a subset of the entries or a subset of the attributes within entries or both) contained in the LDIF file. The command also supports importing data that has been compressed, encrypted or digitally signed or both.

The **`import-ldif`** utility can be run with the server offline or online. If the server is online, administrators can initiate the import from a local or remote client. The LDIF file that contains the import data must exist on the server system. During an online import, the target database repository, or backend, will be removed from service and data held in that backend will not be available to clients.

The **`import-ldif`** tool has been modified to help guard against accidental overwriting of existing backend data with the addition of the `--overwriteExistingEntries` option. This option must be present when performing an import into a backend with a branch that already contains entries (although the option is not needed if a branch contains just a single base entry).

Validating an LDIF file

About this task

Prior to importing data, you can validate an import file using the Directory Server's **`validate-ldif`** tool. When run, the tool binds to the Directory Server, locally or remotely, and validates the LDIF file to

determine whether it violates the server's schema. Those elements that do not conform to the schema will be rejected and written to standard output. You can specify the path to the output file to which the rejected entries are written and the reasons for their rejection. The **validate-ldif** tool works with regular non-compressed LDIF files or gzip-compressed LDIF files.

To process large files faster, you can also set the number of threads for validation. The tool also provides options to skip specified schema elements if you are only validating certain items, such as attributes only. Use the `--help` option to view the arguments.

To validate an LDIF file:

Steps

- Use the **validate-ldif** tool to validate an LDIF file. Make sure the server is online before running this command.

```
$ bin/validate-ldif --ldifFile /path/to/data.ldif \
  --rejectFile rejectedEntries
```

```
1 of 200 entries (0 percent) were found to be invalid.
1 undefined attributes were encountered.
Undefined attribute departmentname was encountered 1 times.
```

Computing the database cache estimate

After successful completion of an import, the **import-ldif** command lists detailed information about the database cache characteristics of the imported data set. The current server configuration is considered along with the capabilities of the underlying hardware to guide decisions for changing JVM size and database-cache-percent for the backend.

The **import-ldif** command will complete with a summary of database cache usage characteristics for the imported data set. Additional files are available in the `/logs/tools` directory that describe the database cache characteristics in more detail.

Tracking skipped and rejected entries

During import, entries can be skipped if they do not belong in the specified backend, or if they are part of an excluded base DN or filter. The `--skipFile {path}` argument can be used on the command line to indicate that any entries that are skipped should be written to a specified file. You can add a comment indicating why the entries were skipped.

Similarly, the `--rejectFile {path}` argument can be added to obtain information about which entries were rejected and why. An entry can be rejected if it violates the server's schema constraints, if its parent entry does not exist, if another entry already exists with the same DN, or if it was rejected by a plugin.

Running an offline import

You can run the **import-ldif** tool offline to import LDIF data encoded with the UTF-8 character set. This data can come from LDIF files, compressed LDIF files (GZIP format), or from data generated using a MakeLDIF template. You do not need to authenticate as an administrator when performing offline LDIF imports.

Performing an offline import

Steps

- Use the **import-ldif** command to import data from an LDIF file. Make sure the Directory Server is offline before running this command. Do not specify any connection arguments when running the command.

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
```

```
  --rejectFile /path/to/reject.ldif --skipFile /path/to/skip.ldif
```

Performing an offline LDIF import using a compressed file

Steps

- Use the **`import-ldif`** command to import data from a compressed gzip formatted file. You must also use the `--isCompressed` option to indicate that the input file is compressed. Make sure the Directory Server is offline before running this command. Do not specify any connection arguments when running the command.

```
$ bin/import-ldif --backendID userRoot --isCompressed \
  --ldifFile /path/to/data.gz --rejectFile /path/to/reject.ldif \
  --skipFile /path/to/skip.ldif
```

Performing an offline LDIF import using a MakeLDIF template

Steps

- Use the **`import-ldif`** command to import data from a MakeLDIF template, which is located in the `<server-root>/config/MakeLDIF`. Make sure the Directory Server is offline before running this command. Do not specify any connection arguments when running the command.

  The following command uses the standard data template and generates 10,000 sample entries, and then imports the file to the server.

```
$ bin/import-ldif --backendID userRoot \
  --templateFile config/MakeLDIF/example.template
```

Running an online LDIF import

Administrators can run LDIF imports while the server is online from another remote server. The online import resembles the offline import, except that you must provide information about how to connect and authenticate to the target server. You can schedule the import of an LDIF file to occur at a particular time using the `--task` and `--start YYYYMMDDhhmmss` options of the **`import-ldif`** tool.

You can also specify email addresses for users that should be notified whenever the import process completes (regardless of success or failure, or only if the import fails). To set up SMTP notifications, see *Working with the SMTP Account Status Notification Handler*.

Performing an online LDIF import

Steps

- Use the **`import-ldif`** tool to import data from an LDIF. Make sure the Directory Server is online before running this command.

```
$ bin/import-ldif --task --hostname server1 --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --backendID userRoot --ldifFile userRoot.ldif
```

Scheduling an online import

Steps

1. Use the **`import-ldif`** tool to import data from an LDIF file at a scheduled time. To specify a time in the UTC time zone, include a trailing “Z”. Otherwise, the time will be treated as a local time in the time zone configured on the server. Make sure the Directory Server is online before running this command.

```
$ bin/import-ldif --task \
  --hostname server1 \
```

```
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --bindPassword password \
  --backendID userRoot \
  --ldifFile /path/to/data.ldif \
  --start 20111026010000 \
  --completionNotify import-complete@example.com \
  --errorNotify import-failed@example.com

Import task 2011102617321510 scheduled to start Oct 26, 2011 1:00:00 AM CDT
```

2. Confirm that you successfully scheduled your import task using the **`manage-tasks`** tool to view a summary of all tasks on the system.

```
$ bin/manage-tasks --summary

ID             Type   Status
-----------------------------------------------
2011102617321510 Import Waiting on start time
```

3. Use the **`manage-tasks`** tool to monitor the progress of this task. Use the task ID of the import task. If you cannot find the task ID, use the `--summary` option to view a list of all tasks scheduled on the Directory Server.

```
$ bin/manage-tasks --info 2011102617321510

Task                      Details
-------------------------------------------------------
ID                        2011102617321510
Type                      Import
Status                    Waiting on start time
Scheduled Start Time      Oct 26, 2011 1:00:00 AM CDT
Actual Start Time
Completion Time
Dependencies Failed       None
Dependency Action         None
Email Upon Completion     admin@example.com
Email Upon Error          admin@example.com

Import        Options
----------------------------
LDIF File  /path/to/data.ldif
Backend ID userRoot
```

Canceling a scheduled import

Steps

- Use the **`manage-tasks`** tool to cancel the scheduled task.

```
$ bin/manage-tasks --cancel 2011102417321510
```

Adding entries to an existing Directory Server

About this task

To add entries to an existing Directory Server while preserving operational attributes, such as `createTimestamp` or `modifiersName`, the Ignore No User Modification control must be attached to the request. The Ignore No User Modification control allows modification of certain attributes that have the No User Modification constraint. Special care should be used with this control.

The Ignore No User Modification is only applied to ADD requests. Using the control to modify an existing entry, resulting in an operational attribute change, will fail.

To append entries to an existing Directory Server:

Steps

- Use **`ldapmodify`** with the Ignore No User Modification control (i.e., the OID is 1.3.6.1.4.1.30221.2.5.5).

```
$ bin/ldapmodify --control 1.3.6.1.4.1.30221.2.5.5 \
  --filename change-record.ldif
```

Filtering data import

The **`import-ldif`** command provides a way to either include or exclude specific attributes or entries during an import. The arguments are summarized as follows:

Inclusion and Exclusion Arguments for import-ldif

Argument	Description
--includeBranch	Base DN of a branch to include in the LDIF import (can be specified multiple times)
--excludeBranch	Base DN of a branch to exclude from the LDIF import (can be specified multiple times)
--includeAttribute	Attribute to include in the LDIF import (can be specified multiple times)
--excludeAttribute	Attribute to exclude from the LDIF import (can be specified multiple times)
--includeFilter	Search filter to identify entries to include in the LDIF import (can be specified multiple times)
--excludeFilter	Search filter to identify entries to exclude from the LDIF import (can be specified multiple times)
--excludeOperational	Exclude operational attributes from the LDIF import.
--excludeReplication	Exclude replication attributes from the LDIF import.
--excludeSoftDelete	Exclude soft delete entries from the LDIF import.

Exporting data

The PingDirectory Server **`export-ldif`** command-line tool exports data from Directory Server backend to an LDAP Data Interchange Format (LDIF) file. The tool must be run in the non-task based mode, which implies that it works outside of the server JVM process. The **`export-ldif`** must be run without connection or task arguments while the server is either online or offline. This tool exports a point-in-time snapshot of the backend which is guaranteed to provide a consistent state of the database, in LDIF, which can be reimported with **`import-ldif`** if necessary.

The data exported by **`export-ldif`** can include all or a portion of the entries (a subset of the entries or a subset of the attributes within entries or both) contained in the backend. This is accomplished by specifying branches, filters, and attributes to include or exclude. The exported LDIF can be compressed, encrypted or digitally signed.

ⓘ **Note:** LDIF exports can be configured as recurring tasks with **`dsconfig create-recurring-task`**, and then scheduled to run when added to a recurring task chain.

Performing an export

Steps

- Use the **`export-ldif`** command to export data to an LDIF file.

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif
```

Performing an export from specific branches

Steps

- Use the **`export-ldif`** command to export data to an LDIF file under a specific branch from the userRoot backend of the local Directory Server into a compressed file. The command also excludes operational attributes from the exported data and wraps long lines at column 80.

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif.gz --
compress \
  --includeBranch ou=people,dc=example,dc=com --excludeOperational \
  --wrapColumn 80
```

Encrypting LDIF exports and signing LDIF files

The Directory Server provides features to encrypt data during an LDIF export using the **`export-ldif`** `--encryptLDIF` option and to allow the encrypted LDIF file to be imported onto the same instance or another server in the same replication topology using the **`import-ldif`** tool. A **`--doNotEncrypt`** argument can be used to force an LDIF export to be unencrypted, even if automatic encryption is enabled. The **`--maxMegabytesPerSecond`** argument can be used to impose a limit on the rate at which the LDIF file may be written to disk.

The **`export-ldif`** tool can be used with the **`--promptForEncryptionPassphrase`**, **`--encryptionPassphraseFile`**, and **`--encryptionSettingsDefinitionID`** arguments to specify which key to use for encrypting the export. The **`import-ldif tool`** will automatically detect encryption and compression, and have **`--promptForEncryptionPassphrase`**, **`--encryptionPassphraseFile`** options as well.

The Directory Server also provides an additional argument that digitally signs the contents of the LDIF file, which ensures that the content has not been altered since the export. To digitally sign the contents of the exported LDIF file, use the **`export-ldif`** `--sign` option. To allow a signed LDIF file to be imported onto the same instance or another server in the same topology, use the **`import-ldif`** `--isSigned` option.

Note that there is not much added benefit to both signing and encrypting the same data, since encrypted data cannot be altered without destroying the ability to decrypt it.

Encrypting an LDIF export

Steps

- Run **`export-ldif`** tool with the **`--encryptLDIF`** option to encrypt the data during an export to an output LDIF file. The following command runs an offline export of the userRoot backend, and encrypts the file when written to an output file called `data.ldif`.

```
$ bin/export-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
  --encryptLDIF
```

Importing an encrypted LDIF file

About this task

An encrypted LDIF file can be imported into the same instance from which it was exported, or into any other server in the same replication topology with that instance. You cannot import an encrypted LDIF file into a server that is not in some way connected to the instance from which it was exported.

Steps

- Run the `import-ldif` tool to import the encrypted LDIF file from the previous example. The command imports the `data.ldif` file, decrypts the contents while overwriting the existing contents to the `userRoot` backend. The tool automatically determines encryption and compression, and it can automatically identify the correct key for exports that were encrypted with a key obtained from an encryption settings definition or an internal topology key.

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
  --overwriteExistingEntries
```

Signing an export

Steps

- Run **`export-ldif`** tool with the **`--sign`** option to digitally sign the data during an export to an output LDIF file. The following command runs an offline export of the `userRoot` backend, and signs the content when written to an output file called `data.ldif`.

```
$ bin/export-ldif --backendID userRoot \
  --ldifFile /path/to/data.ldif --sign
```

Importing a signed LDIF file

Steps

- Run the **`import-ldif`** tool to import the signed LDIF file from the previous example. The command imports the `data.ldif` file, checks the signature of the contents while overwriting the existing contents to the `userRoot` backend. The command requires the `--isSigned` option, which instructs the tool that the contents of the LDIF file is signed.

```
$ bin/import-ldif --backendID userRoot \
  --ldifFile /path/to/data.ldif \
  --overwriteExistingEntries --isSigned
```

Filtering data exports

The **`export-ldif`** command analogous arguments to the **`import-ldif`** tool to provide a way to either include or exclude specific attributes or entries during an export. The arguments are summarized as follows:

Inclusion and Exclusion Arguments for export-ldif

Argument	Description
--includeBranch	Base DN of a branch to include in the LDIF export (can be specified multiple times)
--excludeBranch	Base DN of a branch to exclude from the LDIF export (can be specified multiple times)
--includeAttribute	Attribute to include in the LDIF export (can be specified multiple times)

Argument	Description
--excludeAttribute	Attribute to exclude from the LDIF export (can be specified multiple times)
--includeFilter	Filter to identify entries to include in the LDIF export (can be specified multiple times)
--excludeFilter	Filter to identify entries to exclude from the LDIF export (can be specified multiple times)
--excludeOperational	Exclude operational attributes from the LDIF export.
--excludeReplication	Exclude replication attributes from the LDIF export.
--excludeSoftDelete	Exclude soft delete entries from the LDIF export.

Scrambling data files

The Directory Server **transform-ldif** tool provides backward compatibility with the former **scramble-ldif** tool, with additional functionality for configuring input and output files. The **transform-ldif** tool reads data from one or more source LDIF files and writes the transformed data to a single output file.

Using this tool to scramble data, enables obscuring the values of certain attributes so that it is difficult to determine the original values in the source data, while also preserving the characteristics of the associated attribute syntax. This process is repeatable, so that if the same value appears multiple times, it will yield the same scrambled representation each time. Scrambling can be applied to both LDIF entries and LDIF change records.

The process of scrambling data is not the same as encryption. It should only be used to provide simple obfuscation of data. The following are general guidelines for scrambling attributes:

- If the attribute is **userPassword** and its value starts with a scheme name surrounded by curly braces, such as "{SSHA256}XrgyNdl3fid7KYdhd/Ju47KJQ5PYZqlUlyzxQ28f/QXUnNd9fupj9g==", the scheme name will be left unchanged and the rest of the value will be treated like a generic string.
- If the attribute is **authPassword** and its value contains at least two dollar signs, such as "SHA256$QGbHtDCi1i4=$8/X7XRGaFCovC5mn7ATPDYlkVoocDD06Zy3lbD4AoO4=", the portion up to the first dollar sign (which represents the name of the encoding scheme) is preserved and the remainder of the value is treated like a generic string.
- If an attribute has a Boolean syntax, the scrambled value will be either **TRUE** or **FALSE**. The determination to use a value of **TRUE** or **FALSE** is random, so scrambling Boolean values is not repeatable. By randomizing the scrambling for Boolean values, the syntax and obfuscation of the original value is preserved.
- If an attribute has a distinguished name syntax (or a related syntax, such as a name and optional UID), scrambling is applied to the values of RDN components for any attributes to be scrambled. For example, if the tool is configured to scramble both the **member** and **uid** attributes, and an entry has a member attribute with a value of "uid=john.doe,ou=People,dc=example,dc=com", that member value will be scrambled in a way that only obscures the "john.doe" portion but leaves the attribute names and all values of non-scrambled attributes intact.
- If an attribute has a generalized time syntax, that value is replaced with a randomized timestamp using the same format (the same number of digits and the same time zone indicator). The randomization will be over a time range that is double the difference between the time the **transform-ldif** tool was launched and the timestamp to be scrambled. For values where that time difference is less than one day, one day will be added to the difference before it is doubled.
- If an attribute has an integer, numeric string, or telephone number syntax, scrambling is only applied to numeric digits while all other characters are left intact. If there are multiple digits, then the first digit will be nonzero.

- If an attribute has an octet string syntax, it is scrambled as follows:
  - Each byte that represents a lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
  - Each byte that represents a uppercase ASCII letter is replaced with a randomly-selected uppercase ASCII letter.
  - Each byte that represents an ASCII digit is replaced with a randomly-selected ASCII digit.
  - Each byte that represents a printable ASCII symbol is replaced with a randomly-selected printable ASCII symbol.
  - Each byte that represents an ASCII control character is replaced with a randomly-selected ASCII letter, digit, or symbol.
  - Each non-ASCII byte will be replaced with a randomly-selected non-ASCII byte.
- If an attribute has a value that represents a valid JSON object, the resulting value will also be a JSON object. All field names will be left intact, and only the values of those fields may be scrambled. If the **`--scrambleJSONField`** argument is provided, only the specified fields will have values scrambled. Otherwise, the values of all fields will be scrambled. Field values are scrambled as follows:
  - Null values are not scrambled.
  - Boolean values are replaced with randomly-selected Boolean values. As with attributes with a Boolean syntax, these values are non-repeatable.
  - Number values will have only their digits replaced with randomly-selected digits and all other characters (minus sign, decimal point, exponentiation indicator) are left unchanged.
  - String values will be replaced with a randomly-selected generic string.
  - Array values have scrambling applied as appropriate for each value in the array. If the array field itself should be scrambled, then all values in the array are scrambled. Otherwise, only JSON objects contained inside the array have scrambling applied to appropriate fields.
  - JSON values have scrambling applied as appropriate for their fields.
- If an attribute does not match any of the previous criteria, it is scrambled as follows:
  - Each lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
  - Each uppercase ASCII letter replaced with a randomly-selected uppercase ASCII letter.
  - Each ASCII digit is replaced with a randomly-selected ASCII digit.
  - All other characters are left unchanged.

The following example reads from an LDIF file named **`original.ldif`**, scrambles the values of the **`telephoneNumber`**, **`mobile`**, and **`homeTelephoneNumber`** attributes, and writes the results to **`scrambled.ldif`**:

```
$ bin/transform-ldif --sourceLDIF original.ldif \
  --targetLDIF scrambled.ldif \
  --scrambleAttribute telephoneNumber \
  --scrambleAttribute mobile \
  --scrambleAttribute homeTelephoneNumber \
  --randomSeed 0
```

Backing Up and Restoring Data

The PingDirectory Server provides efficient **`backup`** and **`restore`** command-line tools that support full and incremental backups. The backups can also be scheduled using the UNIX-based cron scheduler or using the Directory Server's Task-based scheduler.

About backing up and restoring data

Administrators should have a comprehensive backup strategy and schedule that comprise of daily, weekly, and monthly backups including incremental and full backups of the directory server data, configuration, and

backends. Administrators should also have a backup plan for the underlying file system. This dual purpose approach provides excellent coverage in the event that a server database must be restored for any reason.

ⓘ **Note:** Backups can be configured as recurring tasks with **dsconfig create-recurring-task**, and then scheduled to run when added to a recurring task chain.

The PingDirectory Server provides efficient **backup** and **restore** command-line tools that support full and incremental backups. The backups can also be scheduled using the UNIX-based cron scheduler or using the Directory Server's Task-based scheduler. The Directory Server can run backups with the server online while processing other requests, so that there is no need to shut down the server or place it in read-only mode prior to starting a backup.

If you back up more than one backend, the **backup** tool creates a subdirectory below a specified backup directory for each backend. If you back up only a single backend, then the backup files will be placed in the specified directory. A single directory can only contain files from one backend, so that you cannot have backup files from multiple different backends in the same backup directory.

When performing a backup, the server records information about the current state of the server and backend, including the server product name, the server version, the backend ID, the set of base DNs for the backend, and the Java class used to implement the backend logic. For JE backends, the backup descriptor also includes information about the Berkeley DB JE version and information about the attribute and VLV indexes that have been defined.

When restoring a backup, the server compares the descriptor obtained from the backup with the current state of the server and backend. If any problems are identified, the server generates warnings or errors. The administrator can choose to ignore the warnings with the `ignoreCompatibilityWarnings` option to the **restore** tool, whereas errors will always cause the restore to fail. For example, when restoring a *newer* backup into an older version of the server, a warning will be generated. When restoring an *older* backup into a new version of the server, no warning will be generated, but because the `config` and `schema` backends require special handling, the server generates an error if the server versions do not match exactly (major, minor, point, and patch version numbers).

Both the **backup** and **restore** tools provide encryption options **--promptForEncryptionPassphrase**, **--encryptionPassphraseFile**, and **--encryptionSettingsDefinitionID** that can be used to specify which key to use for encrypting the backup. For backups encrypted with an encryption settings definition or an internal topology key, the server will automatically determine the correct key. Or, the **--doNotEncrypt** argument can be used to force a backup to be unencrypted even if automatic encryption is enabled.

If needed, the **--maxMegabytesPerSecond** argument can be used to impose a limit on the rate at which the backup may be written to disk.

Retaining backups

The backup tool can be used with either the **--retainPreviousFullBackupCount** or **--retainPreviousFullBackupAge** arguments to identify which previous backups should be preserved. Any other backups in that directory will be removed. A new backup will always be preserved. If the new backup is an incremental backup, then any other backups it depends on will also be preserved. However, older backups in the same directory are eligible to be removed.

If the **--retainPreviousFullBackupCount** argument is provided, that number of the most recent previous full backups will be preserved (along with any incremental backups that depend on them). Any other previous full backups (and their dependent incremental backups) can be removed. If the **--retainPreviousFullBackupAge** argument is provided, its value must be a duration represented as an integer followed by a time unit. Any full backups (and their dependent incremental backups) created longer ago than that duration will be eligible to be removed. If both the **--retainPreviousFullBackupCount** and **--retainPreviousFullBackupAge** arguments are provided, then only backups that don't satisfy either condition will be deleted. A value of zero can be

specified for the **--retainPreviousFullBackupCount** argument so that only the most recent backup is preserved (along with its dependencies), and all previous backups will be removed.

ⓘ **Note:** The **remove-backup** tool also supports the **--retainFullBackupCount** and **--retainFullBackupAge** arguments to delete any backups outside the provided retention criteria.

Listing the available backups on the system

Steps

- Use the **restore** tool to list the backups in a `backup` directory.

```
$ bin/restore --listBackups --backupDirectory /mybackups
```

```
[13:26:21] The console logging output is also available in '/
ds/PingDirectory/logs/ tools/restore.log'

Backup ID:         20120212191715Z

Backing up all backends

Steps

- Use **backup** to save the all of the server's backends. The optional `--compress` option can reduce the amount of space that the backup consumes, but can also significantly increase the time required to perform the backup.

```
$ bin/backup --backUpAll --compress --backupDirectory /path/to/backup
```

Backing up a single backend

Steps

- Go to the server root directory, and use the **backup** tool to save the single backend, userRoot.

```
$ bin/backup --backendID userRoot --compress --backupDirectory /path/to/
backup
```

Performing an offline restore

Steps

- Use the **`restore`** command to restore the userRoot backend. Only a single backend can be restored at a time. The Directory Server must be shut down before performing an offline restore.

```
$ bin/restore --backupDirectory /path/to/backup/userRoot
```

> ⓘ **Note:** The server root directory should never be restored from a file system backup or snapshot.

Assigning an ID to a backup

Steps

- Go to the server root directory, and use the backup tool to save the single backend, userRoot. The following command assigns the backup ID "weekly" to the userRoot backup. The backup file appears under `backups/userRoot` directory as `userRoot-backup-weekly`.

```
$ bin/backup --backupDirectory /path/to/backups/userRoot \
  --backendID userRoot --backupID weekly
```

Running an incremental backup on all backends

About this task

The Directory Server provides support for incremental backups, which backs up only those items that have changed since the last backup (whether full or incremental) on the system, or since a specified earlier backup. Incremental backups must be placed in the same backup directory as the full backup on which they are based.

Not all backends support incremental backups. If a backend does not support incremental backups, use of the **`--incremental`** option will have no effect, and a full backup will be taken.

Steps

- The following command runs an incremental backup on all backends based on the most recent backup:

```
$ bin/backup --backUpAll --incremental --backupDirectory /path/to/backup
```

Running an incremental backup on a single backend

Steps

- Go to the server root directory, and use **`backup`** to save the single backend, userRoot.

```
$ bin/backup --backendID userRoot --incremental --backupDirectory /path/to/
backup
```

Running an incremental backup based on a specific prior backup

Steps

- You can run an incremental backup based on a specific prior backup that is not the most current version on the system. To get the backup ID, use the **`restore`** `--listBackups` command (see below).

```
$ bin/backup --backUpAll --incremental --backupDirectory /path/to/backup \
  --incrementalBaseID backup-ID
```

Restoring an incremental backup

About this task

The process for restoring an incremental backup is exactly the same as the process for restoring a full backup for both the online and offline restore types. The **`restore tool`** will automatically ensure that the full backup and any intermediate incremental backups are restored first before restoring the final incremental backup. The tool will not restore any files in older backups that are no longer present in the final data set.

Scheduling an online backup

About this task

You can schedule a backup to run as a Task by specifying the timestamp with the `--task` and `--start` options. The option is expressed in "YYYYMMDDhhmmss'" format. If the option has a value of "0" then the task is scheduled for immediate execution. You cannot run recurring tasks, so daily operations must be run using cron or through some system that can submit the task.

For online (remote) backups, the backup operation can be conducted while PingDirectory Server is online if you provide information about how to connect and to authenticate to the target Directory Server.

Steps

- You can schedule the backup to occur at a specific time using the Task-based `--start YYYYMMDDhhmmss` option. To specify a time in the UTC time zone format, add a trailing “Z” to the time. Otherwise, the time will be treated as a local time in the time zone configured on the server.

```
$ bin/backup --backUpAll --task --start 20111025010000 \
  --backupDirectory /path/to/backup --completionNotify admin@example.com \
  --errorNotify admin@example.com

Backup task 2011102500084110 scheduled to start Oct 28, 2011 1:00:00 AM CDT
```

To Schedule an Online Restore

About this task

By providing connection and authentication information (and an optional start time), the restore can be performed via the Tasks subsystem while the server is online. The Tasks subsystem allows you to schedule certain operations, such as **`import-ldif`**, **`backup`**, **`restore`**, **`start-server`**, and **`stop-server`**. You can schedule a restore to run as a Task by specifying the timestamp with the `--task` and `--start` options. The option is expressed in "YYYYMMDDhhmmss'" format. If the option has a value of "0" then the task is scheduled for immediate execution. You cannot run recurring tasks, so daily operations must be run using cron or through some system that can submit the task.

Steps

- The backend that is being restored will be unavailable while the restore is in progress. To specify a time in the UTC time zone, add a trailing “Z” to the time. Otherwise, the time will be treated as a local time in the configured time zone on the server.

```
$ bin/restore --task --start 20111025010000 \
  --backupDirectory /path/to/backup/userRoot \
  --completionNotify admin@example.com --errorNotify admin@example.com
```

Encrypting a backup

Steps

- Go to the server root directory, and use the **backup** tool to backup up the single backend, userRoot and encrypt it with the **--encrypt** option.

```
$ bin/backup --encrypt --backendID userRoot --compress --backupDirectory /
path/to/backup
```

Signing a hash of the backup

Steps

- Go to the server root directory, and use the **backup** tool to backup up the single backend, userRoot. Use the **-signHash** option to generate a hash of the backup contents and digitally sign the hash of the backup contents. If you want to generate only a hash of the backup contents, run backup with the **--hash** option.

```
$ bin/backup --signHash --backupDirectory backups/userRoot --backendID
 userRoot \
  --backupDirectory /path/to/backup
```

Restoring a backup

Steps

- Go to the server root directory, and use the **restore** tool to restore a backup. The **backup** tool uses a descriptor file to access property information used for the backup, indicating if the backup was compressed, signed and/or encrypted.

```
$ bin/restore --backupDirectory /path/to/backup
```

Moving or restoring a user database

Part of any disaster recovery involves the restoration of the user database from one server to another. You should have a well-defined backup plan that takes into account whether or not your data is replicated among a set of servers. The plan is the best insurance against significant downtime or data loss in the event of unrecoverable database issue.

ⓘ **Note:** The server root directory should never be restored from a file system backup or snapshot. External backup methods (for example, VM snapshots) are not recommended, especially if data was corrupted during a transaction.

Keep in mind the following general points about database recovery:

- **Regular Backup from Local Replicated Directory Server** . Take a backup from a local replicated directory server and restore to the failed server. This will be more recent than any other backup you have.
- **Restore the Most Recent Backup**. Restore the most recent backup from a local server. In some cases, this may be preferred over taking a new backup if that would adversely impact performance of the server being backed up although it will take longer for replication to play back changes.
- **Contact Support**. If all else fails, contact your authorized support provider and they can work with you (and possibly in cooperation with the Oracle Berkeley DB JE engineers) to try a low-level recovery, including tools that attempt to salvage whatever data they can obtain from the database.

Comparing the data in two Directory Servers

The PingDirectory Server provides an **`ldap-diff`** tool to compare the data on two LDAP servers to determine any differences that they may contain. The differences are identified by first issuing a subtree search on both servers under the base DN using the default search filter `(objectclass=*)` to retrieve the DNs of all entries in each server. When the tool finds an entry that is on both servers, it retrieves the entry from each server and compares all of its attributes. The tool writes any differences it finds to an LDIF file in a format that could be used to modify the content of the source server, so that it matches the content of the target server. Any non-synchronized entries can be compared again for a configurable number of times with an optional pause between each attempt to account for replication delays.

You can control the specific entries to be compared with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. You can also exclude specific attributes by prepending a ^ character to the attribute. (On Windows operating systems, excluded attributes must be quoted, for example, "`^attrToExclude`".) The `@objectClassName` notation can be used to compare only attributes that are defined for a given objectclass.

The **`ldap-diff`** tool can be used on servers actively being modified by checking differing entries multiple times without reporting false positives due to replication delays. By default, it will re-check each entry twice, pausing two seconds between checks. These settings can be configured with the `--numPasses` and `--secondsBetweenPass` options. If the utility cannot make a clean comparison on an entry, it will list any exceptions in comments in the output file.

The Directory Server user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the Directory Server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry:

```
ds-cfg-default-root-privilege-name: unindexed-search
ds-cfg-default-root-privilege-name: bypass-acl
ds-rlim-size-limit: 0
ds-rlim-time-limit: 0
ds-rlim-idle-time-limit: 0
ds-rlim-lookthrough-limit: 0
```

The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For Directory Servers that contain hundreds of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by the `ldap-diff` tool can be customized by editing the `ldap-diff.java-args` setting in the `config/java.properties` file and running the **`dsjavaproperties`** command.

If you do not want to use a subtree search filter, you can use an input file of DNs for the source, target, or both. The format of the file can accept various syntaxes for each DN:

```
dn: cn=this is the first dn
dn: cn=this is the second dn and it is wrapped cn=this is the third dn
# The following DN is base-64 encoded dn::
Y249ZG9uJ3QgeW91IGhhdmUgYmV0dGVyIHRoaW5ncyB0byBkbyB0aGFuIHNlZSB3aGF0IHRoaXMgc2F5cw==
# There was a blank line above dn: cn=this is the final entry.
```

ⓘ **CAUTION:** Do not manually update the servers when the tool identifies differences between two servers involved in replication. First contact your authorized support provider for explicit confirmation, because manual updates to the servers risk introducing additional replication conflicts.

Comparing two Directory Servers using ldap-diff

Steps

1. Use **`ldap-diff`** to compare the entries in two Directory Server instances. Ignore the `userpassword` attribute due to the one-way password hash used for the password storage scheme.

```
$ bin/ldap-diff --outputLDIF difference.ldif \
  --sourceHost server1.example.com --sourcePort 1389 \
  --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
  --targetHost server2.example.com --targetPort 2389 \
  --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
  --baseDN dc=example,dc=com --searchFilter "(objectclass=*)"
 "^userpassword"
```

2. Open the output file in a text editor to view any differences. The file is set up so that you can re-apply the changes without any modification to the file contents. The file shows any deletes, modifies, and then adds from the perspective of the source server as the authoritative source.

```
# This file contains the differences between two LDAP servers.
#
# The format of this file is the LDIF changes needed to bring server
# ldap://server1.example.com:1389 in sync with server
# ldap://server2.example.com:2389.
#
# These differences were computed by first issuing an LDAP search at both
# servers under base DN dc=example,dc=com using search filter
 (objectclass=*)
# and search scope SUB to first retrieve the DNs of all entries. And then
 each
# entry was retrieved from each server and attributes: [^userpassword] were
# compared. # # Any entries that were out-of-sync were compared a total of 3
 times
# waiting a minimum of 2 seconds between each attempt to account for
 replication
# delays.
#
# Comparison started at [24/Feb/2010:10:34:20 -0600]
# The following entries were present only on ldap://server2.example.com:2389
 and
# need to be deleted. This entry existed only on ldap://
server1.example.com:1389
# Note: this entry might be incomplete. It only includes attributes:
# [^userpassword]dn: uid=user.200,ou=People,dc=example,dc=com
# objectClass: person
# objectClass: inetOrgPerson
... (more attributes not shown) ...
# st: DC
dn: uid=user.200,ou=people,dc=example,dc=com
changetype: delete

# The following entries were present on both servers but were out of sync.

dn: uid=user.199,ou=people,dc=example,dc=com
changetype: modify
add: mobile
mobile: +1 300 848 9999
-
delete: mobile
mobile: +1 009 471 1808

# The following entries were missing on ldap://server2.example.com:2389 and
 need
```

```
# to be added. This entry existed only on ldap://server2.example.com:2389
# Note: this entry might be incomplete. It only includes attributes:

# [^userpassword]
dn: uid=user.13,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
... (more attributes not shown) ...
# Comparison completed at [24/Feb/2010:10:34:25 -0600]
```

Comparing configuration entries using config-diff

Steps

- Use **`config-diff`** to compare Directory Server configurations and produce a **`dsconfig`** batch file needed to bring the source inline with the target.

  The following example compares the current configurations of server1 and server2. The changes necessary to bring server1's configuration inline with server2 are written to the console. The same credentials are used to connect to both servers.

  ```
  $ bin/config-diff --sourceHost server1 --sourceBindDN "cn=Directory Manager"
   \
    --sourceBindPassword password --targetHost server2
  ```

  For more information about runtime options, see the *Command Line Tool Reference* or the **`config-diff`** tool help.

Comparing entries using source and target DN files

Steps

- Use **`ldap-diff`** to compare the entries in two Directory Server instances. In the following example, the utility uses a single DN input file for the source and target servers, so that no search filter is used. Ignore the `userpassword` attribute due to the password storage scheme that uses a one-way hashing algorithm.

  ```
  $ bin/ldap-diff --outputLDIF difference.ldif \
    --sourceHost server1.example.com --sourcePort 1389 \
    --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
    --targetHost server2.example.com --targetPort 2389 \
    --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
    --baseDN "dc=example,dc=com" --sourceDNsFile input-file.ldif \
    --targetDNsFile input-file.ldif "^userpassword"
  ```

Comparing Directory Servers for missing entries only using ldap-diff

Steps

- Use **`ldap-diff`** to compare two Directory Servers and return only those entries that are missing on one of the servers using the `--missingOnly` option, which can significantly reduce the runtime for this utility.

  ```
  $ bin/ldap-diff --outputLDIF difference.ldif \
    --sourceHost server1.example.com --sourcePort 1389 \
    --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
    --targetHost server2.example.com --targetPort 2389 \
    --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
    --baseDN dc=example,dc=com --searchFilter "(objectclass=*)"
   "^userpassword" \
  ```

```
  --missingOnly
```

Reverting or replaying changes

The PingDirectory Server provides support for an audit logger that records information about the changes to data within the server. The data is formatted as LDIF, and it can be replayed with tools such as **ldapmodify** or **parallel-update**. The data also includes information encoded as comments that provide additional context about the changes. By default, the log records the changes as requested by clients, but it can also log the changes in reversible form so that they can be undone.

This audit logger can be useful for the following scenarios:

- If one or more undesirable changes have been made (for example, by a malicious or defective client), it can be used to obtain the necessary changes to revert those operations.
- If a catastrophic loss of all servers in the topology occurs that leaves an audit log available with newer data than any backup or LDIF export (for example, concurrent database corruption across all instances), it can be used to recover changes that may not otherwise be available.
- It can be useful for automating the process of identifying changes made in one topology that can be replayed into another topology (for example, to replay production changes into an isolated server or topology for testing purposes or to attempt to reproduce a problem).
- It can be useful for analytics and reporting purposes.

To assist with these and other uses, the LDAP SDK for Java provides an API for consuming, parsing, and reverting audit log messages. This API can be used for the analytics and reporting. Also available is the **extract-data-recovery-log-changes** tool that can extract audit log changes matching a specified set of criteria so that they can be replayed, either as they were originally processed or in a reversible form that makes it possible to revert those changes.

The Data Recovery Log

The **setup** tool automatically creates an audit logger for data recovery purposes in **logs/data-recovery**. The log is always compressed, and it will be encrypted if data encryption is enabled within the server. The logger has the following properties:

- Log files are written into the **logs/data-recovery** directory so that they are isolated from other log files. The active log file is named **data-recovery.gz.encrypted**, while rotated files are named **data-recovery.{timestamp}.gz.encrypted**.
- The log files are gzip-compressed. If data encryption is enabled, they are encrypted with a key obtained from the server's preferred encryption settings definition.
- Each log file contains no more than 10 MB of data, and is rotated after 24 hours. Keeping the log files small ensures that the entire contents of a log file will easily fit into the **extract-data-recovery-log-changes** tool's memory.
- The server will retain rotated data recovery log files for no more than one week. However, as a safeguard against consuming too much disk space in periods of extremely heavy and prolonged write activity, the server will also retain no more than 1,000 data recovery log files for a maximum of 500 MB of disk space.
- Changes are logged in reversible form and include the authentication and authorization identity of the requester, as well as the IP address. If present, the log message includes details from any intermediate client request control included in the request, which may provide information about the downstream client.

The extract-data-recovery-log-changes Tool

The **extract-data-recovery-log-changes** tool creates an LDIF file (compressed and encrypted by default) with a specified subset of changes from the server's data recovery log. That LDIF file can then be applied to the server using either the **ldapmodify** or parallel-update. Before applying the changes, the output file can be decrypted and examined to ensure that the changes it contains look correct. This tool can be useful for disaster recovery.

The **`extract-data-recovery-log-changes`** tool provides arguments for input and output of the extracted changes, including encryption settings, location, and compression.

The direction of whether changes should be extracted in forward mode or reverse mode is also configured. In forward mode (replay), the audit log messages are traversed from oldest to newest, and extracted changes are presented as they were originally requested. In reverse mode (revert), the audit log messages are traversed from newest to oldest, and extracted changes will be converted to a form that will revert the original changes. Regardless of the direction chosen, additional arguments enable identifying the changes to extract by time, requester address or DN, connection ID, origin, content type, or alterations. The following is a sample command to revert all changes by user **`uid=malicious,ou=People,dc=example,dc=com`** between noon and 2 pm on October 15, 2018:

```
$ bin/extract-data-recovery-log-changes \
  --auditLogFile logs/data-recovery/data-
recovery.201810161234.567.gz.encrypted \
  --outputFile revert-malicious-user-changes.ldif \
  --direction revert \
  --startTime 201810151200.000 \
  --endTime 201810151359.999 \
  --includeAuthorizationDN "uid=malicious,ou=People,dc=example,dc=com"
```

Working with Groups

LDAP groups are special types of entries that represent collections of users. Groups are often used by external clients, for example, to control who has access to a particular application or features. They may also be used internally by the server to control its behavior. For example, groups can be used by the access control, criteria, or virtual attribute subsystems.

The specific ways in which clients create and interact with a particular group depends on the type of group being used. In general, there are three primary ways in which clients attempt to use groups:

- To determine whether a specified user is a member of a particular group.
- To determine the set of groups in which a specified user is a member.
- To determine the set of all users that are members of a particular group.

This chapter provides an overview of Directory Server groups concepts and provides procedures on setting up and querying groups in the Directory Server.

Overview of groups

The Directory Server provides the following types of groups:

- **Static Groups**. A static group is an entry that contains an explicit list of member or uniquemember attributes, depending on its particular structural object class. Static groups are ideal for relatively small, infrequently changing elements. Once the membership list grows, static groups become more difficult to manage as any change in a member base DN must also be changed in the group. Static groups use one of three structural object classes: `groupOfNames`, `groupOfUniqueNames`, and `groupOfEntries`.

  The Directory Server also supports nested groups, in which a parent group entry contains child attributes whose DNs reference another group. Nested groups are a flexible means to organize entries that provide inherited group membership and privileges. To maintain good performance throughput, a group cache is enabled by default. The cache supports static group nesting that includes other static, virtual static, and dynamic groups.
- **Dynamic Groups**. A dynamic group has its membership list determined by search criteria using a LDAP URL. Dynamic groups solve the scalability issues encountered for static groups as searches are efficient, constant-time operations. However, if searches range over a very large set of data, performance could be affected.

- **Virtual Static Groups**. A virtual static group is a combination of both static and dynamic groups, in which each member in a group is a virtual attribute that is dynamically generated when invoked. Virtual static groups solve the scalability issues for clients that can only support static groups and are best used when the application targets a search operation for a specific member. Virtual static groups are not good for applications that need to retrieve the entire membership list as the process for constructing the entire membership list can be expensive.

About the isMemberOf and isDirectMemberOf virtual attribute

The existence of both static, nested, dynamic, and virtual static groups can make it unnecessarily complex to work with groups in the server, particularly because the ways you interact with them are so different. And the fact that static groups can use three different structural object classes (not counting the auxiliary class for virtual static groups) does not make things any easier.

To make group operations simpler, the PingDirectory Server provides the ability to generate either an `isMemberOf` and `isDirectMemberOf` virtual attributes in user entries. These attributes dramatically simplify the process for making group-related determinations in a manner that is consistent across all types of groups.

The value of the `isMemberOf` virtual attribute is a list of DNs of all groups (including static, nested, dynamic, and virtual static groups) in which the associated user is a member. The value of the `isDirectMemberOf` virtual attribute is a subset of the values of `isMemberOf`, which represents the groups for which the entry is an explicit or direct member. Both are enabled by default.

Because the `isMemberOf` and `isDirectMemberOf` are operational attributes, only users who specifically have been granted the privilege can see it. The default set of access control rules do not allow any level of access to user data. The only access that is granted is what is included in user-defined access control rules, which is generally given to a `uid=admin` administrator account. It is always a best practice to restrict access to operational and non-operational attributes to the minimal set of users that need to see them. The root bind DN, `cn=Directory Manager`, has the privilege to view operational attributes by default.

To determine whether a user is a member of a specified group using the `isMemberOf` virtual attribute, simply perform a base-level search against the user's entry with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group. The following table illustrates this simple base-level search:

Base DN	uid=john.doe,ou=People,dc=example,dc=com
Scope	base
Filter	(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)
Requested Attributes	1.1

If this search returns an entry, then the user is a member of the specified group. If no entry is returned, then the user is not a member of the given group.

To determine the set of all groups in which a user is a member, simply retrieve the user's entry with a base-level search and include the `isMemberOf` attribute:

Base DN	uid=john.doe,ou=People,dc=example,dc=com
Scope	base
Filter	(objectclass=*)
Requested Attributes	isMemberOf

To determine the set of all members for a specified group, issue a subtree search with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group and requesting the attributes you wish to have for member entries:

Base DN	ou=People,dc=example,dc=com
Scope	sub
Filter	(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)
Requested Attributes	cn, mail

The `isDirectMemberOf` virtual attribute can be used in the examples above in place of `isMemberOf` if you only need to find groups that users are an actual member of. You must use `isMemberOf` for nested group membership.

Note that if this filter targets a dynamic group using an unindexed search, then this may be an expensive operation. However, it will not be any more expensive than retrieving the target group and then issuing a search based on information contained in the member URL.

For static groups, this approach has the added benefit of using a single search to retrieve information from all user entries, whereas it would otherwise be required to retrieve the static group and then perform a separate search for each member's entry.

Using static groups

A static group contains an explicit membership list where each member is represented as a DN-valued attribute. There are three types of static groups supported for use in the Directory Server:

- **groupOfNames**. A static group that is defined with the `groupOfNames` structural object class and uses the `member` attribute to hold the DNs of its members. RFC 4519 requires that the `member` attribute be required in an entry. However, the Directory Server has relaxed this restriction by making the `member` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfNames` object class:

  ```
  dn: cn=Test Group,ou=Groups,dc=example,dc=com
  objectClass: top
  objectClass: groupOfNames
  cn: Test Group
  member: uid=user.1,ou=People,dc=example,dc=com
  member: uid=user.2,ou=People,dc=example,dc=com
  member: uid=user.3,ou=People,dc=example,dc=com
  ```
- **groupOfUniqueNames**. A static group that is defined with the `groupOfUniqueNames` structural object class and uses the `uniquemember` attribute to hold the DNs of its members. RFC 4519 requires that the `uniquemember` attribute be required in an entry. However, the Directory Server has relaxed this restriction by making the `uniquemember` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfUniqueNames` object class:

  ```
  dn: cn=Test Group,ou=Groups,dc=example,dc=com
  objectClass: top
  objectClass: groupOfUniqueNames
  cn: Test Group
  uniquemember: uid=user.1,ou=People,dc=example,dc=com
  uniquemember: uid=user.2,ou=People,dc=example,dc=com
  uniquemember: uid=user.3,ou=People,dc=example,dc=com
  ```
- **groupOfEntries**. A static group that is defined with the `groupOfEntries` object class and uses the `member` attribute to hold the DNs of its members. This group specifies that the `member` attribute is optional to ensure that the last member can be removed from the group. Although the draft proposal (draft-findlay-ldap-groupofentries-00.txt) has expired, the Directory Server supports this implementation. The following entry depicts a group defined with the `groupOfEntries` object class:

  ```
  dn: cn=Test Group,ou=Groups,dc=example,dc=com
  objectClass: top
  objectClass: groupOfEntries
  cn: Test Group
  ```

```
member: uid=user.1,ou=People,dc=example,dc=com
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

Creating static groups

You can configure a static group by adding it using an LDIF file. Static groups contain a membership list of explicit DNs specified by the `uniquemember` attribute.

Creating a static group

Steps

1. Open a text editor, and then create a group entry in LDIF. Make sure to include the `groupOfUniquenames` object class and `uniquemember` attributes. If you did not have `ou=groups` set up in your server, then you can add it in the same file. When done, save the file as `static-group.ldif`. The following example LDIF file creates two groups, `cn=Development` and `cn=QA`.

   ```
   dn: ou=groups,dc=example,dc=com
   objectclass: top
   objectclass: organizationalunit
   ou: groups

   dn: cn=Development,ou=groups,dc=example,dc=com
   objectclass: top
   objectclass: groupOfUniqueNames
   cn: Development
   ou: groups
   uniquemember: uid=user.14,ou=People,dc=example,dc=com
   uniquemember: uid=user.91,ou=People,dc=example,dc=com
   uniquemember: uid=user.180,ou=People,dc=example,dc=com

   dn: cn=QA,ou=groups,dc=example,dc=com
   objectclass: top
   objectclass: groupOfUniqueNames
   cn: QA
   ou: groups
   uniquemember: uid=user.0,ou=People,dc=example,dc=com
   uniquemember: uid=user.1,ou=People,dc=example,dc=com
   uniquemember: uid=user.2,ou=People,dc=example,dc=com
   ```

2. Use **`ldapmodify`** to add the group entries to the server.

   ```
   $ bin/ldapmodify --defaultAdd --filename static-group.ldif
   ```

3. Verify the configuration by using the virtual attribute `isDirectMemberOf` that checks membership for a non-nested group. By default, the virtual attribute is disabled by default, but you can enable it using **`dsconfig`**.

   ```
   $ bin/dsconfig set-virtual-attribute-prop --name isDirectMemberOf --set
    enabled:true
   ```

4. Use **`ldapsearch`** to specifically search the `isDirectMemberOf` virtual attribute to determine if `uid=user.14` is a member of the `cn=Development` group. In this example, assume that administrator has the privilege to view operational attributes.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)" isDirectMemberOf

   dn: uid=user.14,ou=People,dc=example,dc=com
   isDirectMemberOf: cn=Development,ou=groups,dc=example,dc=com
   ```

5. Typically, you would want to use the group as a target in access control instructions. Open a text editor, create an `aci` attribute in an LDIF file, and save the file as `dev-group-aci.ldif`. Add the file

using the **ldapmodify** tool. You can create a similar ACI for the QA group, which is not shown in this example.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target ="ldap:///ou=People,dc=example,dc=com")
  (targetattr != "cn || sn || uid")
  (targetfilter ="(ou=Development)")
  (version 3.0; acl "Dev Group Permissions";
    allow (write) (groupdn = "ldap:///
cn=Development,ou=groups,dc=example,dc=com");)
```

6. Add the file using the **ldapmodify** tool.

```
$ bin/ldapmodify --filename dev-group-aci.ldif
```

Adding a new member to a static group

Steps

- To add a new member to the group, add a new value for the `uniquemember` attribute that specifies the DN of the user to be added. The following example adds a new `uniquemember`, `user.4`:

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
add: uniquemember
uniquemember: uid=user.4,ou=People,dc=example,dc=com
```

Removing a member from a static group

Steps

- To remove a member from a static group, remove that user's DN from the `uniquemember` attribute. The following example removes the DN of `user.1`:

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
delete: uniquemember
uniquemember: uid=user.1,ou=People,dc=example,dc=com
```

Searching static groups

The following sections describe how to compose searches to determine if a user is a member of a static group, to determine all the static groups in which a user is a member, and to determine all the members of a static group.

Determining if a user is a static group member

About this task

To determine whether a user is a member of a specified group, perform a base-level search to retrieve the group entry with an equality filter looking for the membership attribute of a value equal to the DN of the specified user.

For best performance, you will want to include a specific attribute list (just "cn", or "1.1" request that no attributes be returned) so that the entire member list is not returned. For example, to determine whether the user "`uid=john.doe,ou=People,dc=example,dc=com`" is a member of the `groupOfNames` static group "`cn=Test Group,ou=Groups,dc=example,dc=com`", issue a search with the following criteria:

Search Criteria for a Single User's Membership in a Static Group

Base DN	cn=Test Group,ou=Groups,dc=example,dc=com
Scope	base
Filter	(member=uid=john.doe,ou=People,dc=example,dc=com)
Requested Attributes	1.1

If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group. If you do not know the membership attribute for the specified group (it could be either a `member` or `uniqueMember` attribute), then you may want to revise the filter so that it allows either one as follows:

```
(|(member=uid=john.doe,ou=People,dc=example,dc=com)
(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com))
```

Steps

- Run a base-level search to retrieve the group entry with an equality filter looking for the membership attribute.

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com"
  --searchScope base "(member=uid=john.doe,ou=People,dc=example,dc=com)"
 "1.1"
```

Determining the static groups to which a user belongs

About this task

To determine the set of all static groups in which a user is specified as a member, perform a subtree search based at the top of the DIT. The search filter must be configured to match any type of static group in which the specified user is a member.

For example, the following criteria may be used to determine the set of all static groups in which the user, `uid=john.doc,ou=People,dc=example,dc=com`, is a member:

Search Criteria for Determining All the Static Groups for a User

Base DN	dc=example,dc=com
Scope	sub
Filter	(|(&(objectClass=groupOfNames) (member=uid=john.doe,ou=People,dc=example,dc=com)) (&(objectClass=groupOfUniqueNames)(uniqueMem- ber=uid=john.doe,ou=People,dc=example,dc=com)) (&(objectClass=groupOfEntries) (member=uid=john.doe,ou=People,dc=example,dc=com)))
Requested Attributes	1.1

Every entry returned from the search represents a static group in which the specified user is a member.

Steps

- Run a sub-level search to retrieve the static groups to which a user belongs.

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" --searchScope sub \
  "(|(&(objectClass=groupOfNames)
```

```
  (member=uid=john.doe,ou=People,dc=example,dc=com)) \
  (&(objectClass=groupOfUniqueNames)\
  (uniqueMember=uid=john.doe,ou=People,dc=example,dc=com)) \
  (&(objectClass=groupOfEntries) \
  (member=uid=john.doe,ou=People,dc=example,dc=com)))" "1.1"
```

ⓘ **Note:** A base level search of the user's entry for `isMemberOf` or `isDirectMemberOf` virtual attributes will give the same results. You can also use the virtual attributes with virtual static groups.

Determining the members of a static group

About this task

To determine all of the members for a static group, simply retrieve the group entry including the membership attribute. The returned entry will include the DNs of all users that are members of that group. For example, the following criteria may be used to retrieve the list of all members for the group `cn=Test Group,ou=Groups,dc=example,dc=com`:

Search Criteria for All of the Static Group's Members

Base DN	cn=Test Group,ou=Groups,dc=example,dc=com
Scope	base
Filter	(objectClass=*)
Requested Attributes	member uniqueMember

If you want to retrieve additional information about the members, such as attributes from member entries, you must issue a separate search for each member to retrieve the user entry and the desired attributes.

Steps

- Run a base-level search to retrieve all of the members in a static group.

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com" \
  --searchScope base "(objectclass=*)" uniqueMember
```

ⓘ **Note:** If you want to retrieve attributes from member entries, it is more efficient to search all users whose `isMemberOf` attribute contains the group DN, returning the attributes desired.

Using dynamic groups

Dynamic groups contain a set of criteria used to identify members rather than maintaining an explicit list of group members. If a new user entry is created or if an existing entry is modified so that it matches the membership criteria, then the user will be considered a member of the dynamic group. Similarly, if a member's entry is deleted or if it is modified so that it no longer matches the group criteria, then the user will no longer be considered a member of the dynamic group.

In the Directory Server, dynamic groups include the `groupOfURLs` structural object class and use the `memberurl` attribute to provide an LDAP URL that defines the membership criteria. The base, scope, and filter of the LDAP URL will be used in the process of making the determination, and any other elements present in the URL will be ignored. For example, the following entry defines a dynamic group in which all users below `dc=example,dc=com` with an `employeeType` value of contractor will be considered members of the group:

```
dn: cn=Sales Group,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
```

```
cn: Sales Group
memberURL: ldap:///dc=example,dc=com??sub?(employeeType=contractor)
```

Assuming that less than 80,000 entries have the `employeeType` of contractor, you need to create the following index definition to evaluate the dynamic group:

```
$ bin/dsconfig create-local-db-index --backend-name userRoot \
  --index-name employeeType --set index-entry-limit:80000 \
  --set index-type:equality
```

Creating dynamic groups

About this task

You can configure a dynamic group in the same manner as static groups using an LDIF file. Dynamic groups contain a membership list of attributes determined by search filter using an LDAP URL. You must use the `groupOfURLs` object class and the `memberURL` attribute.

To create a dynamic group:

Steps

1. Assume that `uid=user.15` is not part of any group. Use **`ldapsearch`** to verify that `uid=user.15` is not part of any group. In a later step, we will add the user to the dynamic group.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
    "(uid=user.15)" ou
   ```

   ```
   dn: uid=user.15,ou=People,dc=example,dc=com
   ```

2. Assume for this example that `uid=user.0` has an `ou=Engineering` attribute indicating that he or she is a member of the Engineering department.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub "(uid=user.0)"
    ou isMemberOf
   ```

   ```
   dn: uid=user.0,ou=People,dc=example,dc=com
   ou: Engineering
   ```

3. Open a text editor, and then create a dynamic group entry in LDIF. The LDIF defines the dynamic group to include all users who have the `ou=Engineering` attribute. When done, save the file as `add-dynamic-group.ldif`.

   ```
   dn: cn=eng-staff,ou=groups,dc=example,dc=com
   objectclass: top
   objectclass: groupOfURLs
   ou: groups
   cn: eng-staff
   memberURL: ldap:///ou=People,dc=example,dc=com??sub?(ou=Engineering)
   ```

4. Use **`ldapmodify`** to add the group entry to the server.

   ```
   $ bin/ldapmodify --defaultAdd --filename add-dynamic-group.ldif
   ```

5. Use **`ldapsearch`** to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.0` is a member of the `cn=Engineering` group or any other group.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" isMemberOf
   ```

   ```
   dn: uid=user.0,ou=People,dc=example,dc=com
   isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
   ```

6. If your data is relatively small (under 1 million entries), you can search for all users in the group that meet the search criteria (`ou=Engineering`). For very large databases, it is not practical to run a

database-wide search for all users as there can be a performance hit on the Directory Server. The following command returns the DNs of entries that are part of the `cn=eng-staff` dynamic group and sorts them in ascending order by the `sn` attribute.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --sortOrder sn \
  "(isMemberOf=cn=eng-staff,ou=groups,dc=example,dc=com)" dn
```

7. Add `uid=user.15` to the `eng-staff` group by adding an `ou=Engineering` attribute to the entry. This step highlights an advantage of dynamic groups: you can make a change in an entry without explicitly adding the DN to the group as you would with static groups. The entry will be automatically added to the `eng-staff` dynamic group.

```
$ bin/ldapmodify
dn: uid=user.15,ou=People,dc=example,dc=com
changetype: modify
add: ou
ou: Engineering
```

8. Use **`ldapsearch`** to check if the user is part of the `cn=eng-staff` dynamic group.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
 "(uid=user.15)" isMemberOf
```

```
dn: uid=user.15,ou=People,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

Searching dynamic groups

The following sections describe how to compose searches to determine if a user is a member of a dynamic group, to determine all the dynamic groups in which a user is a member, and to determine all the members of a dynamic group.

Determining if a user is a dynamic group member

About this task

To determine whether a user is a member of a specific dynamic group, you must verify that the user's entry is both within the scope of the member URL and that it matches the filter contained in that URL. You can verify that a user's entry is within the scope of the URL using simple client-side only processing. Evaluating the filter against the entry on the client side can be more complicated. While possible, particularly in clients that are able to perform schema-aware evaluation, a simple alternative is to perform a base-level search to retrieve the user's entry with the filter contained in the member URL.

For example, to determine whether the user `uid=john.doe,ou=People,dc=example,dc=com` is a member of the dynamic group with the above member URL, issue a search with the following criteria:

Search Criteria for a Single User's Membership in a Dynamic Group

Base DN	uid=john.doe,ou=People,dc=example,dc=com
Scope	base
Filter	(ou=Engineering)
Requested Attributes	1.1

Note that the search requires the user DN to be under the search base defined in the `memberurl` attribute for the user to be a member. If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group.

Determining the dynamic groups to which a user belongs

About this task

To determine the set of all dynamic groups in which a user is a member, first perform a search to find all dynamic group entries defined in the server. You can do this using a subtree search with a filter of "`(objectClass=groupOfURLs)`".

You should retrieve the `memberURL` attribute so that you can use the logic described in the previous section to determine whether the specified user is a member of each of those groups. For example, to find the set of all dynamic groups defined in the `dc=example,dc=com` tree, issue a search with the following criteria:

Search Criteria for Determining All of the Dynamic Groups for a User

Base DN	dc=example,dc=com
Scope	sub
Filter	(objectClass=groupOfURLs)
Requested Attributes	memberURL

Each entry returned will be a dynamic group definition. You can use the base, scope, and filter of its `memberURL` attribute to determine whether the user is a member of that dynamic group.

Determining the members of a dynamic group

About this task

To determine all members of a dynamic group, issue a search using the base, scope, and filter of the member URL. The set of requested attributes should reflect the attributes desired from the member user entries, or "1.1" if no attributes are needed.

For example, to retrieve the **`cn`** and **`mail`** attributes from the group described above, use the following search:

Search Criteria for Determining the Members of a Dynamic Group

Base DN	dc=example,dc=com
Scope	sub
Filter	(employeeType=contractor)
Requested Attributes	cn, mail

ⓘ **CAUTION:** Note that this search may be expensive if the associated filter is not indexed or if the group contains a large number of members.

Using dynamic groups for internal operations

You can use dynamic groups for internal operations, such as ACI or component evaluation. The Directory Server performs the `memberurl` parsing and internal LDAP search; however, the internal search operation may not be performed with access control rules applied to it.

For example, the following dynamic group represents an organization's employees within the same department:

```
dn: cn=department 202,ou=groups,dc=example,dc=com
objectClass: top
```

```
objectClass: groupOfURLs
cn: department 202
owner: uid=user.1,ou=people,dc=example,dc=com
owner: uid=user.2,ou=people,dc=example,dc=com
memberURL: ldap:///ou=People,dc=example,dc=com??sub?
  (&(employeeType=employee)(departmentNumber=202))
description: Group of employees in department 202
```

The above group could be referenced from within the ACI at the `dc=example,dc=com` entry. For example:

```
dn:dc=example,dc=com
aci: (targetattr="employeeType")
  (version 3.0; acl "Grant write access to employeeType" ;
    allow (all) groupdn="ldap:///cn=department
 202,ou=groups,dc=example,dc=com";)
```

Any user matching the filter can bind to the server with their entry and modify the `employeeType` attribute within any entry under `dc=example,dc=com`.

Using virtual static groups

Static groups can be easier to interact with than dynamic groups, but large static groups can be expensive to manage and require a large amount of memory to hold in the internal group cache. The Directory Server provides a third type of group that makes it possible to get the efficiency and ease of management of a dynamic group while allowing clients to interact with it as a static group. A *virtual static group* is a type of group that references another group and provides access to the members of that group as if it was a static group.

To create a virtual static group, create an entry that has a structural object class of either `groupOfNames` or `groupOfUniqueNames` and an auxiliary class of `ds-virtual-static-group`. It should also include a `ds-target-group-dn` attribute, whose value is the group from which the virtual static group should obtain its members. For example, the following will create a virtual static group that exposes the members of the `cn=Sales Group,ou=Groups,dc=example,dc=com` dynamic group as if it were a static group:

```
dn: cn=Virtual Static Sales Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfNames
objectClass: ds-virtual-static-group
cn: Virtual Static Sales Group
ds-target-group-dn: cn=Sales Group,ou=Groups,dc=example,dc=com
```

Note that you must also enable a virtual attribute that allows the `member` attribute to be generated based on membership for the target group. A configuration object for this virtual attribute does exist in the server configuration, but is disabled by default. To enable it, issue the following change:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
  --set enabled:true
```

If you want to use virtual static groups with the `groupOfUniqueNames` object class, then you will also need to enable the `Virtual Static uniqueMember` virtual attribute in the same way.

Creating virtual static groups

About this task

If your application only supports static groups but has scalability issues, then using a virtual static group could be a possible solution. A virtual static group uses a virtual attribute that is dynamically generated when called after which the operations that determine group membership are passed to another group, such as a dynamic group. You must use the `ds-virtual-static-group` object class and the `ds-target-group-dn` virtual attribute.

Virtual static groups are best used when determining if a single user is a member of a group. It is not a good solution if an application accesses the full list of group members due to the performance expense at constructing the list. If you have a small database and an application that requires that the full membership list be returned, you must also enable the `allow-retrieving-membership` property for the Virtual Static `uniqueMember` virtual attribute using the **`dsconfig`** tool.

To create a virtual static group:

Steps

1. Open a text editor, and then create a group entry in LDIF. The entry contains the `groupOfUniqueNames` object class, but in place of the `uniquemember` attribute is the `ds-target-group-dn` virtual attribute, which is part of the `ds-virtual-static-group` auxiliary object class. When done, save the file as `add-virtual-static-group.ldif`.

```
dn: cn=virtualstatic,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
objectclass: ds-virtual-static-group
ou: groups
cn: virtual static
ds-target-group-dn: cn=eng-staff,ou=groups,dc=example,dc=com
```

2. Use **`ldapmodify`** to add the virtual static group entry to the server.

```
$ bin/ldapmodify -h server1.example.com -p 389 -D
 "uid=admin,dc=example,dc=com" \
  -w password -a -f add-virtual-static-group.ldif
```

3. Use **`dsconfig`** to enable the Virtual Static `uniqueMember` attribute, which is disabled by default.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
 uniqueMember" \
  --set enabled:true
```

4. In the previous section, we set up `uid=user.0` to be part of the `cn=eng-staff` dynamic group. Use **`ldapsearch`** with the `isMemberOf` virtual attribute to determine if `uid=user.0` is part of the virtual static group.

```
$ bin/ldapsearch -h server1.example.com -p 389 -D "cn=Directory Manager" \
  -w secret -b dc=example,dc=com" "(uid=user.0)" isMemberOf
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
isMemberOf: cn=virtualstatic,ou=groups,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

5. Use **`ldapsearch`** to determine if `uid=user.0` is a member of the virtual static group. You should see the returned `cn=virtualstatic` entry if successful.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
  -b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
  "(&(objectclass=groupOfUniqueNames) \
  (uniquemember=uid=user.0,ou=People,dc=example,dc=com))"
```

6. Next, try searching for a user that is not part of the `cn=eng-staff` dynamic group (e.g., `uid=user.20`), nothing will be returned.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
  -b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
  "(&(objectclass=groupOfUniqueNames) \
  (uniquemember=uid=user.20,ou=People,dc=example,dc=com))"
```

Searching virtual static groups

Because virtual static groups behave like static groups, the process for determining whether a user is a member of a virtual static group is identical to that of a member in a static group. Similarly, the process for determining all virtual static groups in which a user is a member is basically the same as the process as that of real static groups in which a user is a member. In fact, the query provided in the static groups discussion returns virtual static groups in addition to real static groups, because the structural object class of a virtual static group is the same as the structural object class for a static group.

You can also retrieve a list of all members of a virtual static group in the same way as a real static group: simply retrieve the `member` or `uniqueMember` attribute of the desired group. However, because virtual static groups are backed by dynamic groups and the process for retrieving member information for dynamic groups can be expensive, virtual static groups do not allow retrieving the full set of members by default. The virtual attribute used to expose membership can be updated to allow this with a configuration change such as the following:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
  --set allow-retrieving-membership:true
```

Because this can be an expensive operation, we recommend that the option to allow retrieving virtual static group membership be left disabled unless it is required.

Creating nested groups

About this task

The PingDirectory Server supports nested groups, where the DN of an entry that defines a group is included as a member in the parent entry. For example, the following example shows a nested static group (e.g., `cn=Engineering Group`) that has `uniquemember` attributes consisting of other groups, such as `cn=Developers Group` and the `cn=QA Group` respectively.

```
dn: cn=Engineering Group,ou=Groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=Groups,dc=example,dc=com
uniquemember: cn=QA,ou=Groups,dc=example,dc=com
```

Nested group support is enabled by default on the Directory Server. To support nested groups without the performance hit, the Directory Server uses a group cache, which is also enabled by default. The cache supports static group nesting that includes other static, virtual static, and dynamic groups. The Directory Server provides a new monitoring entry for the group cache, `cn=Group Cache,cn=Monitor`.

In practice, nested groups are not commonly used for several reasons. LDAP specifications do not directly address the concept of nested groups, and some servers do not provide any level of support for them. Supporting nested groups in LDAP clients is not trivial, and many directory server-enabled applications that can interact with groups do not provide any support for nesting. If nesting support is not needed in your environment, or if nesting support is only required for clients but is not needed for server-side evaluation (such as for groups used in access control rules, criteria, virtual attributes, or other ways that the server may need to make a membership determination), then this support should be disabled.

To create nested static groups:

Steps

1. The following example shows how to set up a nested static group, which is a static group that contains `uniquemember` attributes whose values contain other groups (static, virtual static, or dynamic). Open a text editor, and then create a group entry in LDIF. Make sure to include the `groupOfUniquenames` object class and `uniquemember` attributes. If you did not have `ou=groups` set up in your server, then

you can add it in the same file. When done, save the file as `nested-group.ldif`. Assume that the static groups, `cn=Developers Group` and `cn=QA Group`, have been configured.

```
dn: ou=groups,dc=example,dc=com
objectclass: top
objectclass: organizationalunit
ou: groups

dn: cn=Engineering Group,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=groups,dc=example,dc=com
uniquemember: cn=QA,ou=groups,dc=example,dc=com
```

2. Use **`ldapmodify`** to add the group entry.

```
$ bin/ldapmodify --defaultAdd --filename nested-static-group.ldif
```

3. Verify the configuration by using the `isMemberOf` virtual attribute that checks the group membership for an entry. By default, the virtual attribute is enabled. Use **`ldapsearch`** to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.14` is a member of the `cn=Development` group. In this example, assume that the administrator has the privilege to view operational attributes.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)" isMemberOf

dn: uid=user.14,ou=People,dc=example,dc=com
isMemberOf: cn=Development,ou=groups,dc=example,dc=com
```

4. Typically, you would want to use the group as a target in access control instructions. Open a text editor, create an ACI in LDIF, and save the file as `eng-group-aci.ldif`.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target ="ldap:///ou=People,dc=example,dc=com")
  (targetattr != "cn || sn || uid")
  (targetfilter ="(ou=Engineering Group)")
  (version 3.0; acl "Engineering Group Permissions";
    allow (write) (groupdn = "ldap:///cn=Engineering
 Group,ou=groups,dc=example,dc=com");)
```

5. Add the file using the **`ldapmodify`** tool.

```
$ bin/ldapmodify --filename eng-group-aci.ldif
```

ⓘ **Note:** When nesting dynamic groups, you cannot include other groups as members of a dynamic group. You can only support "nesting" by including the members of another group with a filter in the member URL. For example, if you have two groups `cn=dynamic1` and `cn=dynamic2`, you can nest one group in another by specifying it in the member URL as follows:

```
cn=dynamic1,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
memberURL: ldap:///dc=example,dc=com??sub?
(isMemberOf=cn=dynamic2,ou=groups,dc=example,dc=com)
```

The members included from the other group using this method are not considered "nested" members and will be returned even when using `isDirectMemberOf` when retrieving the members.

Maintaining referential integrity with static groups

The Directory Server can automatically update references to an entry whenever that entry is removed or renamed in a process called *referential integrity*. For example, if a user entry is deleted, then referential integrity plugin will remove that user from any static groups in which the user was a member (this is not necessary for dynamic groups, since no explicit membership is maintained). Similarly, if a modify DN operation is performed to move or rename a user entry, then referential integrity updates static groups in which that user is a member with the new user DN.

Referential integrity support is disabled by default, but may be enabled using the **`dsconfig`** tool as follows:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
  --set enabled:true
```

Other configuration attributes of note for this plugin include:

- **attribute-type**. This attribute specifies the names or OIDs of the attribute types for which referential integrity will be maintained. By default, referential integrity is maintained for the `member` and `uniqueMember` attributes. Any attribute types specified must have a syntax of either distinguished name (OID "1.3.6.1.4.1.1466.115.121.1.12") or name and optional UID (OID "1.3.6.1.4.1.1466.115.121.1.34"). The specified attribute types must also be indexed for equality in all backends for which referential integrity is to be maintained.
- **base-dn**. This attribute specifies the subtrees for which referential integrity will be maintained. If one or more values are provided, then referential integrity processing will only be performed for entries which exist within those portions of the DIT. If no values are provided (which is the default behavior), then entries within all public naming contexts will be included.
- **log-file**. This attribute specifies the path to a log file that may be used to hold information about the DNs of deleted or renamed entries. If the plugin is configured with a nonzero update interval, this log file helps ensure that appropriate referential integrity processing occurs even if the server is restarted.
- **update-interval**. This attribute specifies the maximum length of time that a background thread may sleep between checks of the referential integrity log file to determine whether any referential integrity processing is required. By default, this attribute has a value of "0 seconds", which indicates that all referential integrity processing is to be performed synchronously before a response is returned to the client. A duration greater than 0 seconds indicates that referential integrity processing will be performed in the background and will not delay the response to the client.

In the default configuration, where referential integrity processing is performed synchronously, the throughput and response time of delete and modify DN operations may be adversely impacted because the necessary cleanup work must be completed before the response to the original operation can be returned. Changing the configuration to use a non-zero update interval alleviates this performance impact because referential integrity processing uses a separate background thread and does not significantly delay the response to delete or modify DN operations.

However, performing referential integrity processing in a background thread may introduce a race condition that may adversely impact clients that delete a user and then immediately attempt to re-add it and establish new group memberships. If referential integrity processing has not yet been completed for the delete, then newly-established group memberships may be removed along with those that already existed for the previous user. Similarly, if the newly-created user is to be a member of one or more of the same groups as the previous user, then attempts by the client to re-establish those memberships may fail if referential integrity processing has not yet removed the previous membership. For this reason, we recommend that the default synchronous behavior be maintained unless the performance impact associated with it is unacceptable and clients are not expected to operate in a manner that may be adversely impacted by delayed referential integrity processing.

ⓘ **Note:** The internal operations of the referential integrity plugin are not replicated. So, in a replicated topology, you must enable the referential integrity plugin consistently on all servers in the topology to ensure that changes made by the referential integrity plugin are passed along to a replication server.

For more information about administering the referential integrity plugin, see Chapter 6, “Configuring the Directory Server” in the *PingDirectory Server Administration Guide*.

Monitoring the group membership cache

The Directory Server logs information at startup about the memory consumed by the group membership cache. This hard-coded cache contains information about all of the group memberships for internal processing, such as ACIs. The group membership cache is enabled by default.

The information about this cache is logged to the standard output log (`server.out`) and the standard error log. When using groups, you can use the log information to tune the server for best performance. For example, at startup the server logs a message like the following to the `server.out` log:

```
[16/Aug/2011:17:14:39.462 -0500] category=JEB severity=NOTICE msgID=1887895587
msg="The database cache now holds 3419MB of data and is 32 percent full"
```

The error log will contain something like the following:

```
[16/Aug/2011:18:40:39.555 -0500] category=EXTENSIONS severity=NOTICE
 msgID=1880555575
msg="'Group cache (174789 static group(s) with 7480151 total memberships and
 1000002
unique members, 0 virtual static group(s), 1 dynamic group(s))' currently
 consumes
149433592 bytes and can grow to a maximum of 149433592 bytes"
```

Using the entry cache to improve the performance of large static groups

The PingDirectory Server provides an entry cache implementation, which allows for fine-grained control over the kinds of entries that may be held in the cache. You can define filters to specify the entries included in or excluded from the cache, and you can restrict the cache so that it holds only entries with at least a specified number of values for a given set of attributes.

Under most circumstances, we recommend that the Directory Server be used *without* an entry cache. The Directory Server is designed to efficiently retrieve and decode entries from the database in most cases. The database cache is much more space-efficient than the entry cache, and heavy churn in the entry cache can adversely impact garbage collection behavior.

However, if the Directory Server contains very large static groups, such as those containing thousands or millions of members, and clients need to frequently retrieve or otherwise interact with these groups, then you may want to enable an entry cache that holds only large static groups.

In servers containing large static groups, you can define an entry cache to hold only those large static groups. This entry cache should have an include filter that matches only group entries (for example, "`(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)(objectclass=groupOfEntries))`"). The filter contains a minimum value count so that only groups with a large number of members (such as those with at least 100 `member` or `uniqueMember` values) will be included. The Directory Server provides an entry cache implementation with these settings although it is disabled by default.

Enabling the entry cache

Steps

- Run **`dsconfig`** to enable the entry cache.

```
$ bin/dsconfig set-entry-cache-prop --cache-name "Static Group Entry Cache"
 \
  --set enabled:true
```

Creating your own entry cache for large groups

Steps

- You can create your own entry cache for large groups using the **`dsconfig create-entry-cache`** subcommand.

```
# bin/dsconfig create-entry-cache --type fifo \
  --set enabled:true \
  --set cache-level:10 \
  --set max-entries:175000 \
  --set "include-filter:(objectClass=groupOfUniqueNames)" \
  --set min-cache-entry-value-count:10000 \
  --set min-cache-entry-attribute:uniquemember
```

Monitoring the entry cache

You can monitor the memory consumed by your entry cache using the `entry-cache-info` property in the periodic stats logger. You can retrieve the monitor entry over LDAP by issuing a search on `baseDN="cn=monitor"` using `filter="(objectClass=ds-fifo-entry-cache-monitor-entry)"`. For example, the entry might appear as follows:

```
dn: cn=Static Group Entry Cache Monitor,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-fifo-entry-cache-monitor-entry
objectClass: extensibleObject
cn: Static Group Entry Cache Monitor
cacheName: Static Group Entry Cache
entryCacheHits: 6416407
entryCacheTries: 43069073
entryCacheHitRatio: 14
maxEntryCacheSize: 12723879900
currentEntryCacheCount: 1
maxEntryCacheCount: 175000
entriesAddedOrUpdated: 1
evictionsDueToMaxMemory: 0
evictionsDueToMaxEntries: 0
entriesNotAddedAlreadyPresent: 0
entriesNotAddedDueToMaxMemory: 0
entriesNotAddedDueToFilter: 36652665
entriesNotAddedDueToEntrySmallness: 0
lowMemoryOccurrences: 0
percentFullMaxEntries: 0
jvmMemoryMaxPercentThreshold: 75
jvmMemoryCurrentPercentFull: 24
jvmMemoryBelowMaxMemoryPercent: 51
isFull: false
capacityDetails: NOT FULL: The JVM is using 24% of its available memory.
 Entries can be
added to the cache until the overall JVM memory usage reaches the configured
 limit of
75%. Cache has 174999 remaining entries before reaching the configured limit
 of 175000.
```

By default, the entry cache memory is set to 75%, with a maximum of 90%.

Tuning the index entry limit for large groups

The Directory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the DIT. You can specify an index entry limit property, which defines the maximum number of entries that are allowed to match a given index

key before it is no longer maintained by the server. If the index keys have reached this limit (which is 4000 by default), then you must rebuild the indexes using the **rebuild-index** tool as follows:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index objectclass
```

In the majority of Directory Server environments, the default index entry limit value of 4000 entries should be sufficient. However, group-related processing, it may be necessary to increase the index entry limit. For directories containing more than 4000 groups with the same structural object class (i.e., more than 4000 entries, 4000 `groupOfUniqueNames` entries, 4000 `groupOfEntries` entries, or 4000 `groupOfURLs` entries), then you may want to increase the index entry limit for the `objectClass` attribute so that it has a value larger than the maximum number of group entries of each type. Set `index-entry-limit` property using a command line like the following:

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name objectClass --set index-entry-limit:175000
```

As an alternative, a separate backend may be created to hold these group entries, so that an unindexed search in that backend yields primarily group entries. If you make no changes, then the internal search performed at startup to identify all groups and any user searches looking for groups of a given type may be very expensive.

For directories in which any single user may be a member of more than 4000 static groups of the same type, you may need to increase the index entry limit for the `member` and/or `uniqueMember` attribute to a value larger than the maximum number of groups in which any user is a member. If you do not increase the limit, then searches to retrieve the set of all static groups in which the user is a member may be unindexed and therefore very expensive.

Summary of commands to search for group membership

The following summary of commands show the fastest way to retrieve direct or indirect member DNs for groups.

- To retrieve direct member (non-nested) DNs of group "`cn=group.1,ou=groups,dc=example,dc=com`".

  ```
  $ bin/ldapsearch --baseDN "cn=group.1,ou=Groups,dc=example,dc=com"
   "(objectClass=*)" uniqueMember member
  ```
- To retrieve direct member entries (non-nested) under "`dc=example,dc=com`" of group "`cn=group.1,ou=groups,dc=example,dc=com`". This is useful when attributes from member entries are used in the filter or being returned.

  ```
  $ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com"
   "(isDirectMemberOf=cn=group.1,ou=Groups,dc=example,dc=com)"
  ```
- To retrieve group DNs in which user "`uid=user.2,ou=people,dc=example,dc=com`" is a direct member (non-nested, static groups).

  ```
  $ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com"
   "(objectClass=*)" isDirectMemberOf
  ```
- To retrieve all member entries under `ou=people,dc=example,dc=com` of group "`cn=group.1,ou=groups,dc=example,dc=com`".

  ```
  $ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com"
   "(isMemberOf=cn=group.1,ou=Groups,dc=example,dc=com)"
  ```
- To retrieve the group DNs in which user "`uid=user.2,ou=people,dc=example,dc=com`" is a member.

  ```
  $ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com"
   "(objectClass=*)" isMemberOf
  ```

Migrating Sun/Oracle groups

You can migrate Sun/Oracle static and dynamic groups to PingDirectory Server groups. The following sections outline the procedures for migrating static groups to both Ping Identity static groups and virtual static groups as well as how to migrate dynamic groups. For information about the differences in access control evaluation between Sun/Oracle and the PingDirectory Server, see Migrating ACIs from Sun/Oracle to PingDirectory Server.

Migrating static groups

About this task

The PingDirectory Server supports static LDAP groups with structural object classes of `groupOfNames`, `groupOfUniqueNames`, or `groupOfEntries`. In general, static groups may be imported without modification.

A FIFO entry cache can be enabled to cache group-to-user mappings, which improves performance when accessing very large entries, though at the expense of greater memory consumption. The PingDirectory Server provides an out-of-the-box FIFO entry cache object for this purpose. This object must be explicitly enabled using **`dsconfig`** as described in *Using the Entry Cache to Improve the Performace of Large Static Groups*.

To migrate static groups:

Steps

1. Run the **`migrate-ldap-schema`** tool to enumerate any schema differences between the DSEE deployment and the Ping Identity deployment.
2. Run the **`migrate-sun-ds-config`** tool to enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment.
3. Import or configure any necessary schema and/or configuration changes recorded by the above tools.
4. Import the existing users and groups using the **`import-ldif`** tool.
5. From the PingDirectory Server root directory, open the `sun-ds-compatibility.dsconfig` file in the `docs` folder using a text editor.
6. Find the **FIFO Entry Cache** section and, after reading the accompanying comments, enable the corresponding **`dsconfig`** command by removing the comment character ("#").

   ```
   $ bin/dsconfig set-entry-cache-prop \
     --cache-name "Static Group Entry Cache" --set enabled:true
   ```
7. To ensure that references to an entry are updated automatically when the entry is deleted or renamed, enable the Referential Integrity plugin.

   ```
   $ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" --set
    enabled:true
   ```

   If this Directory Server is part of a replication topology, you should enable the Referential Integrity plugin for each replica.

Migrating static groups to virtual static groups

About this task

In many cases, electing to use virtual static groups in place of static groups can produce marked performance gains without any need to update client applications. The specifics of a migration to virtual static groups varies depending on the original DIT, but the general approach involves identifying common membership traits for all members of each group and then expressing those traits in the form of an LDAP URL.

In the following example, the common membership trait for all members of the All Users group is the parent DN ou=People,dc=example,dc=com. In other cases, a common attribute may need to be used. For example, groups based on the location of its members could use the `l` (location) or `st` (state) attribute.

In the following example, consider the common case of an "All Users" group, which contains all entries under the parent DN "`ou=People,dc=example,dc=com`". When implemented as a virtual static group, this group may have a large membership set without incurring the overhead of a static group.

To migrate dsee static groups to virtual static groups:

Steps

1. First, create a dynamic group.

```
dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: Dynamic All Users
memberURL: ldap:///ou=People,dc=example,dc=com??sub?(objectClass=person)
```

2. Next, create a virtual static group that references the dynamic group.

```
dn: cn=All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
objectClass: ds-virtual-static-group
cn: All Users
ds-target-group-dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
```

3. Finally, the `Virtual Static uniqueMember` virtual attribute must be enabled to populate the All Users group with `uniqueMember` virtual attributes.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
 uniqueMember" \
  --set enabled:true
```

4. Confirm that the virtual static group is correctly configured by checking a user's membership in the group.

```
$ bin/ldapsearch --baseDN "cn=All Users,ou=Groups,dc=example,dc=com" \
  --searchScope base "(uniqueMember=uid=user.0,ou=People,dc=example,dc=com)"
 1.1

dn: cn=All Users,ou=Groups,dc=example,dc=com
```

5. The ability to list all members of a virtual static group is disabled by default. You may enable this feature, but only if specifically required by a client application.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
 uniqueMember" \
  --set allow-retrieving-membership: true
```

ⓘ **Note:** The virtual static group may also be implemented using the `groupOfNames` object class instead of `groupOfUniqueNames`. In that case, you must update the `Virtual Static member` configuration object instead of the `Virtual Static uniqueMember` configuration object.

Migrating dynamic groups

About this task

The PingDirectory Server supports dynamic groups with the `groupofURLs` object class. In general, dynamic groups may be imported without modification.

To migrate dynamic groups:

Steps

1. Run the **`migrate-ldap-schema`** tool to enumerate any schema differences between the DSEE deployment and the Ping Identity deployment.
2. Run the **`migrate-sun-ds-config`** tool to enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment.
3. Import or configure any necessary schema and/or configuration changes recorded by the above tools.
4. Import the existing users and groups using the **`import-ldif`** tool.

Working with Indexes

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT). Indexes are associated with attributes and stored in database index files, which are managed separately for each base DN in the Directory Server.

Overview of indexes

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT). Indexes are associated with attributes and stored in database index files, which are managed separately for each base DN in the Directory Server. The Directory Server automatically creates index files when you first initialize a base DN or when you use the **`dsconfig`** tool to create a local DB backend. During modify operations, the Directory Server updates the database index files. If encryption is enabled on the server, indexes will be encrypted.

The PingDirectory Server comes with the following types of indexes:

- **Default system indexes** to ensure that the server operates efficiently. Indexes consist of database files that contain index keys mapping to the list of entry IDs.
- **Default Local DB indexes** that are created for each database suffix. Modify the index to meet your system's requirements using the **`dsconfig`** tool.
- **Local DB VLV indexes** that allow a client to request the server to send search results using the Virtual List View control.
- **Filtered Indexes** that provide the ability to index an attribute but only for entries that match a specified filter based on an equality index. The filtered index can only be used for searches containing that filter. The filtered index can be maintained independently of the equality index for that attribute and even if a normal equality index is not maintained for that attribute.

General tips on indexes

Administrators should keep the following tips in mind when working with indexes:

- **Important Critical Indexes**. The Directory Server has several built-in indexes on the Local DB Backend that are critical to internal server processing and should never be removed.

  ```
  aci, ds-entry-unique-id, objectClass
  ```

- **Built-in Indexes for Efficient Queries**. The Directory Server has built-in indexes on the Local DB Backend. Internal processing of the server relies on the `aci`, `ds-soft-delete-from-dn`, `ds-soft-delete-timestamp`, `entryUUID`, `member`, `objectClass`, and `uniqueMember` indexes, which must not be removed. The `mail` and `uid` indexes can be removed, but these attributes are referenced from the Password Modify Extended Operation and will cause problems with components such as the Exact Match Identity Mapper. If the `mail` or `uid` indexes are removed, additional configuration changes may be necessary to ensure that the server starts properly. The `cn`, `givenName`, `mail`, `sn`,

and `telephoneNumber` indexes can be safely removed if clients do not query on these attributes. This will reduce the size of the database both on disk and in memory.

- **Online Rebuilds**. Whenever an online index rebuild is in progress, the data in that backend will be available and writable although the index being rebuilt will not be used; therefore, searches which attempt to use that attribute might be unindexed.
- **Index Rebuild Administrative Alert**. The Directory Server generates an administrative alert when the rebuild process begins and ends. It will have a degraded-alert-type of "index-rebuild-in-progress" so that a Directory Proxy Server, such as the Directory Server can avoid using that server while the rebuild is in progress.
- **System Indexes Cannot be Rebuilt**. The contents of the backend must be exported and re-imported in order to rebuild system indexes. See the table below for the list of system indexes.
- **Indexing Certain Attributes**. You should ensure that the following recommendations are used when setting up the indexes.
  - Equality and substring indexes should not be used for attributes that contain binary data.
  - Approximate indexes should be avoided for attributes containing numbers, such as telephone numbers.
- **Unindexed Searches**. Unindexed attributes result in longer search times as the database itself has to be searched instead of the database index file. Only users with the `unindexed-search` privilege are allowed to carry out unindexed searches. In general, applications should be prevented from performing unindexed searches, so that searches that are not indexed would be rejected rather than tying up a worker thread. The ways to achieve this include:
  - Make sure that only the absolute minimum set of users have the `unindexed-search` privilege. This privilege can be used without any other restrictions.
  - To allow unindexed searches with some control, the Permit Unindexed Search request control can be used with the `unindexed-search-with-control` privilege. With this privilege, a user will only be permitted to request an unindexed search if the search request includes the Permit Unindexed Search request control. The `unindexed-search privilege` allows a client to request an unindexed search without this control.
  - The Reject Unindexed Search request control can be used to explicitly indicate that a client does not want the server to process an unindexed search request, regardless of priviledges. See the LDAP SDK for information about these controls. These capabilities are also available with the `ldapsearch` tool.
  - Make sure that `allow-unindexed-searches` property is set to false in all client connection policies, in which unindexed searches should never be necessary. If the client connection policy should allow undindexed searches, set the `allow-unindexed-searches-with-control` property to true. If `allow-unindexed-searches` is false but, `allow-unindexed-searches-with-control` is true, the policy will only permit an unindexed search if the request includes the Permit Unindexed Search request control. See the LDAP SDK and the `ldapsearch` tool for more information.
  - Set a nonzero value for the `maximum-concurrent-unindexed-searches` global configuration property to ensure that if unindexed searches are allowed, only a limited number of them will be active at any given time. Administrators can configure the maximum number of concurrent unindexed searches by setting a property under Global Configuration.

    To change the maximum number of concurrent unindexed searches, use the **`dsconfig`** tool to set a value for the number. A value of "0" (default) represents no limit on the number of concurrent unindexed searches.

    ```
    $ bin/dsconfig set-global-configuration-prop \
      --set maximum-concurrent-unindexed-searches:2
    ```
- **Index Entry Limit**. The Directory Server specifies an index entry limit property. This property defines the maximum number of entries that are allowed to match a given index key before it is no longer maintained by the server. If the index keys have reached this limit (default value is 4000), then you must

rebuild the indexes using the **`rebuild-index`** tool. If an index entry limit value is set for the local DB backend, it overrides the value set for the overall JE backend index entry limit configuration (i.e., 4000).

To change the default index entry limit, use the **`dsconfig`** tool as seen in the following example:

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name cn --set index-entry-limit:5000
```

- **Rebuild Index vs Full Import**. You can expect a limited amount of database growth due to the existence of old data when running **`rebuild-index`** versus doing a full import of your database.

Index types

The PingDirectory Server supports several types of indexes to quickly find entries that match search criteria in LDAP operations. The Directory Server uses an attribute's matching rules to normalize its values and uses those values as index keys to a list of matching entry IDs. Entry IDs are integer values that are used to uniquely identify an entry in the backend by means of a set of database index files (`id2entry`, `dn2id`, `dn2uri`, `id2children`, `id2subtree`).

Matching rules are elements defined in the schema that tell the server how to interact with the particular attribute. For example, the uid attribute has an equality matching rule defined in the schema, and thus, has an equality index maintained by the Directory Server. The following table describes the index types:

Directory Server Index Types

Index Type	Description
Approximate	Used to efficiently locate entries that match the approximate search filter. It is used to identify which entries are approximately equal to a given assertion. Approximate indexes can only be applied to attributes that have a corresponding approximate matching rule.
Equality	Used to efficiently locate entries that match the equality search filter. It is used to identify which entries are exactly equal to a given assertion. Equality indexes can only be applied to attributes that have a corresponding equality matching rule. An offshoot of the equality index is the filtered index, which uses a defined search filter for a specific attribute. The filtered index can be maintained independently of the equality index for a specific attribute.
Ordering	Used to efficiently locate entries that match the ordering search filter. It is used to identify which entries have a relative order of values for an attribute. Ordering indexes can only be applied to attributes that have a corresponding ordering matching rule.
Presence	Used to efficiently locate entries that match the presence search filter. It is used to identify which entries have at least one value for a specified attribute. There is only one presence index key per attribute.
Substring	Used to efficiently locate entries that match the substring search filter. It is used to identify which entries contain specific substrings to a given assertion. Substring indexes can only be applied to attributes that have a corresponding substring matching rule.

System indexes

The PingDirectory Server contains a set of system database index files that ensure that the server operates efficiently. These indexes cannot be modified or deleted.

System Indexes

Index	Description
dn2id	Allows quick retrieval of DNs. The DN database, or `dn2id`, has one record for each entry. The key is the normalized entry DN and the value is the entry ID.
id2entry	Allows quick retrieval of entries. The `id2entry` database contains the LDAP entries. The database key is the entry ID and the value is the entry contents.
referral	Allows quick retrieval of referrals. The referral database called `dn2uri` contains URIs from referral entries. The key is the DN of the referral entry and the value is that of a labeled URI in the ref attribute for that entry.
id2children	Allows quick retrieval of an entry and its children. The `id2children` database provides a mapping between an entry's unique identifier and the entry unique identifiers of the corresponding entry's children.
id2subtree	Allows quick retrieval of an entry's subtree. The `id2subtree` database provides a mapping between an entry's unique identifier and its unique identifiers in its subtree.

Viewing the system indexes

Steps

Use the **`dbtest`** command to view the system and user indexes. The index status indicates if it is a trusted index or not. An index is either trusted or untrusted. An untrusted index requires rebuilding.

```
$ bin/dbtest list-index-status --baseDN dc=example,dc=com --backendID userRoot
```

Managing local DB indexes

You can modify the local DB indexes to meet your system's requirements using the **`dsconfig`** tool. If you are using the **`dsconfig`** tool in interactive command-line mode, you can access the **Local DB Index** menu from the Basic object menu.

Viewing the list of local DB indexes

Steps

- Use **`dsconfig`** with the `list-local-db-indexes` option to view the default list of indexes.

```
$ bin/dsconfig list-local-db-indexes --backend-name userRoot
```

```
Local DB Index     : Type    : index-type
-------------------:---------:--------------------
aci                : generic : presence
cn                 : generic : equality, substring
ds-entry-unique-id : generic : equality
givenName          : generic : equality, substring
mail               : generic : equality
member             : generic : equality
objectClass        : generic : equality
sn                 : generic : equality, substring
telephoneNumber    : generic : equality
uid                : generic : equality
uniqueMember       : generic : equality
```

Viewing a property for all local DB indexes

Steps

- Use **dsconfig** with the `--property` option to view a property assigned set for all local DB indexes. Repeat the option for each property that you want to list. In this example, the `prime-index` property specifies if the backend is configured to prime the index at startup.

```
$ bin/dsconfig list-local-db-indexes --property index-entry-limit \
  --property prime-index --backend-name userRoot
```

Viewing the configuration parameters for local DB index

Steps

- To view the configuration setting of a local DB index, use **dsconfig** with the `get-local-db-index-prop` option and the `--index-name` and `--backend-name` properties. If you want to view the advanced properties, add the `--advanced` option to your command.

```
$ bin/dsconfig get-local-db-index-prop --index-name aci \
  --backend-name userRoot
```

Modifying the configuration of a local DB index

About this task

You can easily modify an index using the **dsconfig** tool. Any modification or addition of an index requires the indexes to be rebuilt. In general, an index only needs to be built once after it has been added to the configuration.

If you add an index, then import the data using the **import-ldif** tool, then the index will be automatically rebuilt. If you add an index, then add the data using some other method than **import-ldif**, you must rebuild the index using the **rebuild-index** tool.

Steps

1. Use **dsconfig** with the `set-local-db-index-prop` option and the `--index-name` and `--backend-name` properties. In this example, update the `prime-index` property, which loads the index at startup. This command requires the `--advanced` option to access this property.

```
$ bin/dsconfig set-local-db-index-prop --index-name uid \
  --backend-name userRoot --set prime-index:true
```

2. View the index to verify the change.

```
$ bin/dsconfig get-local-db-index-prop --index-name uid \
  --backend-name userRoot
```

3. Stop the Directory Server. You can do an index rebuild with the server online; however, keep in mind the tips presented in *General Tips on Indexes*.

```
$ bin/stop-server
```

4. Run the **rebuild-index** tool.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index uid
```

5. Restart the Directory Server if shutdown.

```
$ bin/start-server
```

Creating a new local DB index

Steps

1. To create a new local DB index, use **dsconfig** with the `--create-local-db-index` option and the `--index-name`, `--backend-name`, and `--set index-type: <value>` options.

```
$ bin/dsconfig create-local-db-index \
  --index-name roomNumber --backend-name userRoot \
  --set index-type:equality
```

2. View the index.

```
$ bin/dsconfig get-local-db-index-prop \
  --index-name roomNumber --backend-name userRoot
```

3. Stop the Directory Server. You can do an index rebuild with the server online; however, keep in mind the tips presented in *General Tips on Indexes* on page 148.

```
$ bin/stop-server
```

4. Rebuild the index using the **rebuild-index** tool.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index roomNumber
```

5. Restart the Directory Server.

```
$ bin/start-server
```

Deleting a local DB index

About this task

You can delete an index using the **dsconfig** tool. Check that no plugin applications are using the index before deleting it. When the index is deleted, the corresponding index database will also be deleted. The disk space is reclaimed once the cleaner threads begin.

Steps

- Use **dsconfig** with the `delete-local-db-index` option to remove it from the database.

```
$ bin/dsconfig delete-local-db-index \
  --index-name roomNumber --backend-name userRoot
```

Working with composite indexes

The PingDirectory Server composite index can be generated from multiple pieces of information (a combination of multiple filter components, or a combination of filter components and a base DN). A composite index can also be based on only a single piece of information.

To improve searches over a large number of entries, equality composite indexes can be used to combine a mandatory equality filter pattern with an optional base DN pattern to improve the performance of searches in directories with a very large number of entries, and in particular with a very large number of non-leaf entries. Equality composite indexes offer two advantages over existing equality attribute indexes in these types of deployments.

Base DN Pattern - If a directory environment has many branches, but searches are often done that are within specific individual branches, the base DN pattern can be used to make search processing more efficient. The server will only need to search entries within a target branch.

For example, if the directory contains an **"ou=Customers,dc=example,dc=com"** branch, with a separate branches below that for sets of customers, like "ou=ACME,ou=Customers,dc=example,dc=com", and

"ou=SHOPCO,ou=Customers,dc=example,dc=com", a composite index with a filter pattern of **"(sn=?)"** and a base DN pattern of **"ou=?,ou=Customers,dc=example,dc=com"** can be defined. Then a search with a filter of **"(sn=Smith)"** and a base DN of **"ou=ACME,ou=Customers,dc=example,dc=com"** can be used to narrow the search to the Smiths in the ACME branch.

Index Pages - If many entries have the same value for a specific attribute, composite indexes can break large ID sets up across multiple pages, unlike the traditional attribute index. Using the previous example, if a search of the directory returns 50,000 Smiths, the results can be served in blocks of 5,000 IDs. An attribute index will return either one Smith record whose value is a block that contains all 50,000 of the matching entry IDs (if the index isn't exploded), or 50,000 Smith records that each have a value of the matching entry ID (when the index is exploded). The non-exploded form is efficient for searching because all of the entry IDs are returned in a single read, but it's expensive for writing because if a Smith must be added or removed, the entire block of 50,000 entry IDs must be rewritten. The exploded form is efficient for writing (adding or removing a Smith involves just that one entry ID), but it's expensive for searching because it takes 50,000 reads to get all entry IDs for all of the Smiths.

Composite indexes break up the block of entry IDs across multiple pages (a page size of up to 5000). If the directory contains 50,000 Smiths, instead of having to choose between one block of 50,000 IDs or 50,000 blocks of one ID, ten blocks of 5,000 IDs are returned. This improves the efficiency of a read or write across many entries.

There is little performance overhead to the paging mechanism. Use an equality composite index for an attribute that has a lot of entries that have the same value (such as givenName or sn), not for an attribute with very few entries with the same value (such as id or mail). For attributes in which all of the values match a small number of entries, it's better to use an equality attribute index.

When configuring a composite index, define the following properties:

Composite Index Properties

Composite Index Properties	Description
index-filter-pattern	Specifies a single-valued filter property used to identify a portion of the index criteria. This can only be specified at the time that the index definition is created and is required.
index-base-dn-pattern	Specifies a single-valued DN property that may indicate that the index should be scoped to a specific subtree or subtree pattern. This can only be specified at the time the index definition is created and is optional.

Working with JSON indexes

JSON indexing is similar to general attribute indexing. Where an attribute can be indexed several ways and requires a separate database for each index type, there is only a single database for each JSON field that can be used for different JSON filter types. This database primarily behaves like the database for an equality attribute index. Each database entry key is the normalized form for a value for the target JSON field, and the corresponding database entry value is an list of the entry IDs for all entries in which the associated attribute type has a JSON object with that value for the target field. The database is configured with a comparator (based on the data type for the target field) that enables iterating through values in a logical order to facilitate inequality and subInitial searches.

JSON indexes are automatically created when the JSON Field constraint indicates that a JSON field should be indexed. Indexes can be viewed with the following command:

```
$ bin/dbtest list-index-status \
  --backendID userRoot \
  --baseDN dc=example,dc=com
```

The JSON object filter types that can be enhanced through the use of JSON indexes include:

- `equals`. Identifies entries that have a specific value for the target field. This filter type only requires retrieving a single index key. However, depending on the nature of the search filter, the ID list may contain references to entries that don't actually match the filter (such as if the field is a string, and the filter is configured to use case-sensitive matching).
- `equalsAny`. Identifies entries that have any of a specified set of values for the target field. This filter type only requires retrieving the index keys that correspond to the target values in the filter and merging their ID lists.
- `greaterThan/lessThan`. Identifies entries that have at least one value for the target field that is greater or less than (or possibly equal to) a specified value. This index is similar in use to the `containsField` index, except that it only needs to iterate through a subset of the keys. A filter can contain both `greaterThan` and `lessThan` filters to represent a bounded range.
- `substring`. Identifies entries that have a string value for the target field that matches a given `substring`. The index can only be used for substring filters that include a `subInitial` component. In this case, the server iterates through all of the index keys that match the `startsWith` component, and manually compares values against the remainder of the substring assertion.

JSON indexing is available in local database backends backed by Berkeley DB Java Edition. This includes the following:

- Add, delete, modify, and modify DN operations that make changes to JSON objects stored in the server.
- LDIF imports that include JSON objects, including updates to the cache size estimates for the JSON indexes.
- The `rebuild-index` tool and corresponding backend code to make it possible to generate and rebuild indexes for JSON data. It must be possible to build all JSON indexes for all or a specified subset of fields associated with a given attribute type. The `verify-index` tool should also work with JSON indexes to make it possible to check their validity.
- Matching entry count control and debugsearchindex return attribute provide information about relevant JSON index usage.
- Support for monitoring index content and usage.

ⓘ **Note:** Exploded indexes and the entry balancing global index do not support JSON objects.

Working with local DB VLV indexes

Local DB VLV indexes allow a client to request a subset of results from a sorted list that match a specific search base, scope, and filter. The client can navigate through the list by passing a context back to the server with the virtual list view control. The Local DB VLV index can be used only when the client request contains the virtual list view (VLV) control and the client has been authorized with an ACI with a **`targetcontrol`** of **2.16.840.1.113730.3.4.9**.

ⓘ **Note:** A client request, which includes a virtual list view control, can be successfully processed without a matching Local DB VLV index if the search is completely indexed. This is not an efficient means of using VLV, since the server has to retrieve each entry twice.

Viewing the list of local DB VLV indexes

Steps

- Use **`dsconfig`** with the `list-local-db-indexes` option to view the default list of indexes. In the example, no VLV indexes are defined.

```
$ bin/dsconfig list-local-db-vlv-indexes --backend-name userRoot
```

Creating a new local DB VLV index

Steps

1. Use **dsconfig** with the `create-local-db-vlv-index` option and the `--index-name`, `--backend-name`, and `--set index-type:(propertyValue)` options. If you do not set any property values, the default values are assigned.

```
$ bin/dsconfig create-local-db-vlv-index \
  --index-name givenName --backend-name userRoot --set base-
dn:dc=example,dc=com \
  --set scope:whole-subtree --set filter:"(objectclass=*)" \
  --set sort-order:givenName
```

2. Rebuild the index using the **rebuild-index** tool. You must add the “vlv.” prefix to the index name to rebuild the VLV index. The following command can be run with the server on or offline with the addition of the `--task` and connection options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index vlv.givenName
```

Modifying a VLV index’s configuration

Steps

1. Use **dsconfig** with the `set-local-db-vlv-index-prop` option and the `--index-name` and `--backend-name` properties. In this example, update the `base-dn` property.

```
$ bin/dsconfig set-local-db-vlv-index-prop --index-name givenName \
  --backend-name userRoot --set base-dn:ou=People,dc=example,dc=com
```

2. Rebuild the index using the **rebuild-index** tool. You must add the prefix "vlv." to the index name. The following command can be run with the server on or offline with the addition of the `--task` and connection options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index vlv.givenName
```

Deleting a VLV index

About this task

You can delete a VLV index using the **dsconfig** tool. Check that the index is not being used in any plugin applications before deleting it.

Steps

1. Use **dsconfig** with the `delete-local-db-vlv-index` option to remove it from the database.

```
$ bin/dsconfig delete-local-db-vlv-index --index-name givenName \
  --backend-name userRoot
```

2. Verify the deletion by trying to view the vlv index.

```
$ bin/dsconfig get-local-db-vlv-index-prop --index-name givenName \
  --backend-name userRoot
```

Working with filtered indexes

The PingDirectory Server filtered index is useful when client search requests consisting of a compound &-filter with individual components matching a large number of entries, potentially greater than the index entry limit, have an intersection of a relatively small number of entries.

For example, assume a database contains several thousand company profiles and each company profile is represented by many entries. The "**(objectClass=company)**" filter matches a small set of entries per company, and therefore may exceed the index entry limit since there are many companies. Also assume that the "**(companyDomain=example.com)**" filter matches many of the entries for the company with domain **example.com** and can also result in an unindexed search. The more narrow filter "**(&(objectClass=company)(companyDomain=example.com))**" also results in an unindexed search but only matches a small number of entries. The filtered index makes it possible to index this compound filter by defining an equality index on the **companyDomain** attribute with a static filter of "**(objectClass=company)**" in the **equality-index-filter** property of the index.

Filtered indexing is primarily useful for cases in which clients frequently issue searches with AND filters that meet the following criteria:

- The AND filter itself matches a relatively small number of entries, but each of the individual components may match a very large number of entries.
- The filter has a dynamic component that does change, and that dynamic component always uses the same attribute.
- The filter has a static component that doesn't change.
- The filter must be narrowed to a base DN, for data structures with many branches, or if indexed attribute values appear in a very large number of entries.

The filtered index can be maintained independently from the equality filter for that attribute. Further, the filtered index will be used only for searches containing the equality component with the associated attribute type ANDed with this filter. When configuring a filtered index, be aware of the **equality-index-filter** and **maintain-equality-index-without-filter** properties of the index.

Once configured and built with the **rebuild-index** tool or **import-ldif**, searches with filters based on the above example will be processed with the index:

```
(&(objectClass=company)(companyDomain=example.com))
(&(objectClass=company)(|(companyDomain=example.com)
(companyDomain=example.org)))
(&(companyDomain=example.com)(objectClass=company))
(&(companyDomain=example.com)(&(objectClass=company)))
(&(companyDomain=example.com)(objectClass=company)(something=else))
(&(companyDomain=example.com)(&(objectClass=company)(something=else)))
(|(&(objectClass=company)(companyDomain=example.com))(&(objectClass=company)
(companyDomain=example.org)))
```

When configuring a filtered index, define the following properties:

Filtered Index Properties

Filtered Index Properties	Description
equality-index-filter	Specifies a search filter that may be used in conjunction with an equality component for the associated attribute type. If an equality index filter is defined, then an additional equality index will be maintained for the associated attribute, but only for entries that match the provided filter. Further, the index will be used only for searches containing an equality component with the associated attribute type ANDed with this filter.
maintain-equality-index-without-filter	Specifies whether to maintain a separate equality index for the associated attribute without any filter, in addition to maintaining an index for each equality index filter that is defined. If this is false, then the attribute will not be indexed for equality by itself but only in conjunction with the defined equality index filters.

Creating a filtered index

Steps

1. Use the **dsconfig** tool to create a filtered index. The following command creates an equality index on the `companyDomain` attribute and maintains an index for the equality filter defined "`(objectclass=company)`". After you have created the index, you must rebuild the indexes.

```
$ bin/dsconfig create-local-db-index --backend-name "userRoot" \
  --index-name companyDomain --set maintain-equality-index-without-
filter:true \
  --set index-type:equality --set equality-index-
filter:"(objectclass=company)"
```

2. Stop the Directory Server using **bin/stop-server**.
3. Run the **rebuild-index** tool.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index companyDomain
```

4. Start the Directory Server using **bin/start-server**.

Tuning indexes

The PingDirectory Server provides several tools to help you optimize your indexes and improve the overall read and write performance for your system. The server now supports an optional expanded index database using an *exploded* format to process high write load operations. To view the current state of the server's indexes and make adjustments to the index databases, the Directory Server automatically generates an Index Summary Statistics Table after each LDIF import or index rebuild. The **dbtest** tool also includes an Index Histogram to determine the key datasize for the indexes. This section provides descriptions of each of these tools.

About the exploded index format

The `index-entry-limit` Backend configuration property specifies the maximum number of entries kept in an index record, before the server stops maintaining that record, begins scanning the whole database, and runs an expensive unindexed search. If any index keys have already reached this limit, indexes must be rebuilt before they can be allowed to use a new limit. If `index-entry-limit` is configured to be larger than 50000, then any keys that match more than 50000 entries will be stored in a separate database in an expanded (or "exploded") format.

All keys whose entry count is less than 50000 continue to be stored in one database in a consolidated format, such that changes to the key require rewriting all the entry IDs matching the key. All keys whose entry count is greater than 50000 and less than the `index-entry-limit` are stored in a separate database in an exploded format, such that changes to the key require writing only to the updated entry ID.

If the `index-entry-limit` is increased to 100000, any key with an entry count less than 50000 continues to be stored in consolidated format. If a key has an entry count greater than 50000, it will be stored in a separate database where each key is stored with its entry ID individually. The consolidated format is very efficient for read operations because the server can retrieve a row of entry IDs at once, while the exploded format is far more efficient for high volumes of write operations since it avoids large on-disk growth.

Monitoring index entry limits

Index keys that have reached their limit require indexes to be rebuilt before they can be allowed to use a new limit. There are several ways to monitor index limits to avoid a potentially costly rebuild. There are cases in which it is acceptable for index keys to exceed the index entry limit. For example, the `objectClass` attribute type should be indexed for equality because the server needs to use it to find all group entries when bringing a backend online, and also because applications frequently need to find entries of a specific type. However, it doesn't make sense for the "top" objectClass key to be indexed, because it appears in every entry in the server.

Choose an index entry limit value that is high enough to ensure that all of the right keys are indexed, but keys that occur too frequently are not. The `verify-index` tool `--listKeysNearestIndexEntryLimt` argument lists a specified number of keys that are closest to the limit without having exceeded it. The index entry limit should be larger than the number of entries matching the largest key to remain indexed, with enough overhead to account for future growth. Use this command regularly to determine if the index entry limit needs to be adjusted.

The `verify-index` tool also provides the `--listKeysExceedingIndexEntryLimit` argument to list all keys for which the value has exceeded the index entry limit and the number of entries in which they appear. If there are keys for which the limit has already exceeded but that need to be maintained, adjust the index entry limit to be higher than the number of entries that contain that key (with additional room for future growth) and run the `rebuild-index` tool (or export to LDIF and re-import).

The server provides other ways to determine if index keys have exceeded, or are close to exceeding, the index entry limit. Some of these include:

- When performing an LDIF import, the tool includes an "Index Summary Statistics" section that provides usage information for each index, including the number of keys for which the index entry limit has been exceeded, and also the number of keys for which the number of matching entries falls within a number of predefined buckets (such as 1–4 entries, 5–9 entries, 10–99 entries, and 100–999 entries).
- If, during a search operation, the server accesses one or more index keys whose values have exceeded the index entry limit, the access log message for that operation will include an `indexesWithKeysAccessedExceedingEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field may appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to, or tried to write to, at least one index key whose value exceeded the index entry limit.
- If, during a search operation, the server accesses one or more index keys whose values have not yet exceeded the index entry limit but are more than 80 percent to reaching that limit, the access log message for that operation will include an `indexesWithKeysAccessedNearEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field may appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to at least one index key whose value was within 80 percent of the index entry limit.
- If a search operation requests either includes the `debugsearchindex` attribute, or the matching entry count request control with debugging enabled, the debug information will include any indexes accessed that have exceeded the index entry limit, or that are within 80 percent of the configured index entry limit.
- The monitor entry for each configured index includes attributes that provide information about the number of index keys that have been encountered (since the backend was brought online, or since the index entry limit was changed) in a number of different categories. These monitor attributes include:
  - `ds-index-exceeded-entry-limit-count-since-db-open` — The number of index keys for which the number of matching entries has crossed the index entry limit due to a write operation.
  - `ds-index-unique-keys-near-entry-limit-accessed-by-search-since-db-open` — The number of unique index keys that have been accessed by a search operation for which the number of matching entries is within 80 percent of the index entry limit.
  - `ds-index-unique-keys-exceeding-entry-limit-accessed-by-search-since-db-open` — The number of unique index keys that have been accessed by a search operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.
  - `ds-index-unique-keys-near-entry-limit-accessed-by-write-since-db-open` — The number of unique index keys that have been accessed by a write operation for which the number of matching entries is within 80 percent of the index entry limit.
  - `ds-index-unique-keys-exceeding-entry-limit-accessed-by-write-since-db-open` — The number of unique index keys that have been accessed by a write operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.

About the dbtest Index Status table

The **`dbtest`** tool has a **`list-all --analyze`** option that generates the current status of all of the databases on your system, including all index databases. The table shows the type, entry count (i.e., the number of records in the dtabase), index status (TRUSTED to indicate that the indexes are up-to-date, or UNTRUSTED if the index needs rebuilding), the total data size for each key, the average data size for each key and the maximum data size for each key. Note also that any indexes that are in exploded format are listed on this table.

Index Name	Index Type	JE Database Name	Index Status
id2children	Index	dc_example_dc_com_id2children	TRUSTED
id2subtree	Index	dc_example_dc_com_id2subtree	TRUSTED
uid.equality	Index	dc_example_dc_com_uid.equality	TRUSTED
aci.presence	Index	dc_example_dc_com_aci.presence	TRUSTED
ds-soft-delete-timestamp.ordering	Index	dc_example_dc_com_ds-soft-delete-timestamp.ordering	TRUSTED
ds-soft-delete-from-dn.equality	Index	dc_example_dc_com_ds-soft-delete-from-dn.equality	TRUSTED
givenName.equality	Index	dc_example_dc_com_givenName.equality	TRUSTED
givenName.substring	Index	dc_example_dc_com_givenName.substring	TRUSTED
objectClass.equality	Index	dc_example_dc_com_objectClass.equality	TRUSTED
member.equality	Index	dc_example_dc_com_member.equality	TRUSTED
uniqueMember.equality	Index	dc_example_dc_com_uniqueMember.equality	TRUSTED
cn.equality	Index	dc_example_dc_com_cn.equality	TRUSTED
cn.substring	Index	dc_example_dc_com_cn.substring	TRUSTED
sn.equality	Index	dc_example_dc_com_sn.equality	TRUSTED
sn.substring	Index	dc_example_dc_com_sn.substring	TRUSTED
telephoneNumber.equality	Index	dc_example_dc_com_telephoneNumber.equality	TRUSTED
mail.equality	Index	dc_example_dc_com_mail.equality	TRUSTED
ds-entry-unique-id.equality	Index	dc_example_dc_com_ds-entry-unique-id.equality	TRUSTED

MY TITLE dbtest Output Including Index Databases

Configuring the index properties

About this task

By default, the `index-entry-limit` is set to 4000, which means the server will stop maintaining index values for keys that match more than 4000 entries. This can be changed with the **`dsconfig`** tool.

Before running the following commands, be aware that you will need to do an index rebuild on the system, which requires a system shutdown, unless the command is run as a task.

To configure the index properties:

Steps

1. Run **`dsconfig`** and set the `index-entry-limit` to 5000. By default, the value is set to 4000. Remember to include the bind parameters for your system. Once you enter the command, confirm that you want to apply the changes.

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set index-entry-limit:5000 \
One or more configuration property changes require administrative action
or confirmation/notification. Those properties include:
* index-entry-limit: If any index keys have already reached this limit,
indexes must be rebuilt before they will be allowed to use the new limit.
Setting a large limit (greater than 10,000) could have a big impact on
write performance and database growth on disk.
Continue? Choose 'no' to return to the previous step (yes / no) [yes]: yes
```

2. Stop the server.

```
$ bin/stop-server
```

3. Rebuild the index.

```
$ bin/rebuild-index --baseDN dc=example,dc=com \
  --index cn --index givenName --index objectClass \
  --index sn --maxThreads 10
```

4. View the Index Summary Statistics table, which is automatically displayed to system out after running the **`rebuild-index`** command. You can also access the table at `logs/tools/rebuild-index-summary.txt`. Repeat the last three steps to make more adjustments to your indexes.

```
          --- Index Summary Statistics ---
Index                                 : Limit : >Limit : Max    : 1-9    : 10-99 : 100-999 : 1000-9999 : 10000-99999 : 100000-999999
--------------------------------------:-------:--------:--------:--------:-------:---------:-----------:-------------:--------------
dc_example_dc_com_cn.equality         : 5000  :        : 1      : 100001 :       :         :           :             :
dc_example_dc_com_cn.substring        : 5000  : 9      : 15401  : 131746 : 22372 : 545     : 39        : 3           :
dc_example_dc_com_givenName.equality  : 5000  :        : 16     : 3788   : 4817  :         :           :             :
dc_example_dc_com_givenName.substring : 5000  : 8      : 23809  : 7039   : 12062 : 483     : 42        : 3           :
dc_example_dc_com_objectClass.equality: 5000  : 4      : 100003 : 3      :       :         :           :             : 4
dc_example_dc_com_sn.equality         : 5000  :        : 8      : 13419  :       :         :           :             :
dc_example_dc_com_sn.substring        : 5000  : 9      : 15401  : 33967  : 7055  : 459     : 39        : 3           :

The first three columns of numbers provide (1) "Limit" - the index entry limit (or blank if there is no limit),
(2) ">Limit" - the number of keys whose entry count exceeds the entry limit, and (3) "Max" - the
maximum entry count for any key in the index. The remaining columns provide the number of keys
whose entry count falls in the range indicated in the column heading
```

5. Restart the server.

```
$ bin/start-server
```

About the Index Summary Statistics table

The Directory Server now automatically generates an Index Summary Statistics Table, which can be used to determine the optimal configuration for your system's indexes. This table is only generated when the `rebuild-index` tool is run in offline mode. The table is generated after any LDIF import or an index rebuild, and is written to system out and to `logs/tools/rebuild-index-summary.txt`. The table lists the current index entry limit (set by the `index-entry-limit` property on the local DB configuration), the number of keys whose entry count exceeds this limit if any, and the maximum entry count for any key in the index. The table then displays a histogram of the number of keys whose entry falls within a range of values. An example of the Index Summary Statistics table is show below for the `sn.equality` and the `sn.substring` indexes.

The following figure shows that there are seven substrings whose entry counts exceed the `index-entry-limit` of 4000. Six of the substrings are in the 10000-99999 range with the maximum entry count being 13419. By deduction, one more substring must be present in the 1000-9999 range that exceeds the `index-entry-limit` of 4000. These substrings could be expensive for search operations.

```
          --- Index Summary Statistics ---
Index                            : Limit : >Limit : Max   : 1-9    : 10-99 : 100-999 : 1000-9999 : 10000-99999
---------------------------------:-------:--------:-------:--------:-------:---------:-----------:------------
dc_example_dc_com_sn.equality    : 4000  :        : 2     : 100000 :       :         :           :
dc_example_dc_com_sn.substring   : 4000  : 7      : 13419 : 150814 : 7109  : 407     : 36        : 6
```

MY TITLE Example of an Index Summary Statistics Table

Managing Entries

The Directory Server is a fully LDAPv3-compliant server that comes with a comprehensive set of LDAP command-line tools to search, add, modify, and delete entries.

This chapter presents the following topics:

Searching entries

The Directory Server provides an **`ldapsearch`** tool to search for entries or attributes within your server. The tool requires the LDAP connection parameters needed to bind to the server, including the `baseDN` option to specify the starting point of the search within the server, and the search scope. The `searchScope` option determines the depth of the search:

- `base` (search only the entry specified)

- `one` (search only the children of the entry and not the entry itself)
- `sub` (search the entry and its descendents)

The **`ldapsearch`** tool provides basic functionality as specified by the RFC 2254 but provides additional features that takes advantage of the Directory Server's control mechanisms. For more information, run the **`ldapsearch`** `--help` function.

Searching the root DSE

About this task
The Root DSE is a special entry that resides at the root of the directory information tree (DIT). The entry holds operational information about the server and its supported controls. Specifically, the root DSE entry provides information about the supported LDAPv3 controls, SASL mechanisms, password authentication schemes, supported LDAP protocols, additional features, naming contexts, extended operations, and server information.

ⓘ **Note:** The Directory Server provides an option to retrieve the Root DSE's operational attributes and add them to the user attribute map of the generated entry. This feature allows client applications that have difficulty handling operational attributes to access the root DSE using the `show-all-attributes` configuration property. Once this property is set, the associated attribute types are re-created and re-registered as user attributes in the schema (in memory, not on disk). Once you set the property, you can use **`ldapsearch`** without "+" to view the root DSE.

Use the **`dsconfig`** tool to set the `show-all-attributes` property to TRUE, as follows:

```
$ bin/dsconfig set-root-dse-backend-prop --set show-all-attributes:true
```

Steps

- Use **`ldapsearch`** to view the root DSE entry on the Directory Server. Be sure you include the "+" to display the operational attributes in the entry.

  ```
  $ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" "+"
  ```

Searching all entries in the Directory Server

Steps

- Use **`ldapsearch`** to search all entries in the Directory Server. The filter `"(objectclass=*)"` matches all entries. If the `--searchScope` option is not specified, the command defaults to a search scope of sub:

  ```
  $ bin/ldapsearch --baseDN dc=example,dc=com \
    --searchScope sub "(objectclass=*)"
  ```

Searching for an access control instruction

Steps

- Use **`ldapsearch`** to search the `dc=example,dc=com` base DN entry. The filter `"(aci=*)"` matches all `aci` attributes under the base DN, and the `aci` attribute is specified so that only it is returned. The `cn=Directory Manager` bind DN has the privileges to view an ACI.

  ```
  $ bin/ldapsearch --baseDN dc=example,dc=com "(aci=*)" aci
  ```

  ```
  dn: dc=example,dc=com
  aci: (targetattr!="userPassword")
    (version 3.0; acl "Allow anonymous read access for anyone";
  ```

```
    allow (read,search,compare) userdn="ldap:///anyone";)
aci: (targetattr="*")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)
aci: (targetattr="*")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

Searching for the schema

Steps

- Use **ldapsearch** to search the `cn=schema` entry. The base DN is specified as `cn=schema`, and the filter "`(objectclass=*)`" matches all entries. The command uses a special attribute "+" to return all operational attributes:

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base "(objectclass=*)" "+"
```

Searching for a single entry using base scope and base DN

Steps

- Use **ldapsearch** to search for a single entry by specifying the base scope and DN:

```
$ bin/ldapsearch --baseDN uid=user.14,ou=People,dc=example,dc=com \
  --searchScope base "(objectclass=*)"
```

Searching for a single entry using the search filter

Steps

- Search for a single entry by specifying the `sub` scope and a search filter that describes a single entry:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub "(uid=user.14)"
```

Searching for all immediate children for restricted return values

Steps

- Search for all immediate children of `ou=People,dc=example,dc=com`. The attributes returned are restricted to `sn` and `givenName`. The special attribute "+" returns all operational attributes:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope one '(objectclass=*)' sn givenName "+"
```

Searching for all children of an entry in sorted order

Steps

- Search for all children of the `ou=People,dc=example,dc=com` subtree. The resulting entries are sorted by the server in ascending order by `sn` and then in descending order by `givenName`:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub --sortOrder sn,-givenName '(objectclass=*)'
```

Limiting the number of returned search entries and search time

Steps

- Search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree by specifying a compound filter. No more than 200 entries will be returned and the server will spend no more than 5 seconds processing the request. Returned attributes are restricted to a few operational attributes:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub --sizeLimit 200 --timeLimit 5 \
  "(&(sn<=Doe)(employeeNumber<=1000))" ds-entry-unique-id entryUUID
```

Getting information about how indexes are used in a search operation

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT). Information about the can be obtained about the server's use of indexes in the course of processing a search operation. The following are two basic ways to accomplish this.

Issue a search request with the desired base DN, scope, and filter, and request that the server return the special **`debugsearchindex`** attribute. Users will need to be granted access to the **`debugsearchindex`** operational attribute and the **`cn=debugsearch`** portion of the DIT with the following command:

```
$ bin/dsconfig set-access-control-handler-prop \
 --add "global-aci:(targetattr=\"debugsearchindex\")(target=\"ldap:///
cn=debugsearch\")
    (version 3.0; acl \"Allow members of the Index Debugging Users group
    to request the debugsearchindex operational attribute \"; allow
    (read,search,compare) groupdn=\"ldap:///cn=Index Debugging
    Users,ou=Groups,dc=example,dc=com\";)"
```

To issue a search request for the server return the special **`debugsearchindex`** attribute, use the **`ldapsearch`** command such as:

```
$ bin/ldapsearch --hostname ds.example.com \
 --port 389 --bindDN uid=admin,dc=example,dc=com \
 --bindPassword password \
 --baseDN dc=example,dc=com \
 --searchScope sub "(&(givenName=John)(sn=Doe))" debugsearchindex
 dn: cn=debugsearch
 debugsearchindex: 0.040 ms - Beginning index processing for search
     request with base DN 'dc=example,dc=com', scope wholeSubtree,
     and filter (&(givenName=John)(sn=Doe)).
 debugsearchindex: 0.067 ms - Unable to optimize the AND filter
     beyond what the client already provided.
 debugsearchindex: 0.834 ms - Candidate set obtained for single-key
     filter (givenName=John) from index dc_example_dc_com_givenName.equality.
     Candidate set:  CandidateSet(isDefined=true, isExploded=false,
     isResolved=true, size=2, originalFilter=(givenName=John),
     remainingFilter=null, matchingEntryCountType=UNEXAMINED_COUNT)
 debugsearchindex: 0.030 ms - Final candidate set for filter (givenName=John)
     obtained from an unexploded index key in
 dc_example_dc_com_givenName.equality.
     Since the scope of the search includes the entire entry container, there
 is
     no need to attempt to further pare down the results based on the search
 scope.
     Candidate set:  CandidateSet(isDefined=true, isExploded=false,
 isResolved=true,
     size=2, originalFilter=(givenName=John), remainingFilter=null,
     matchingEntryCountType=UNEXAMINED_COUNT)
 debugsearchindex: 0.020 ms - Short-circuiting index processing for AND filter
```

```
    (&(givenName=John)(sn=Doe)) after evaluating single-key component
    (givenName=John) because the current ID set size of 2 is within the
     short-circuit threshold of 5.
debugsearchindex: 0.030 ms - Obtained a candidate set of size 2 for AND
filter
    (&(givenName=John)(sn=Doe)) with remaining filter (sn=Doe).  Even though
    there is still more of the filter to evaluate, the current candidate set
is
    within the short-circuit threshold of 5, so no additional index
processing will
    be performed to try to pare down the results based on the remaining
filter or the
    search scope.  Candidate set:  CandidateSet(isDefined=true,
isExploded=false,
    isResolved=true, size=2, originalFilter=(&(givenName=John)(sn=Doe)),
    remainingFilter=(sn=Doe), matchingEntryCountType=UPPER_BOUND)
debugsearchindex: 0.016 ms - Completed all index processing.  Candidate set:
    CandidateSet(isDefined=true, isExploded=false, isResolved=true, size=2,
    originalFilter=(&(givenName=John)(sn=Doe)), remainingFilter=(sn=Doe),
    matchingEntryCountType=UPPER_BOUND)
```

The second way would be to issue a search request with the desired base DN, scope, and filter, and include the matching entry count request control with the debug option set to **`true`**. To do this with **`ldapsearch`**, use a command such as:

```
$ bin/ldapsearch --hostname ds.example.com --port 389 \
 --bindDN uid=admin,dc=example,dc=com --bindPassword password \
 --baseDN dc=example,dc=com \
 --searchScope sub --matchingEntryCountControl examineCount=0:debug
 "(&(givenName=John)(sn=Doe))"
 Upper Bound on Matching Entry Count:  2
 Matching Entry Count Debug Messages:
 * naw-desktop:1389 - 0.104 ms - Beginning index processing for search request
 with
    base DN 'dc=example,dc=com', scope wholeSubtree, and filter
 (&(givenName=John)(sn=Doe)).
 * naw-desktop:1389 - 0.105 ms - Unable to optimize the AND filter beyond what
 the client already provided.
 * naw-desktop:1389 - 0.614 ms - Candidate set obtained for single-key filter
 (givenName=John) from index
    dc_example_dc_com_givenName.equality.  Candidate set:
    CandidateSet(isDefined=true, isExploded=false, isResolved=true,
    size=2, originalFilter=(givenName=John), remainingFilter=null,
 matchingEntryCountType=UNEXAMINED_COUNT)
 * naw-desktop:1389 - 0.090 ms - Final candidate set for filter
    (givenName=John) obtained from an unexploded index key in
    dc_example_dc_com_givenName.equality.  Since the scope of the search
    includes the entire entry container, there is no need
    to attempt to further pare down the results based on the search scope.
    Candidate set:  CandidateSet(isDefined=true, isExploded=false,
 isResolved=true,
    size=2, originalFilter=(givenName=John), remainingFilter=null,
 matchingEntryCountType=UNEXAMINED_COUNT)
 * naw-desktop:1389 - 0.045 ms - Short-circuiting index processing for AND
 filter
    (&(givenName=John)(sn=Doe)) after evaluating single-key component
    (givenName=John) because the current ID set size of 2 is within the short-
circuit threshold of 5.
 * naw-desktop:1389 - 0.111 ms - Obtained a candidate set of size 2 for AND
 filter
    (&(givenName=John)(sn=Doe)) with remaining filter (sn=Doe).  Even though
 there is
    still more of the filter to evaluate, the current candidate set is within
```

```
   the short-circuit threshold of 5, so no additional index processing will
be performed
   to try to pare down the results based on the remaining filter or the
search scope.
   Candidate set:  CandidateSet(isDefined=true, isExploded=false,
isResolved=true, size=2,
   originalFilter=(&(givenName=John)(sn=Doe)), remainingFilter=(sn=Doe),
   matchingEntryCountType=UPPER_BOUND)
* naw-desktop:1389 - 0.040 ms - Completed all index processing.  Candidate
set:
   CandidateSet(isDefined=true, isExploded=false, isResolved=true, size=2,
   originalFilter=(&(givenName=John)(sn=Doe)), remainingFilter=(sn=Doe),
   matchingEntryCountType=UPPER_BOUND)
* naw-desktop:1389 - The search is partially indexed
(candidatesAreInScope=true,
   unindexedFilterPortion=(sn=Doe))
* naw-desktop:1389 - Constructing an UPPER_BOUND response with a count of 2
```

Working with the matching entry count control

The **ldapsearch** command can be used with the **--matchingEntryCountControl** option to determine the count of entries that match a search filter. Users will need to be granted access to this control by its OID **1.3.6.1.4.1.30221.2.5.36** with the following command:

```
$ bin/dsconfig set-access-control-handler-prop \
 --add "global-aci:(targetcontrol=\"1.3.6.1.4.1.30221.2.5.36\")
   (version 3.0; acl \"Allow members of the Index Debugging Users group to
   use the matching entry count request control \"; allow (read)
   groupdn=\"ldap:///cn=Index Debugging Users,ou=Groups,dc=example,dc=com\";)"
```

An **examineCount** control can be used for searches that are at least partially indexed, in order to determine whether to return an examined count, an unexamined count, or an upper bound count. The factors that determine what is returned are:

- A search is fully indexed if indexes can be used to identify the entry IDs for all entries that match the filter without ambiguity. Indexes can also be used to make sure that all of those candidates are within the scope of the search.
- A search is partially indexed if indexes can be used to identify the entry IDs for all entries that match the search criteria, but the candidate list may potentially also include entries that either don't match the filter or are outside the scope of the search.
- A search is unindexed if it is not possible to retrieve a candidate list based on either the filter or the search scope.
- An unexamined count is a count of the exact number of entries that match the search criteria, only through the use of index processing.
- An examined count is the same as an unexamined count, except that all of the candidate entries are examined to determine whether they would have been returned to the client. An examined count may be less than an unexamined count if the set of matching entries includes those that would be removed by access control evaluation, or special entries like LDAP sub-entries, replication conflict entries, or soft-deleted entries.
- An upper bound count is the maximum number of entries that match the criteria, but indicates that the server could not determine exactly how many matching entries there were without examining each candidate, which it did not do.
- If a search is fully indexed, the result is an examined count or an unexamined count. If **alwaysExamine** is true and **examineCount** is greater than or equal to the number of candidates, the result is an examined count. If **alwaysExamine** is false, or if the number of candidates exceeds **examineCount**, the result is an unexamined count.
- If a search is partially indexed, the result is either an examined count or an upper bound count. The **alwaysExamine** flag isn't relevant in this case. If **examineCount** is greater than or equal to the number of candidates, the result is an examined count. If not, the result is an upper bound count.

- If a search is unindexed, the result is either an examined count or an unknown count. If **allowUnindexed** is true, the unindexed search is processed, which can be very expensive. Instead of getting the matching entries back, the examined count is returned. If **allowUnindexed** is false, an unknown count is returned. If **allowUnindexed** is true, the requester needs to have the **unindexed-search** privilege to get the exact count.

The following is a sample `ldapsearch` with the `--matchingEntryCountControl` option:

```
$./ldapsearch \
  --bindDN "cn=directory manager" \
  --bindPassword password \
  --baseDN dc=example,dc=com \
  --matchingEntryCountControl
 examineCount=100:alwaysExamine:allowUnindexed:debug \
  "(objectclass=*)"
```

Adding entries

Depending on the number of entries that you want to add to your Directory Server, you can use the **ldapmodify** tool for small additions. The **ldapmodify** tool provides two methods for adding a single entry: using a LDIF file or from the command line. The attributes must conform to your schema and contain the required object classes.

Adding requests with the **ignore-no-user-modification** control enable a client to include attributes that are not normally allowed from external sources. For example, the **userPassword** attribute is a user-modifiable attribute. An add request with the **ignore-no-user-modification** control allows a one-time exception to the password policy, even if the requesting client does not have the **bypass-pw-policy** privilege. This exception enables specifying pre-encoded passwords.

ⓘ **Note:** When adding an entry, the server can ensure that the entry's RDN is unique and does not contain any sensitive information by replacing the provided entry's RDN with the server-generated entryUUID value. An LDAP client written with the LDAP SDK for Java can use the **NameWithEntryUUIDRequestControl** to explicitly indicate which add requests should be named in this way, or the **ldapmodify** tool with the **--nameWithEntryUUID** argument. Also, the **auto-name-with-entry-uuid-connection-criteria** and **auto-name-with-entry-uuid-request-criteria** global configuration properties can be used to identify which add requests should be automatically named this way.

The uniqueness request control can also be used with **ldapmodify** for enforcing uniqueness on a per-request basis. Provide at least one of the **uniquenessAttribute** or **uniquenessFilter** arguments with the request. For more information about this control, see the LDAP SDK documentation and the **com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl** class for using the control.

Adding an entry using an LDIF file

Steps

1. Open a text editor and create an entry that conforms with your schema. For example, add the following entry in the file and save the file as `add-user.ldif`. For the `userPassword` attribute, enter the cleartext password. The Directory Server encrypts the password and stores its encrypted value in the server. Make sure that the LDIF file has limited read permissions for only authorized administrators.

```
dn: uid=user.2000,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
```

```
postalAddress: Toby Hall$73600 Mash Street$Cincinnati, OH 50563 postalCode:
 50563
description: This is the description for Toby Hall.
uid: user.2000
userPassword: wordsmith employeeNumber: 2000
initials: TBH
givenName: Toby
pager: +1 596 232 3321
mobile: +1 039 311 9878
cn: Toby Hall
sn: Hall
telephoneNumber: +1 097 678 9688
street: 73600 Mash Street
homePhone: +1 214 233 8484
l: Cincinnati
mail: user.2000@maildomain.net
st: OH
```

2. Use the **`ldapmodify`** tool to add the entry specified in the LDIF file. You will see a confirmation message of the addition. If the command is successful, you will see generated success messages with the "#" symbol.

```
$ bin/ldapmodify --defaultAdd --filename add-user.ldif
```

```
# Processing ADD request for uid=user.2000,ou=People,dc=example,dc=com
# ADD operation successful for DN uid=user.2000,ou=People,dc=example,dc=com
```

Adding an entry using the changetype LDIF directive

About this task

RFC 2849 specifies LDIF directives that can be used within your LDIF files. The most commonly used directive is `changetype`, which follows the `dn:` directive and defines the operation on the entry. The main advantage of using this method in an LDIF file is that you can combine adds and modifies in one file.

Steps

1. Open a text editor and create an entry that conforms with your schema. For example, add the following entry in the file and save the file as `add-user2.ldif`. Note the use of the `changetype` directive in the second line.

```
dn: uid=user.2001,ou=People,dc=example,dc=com
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Seely Dorm$100 Apple Street$Cincinnati, OH 50563
postalCode: 50563
description: This is the description for Seely Dorm.
uid: user.2001
userPassword: pleasantry
employeeNumber: 2001
initials: SPD
givenName: Seely pager: +1 596 665 3344
mobile: +1 039 686 4949
cn: Seely Dorm
sn: Dorm
telephoneNumber: +1 097 257 7542
street: 100 Apple Street
homePhone: +1 214 521 4883
l: Cincinnati
```

```
mail: user.2001@maildomain.net
st: OH
```

2. Use the **ldapmodify** tool to add the entry specified in the LDIF file. You will see a confirmation message of the addition. In this example, you do not need to use the `--defaultAdd` or its shortform `-a` option with the command.

```
$ bin/ldapmodify --filename add-user2.ldif
```

Adding multiple entries in a single file

About this task

You can have multiple entries in your LDIF file by simply separating each DN and its entry with a blank line from the next entry.

Steps

1. Open a text editor and create a couple of entries that conform to your schema. For example, add the following entries in the file and save the file as `add-user3.ldif`. Separate each entry with a blank line.

```
dn: uid=user.2003,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass:
organizationalPerson
objectClass: inetOrgPerson
...(similar attributes to previous examples)...

dn: uid=user.2004,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
...(similar attributes to previous examples)...
```

2. Use the **ldapmodify** tool to add the entries specified in the LDIF file. In this example, we use the short form arguments for the **ldapmodify** tool.

   The `-h` option specifies the host name, the `-p` option specifies the LDAP listener port, `-D` specifies the bind DN, `-w` specifies the bind DN password, `-a` specifies that entries that omit a changetype will be treated as add operations, and `-f` specifies the path to the input file. If the operation is successful, you will see commented messages (those begining with "#") for each addition.

```
$ bin/ldapmodify -h server.example.com -p 389 \
  -D "cn=admin,dc=example,dc=com" -w password -a -f add-user3.ldif
```

```
# Processing ADD request for uid=user.2003,ou=People,dc=example,dc=com
# ADD operation successful for DN uid=user.2003,ou=People,dc=example,dc=com
# Processing ADD request for uid=user.2004,ou=People,dc=example,dc=com
# ADD operation successful for DN uid=user.2004,ou=People,dc=example,dc=com
```

Deleting entries using ldapdelete

You can delete an entry using the **ldapdelete** tool. You should ensure that there are no child entries below the entry as that could create an orphaned entry. Also, make sure that you have properly backed up your system prior to removing any entries.

Deleting an entry using ldapdelete

Steps

Use **ldapdelete** to delete an entry. The following example deletes the `uid=user.14` entry.

```
$ bin/ldapdelete uid=user.14,ou=People,dc=example,dc=com
```

Deleting multiple entries using an LDIF file

Steps

1. You can generate a file of DNs that you would like to delete from the Directory Server.

   The following command searches for all entries in the `ou=Accounting` branch and returns the DNs of the subentries.

   ```
   $ bin/dump-dns -D "cn=admin,dc=example,dc=com" -w password --baseDN \
                          "ou=Accounting,ou=People,dc=example,dc=com" --
   outputFile /usr/local/entry_dns.txt
   ```
2. Run the **ldapdelete** command with the file to delete the entries. The command uses the `--continueError` option, which will continue deleting through the whole list even if an error is encountered for a DN entry.

   ```
   $ bin/ldapdelete --filename /usr/local/entry_dns.txt --continueError
   ```

Deleting entries using ldapmodify

About this task

You can use the LDIF changetype directive to delete an entry from the Directory Server using the **ldapmodify** tool. You can only delete leaf entries.

To delete an entry using **ldapmodify**:

Steps

- From the command line, use the **ldapmodify** tool with the `changetype:delete` directive. Enter the DN, press **Enter** to go to the next line, then enter the changetype directive. Press **Control-D** twice to enter the EOF sequence (UNIX) or **Control-Z** (Windows).

  ```
  $ bin/ldapmodify --hostname server1.example.com -port 389 --bindDN
   "uid=admin,dc=example,dc=com" --bindPassword password
  dn:uid=user.14,ou=People,dc=example,dc=com
  changetype: delete
  ```

Modifying entries using ldapmodify

You can use the **ldapmodify** tool to modify entries from the command line or by using an LDIF file that has the `changetype:modify` directive and value. If you have more than one change, you can separate them using the - (dash) symbol.

Modifying an attribute from the command line

Steps

1. Use the **ldapsearch** tool to locate a specific entry.

   ```
   $ bin/ldapsearch -h server.example.com -p 389 -D
    "cn=admin,dc=example,dc=com" \
   ```

```
  -w password -b dc=example,dc=com "(uid=user.2004)"
```

2. Use the **ldapmodify** command to change attributes from the command line. Specify the modification using the `changetype:modify` directive, and then specify which attributes are to be changed using the `replace` directive. In this example, we change the telephone number of a specific user entry. When you are done typing, you can press **CTRL-D** (Unix EOF escape sequence) twice or **CTRL-Z** (Windows) to process the request.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
 "cn=admin,dc=example,dc=com" \
  -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

Modifying multiple attributes in an entry from the command line

Steps

1. Use the **ldapsearch** tool to locate a specific entry.

```
$ bin/ldapsearch -h server.example.com -p 389 -D
 "cn=admin,dc=example,dc=com" \
  -w password -b dc=example,dc=com "(uid=user.2004)"
```

2. Use the **ldapmodify** command to change attributes from the command line. Specify the modification using the `changetype:modify` directive, and then specify which attributes are to be changes using the add and replace directive.

   In this example, we add the `postOfficeBox` attribute, change the mobile and telephone numbers of a specific user entry. The `postOfficeBox` attribute must be present in your schema to allow the addition. The three changes are separated by a dash ("-"). When you are done typing, you can press **CTRL-D** (Unix EOF escape sequence) twice or **CTRL-Z** (Windows) to process the request.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
 "cn=admin,dc=example,dc=com" -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postOfficeBox
postOfficeBox: 111
-
replace: mobile
mobile: +1 039 831 3737
-
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

Adding an attribute from the command line

Steps

- Use the **ldapmodify** command from the command line. Specify the modification using the `changetype:modify` directive, and then specify which attributes are to be added using the `add` directive. In this example, we add another value for the `cn` attribute, which is multi-valued. When you are done typing, you can press **CTRL-D** (UNIX EOF escape sequence) twice to process the request.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
 "cn=admin,dc=example,dc=com" \
  -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: cn
```

```
cn: Sally Tea Tree
```

An error could occur if the attribute is single-valued, if the value already exists, if the value does not meet the proper syntax, or if the value does not meet the entry's objectclass requirements. Also, make sure there are no trailing spaces after the attribute value.

Adding an attribute using the language subtype

About this task

The Directory Server provides support for attributes using language subtypes. The operation must specifically match the subtype for successful operation. Any non-ASCII characters must be in UTF-8 format.

Steps

The Directory Server provides support for attributes using language subtypes. The operation must specifically match the subtype for successful operation. Any non-ASCII characters must be in UTF-8 format.

```
$ bin/ldapmodify -h server.example.com -p 389 -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postalAddress; lang-ko
postalAddress; lang-ko:Byung-soon Kim$2020-14 Seoul
```

Adding an attribute using the binary subtype

About this task

The Directory Server provides support for attributes using binary subtypes, which are typically used for certificates or JPEG images that could be stored in an entry. The operation must specifically match the subtype for successful operation. The version directive with a value of "1" must be used for binary subtypes. Typical binary attribute types are `userCertificate` and `jpegPhoto`.

Steps

- Use the **`ldapmodify`** command to add an attribute with a binary subtype. The attribute points to the file path of the certificate.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
 "cn=admin,dc=example,dc=com" \
  -w password
version: 1
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: userCertificate;binary
userCertificate;binary:<file:///path/to/cert
```

Deleting an attribute

Steps

Use **`ldapmodify`** with the LDIF `delete` directive to delete an attribute.

```
$ bin/ldapmodify -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com"
 \
  -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
```

```
delete: employeeNumber
```

Deleting one value from an attribute with multiple values

About this task

You can use the LDIF `delete` directive to delete a specific attribute value from an attribute. For this example, assuming you have multiple values of `cn` in an entry (e.g., `cn: Sally Tree`, `cn: Sally Tea Tree`).

Steps

- Use **`ldapmodify`** to delete a specific attribute of a multi-valued pair, then specify the attribute pair that you want to delete. In this example, we keep `cn:Sally Tree` and delete the `cn: Sally Tea Tree`.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
 "cn=admin,dc=example,dc=com" \
  -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
delete: cn
cn: Sally Tea Tree
```

Renaming an entry

About this task

Renaming an entry involves changing the relative distinguished name (RDN) of an entry. You cannot rename a RDN if it has children entries as this violates the LDAP protocol.

Steps

- Use the **`ldapmodify`** tool to rename an entry. The following command changes `uid=user.14` to `uid=user.2014` and uses the changetype, `newrdn`, and `deleteoldrdn` directives.

```
$ bin/ldapmodify
dn: uid=user.14,ou=People,dc=example,dc=com
changetype:moddn
newrdn: uid=user.2014
deleteoldrdn: 1
```

Moving an entry within a Directory Server

About this task

You can use **`ldapmodify`** to move an entry from one base DN to another base DN. Before running the **`ldapmodify`** command, you must assign access control instructions (ACIs) on the parent entries. The source parent entry must have an ACI that allows export operations: `allow(export)`. The target parent entry must have an ACI that allows import operations: `allow(import)`. For more information on access control instructions, see *Working with Access Control*.

Steps

- Use the **`ldapmodify`** command to move an entry from the Contractor branch to the `ou=People` branch.

```
$ bin/ldapmodify
dn: uid=user.14,ou=contractors,dc=example,dc=com
changetype:moddn
newrdn: uid=user.2014
```

```
deleteoldrdn: 0
newsuperior: ou=People,dc=example,dc=com
```

Moving an entry from one machine to another

About this task

The Directory Server provides a tool, **move-subtree**, to move a subtree or one entry on one machine to another. The subtree or entry must exist on the source server and must not be present on the target server. The source server must also support the 'real attributes only' request control. The target server must support the Ignore NO-USER-MODIFICATION request control.

ⓘ **Note:** The **move-subtree** tool moves a subtree or multiple entries from one machine to another. The tool does not copy the entries. Once the entries are moved, they are no longer present on the source server.

Steps

- Use the **move-subtree** tool to move an entry (e.g., `uid=test.user,ou=People,dc=example,dc=com`) from the source host to the target host.

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
  --sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword password
 \
  --targetHost target.example.com --targetPort 389 \
  --targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword password
 \
  --entryDN uid=test.user,ou=People,dc=example,dc=com
```

Moving multiple entries from one machine to another

About this task

The **move-subtree** tool provides the ability to move multiple entries listed in a DN file from one machine to another. Empty lines and lines beginning with the octothorpe character (#) will be ignored. Entry DNs may optionally be prefixed with `dn:` , but long DNs cannot be wrapped across multiple lines.

Steps

1. Open a text file, enter a list of DNs, one DN per line, and then save the file. You can also use the **ldapsearch** command with the special character "1.1" to create a file containing a list of DNs that you want to move. The following example searches for all entries that match (`department=Engineering`) and returns only the DNs that match the criteria. The results are re-directed to an output file, `test-dns.ldif`:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --searchScope sub "(department=Engineering)" "1.1" > test-dns.ldif
```

2. Run the **move-subtree** tool with the `--entryDNFile` option to specify the file of DNs that will be moved from one machine to another.

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
  --sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword password
 \
  --targetHost target.example.com --targetPort 389 \
  --targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword password
 \
  --entryDNFile /path/to/file/test-dns.ldif
```

3. If an error occurs with one of the DNs in the file, the output message shows the error. The **move-subtree** tool will continuing processing the remaining DNs in the file.

```
An error occurred while communicating with the target server: The entry
uid=user.2,ou=People,dc=example,dc=com cannot be added because an entry with
 that name
already exists
Entry uid=user.3,ou=People,dc=example,dc=com was successfully moved from
source.example.com:389 to target.example.com:389
Entry uid=user.4,ou=People,dc=example,dc=com was successfully moved from
source.example.com:389 to target.example.com:389
```

Working with the parallel-update tool

The PingDirectory Server provides a **parallel-update** tool, which reads change information (add, delete, modify, and modify DN) from an LDIF file and applies the changes in parallel. This tool is a multi-threaded version of the **ldapmodify** tool that is designed to process a large number of changes as quickly as possible.

The **parallel-update** tool provides logic to prevent conflicts resulting from concurrent operations targeting the same entry or concurrent operations involving hierarchically-dependent entries (for example, modifying an entry after it has been added, or adding a child after its parent). The tool also has a retry capability that can help ensure that operations are ultimately successful even when interdependent operations are not present in the correct order in the LDIF file (for example, the change to add a parent entry is provided later in the LDIF file than a change to add a child entry).

After the tool has applied the changes and reaches the end of the LDIF file, it automatically displays the update statistics described in the following table

Parallel-Update Tool Result Statistics

Processing Statistic	Description
Attempts	Number of update attempts
Successes	Number of successful update attempts
Rejects	Number of rejected updates
ToRetry	Number of updates that will be retried
AvgOps/S	Average operations per second
RctOps/S	Recent operations per second. Total number of operations from the last interval of change updates.
AvgDurMS	Average duration in milliseconds
RctDurMS	Recent duration in milliseconds. Total duration from the last interval of change updates.

Running the parallel-update tool

Steps

1. Create an LDIF file with your changes. The third change will generate a rejected entry because its `userPassword` attribute contains an encoded value, which is not allowed.

```
dn:uid=user.2,ou=People,dc=example,dc=com
changetype: delete

dn:uid=user.99,ou=People,dc=example,dc=com
```

```
changetype: moddn
newrdn: uid=user.100
deleteoldrdn: 1

dn:uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==

dn:uid=user.100,ou=People,dc=example,dc=com
changetype: modify
replace: st
st: TX
-
replace: employeeNumber
employeeNumber: 100
```

2. Use **`parallel-update`** to apply the changes in the LDIF file to a target server. In this example, we use ten concurrent threads. The optimal number of threads depends on your underlying system. The `--ldifFile` and `--rejectFile` options are also required.

```
$ bin/parallel-update --hostname 127.0.0.1 \
  --ldifFile changes.ldif --rejectFile reject.ldif --numThreads 10
```

```
Reached the end of the LDIF file
Attempts Successes Rejects ToRetry AvgOps/S RctOps/S AvgDurMS RctDurMS
-------- --------- ------- ------- -------- -------- -------- ---------
       4         3       1       0        3        3       26       26
All processing complete Attempted 4 operations in 1 seconds
```

3. View the rejects file for any failed updates.

```
# ResultCode=53, Diagnostic Message=Pre-encoded passwords are not allowed
 for
# the password attribute userPassword
dn: uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==
```

Working with the Watch-Entry Tool

About this task

The PingDirectory Server provides a **`watch-entry`** tool, which demonstrates replication or synchronization latency by watching an LDAP entry for changes. If the entry changes, the background of modified attributes will temporarily be red. Attributes can also be directly modified with this tool as well.

To run the **`watch-entry`** tool:

Steps

- Perform the following to connect to **server.example.com** as **uid=admin,dc=example,dc=com** and watch entry **uid=kate,ou=people,dc=example,dc=com** for changes:

```
$ bin/watch-entry --hostname server.example.com --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --entryDN uid=user,ou=people,dc=example,dc=com
```

Working with LDAP transactions

The PingDirectory Server provides support for *batched transactions*, which are processed all at once at commit time. Applications developed to perform batched transactions should include as few operations in the transaction as possible. The changes are not actually processed until the commit request is received. Therefore, the client cannot know whether the changes will be successful until commit time. If any of the operations fail, then the entire set of operations fails.

Batched transactions are write operations (add, delete, modify, modify DN, and password modify) that are processed as a single atomic unit when the commit request is received. If an abort request is received or an error occurs during the commit request, the changes are rolled back. The batched transaction mechanism supports the standard LDAP transaction implementation based on RFC 5805. It is not currently possible to process a transaction that requires changes to be processed across multiple servers or multiple Directory Server backends.

Directory servers may limit the set of controls that are available for use in requests that are part of a transaction. RFC 5805 section 4 indicates that the following controls may be used in conjunction with the transaction specification request control: assertion request control, manageDsaIT request control, pre-read request control, and post-read request control. The proxied authorization v1 and v2 controls cannot be included in requests that are part of a transaction, but they can be included in the start transaction request to indicate that all operations within the transaction should be processed with the specified authorization identity.

The PingDirectory Server supports the following additional controls in conjunction with operations included in a transaction: account usable request control, hard delete request control, intermediate client request control, password policy request control, replication repair request control, soft delete request control, soft deleted entry access request control, subtree delete request control, and undelete request control.

Requesting a batched transaction using ldapmodify

Steps

1. Use the **ldapmodify** tool's `--useTransaction` option. It provides a mechanism for processing multiple operations as part of a single batched transaction. Create a batch text file with the changes that you want to apply as a single atomic unit:

```
dn:uid=user.3,ou=People,dc=example,dc=com
changetype: delete
dn:uid=user.1,ou=People,dc=example,dc=com
changetype: modify
replace: pager
pager: +1 383 288 1090
```

2. Use **ldapmodify** with the `--useTransaction` and `--filename` options to run the batched transaction.

```
$ bin/ldapmodify --useTransaction --filename test.ldif
```

```
#Successfully created a transaction with transaction ID 400
#Processing DELETE request for uid=user.3,ou=People,dc=example,dc=com
#DELETE operation successful for DN uid=user.3,ou=People,dc=example,dc=com
#This operation will be processed as part of transaction 400
```

```
#Processing MODIFY request for uid=user.1,ou=People,dc=example,dc=com
#MODIFY operation successful for DN uid=user.1,ou=People,dc=example,dc=com
#This operation will be processed as part of transaction 400
#Successfully committed transaction 400
```

Working with Virtual Attributes

The PingDirectory Server provides mechanisms to support virtual attributes in an entry. Virtual attributes are abstract, dynamically generated attributes that are invoked through an LDAP operation, such as **`ldapsearch`**, but are not stored in the Directory Server backend. While most virtual attributes are operational attributes, providing processing-related information that the server requires, the virtual attribute subsystem allows you to create user-defined virtual attributes to suit your directory server requirements.

Overview of virtual attributes

The PingDirectory Server allows its entries to hold virtual attributes. Virtual attributes are dynamically generated attributes that are invoked through an LDAP operation, such as **`ldapsearch`**, but are not stored in the Directory Server backend. Most virtual attributes are operational attributes, providing processing-related information that the server requires. However, the virtual attribute subsystem allows you to create user-defined virtual attributes to suit your requirements.

Viewing the list of default virtual attributes

The Directory Server has a default set of virtual attributes that can be viewed using the **`dsconfig`** tool. Some virtual attributes are enabled by default and are useful for most applications. You can easily enable or disable each virtual attribute using the **`dsconfig`** tool.

The default set of virtual attributes are described in the table below. You can enable or disable these attributes using the **`dsconfig`** tool.

Virtual Attributes

Virtual Attributes	Description
ds-entry-checksum	Generates a simple checksum of an entry's contents, which can be used with an LDAP assertion control to ensure that the entry has not been modified since it was last retrieved.
ds-instance-name	Generates the name of the Directory Server instance from which the associated entry was read. This virtual attribute can be useful in load-balancing environments to determine the instance from which an entry was retrieved.
ds-pwp-state-json	Generates an operational attribute whose values is a JSON object with information about a user's current password policy state.
entryDN	Generates an `entryDN` operational attribute in an entry that holds a normalized copy of the entry's current distinguished name (DN). Clients can use this attribute in search filters.
hasSubordinates	Creates an operational attribute that has a value of TRUE if the entry has subordinate entries.
isDirectMemberOf	Generates an `isDirectMemberOf` operational attribute that contains the DNs of the groups in which the user is a member. isDirectMemberOf includes only static groups in which the user is explicitly named as a member. Compare to isMemberOf.

Virtual Attributes	Description
isMemberOf	Generates an `isMemberOf` operational attribute that contains the DNs of the groups in which the user is a member. isMemberOf includes all of the following: ▪ Static groups in which the user is explicitly named as a member ▪ Dynamic groups in which the user is a member because of the criteria for that group ▪ Static groups in which the user is a member because they are a member of a nested group that is listed as a member of the static group Compare to isDirectMemberOf.
numSubordinates	Generates an operational attribute that returns the number of child entries. While there is no cost if this operational attribute is enabled, there could be a performance cost if it is requested. Note that this operational attribute only returns the number of immediate children of the node.
subschemaSubentry	A special entry that provides information in the form of operational attributes about the schema elements defined in the server. It identifies the location of the schema for that part of the tree. ▪ ldapSyntaxes - set of attribute syntaxes ▪ matchingRules - set of matching rules ▪ matchingRuleUse - set of matching rule uses ▪ attributeTypes - set of attribute types ▪ objectClasses - set of object classes ▪ nameForms - set of name forms ▪ dITContentRules - set of DIT content rules ▪ dITStructureRules - set of DIT structure rules
User Defined Virtual Attribute	Generates virtual attributes with user-defined values in entries that match the criteria defined in the plugin's configuration. User-defined virtual attributes are intended to specify a hard-coded value for entries matching a given set of criteria.
Virtual Static Member	Generates a member attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group. Do not modify the filter in the `Virtual Static Member` attribute as it is an advanced property and modifying it can lead to undesirable side effects.
Virtual Static Uniquemember	Generates a `uniqueMember` attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group. Do not modify the filter in the `Virtual Static Uniquemember` attribute as it is an advanced property and modifying it can lead to undesirable side effects.

Viewing the list of default virtual attributes using dsconfig non-interactive mode

Steps

- Use **`dsconfig`** to view the virtual attributes.

```
$ bin/dsconfig list-virtual-attributes
```

Viewing virtual attribute properties

About this task

Each virtual attribute has basic properties that you can view using the **dsconfig** tool. The complete list of properties is described in the *PingDirectory Server Configuration Reference*. Some basic properties are as follows:

- **Description**. A description of the virtual attribute.
- **Enabled**. Specifies whether the virtual attribute is enabled for use.
- **Base-DN**. Specifies the base DNs for the branches containing entries that are eligible to use this virtual attribute. If no values are given, the server generates virtual attributes anywhere in the server.
- **Group-DN**. Specifies the DNs of the groups whose members can use this virtual attribute. If no values are given, the group membership is not taken into account when generating the virtual attribute. If one or more group DNs are specified, then only members of those groups are allowed to have the virtual attribute.
- **Filter**. Specifies the filters that the server applies to entries to determine if they require virtual attributes. If no values are given, then any entry is eligible to have a virtual attribute value generated.

To view virtual attribute properties:

Steps

- Use **dsconfig** to view the properties of a virtual attribute.

```
$ bin/dsconfig get-virtual-attribute-prop --name isMemberOf
```

Enabling a virtual attribute

You can enable a virtual attribute using the **dsconfig** tool. If you are using **dsconfig** in interactive command-line mode, you can access the virtual attribute menu on the Standard object menu.

Enabling a virtual attribute using dsconfig interactive mode

Steps

1. Use **dsconfig** to enable a virtual attribute. Specify the connection port, bind DN, password, and host information. Then type the LDAP connection parameter for your Directory Server: 1 for LDAP, 2 for SSL, 3 for StartTLS.

```
bin/dsconfig
```

2. On the Directory Server main menu, type `o` to change the object menu, and then type the number corresponding to **Standard**.
3. On the Directory Server main menu, type the number corresponding to virtual attributes.
4. On the **Virtual Attribute management** menu, type the number to view and edit an existing virtual attribute.
5. From the list of existing virtual attributes on the system, select the virtual attribute to work with. For this example, type the number corresponding to the `numSubordinates` virtual attribute.
6. On the **numSubordinates Virtual Attribute Properties** menu, type the number to enable the virtual attribute. On the **Enabled Property** menu for the `numSubordinates` virtual attribute, type the number to change the value to TRUE.
7. On the **numSubordinates Virtual Attribute Properties** menu, type `f` to apply the changes.

8. Verify that the virtual attribute is enabled. Note that this example assumes you have configured the group entries.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(ou=People)" numSubordinates
```

```
dn: ou=People,dc=example,dc=com
numSubordinates: 1000
```

Enabling a virtual attribute using dsconfig non-interactive mode

Steps

- Use **dsconfig** to enable the `numSubordinates` virtual attribute.

```
$ bin/dsconfig set-virtual-attribute-prop \
  --name numSubordinates --set enabled:true
```

Creating user-defined virtual attributes

User-defined virtual attributes allow you to specify an explicit value to use for the virtual attribute. There are no restrictions on the length of the value for a user-defined virtual attribute. You must only ensure that the new virtual attribute conforms to your schema, otherwise you will see an error message when you configure it.

You can define your virtual attributes using the **dsconfig** tool on the Standard object menu. Only the value property is specific to the user-defined virtual attribute. All the other properties are common across all kinds of virtual attributes, which include the following:

- **enabled** -- Indicates whether the virtual attribute should be used.
- **attribute-type** -- The attribute type for the virtual attribute that will be generated.
- **base-dn**, **group-dn**, **filter** -- May be used to select which entries are eligible to contain the virtual attribute.
- **client-connection-policy** -- May be used to configure who can see the virtual values.
- **conflict-behavior** -- Used to indicate how the server should behave if there are one or more real values for the same attribute type in the same entry. The server can either return only the real value(s), only the virtual value(s), or merge both real and virtual values.
- **require-explicit-request-by-name** -- Used to indicate whether the server should only generate values for the virtual attribute if it was included in the list of requested attributes.
- **multiple-virtual-attribute-evaluation-order-index**, **multiple-virtual-attribute-merge-behavior** -- Used to control the behavior the server should exhibit if multiple virtual attributes may be used to contribute values to the same attribute.

Creating a user-defined virtual attribute in interactive mode

About this task

The following example shows how to create a user-defined virtual attribute that assigns an Employee Password Policy to any entry that matches the filter `"(employeeType=employee)"`.

Steps

1. Run **dsconfig** to configure the user-defined virtual attribute. Specify the connection port, bind DN, password, and host information. Then type the LDAP connection parameter for your Directory Server: 1 for LDAP, 2 for SSL, 3 for StartTLS.
2. On the Directory Server main menu, type `o` to change the object menu, and then type the number to select Standard.
3. On the Directory Server main menu, type the number corresponding to virtual attributes.
4. On the **Virtual Attribute management** menu, type the number to create a new virtual attribute.

5. Next, you can use an existing virtual attribute as a template for your new attribute, or your can create a new attribute from scratch. In this example, type `n` to create a new Virtual Attribute from scratch.
6. On the **Virtual Attribute Type** menu, enter a number corresponding to the type of virtual attribute that you want to create. In this example, type the number corresponding to User Defined Virtual Attribute.
7. Next, enter a name for the new virtual attribute. In this example, enter "`Employee Password Policy Assignment`."
8. On the **Enabled Property** menu, enter the number to set the property to true (enable).
9. On the **Attribute-Type Property** menu, type the `attribute-type` property for the new virtual attribute. You can enter the OID number or attribute name. The `attribute-type` property must conform to your schema. For this example, type "`ds-pwp-password-policy-dn`".
10. Enter the value for the virtual attribute, and then press Enter or Return to continue. In this example, enter `cn=Employee Password Policy,cn=Password Policies,cn=config`, and then type Enter or Return to continue.
11. On the **User Defined Virtual Attributes** menu, enter a description for the virtual attribute. Though optional, this step is useful if you plan to create a lot of virtual attributes. Enter the option to change the value, and then type a description of the virtual attribute. In this example, enter: `Virtual attribute that assigns the Employee Password Policy to all entries that match (employeeType=employee).`
12. On the **User Defined Virtual Attribute** menu, type the number corresponding to the filter.
13. On the **Filter Property** menu, enter the option to add one or more filter properties, type the filter, and then press **Enter** to continue. In this example, type `(employeeType=employee)`. Press the number to use the filter value entered.
14. On the **User Defined Virtual Attribute** menu, type `f` to finish creating the virtual attribute.
15. Verify that the attribute was created successfully. Add the `employeeType=employee` attribute to an entry (e.g., `uid=user.0`) using **`ldapmodify`**. Add the `employeeType=contractor` attribute to another entry (e.g., `uid=user.1`).
16. Use **`ldapsearch`** to search for the user with the `employeeType=employee` attribute (e.g., `uid=user.0`). You will notice the `ds-pwp-password-policy-dn` attribute has the assigned password policy as its value.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
  ds-password-policy-dn

dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Employee Password Policy,cn=Password
 Policies,cn=config
```

17. Run **`ldapsearch`** again using the filter "`(uid=user.1)`", the `ds-pwp-password-policy-dn` attribute will not be present in the entry, because the entry has the attribute, `employeeType=contractor`.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.1)" \
  ds-password-policy-dn

dn: uid=user.1,ou=People,dc=example,dc=com
```

Creating a user-defined virtual attribute using dsconfig in non-interactive mode

Steps

- You can also use **`dsconfig`** in non-interactive command-line mode to create a virtual attribute. The following command sets up the Employee Password Policy Assignment virtual attribute introduced in the previous section:

```
$ bin/dsconfig create-virtual-attribute \
  --name "Employee Password Policy Assignment" \
```

```
  --type user-defined \
  --set enabled:true \
  --set attribute-type:ds-pwp-password-policy-dn \
  --set "filter:(employeeType=employee)" \
  --set "value:cn=Employee Password Policy,cn=Password Policies,cn=config"
```

Creating mirror virtual attributes

The PingDirectory Server provides a feature to mirror the value of another attribute in the same entry or mirror the value of the same or a different attribute in an entry referenced by the original entry. For example, given a DIT where users have a manager attributed with a value of the DN of the employee as follows:

```
dn: uid=apeters,ou=people,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
uid: apeters
... (more attributes) ...
```

You can set up a mirror virtual attribute, so that the returned value for the `managerName` virtual attribute can be the `cn` value of the entry referenced by the `manager` attribute as follows:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)" \
dn: uid=apeters,ou=people,dc=example,dc=com

objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
managerName: John Doe
uid: apeters
... (more attributes not shown) ...
```

Creating a mirror virtual attribute using dsconfig in non-interactive mode

About this task

You can also use **`dsconfig`** in non-interactive command-line mode to create a mirror virtual attribute. The following example sets up the `managerName` virtual attribute introduced in the previous section:

Steps

1. Update the schema to define the `managerName` attribute. In a text editor, create a file with the following schema definition for the attribute and save it as `98-myschema.ldif`, for example, in the `<server-root>/config/schema` folder. You can optionally add the attribute to an object class.

```
dn: cn=schema
objectClass: top
objectClass: ldapSubent
ry
objectClass: subschema attributeTypes: ( 1.3.6.1.4.1.32473.3.1.9.4 NAME
 'managerName'
  EQUALITY caseIgnoreMatch SUBSTR caseIgnoreSubstringsMatch SYNTAX
 1.3.6.1.4.1.1466.115.121.1.44{256}
  X-ORIGIN 'Directory Server Example' )
```

2. Restart the Directory Server.

```
$ bin/stop-server --restart
```

3. Use **dsconfig** to create the virtual attribute.

```
$ bin/dsconfig create-virtual-attribute \
  --name "managerName" \
  --type mirror \
  --set "description:managerName from manager cn" \
  --set enabled:true \
  --set attribute-type:managerName \
  --set source-attribute:cn \
  --set source-entry-dn-attribute:manager
```

4. Verify the mirror virtual attribute by searching for an entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)"
```

```
dn: uid=apeters,ou=People,dc=example,dc=com
... (attributes) ...
manager: uid=jdoe,ou=People,dc=example,dc=com
managerName: John Doe
```

Editing a virtual attribute

You can edit virtual attributes by using the **dsconfig** tool. Ensure that the virtual attribute conforms to your plugin schema. Otherwise, an error message appears when you attempt to edit the virtual attribute. If you are using **dsconfig** in interactive command-line mode, you can access the virtual attribute menu on the Standard object menu.

Editing a virtual attribute using dsconfig in non-interactive mode

Steps

- Use **dsconfig** to change a property's value.

```
$ bin/dsconfig set-virtual-attribute-prop --name dept-number \
  --set "value:111"
```

Deleting a virtual attribute

About this task

You can delete virtual attributes using the **dsconfig** tool. If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu on the Standard object menu.

To delete a virtual attribute:

Steps

- Use **dsconfig** to delete an existing virtual attribute.

```
$ bin/dsconfig delete-virtual-attribute --name dept-number
```

Working with Composed Attributes

PingDirectory Server's support for virtual attributes is a useful facility that can dynamically generate values in entries for a wide range of use cases. These are used to generate key operational attributes like entryDN, subschemaSubentry, isMemberOf, numSubordinates, hasSubordinates, and ds-entry-

checksum. The values of other attributes in the same or different entries can be mirrored, and values can be constructed from other attributes in the same entry. Items such as password policies and privileges can be dynamically, and it is also possible to create custom virtual attribute providers with the Server SDK using a wide variety of logic.

However, virtual attributes are not an ideal solution for all use cases. This section provides information on conposed attributes, which dynamically generate attribute values to complement virtual attributes. Composed attributes are suited for some scenarios that virtual attributes do not support.

Virtual attribute limitations

Performance limitations

There may be performance limitations associated with generating virtual attributes. Although the performance impact of actually generating the values is limited by only computing these values if they are to be returned to the client, there can still be a noticeable impact on performance. In addition, virtual attributes may be included or excluded based on a range of criteria and the evaluation of this criteria (for example, based on group membership) may impact performance..

Indexing limitations

Virtual attributes do not mix well with indexing. You cannot index the values of a virtual attribute since these values can change from one invocation to the next.

Some virtual attributes do implement support for an index-like functionality in that they offer logic that may be able to quickly identify entries that have specified virtual attribute values. These include the following:

- When mirroring values from another attribute in the same entry, and when that source attribute type is indexed, the mirror virtual attribute provider can use an internal search to identify matching entries.
- The entryDN virtual attribute provider can retrieve the entry with the specified DN.
- The isMemberOf virtual attribute provider can use the server's group manager to identify the members of a targeted group.

However, this is not an option for all types of virtual attributes. For example, it is not available for user-defined virtual attributes that have a static value, for constructed virtual attributes whose values are composed from multiple other attributes in the same entry, for mirror virtual attributes whose values come from other entries, or for any custom virtual attribute types implemented using the Server SDK.

In addition, there is not a good solution for the case where you want to have a mix of real and virtual values for the same attribute type (whether in the same entry or in different entries). If you define an index for that attribute type, it will only include entries with real values; entries with virtual values will be overlooked. On the other hand, if there is no index but the virtual attribute provider does support some search functionality, only entries with virtual values will be matched and entries with only real values will be excluded.

Unexpected behavior for write operations

Another significant issue with virtual attributes is that they can result in unexpected behaviors when targeted by write operations. These behaviors include the following:

- Attempting to delete a virtual value will fail with a "no such attribute" result.
- If the virtual attribute provider is configured with a conflict-behavior of real-overrides-virtual, then attempting to add a value to an entry that only has virtual values will cause the virtual values to disappear.
- If the virtual attribute provider is configured with a conflict-behavior of real-overrides-virtual, then attempting to remove all real values of an entry will cause the virtual values to appear.
- If the virtual attribute provider is configured with a conflict-behavior of virtual-overrides-real, then attempting to add new values or replace the set of existing values will yield a success result, but the operation will have no visible effect on the entry.

- If the virtual attribute provider is configured with a conflict-behavior of merge-real-and-virtual, then attempting to replace the set of values for an entry will yield a success result, but only the real values will have been replaced, and the virtual values will remain.

There is currently no method to prevent attempts to write to attributes with virtual values. The NO-USER-MODIFICATION constraint in attribute type definitions is honored, but this constraint can only be applied to operational attribute types; this is not an acceptable limitation in many cases. Access control restrictions could work for many clients, but will not have any effect for requesters with the bypass-acl privilege.

Overview of composed attributes

Composed attributes are generated when an entry is written. This includes entries that are created by add operations and LDIF imports; these may also be created, updated, or removed when processing modify and modify DN operations. The server may optionally permit or reject attempts to alter the generated values.

Composed values are based solely on a combination of static text and the contents of the entry in which the value is to be generated. It is not possible to construct values using content from other entries in the server, as the necessary content may not be available at the time the value is to be generated (for example, if the referenced entry does not yet exist), and it would also be difficult to ensure that the valuet is kept up to date whenever the referenced entry changes or is removed. Values are generated using the same logic that is available for constructed virtual attributes, as well as for constructed attribute mapping functionality in the Synchronization Server.

The composed attribute functionality is implemented using a plugin. The plugin is invoked during the pre-operation phases for add, modify, and modify DN operations, and it also operatse during LDIF import.

The server also provides an administrative task that can be used to iterate through all entries in a backend and generate values as necessary. This is useful when a new composed attribute plugin instance is created after the backend has already been populated and you do not wish to export the data to LDIF and re-import.

The server does not provide any first-class extensibility mechanisms for composed attributes. Unlike virtual attributes, which can be created through the Server SDK, composed attribute support is intentionally limited to what can be provided by the server. You can implement your own plugins to generate your own data if necessary.

Composed attribute plugin configuration properties

The composed attribute plugin provides the following configuration properties:

- plugin-type - The plugin type values for which the server will be registered. This is a mandatory multi-valued property with a default that includes all of the ldifimport, preoperationadd, preoperationmodify, and preoperationmodifydn values. It is recommend in general that you do not override this default set, but this may be useful in some rare corner cases. The available options include:
  - ldifimport - Indicates that values should be generated for the target attribute in any appropriate entries created during LDIF import processing.
  - preoperationadd - Indicates that values should be generated for the target attribute in any appropriate entries created by add operations.
  - preoperationmodify - Indicates that values should be generated or altered for the target attribute in any appropriate entries updated by modify operations.
  - preoperationmodifydn - Indicates that values should be generated or altered for the target attribute in any appropriate entries updated by modify DN operations.
- attribute-type - The name or OID of the attribute type for which values are to be generated. This attribute type must be defined in the schema. This is a mandatory, single-valued property with no default. If multiple composed attribute types are desired, then a separate instance of the plugin should be configured for each. However, if multiple values should be composed for the same attribute type

from different sets of source attributes, then a single instance of the plugin is recommended with multiple value patterns.

- value-pattern - The value pattern that specifies the logic that should be used when constructing values. This pattern must be compatible with the format expected by the com.unboundid.directory.server.sync.mapping.ConstructedValue class. This is a mandatory, multi-valued property in which the order of the values will be preserved. If this is configured with multiple values, then the behavior the plugin should exhibit will be controlled by the multiple-value-pattern-behavior property. Note that a value pattern will only be used for an entry if that entry contains all of the attributes referenced in the value pattern. Also note that virtual attributes are not considered when generating values.
- multiple-value-pattern-behavior - The behavior that the server should exhibit if multiple value-pattern values are configured. This will be a single-valued property with a default value of use-first-non-rejected-value-pattern-with-non-empty-values-but-may-reject.

  ⓘ **Note:** The primary reason that a rejection may occur is as a result of multivalued source attributes, but it could also occur if an unexpected error occurs while trying to generate values.

  The available options include:

  - use-first-non-rejected-value-pattern-with-non-empty-values-but-may-reject - Indicates that the server should only use values generated from the first value pattern that is not rejected and yields a non-empty result. If all value patterns yield empty results (for example, if the entry is missing at least one source attribute for each of the value patterns), then no composed value will be generated. If no value pattern yields a non-empty result but at least one is rejected, then the operation will fail, or the entry will be rejected if performing an LDIF import.
  - use-first-non-rejected-value-pattern-with-non-empty-values-and-never-reject - Indicates that the server should only use values generated from the first value pattern that is not rejected and yields a non-empty result. If none of the value patterns yield non-empty results (regardless of whether any of them is rejected), then no composed value will be generated.
  - use-first-rejection-or-first-value-pattern-with-non-empty-values - Indicates that the server should only use values generated from the first value pattern that yields non-empty results, but if a rejection is encountered before a non-empty result is obtained, then the operation (or LDIF entry) will be rejected. If none of the value patterns is not rejected and yields a non-empty result, then no composed value will be generated.
  - use-all-non-rejected-value-patterns-with-non-empty-values-but-may-reject - Indicates that the server should use all values generated by all of the value patterns that were not rejected for the entry. As long as at least one value pattern generated a non-empty result, then the entire set of values generated by all value patterns will be used. If none of the value patterns yielded non-empty results but none were rejected, then no composed value will be generated. If none of the value patterns yielded non-empty results and at least one was rejected, then the operation will fail or the LDIF entry will be rejected.
  - use-all-non-rejected-value-patterns-with-non-empty-values-and-never-reject - Indicates that the server should use all values generated by all of the value patterns that were not rejected for the entry. As long as at least one value pattern generated a non-empty result, then the entire set of values generated by all value patterns will be used. If none of the value patterns yielded non-empty results (regardless of whether any of them was rejected), then no composed value will be generated.
  - use-first-rejection-or-all-value-patterns-with-non-empty-values - Indicates that the server should use all of the values generated by all of the value patterns as long as none of them is rejected. If any value pattern is rejected, then the operation will fail or the LDIF entry will be rejected. If none of the value patterns is rejected but none of them generates any values, then no composed values will be generated.
- multi-valued-attribute-behavior - The behavior that the server should exhibit if any of the attributes used in the value pattern have multiple values. Note that at most one source attribute may have multiple values; if multiple source attributes have multiple values, and if this property is configured to try to use all of them, then the attempt to generate composed values for the entry may fail. This will be a

single-value property with a default value of use-all-values-if-possible-but-reject-if-not. Available options include:

  - use-first-value - Indicates that the server should only use the first value for each source attribute referenced in the value pattern. With this value, entries should never be rejected for having multivalued attributes.
  - reject-entries-with-any-multivalued-source-attribute - Indicates that the server should reject any entry that has more than one value for any of the source attributes.
  - use-all-values-if-possible-but-reject-if-not - Indicates that the server should use all values for the source attributes, as long as at most one of them has multiple values. If multiple source attributes have multiple values, the entry will be rejected.
  - use-all-values-if-possible-but-only-first-value-if-not - Indicates that the server should use all values for the source attributes, as long as at most one of them has multiple values. If multiple source attributes have multiple values, then only the first value from each source attribute will be used so that the entry will not be rejected.
- target-attribute-exists-during-initial-population-behavior - The behavior that the server should exhibit for add operations and LDIF imports for entries that already contain one or more values for the target attribute. This will be a single-valued property with a default of preserve-existing-values. The available options include:
  - preserve-existing-values - Indicates that the server should preserve existing values in entries that are added or imported, and should only construct values for entries that do not already contain the target attribute.
  - overwrite-existing-values - Indicates that the server should only use generated values for the target attribute and that any values provided during an add or LDIF import will be discarded.
  - merge-existing-and-composed-values - Indicates that the server should preserve any existing values for the target attribute, but should also construct any additional values.

    ⓘ **Note:** This option may only be used if the target attribute type allows multiple values.
  - reject-existing-values-in-add-but-preserve-in-ldif-import - Indicates that the server should reject any add operation that attempts to provide any values for the target attribute, but that it should preserve any existing values when performing an LDIF import. Note that the server will not reject entries that already contain the target attribute when performing an LDIF import since this would interfere with the ability to export data to LDIF from a server that contains composed values and then re-import the LDIF file.
  - reject-existing-values-in-add-but-overwrite-in-ldif-import - Indicates that the server should reject any add operation that attempts to provide any values for the target attribute, but that it should replace any existing values in an LDIF import with the values which would be composed for that entry.
  - reject-existing-values-in-add-but-merge-in-ldif-import - Indicates that the server should reject any add operation that attempts to provide any values for the target attribute, but should preserve any existing values when performing an LDIF import and add any additional values that should be composed for the entry.
- update-source-attribute-behavior - The behavior that the server should exhibit for entries that are updated by modify or modify DN operations that alter values for one of the attributes used in the value pattern. This will be a single-valued property with a default of replace-composed-values. The available options include:
  - replace-composed-values - Indicates that the server should only update values for the target attribute that match those that would have been generated by the plugin. Values that would not have been generated by the plugin will be preserved.
  - replace-all-values - Indicates that the server should always replace the target attribute with new composed values, even if the existing values were not generated by the plugin.
  - preserve-existing-values - Indicates that the server should always preserve the existing values for the target attribute, even if they were generated by the plugin.

- source-attribute-removal-behavior - The behavior that the server should exhibit when an entry is updated in a manner that removes one or more source attributes needed to compose values for the target attribute. This will be a single-valued property with a default of preserve-non-composed-values. The available options include:
  - preserve-non-composed-values - Indicates that the server will attempt to remove any values for the target attribute that would have been generated for that entry by the associated value patterns, but that it will preserve any other values that may exist for the target attribute. However, if the target attribute is required by any of the object classes in the entry and if that entry only contains composed values for the target attribute, then the composed values will be preserved to avoid violating the schema.
  - preserve-all-values - Indicates that the server will preserve any values that exist for the target attribute, regardless of whether they would have been composed by any of the value patterns.
  - remove-all-values-but-preserve-all-if-required - Indicates that the server will attempt to remove all values for the target attribute from the entry, regardless of whether they would have been composed, but that it will fall back to a behavior of preserve-all-values if the target attribute type is required by any of the entry's object classes.
  - remove-all-values-but-preserve-non-composed-values-if-required - Indicates that the server will attempt to remove all values for the target attribute from the entry, regardless of whether they would have been composed, but that it will fall back to a behavior of preserve-non-composed-values if the target attribute type is required by any of the entry's object classes.
- update-target-attribute-behavior - The behavior that the server should exhibit when a client attempts to alter the target attribute with a modify or modify DN operation. This will be a single-valued property with a default of always-allow. The aAvailable options include
  - always-allow - Indicates that the server will always permit clients to alter the value of the target attribute, regardless of whether these values were generated.
  - allow-only-for-non-composed-values - Indicates that the server will only permit clients to alter values for the target attribute that were not generated by the plugin. Attempts to alter composed values will be rejected.
  - never-allow - Indicates that the server should reject any attempt to alter the target attribute, regardless of the values it may have.
- include-base-dn - A base DN that may be used to restrict the set of entries for which values will be composed. The include/exclude criteria configuration options are described in more detail below.
- exclude-base-dn - A base DN that may be used to restrict the set of entries for which values will be composed. The include/exclude criteria configuration options are described in more detail below.
- include-filter - A search filter that may be used to restrict the set of entries for which values will be composed. The include/exclude criteria configuration options ware described in more detail below.
- exclude-filter - A search filter that may be used to restrict the set of entries for which values will be composed. The include/exclude criteria configuration options are described in more detail below.
- updated-entry-newly-matches-criteria-behavior - The behavior that the server should exhibit if an entry that previously did not satisfy either the base DN or filter criteria, but is updated so that it does match any configured base DN or filter criteria. This will be a single-valued property with a default value of preserve-existing-values-and-compose-new-values. The available options include:
  - preserve-existing-values-without-composing-new-values - Indicates that if the entry already had one or more values for the target attribute, those values will be preserved and no additional composed values will be added. If the entry did not contain the target attribute, then no composed values will be generated for the entry.
  - preserve-existing-values-or-compose-new-values - Indicates that if the entry already had one or more values for the target attribute, those values will be preserved and no additional composed values will be added. However, if the entry did not contain the target attribute, then composed values will be generated for the entry.
  - preserve-existing-values-and-compose-new-values - Indicates that if the entry already had one or more values for the target attribute, those values will be preserved and any additional values that

would be composed for that entry will also be added. If the entry did not contain the target attribute, then composed values will be generated for the entry.

  - compose-new-values-without-preserving-existing-values - Indicates that if the entry already had one more composed values for the target attribute, then those values will be removed and replaced with the composed values that would be generated for it. If the entry did not contain the target attribute, then composed values will be generated for it. If no composed values would be generated for the entry (for example, if it was missing at least one source attribute for each value pattern), then the entry will not include the target attribute, regardless of whether it contained existing values for the attribute.

- updated-entry-no-longer-matches-criteria-behavior - The behavior that the server should exhibit if an entry previously satisfied the configured base DN and filter criteria but has been updated so that it no longer matches that criteria. This will be a single-valued property with a default of preserve-all-values. The avvailable options include:

  - preserve-all-values - Indicates that the server will preserve any values that exist for the target attribute, regardless of whether they would have been composed by any of the value patterns.
  - preserve-non-composed-values - Indicates that the server will attempt to remove any values for the target attribute that would have been generated for that entry by the associated value patterns, but will preserve any other values that may exist for the target attribute. However, if the target attribute is required by any of the object classes in the entry, and if that entry only contains composed values for the target attribute, then the composed values will be preserved to avoid violating the schema.
  - remove-all-values-but-preserve-all-if-required - Indicates that the server will attempt to remove all values for the target attribute from the entry, regardless of whether they would have been composed, but that it will fall back to a behavior of preserve-all-values if the target attribute type is required by any of the entry's object classes.
  - remove-all-values-but-preserve-non-composed-values-if-required —-Indicates that the server will attempt to remove all values for the target attribute from the entry, regardless of whether they would have been composed, but that it will fall back to a behavior of preserve-non-composed-values if the target attribute type is required by any of the entry's object classes.

By default, attribute values will be composed for every entry in any public backend that contains all of the source attributes used in the appropriate value patterns. If you wish to restrict composed values to a specific set of entries, that can be done with the include-base-dn, exclude-base-dn, include-filter, and exclude-filter properties.

If the include-base-dn property is provided, then values will only be composed for entries at or below one of those base DNs. If the exclude-base-dn property is provided, then values will not be composed for any entries at or below one of those base DNs. If both properties are provided and a given entry resides below both an include and an exclude base DN, then the exclude base DN will take precedence, and values will not be generated for that entry. If neither property is specified, then the naming contexts of all public backends will be used as the default set of include base DNs.

If the include-filter property is provided, then values will only be composed for entries that match at least one of those filters. If the exclude-filter property is provided, then values will not be composed for any entries that match at least one of those filters. If both properties are provided and a given entry matches both include and exclude filters, then the exclude filter will take precedence, and values will not be generated for that entry. If neither property is specified, then the server will behave as if an include filter of "(&)" had been specified. Note that no virtual attributes will be considered when evaluating this filter, although composed values may be taken into consideration. See *Composed attribute dependency considerations* on page 541 for more information about the order in which composed attribute definitions will be evaluated.

Populate composed attribute values task

When a composed attribute plugin is created in the server, it takes effect immediately and starts creating values for any appropriate add, modify, and modify DN operations. However, existing entries will not automatically be populated with generated values. This can be achieved by exporting the data to LDIF and re-importing it, but this would require temporarily taking each instance out of service since importing

into a single instance will have no effect on the data in other instances. The LDIF import option is really only feasible when you are starting from scratch, not when you have existing data. To address this need, a “populate composed attribute values” task is provided. This task iterates through all entries in one or more backends and generates values as appropriate for any entries.

This task provides several number of configuration attributes, including the following:

- ds-task-populate-composed-attribute-plugin-config - An optional, multi-valued attribute that can be used to specify the names or DNs of the composed attribute plugin configuration entries for which values should be generated. If this attribute is omitted, then values will be generated for all defined and enabled composed attribute plugin instances.
- ds-task-populate-composed-attribute-backend-id - An optional, multi-valued attribute that may be used to specify the backend IDs of the backends in which values should be generated. If this attribute is omitted, then an appropriate set of backends will be determined based on the include and exclude base DNs for the selected plugins.
- ds-task-populate-composed-attribute-max-rate-per-second - An optional, single-valued integer attribute that can be used to specify the maximum number of entries to be updated per second. If this attribute is omitted, then no rate limit will be imposed.

The task uses the same logic that the plugin uses for entries imported from LDIF when deciding what values to include in the entry, but it will use internal modify operations to make any necessary updates to the entry. These changes will be replicated to other servers in the topology, so the task only needs to be invoked on a single instance. However, it is recommended running it only after the composed attribute plugins have been configured on all instances in the topology, as this will ensure that no entries (including those added or updated while the task is running) are overlooked.

A populate-composed-attribute-values command-line tool that can be used to invoke the task and monitor its progress is provided. Since this processing is not expected to be needed on a regular basis, this is not offered as a recurring task.

Composed attribute dependency considerations

Composed attributes must not have any dependency on virtual attributes. The server will not use virtual attribute values when generating values from a value pattern, and it will also not use virtual attribute values when determining whether an entry matches an include or exclude filter.

There is normally no need to have one composed attribute depend on another. If one composed attribute is constructed from other attributes in the entry, then another composed attribute that needs to use another composed attribute as its source can simply include the value pattern for that first composed attribute as part of its own value pattern. However, this may not be sufficient if the composed values can be overridden by clients.

If there is a reason that one composed attribute needs to depend on another, then it should be sufficient to ensure that the following requirements are satisfied:

- Any composed attribute plugins that have dependencies should be configured so that they will be invoked in the appropriate order. This may be accomplished through the plugin-order-ldif-import, The populate composed attribute values task should be run separately for each of the attributes to be generated. The first run should be to generate values for any composed attributes that are not dependent on any other composed attributes. The second run should generate values for any composed attributes that were created during the first run. If multiple levels of nesting are required, then additional runs of the task will also be required.plugin-order-pre-operation-add, plugin-order-pre-operation-modify, and plugin-order-pre-operation-modify-dn properties in the plugin root configuration.
-

Schema validation considerations

The server only generates composed attributes for entries in which that attribute is allowed to be present. For user attributes, tist means that the target attribute type must be permitted by at least one of the

object classes associated with the entry. If an entry does not have any object class that permits the target attribute, then an attempt to generate composed values for the entry will fail with an objectClassViolation (65) result. This restriction does not exist for operational attributes.

The server allows composed attributes to satisfy mandatory attribute requirements. That is, if the target attribute is declared as a MUST type for any of the entry's object classes, then it must be possible for a client to add an entry that does not include any values for that attribute type as long as the server will compose a value for that attribute.

The server also enforces attribute syntax restrictions for composed attributes. If a composed attribute would violate the syntax for the associated attribute type, then the operation that would result in that composed attribute value isrejected with an INVALID_ATTRIBUTE_SYNTAX result. This may be overridden on a per-attribute-type basis using the permit-syntax-violations-for-attribute property in the global configuration.

ⓘ **Note:** If this option is used to permit values that violate the associated syntax, then matching operations involving malformed values may not behave in a predictable manner,

.

The server should also enforce the SINGLE-VALUE constraint for the target attribute type. If an attribute type is defined with this constraint, it is not possible to configure the composed attribute plugin in a manner that could generate multiple values for that attribute and any operation that would result in multiple values for the target attribute is rejected.

Composed attributescannot set values for operational attributes that are defined with the NO-USER-MODIFICATION constraint.

Replication considerations

The composed attribute configuration should be identical for all servers in the replication topology. Whenever a composed attribute plugin is configured for one instance, the same definition should be added to all other instances in the topology.

Composed attribute values should only be generated for the server that processes the request from the client. When that operation is replicated to other servers, the composed attribute changes should be included as part of that operation.

Replicated changes involving composed attributes should not be subject to restrictions that would prevent external clients from writing to those values. This includes composed values for operational attribute types with the NO-USER-MODIFICATION constraint as well as for cases in which the plugin forbids clients from modifying values.

ⓘ **Note:** The plugin rejects any modify DN operation that alters source attributes in a way that would result in composed attribute changes.

Synchronization Server considerations

There should not be any issues synchronizing changes involving composed attributes from a PingDirectory Server instance to some other type of endpoint. Changes that create or update composed attributes should be written to the LDAP changelog, just like changes to regular attributes.

Synchronization to a PingDirectory Server configured with one or more composed attribute plugin instances may be more problematic. In particular, it may not be possible to a composed attribute type if the plugin that generates values for that attribute is configured to prohibit external clients from altering values of that attribute.

If the PingDirectory Server is used as a sync destination in an environment in which some attribute values may need to be composed, then it may be desirable to compose those values in the Synchronization

Server using a constructed attribute mapping rather than attempting to generate them in the Directory Server with the composed attribute plugin.

Directory Proxy Server considerations

The use of PingDirectoryProxy Server is not expected to require any special consideration in an environment involving composed attributes. This should be true for both simple and entry-balanced proxy configurations.

Troubleshooting considerations

For operations that are rejected for reasons related to composed attribute processing (for example, if an add, modify, or modify DN operation is rejected because the composed value would have violated the syntax for the target attribute type, or if an attempt was made to alter a composed attribute value in a way that is not permitted by the plugin), the diagnostic message is returned to the client and included in the access log.

The composed attribute plugin also contains detailed debug logging support. If you encounter unexpected behavior when using the composed attribute plugin, you should enable debugging for the plugin to provide information to help diagnose the problem.

Security considerations

The primary security consideration for composed attributes is that they may expose the values of other attributes. For example, if the cn attribute is composed from the values of the givenName and sn attributes, then a user with permission to read the cn attribute could determine the values of the givenName and sn attributes even if they do not have permission to read these attributes directly. However, this is not usually a significant concern and you can address this by ensuring that the user's access-control configuration restricts access to source attributes used in a composed attribute value pattern and imposes similar restrictions to the composed attribute.

Limitations of composed attributes relative to virtual attributes

Composed attribute support provides an alternative to a specific set of use cases, and these use cases may also be addressed by virtual attribute support. While the composed attribute solution may provide improvements in performance, searchability, and write behavior, it also has a number of limitations relative to the virtual attribute subsystem. Some of those limitations include:

- When creating a composed attribute plugin in the server, manual action is required to populate composed values in existing entries. When enabling a virtual attribute, the attribute is immediately available to clients.
- When removing a virtual attribute from the server, values that would have been generated for the attribute will no longer be present. When removing or disabling a composed attribute plugin, composed values that had already been generated will remain.
- Virtual attributes can be configured so that the values are only generated under certain conditions (for example, only for certain clients), and so that different values may be generated for different clients. Composed attributes will be the same for all clients (although access controls can be used to restrict which clients have access to them).
- Virtual attributes do not require any additional storage or memory usage. Composed attributes actually exist in the database and therefore require additional disk space and memory for caching.
- The composed attribute plugin can only generate values from a combination of static text and values from other attributes in the same entry. Virtual attributes can use a much wider range of logic when generating values, including custom logic implemented using the Server SDK.

Encrypting Sensitive Data

The Directory Server provides several ways that you can protect sensitive information in the server. If not enabled during server setup, you can enable on-disk encryption for data in backends as well as in the changelog and the replication databases, and you can also protect sensitive attributes by limiting the ways that clients may interact with them.

This chapter presents the following topics:

About encrypting and protecting sensitive data

The Directory Server provides an encryption-settings database that holds encryption and decryption definitions to protect sensitive data. You can enable on-disk encryption for data in backends as well as in the changelog and the replication databases. You can also protect sensitive attributes by limiting the ways that clients may interact with them.

About the Encryption-Settings Database

The encryption-settings database is a repository that the server uses to hold information for encrypting and decrypting data. The database contains any number of *encryption-settings definitions* that specifies information about the cipher transformation and encapsulates the key used for encryption and decryption.

Before data encryption can be enabled, you first need to create an encryption-settings definition. An encryption-settings definition specifies the cipher transformation that should be used to encrypt the data, and encapsulates the encryption key. The `encryption-settings` command-line tool can be used to manage the encryption settings database, including creating, deleting, exporting, and importing encryption-settings definitions, listing the available definitions, and indicating which definition should be used for subsequent encryption operations.

Although the encryption-settings database can have multiple encryption-settings definitions, only one of them can be designated as the *preferred* definition. The preferred encryption-settings definition is the one that will be used for any subsequent encryption operations. Any existing data that has not yet been encrypted remains unencrypted until it is rewritten (e.g., as a result of a modify or modify DN operation, or if the data is exported to LDIF and re-imported). Similarly, if you introduce a new preferred encryption-settings definition, then any existing encrypted data will continue to use the previous definition until it is rewritten. If you do change the preferred encryption-settings definition for the server, then it is important to retain the previous definitions until you are confident that no remaining data uses those older keys.

Supported Encryption Ciphers and Transformations

The set of encryption ciphers that are supported by the Directory Server is limited to those ciphers supported by the JVM in which the server is running. For specific reference information about the algorithms and transformations available in all compliant JVM implementations, see the following:

- Java Cryptography Architecture Reference Guide
- Java Cryptography Architecture Standard Algorithm Name Documentation

When configuring encryption, the cipher to be used must be specified using a key length (in bits) and either a cipher algorithm name (e.g., "AES") or a full cipher transformation which explicitly specifies the mode and padding to use for the encryption (e.g., "AES/CBC/ PKCS5Padding"). If only a cipher algorithm is given, then the default mode and padding for that algorithm will be automatically selected.

The following cipher algorithms and key lengths have been tested using the Sun/Oracle JVM:

Cipher Algorithms

Cipher Algorithm	Key Length (bits)
AES	128
Blowfish	128
DES	64
DESede	192
RC4	128

ⓘ **Note:** By default, some JVM implementations may come with limited encryption strength, which may restrict the key lengths that can be used. For example, the Sun/Oracle JVM does not allow AES with 192-bit or 256-bit keys unless the unlimited encryption strength policy files are downloaded and installed.

The Directory Server supports four Cipher Stream Providers, which are used to obtain cipher input and output streams to read and write encrypted data.

Cipher Stream Providers

Cipher Stream Providers	Description
Default	Default cipher stream provider using a hard-coded default key.
File-Based	Used to read a specified file in order to obtain a password used to generate cipher streams for reading and writing encrypted data.
Third-Party	Used to provide cipher stream provider implementations created in third-party code using the Server SDK.
Wait-for-Passphrase	Causes the server to wait for an administrator to enter a passphrase that will be used to derive the key for cipher streams. You can supply the passphrase to the server by running **`encryption-settings supply-passphrase`**.

Using the encryptions-settings Tool

About this task

The **`encryption-settings`** tool provides a mechanism for interacting with the server's encryption-settings database. It may be used to list the available definitions, create new definitions, delete existing definitions, and indicate which definition should be the preferred definition. It may also be used to export definitions to a file for backup purposes and to allow them to be imported for use in other Directory Server instances.

To list the available encryption definitions:

Steps

- Use the **`encryption-settings`** tool with the **`list`** subcommand to display the set of available encryption settings definitions. This subcommand does not take any arguments. For each definition, it will include the unique identifier for the definition, as well as the cipher transformation and key length that will be used for encryption and whether it is the preferred definition.

```
$ bin/encryption-settings list
```

```
Encryption Settings Definition ID: 4D86C7922F71BB57B8B5695D2993059A26B8FC01
Preferred for New Encryption: false
```

```
Cipher Transformation: DESede
Key Length (bits): 192

Encryption Settings Definition ID: F635E109A8549651025D01D9A6A90F7C9017C66D
Preferred for New Encryption: true
Cipher Transformation: AES
Key Length (bits): 128
```

Creating encryption-settings definitions

About this task

To create a new encryption-settings definition, use the `create` subcommand. This subcommand takes the following arguments:

- **--cipher-algorithm {algorithm}**. Specifies the base cipher algorithm that should be used. This should just be the name of the algorithm (e.g., "AES", "DES", "DESede", "Blowfish", "RC4", etc.). This argument is required.
- **--cipher-transformation {transformation}**. Specifies the full cipher transformation that should be used, including the cipher mode and padding algorithms (e.g., "AES/CBC/ PKCS5Padding"). This argument is optional, and if it is not provided, then the JVM-default transformation will be used for the specified cipher algorithm.
- **--key-length-bits {length}**. Specifies the length of the encryption key in bits (e.g., 128). This argument is required.
- **--set-preferred**. Indicates that the new encryption-settings definition should be made the preferred definition and therefore should be used for subsequent encryption operations in the server. When creating the first definition in the encryption-settings database, it will automatically be made the preferred definition.

To create an encryption-settings definition:

Steps

- Use the **`encryption-settings`** tool with the `create` subcommand to specify the definition.

```
$ bin/encryption-settings create --cipher-algorithm AES \
  --key-length-bits 128 --set-preferred

Successfully created a new encryption settings definition with ID
F635E109A8549651025D01D9A6A90F7C9017C66D
```

Changing the preferred encryption-settings definition

About this task

To change the preferred encryption-settings definition, use the **`encryption-settings`** tool with the `set-preferred` subcommand. This subcommand takes the following arguments:

- **--id {id}**. Specifies the ID for the encryption-settings definition to be exported. This argument is required.

Steps

- Use the **`encryption-settings`** tool with the `set-preferred` subcommand to change a definition to a preferred definition.

```
$ bin/encryption-settings set-preferred --id
 4D86C7922F71BB57B8B5695D2993059A26B8FC01

Encryption settings definition 4D86C7922F71BB57B8B5695D2993059A26B8FC01 was
```

```
successfully set as the preferred definition for subsequent encryption
 operations
```

Deleting an encryption-settings definition

About this task

To delete an encryption-settings definition, use the **`encryption-settings`** tool with the `delete` subcommand. The subcommand takes the following arguments:

- **--id {id}**. Specifies the ID for the encryption-settings definition to be deleted. This argument is required.

Never delete an encryption-settings definition if data in the server is still encrypted using the settings contained in that definition. Any data still encrypted with a definition that has been removed from the database will be inaccessible to the server and will cause errors for any attempt to access it. This includes the replicationChanges and changelog databases, which the **`re-encode-entries`** tool will not re-encode with the new encryption-settings definition. Therefore, wait for the amount of time defined in the **`replication-purge-delay`**, of the Replication Server, and **`changelog-maximum-age`** of the changelog Backend (if enabled) before removing previous encryption-settings definitions. To safely delete a compromised encryption-settings definition, see the *Dealing with a Compromised Encryption Key* section.

To stop using a definition for encryption and use a different definition, make sure that the desired definition exists in the encryption-settings database and set it to be the preferred definition. As long as the encryption key has not been compromised, there is no harm in having old encryption-settings definitions available to the server, and it is recommended that they be retained just in case they are referenced by something.

The preferred encryption-settings definition cannot be deleted unless it is the only one left. To delete the currently-preferred definition when one or more other definitions are available, make one of the other definitions preferred as described in the previous section.

Steps

- Use the **`encryption-settings`** command with the `delete` subcommand. Make sure to include the `--id` argument to specify the definition.

```
$ bin/encryption-settings delete --id
 F635E109A8549651025D01D9A6A90F7C9017C66D
```

```
Successfully deleted encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D
```

Configuring the encryption-settings database

About this task

Because the encryption-settings database contains the encryption keys used to protect server data, the contents of the encryption-settings database is itself encrypted. By default, the server will derive a key to use for this purpose, but it is recommended that you customize the logic used to access the encryption-settings database with a cipher stream provider. The Server SDK provides an API that can be used to create custom cipher stream provider implementations, but the server also comes with one that will obtain the key from a PIN file that you create (see the example procedure below).

Steps

1. Use **`dsconfig`** to configure the server so that the encryption-settings database is encrypted with a PIN contained in the file `config/encryption-settings.pin`.

```
$ bin/dsconfig create-cipher-stream-provider \
  --provider-name "Encryption Settings PIN File" \
```

```
  --type file-based \
  --set enabled:true \
  --set password-file:config/encryption-settings.pin
```

2. Use **`dsconfig`** to set the global configuration property for the cipher stream provider, which sets the on-disk encryption.

```
$ bin/dsconfig set-global-configuration-prop \
  --set "encryption-settings-cipher-stream-provider:Encryption Settings PIN
 File"
```

3. Use the `encryption-settings` tool to create a new encryption-settings definition. This command automatically generates a new 256-bit encryption key for use with AES encryption, and mark it as the preferred definition for future encryption operations in the server. Note that this command will fail if you do not have the unlimited encryption strength policy installed as described in the previous section (if you do not have that policy installed, then you are restricted to a 128-bit key for AES encryption).

```
$ bin/encryption-settings create \
  --cipher-algorithm AES \
  --key-length-bits 256 \
  --set-preferred
```

4. Obtain a list of the definitions in the encryption-settings database.

```
$ bin/encryption-settings list
```

5. You can export an encryption-settings definition from the database using a command like the following where the encryption-settings ID should be changed as necessary to suit your deployment:

```
$ bin/encryption-settings export \
  --id DA39A3EE5E6B4B0D3255BFEF95601890AFD80709 \
  --output-file /tmp/exported-key \
  --pin-file /tmp/exported-key.pin
```

6. If no PIN file is specified, then you will be interactively prompted to provide it. To import an encryption-settings definition into the database on another server.

```
$ bin/encryption-settings import \
  --input-file /tmp/exported-key \
  --pin-file /tmp/exported-key.pin \
  --set-preferred
```

Encrypting passphrase files

Using an encrypted passphrase or tools.properties file enables you to have credentials available for use by the server and command-line tools, but not stored in the clear. These files should be encrypted with the encrypt-file tool, including:

- Certificate keystore and truststore PIN files. When setting up an instance with encryption enabled and at least one of SSL or StartTLS enabled, the installer will automatically encrypt the PIN files for the config/keystore, config/truststore, and config/ads-truststore certificate databases.
- Passphrase files specified by command-line arguments. For example, most LDAP tools offer **`--bindPasswordFile`**, **`--keystorePasswordFile`**, and **`--truststorePasswordFile`** arguments.
- The **`config/tools.properties`** file, which will automatically be used to obtain a default set of arguments for most command-line tools. Alternately, the **`--propertiesFilePath`** argument can be used to specify an alternate properties file.

These files should be encrypted with the following considerations:

- If the file is encrypted with a key obtained from the server's encryption settings database, then the server and associated command-line tools should be able to retrieve the appropriate key from the encryption settings database so that the clear-text contents of the file can be accessed without any interaction (although if the cipher stream provider configured to protect the contents of the encryption

settings database requires interaction, like the wait for passphrase cipher stream provider, then command-line tools may require interaction to unlock the encryption settings database).

- If the file is encrypted with a passphrase that the user specifies rather than one obtained from the encryption settings database, then the user will be interactively prompted for that passphrase when running the tool. This option cannot be used for keystore and truststore PIN files that need to be accessed by the server.

To encrypt a file with the server's preferred encryption settings definition, use a command such as:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted
```

To use a key from an encryption settings definition that isn't the default, use the **`--encryption-settings-id`** argument to specify the ID of the desired encryption settings definition (which can be obtained with **`cencryption-settings list`**), such as:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted \
  --encryption-settings-id 4B6899D6716FC3AFFD71F7B447EB135063A0E724
```

To encrypt the file with a passphrase rather than a key from an encryption settings definition, use either the **`--prompt-for-passphrase`** argument to interactively prompt for the passphrase, or use the **`--passphrase-file`** argument to specify the path to a file containing the clear-text passphrase. For example:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted \
  --prompt-for-passphrase
```

About backing up and restoring the encryption-settings definitions

If using data encryption in a Directory Server instance, do not lose the encryption-settings definitions used to encrypt data in the server. If an encryption-settings definition is lost, any data encrypted with that definition will be completely inaccessible. Make sure the encryption-settings definitions are backed up regularly.

The Directory Server provides two different mechanisms for backing up and restoring encryption-settings definitions. One or more encryption-settings definitions can be exported and imported using the **`encryption-settings`** tool. Or, the entire encryption-settings database can be backed up and restored using the Directory Server's **`backup`** and **`restore`** tools.

If a pin file is used to define a passphrase to the encryption-settings database, the passphrase must be backed up and kept secure independently of the userRoot and encryption-settings database backups. The passphrase in the pin file is needed if the encryption-settings database is to be restored into a different server root.

Exporting encryption-settings definitions

About this task

To back up an individual definition (or to export it from one server so that you can import it into another), use the `export` subcommand to the **`encryption-settings`** command. The subcommand takes the following arguments:

- **--id {id}**. Specifies the ID for the encryption-settings definition to be exported. This argument can be specified multiple times. If it is omitted, all definitions are exported.
- **--output-file {path}**. Specifies the path to the output file to which the encryption-settings definition will be written. This argument is required.

- **--pin-file {path}**. Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition. If this argument is not provided, then the PIN will be interactively requested from the server.

Steps

- Use the **`encryption-settings`** tool with the `export` subcommand to export the definition to a file.

```
$ bin/encryption-settings export --id
 F635E109A8549651025D01D9A6A90F7C9017C66D \
  --output-file /tmp/exported-key
Enter the PIN to use to encrypt the definition:
Re-enter the encryption PIN:
```

```
Successfully exported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D to file /tmp/exported-key
```

Importing encryption-settings definitions

About this task

To import an encryption-settings definition that has been previously exported, use the **`encryption-settings`** tool with the `import` subcommand. The subcommand takes the following arguments:

- **--input-file {path}**. Specifies the path to the file containing the exported encryption-settings definition. This argument is required.
- **--pin-file {path}**. Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition. If this argument is not provided, then the PIN will be interactively requested from the server.
- **--set-preferred**. Specifies that the newly-imported encryption-settings definition should be made for the preferred definition for subsequent encryption-settings.

Steps

- Use the **`encryption-settings`** tool with the `import` subcommand to import the definition to a file.

```
$ bin/encryption-settings import --input-file /tmp/exported-key --set-
preferred
Enter the PIN used to encrypt the definition:
```

```
Successfully imported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D from file /tmp/exported-key
```

Enabling data encryption in the server

About this task

Encryption can be enabled during server setup, by defining an encryption key and passphrase. This configuration should be used across all servers in a topology. On legacy systems or post setup, data encryption can be configured by having at least one encryption-settings definition available for use. Then, set the value of the `encrypt-data` global configuration property to true.

Setting the global configuration property will automatically enable data encryption for all types of backends that support it (including the changelog backend and indexes), as well as for the replication server database. All subsequent write operations will cause the corresponding records written into any of these locations to be encrypted. Any existing data will remain unencrypted until it is rewritten by a write operation. If you wish to have existing data encrypted, then you will need to export that data to LDIF and re-import it. This will work for both the data backends, the changelog, and indexes, but it is not an option for the replication database, so existing change records will remain unencrypted until they are purged. If this

is not considered acceptable in your environment, then follow the steps in *Dealing with a Compromised Encryption Key* to safely purge the replication database.

Configuration for backups and LDIF exports can be done with the following global properties:

- **automatically-compress-encrypted-ldif-exports**. Indicates whether to automatically compress LDIF exports that are also encrypted. If set to true, any LDIF export that is encrypted (either explicitly with **--encryptLDIF**,or implicitly with the **encrypt-ldif-exports-by-default** configuration property) will automatically be gzip-compressed. If this is false, encrypted LDIF exports can still be manually compressed using the **--compress** command-line argument.
- **backup-encryption-settings-definition-id**. The unique identifier for the encryption settings definition to use to generate the encryption key for encrypted backups by default. If this property is given a value, then a definition with that ID must exist in the server's encryption settings database. If this property is not given a value, but the server is configured with at least one encryption settings definition, then the preferred definition is used. If no encryption settings definitions are available, the server will use an internal key shared among servers in the topology. Regardless of this property's value, it can be overridden with the **backup** command-line tool. Providing one of the **--promptForEncryptionPassphrase** or **--encryptionPassphraseFile** arguments will generate the encryption key from the provided passphrase. Or, the **--encryptionSettingsDefinitionID** argument can be used to generate the key from the specified encryption settings definition.
- **encrypt-backups-by-default**. Indicates whether the server should encrypt backups by default. If set to true, a defined **backup-encryption-settings-definition-id** value will be used to generate the encryption key for the backup. If this property is true, and if a **backup-encryption-settings-definition-id** value is not specified, the server will try to use the preferred encryption settings definition to generate the encryption key. If the server is not configured with any encryption settings definitions, an internal key that is shared among instances in the topology is used. Regardless of this property's value, it can be overridden with the **backup** command-line tool's **--encrypt** argument, even if this property is set to false. The **--doNotEncrypt** argument will always cause the backup to be unencrypted, even if this property has a value of true.
- **encrypt-ldif-exports-by-default**. Indicates whether the server should encrypt LDIF exports by default. If set to true, and an **ldif-export-encryption-settings-definition-id** value is specified, then that encryption settings definition is used to generate the encryption key for the export. If this property is true, and an **ldif-export-encryption-settings-definition-id** value is not specified, the server will first try to use the preferred encryption settings definition to generate the encryption key. If the server is not configured with any encryption settings definitions, then an internal key that is shared among instances in the topology is used. Regardless of this property's value, the default behavior can be overridden with the **export-ldif** command-line tool. The tool's **--encryptLDIF** argument will always encrypt the export, and the **--doNotEncryptLDIF** argument will always create an unencrypted export.

Steps

- Use **dsconfig** to set the global configuration property for data encryption to true.

```
$ bin/dsconfig set-global-configuration-prop --set encrypt-data:true
```

Using data encryption in a replicated environment

Data encryption is only used for the on-disk storage for data within the server. Whenever clients access that data, it is presented in unencrypted form (although the communication with those clients may itself be encrypted using SSL or StartTLS). Replication, the communication of updates between replication servers, is always encrypted using SSL. Each server may apply data encryption in a completely independent manner and have different sets of encryption-settings definitions. It is also possible to have a replication topology containing some servers with data encryption enabled and others with it disabled.

However, when initializing the backend of one server from another server with data encryption enabled, then the server being initialized must have access to all encryption-settings definitions that may have been used for data contained in that backend. To do this, perform an export of the encryption-settings database

on the source server using **`bin/encryption-settings export`** and import it on the target server using **`bin/encryption-settings import`**.

Dealing with a compromised encryption key

About this task

If an encryption-settings definition becomes compromised such that an unauthorized individual obtains access to the encryption key, then any data encrypted with that definition is also vulnerable because it can be decrypted using that key. It is very important that the encryption-settings database be protected (for example, using file permissions or file system ACLs) to ensure that its contents remain secure.

In the event that an encryption-settings definition is compromised, stop using the definition immediately. Any data encrypted with the compromised key should be re-encrypted with a new definition or purged from the server. This can be done on one server at a time to avoid an environment-wide downtime, but it should be completed as quickly as possible on all servers that had used that definition at any point in the past in order to minimize the risk of that data becoming exposed.

The recommended process for responding to a compromised encryption settings definition is as follows:

Steps

1. Create a new encryption-settings definition and make it the preferred definition for new writes.
2. Ensure that client traffic is routed away from the server instance to be updated. For example, if the Directory Server is accessed through a Directory Proxy Server, then you may set the `health-check-state` configuration property for any LDAP external server definitions that reference that server to have a value of unavailable.
3. Ensure that external clients are not allowed to write operations in the directory server instance. This may be accomplished by setting the `writability-mode` global configuration property to have a value of `internal-only`.
4. Wait for all outstanding local changes to be replicated out to other servers. This can be accomplished by looking at the monitor entries with the `ds-replication-server-handler-monitor-entry` object class to ensure that the value of the `update-sent` attribute is no longer increasing.
5. Stop the directory server instance.
6. Delete the replication server database by removing all files in the `changeLogDb` directory below the server root. As long as all local changes have been replicated out to other servers, this will not result in any data loss in the replication environment.
7. Export the contents of all local DB and changelog backends to LDIF. Then, re-import the data from LDIF, which will cause it to be encrypted using the new preferred encryption settings definition.
8. Export the compromised key from the encryption settings database to back it up in case it may be needed again in the future (e.g., if some remaining data was later found to have been encrypted with the key contained in that definition). Then, delete it from the encryption settings database so that it can no longer be used by that directory server instance.
9. Start the directory server instance.
10. Allow replication to bring the server back up-to-date with any changes processed while it was offline.
11. Re-allow externally-initiated write operations by changing the value of the global `writability-mode` configuration property back to enabled.
12. Re-configure the environment to allow client traffic to again be routed to that server instance (e.g., by changing the value of the "health-check-state" property in the corresponding LDAP external instance definitions in the Directory Proxy Server instances back to "dynamically-determined").

Configuring sensitive attributes

Data encryption is only applied to the on-disk storage for a Directory Server instance. It does not automatically protect information accessed or replicated between servers, although the server offers other

mechanisms to provide that protection (i.e., SSL, StartTLS, SASL). Ensuring that all client communication uses either SSL or StartTLS encryption and ensuring that all replication traffic uses SSL encryption ensures that the data is protected from unauthorized individuals who may be able to eavesdrop on network communication. This communication security may be enabled independently of data encryption (although if data encryption is enabled, then it is strongly recommended that secure communication be used to protect network access to that data).

However, for client data access, it may not be as simple as merely enabling secure communication. In some cases, it may be desirable to allow insecure access to some data. In other cases, it may be useful to have additional levels of protection in place to ensure that some attributes are even more carefully protected. These kinds of protection may be achieved using sensitive attribute definitions.

Each sensitive attribute definition contains a number of configuration properties, including:

- **`attribute-type`** . Specifies the set of attribute types whose values may be considered sensitive. At least one attribute type must be provided, and all specified attribute types must be defined in the server schema.
- **`include-default-sensitive-operational-attributes`** . Indicates whether the set of sensitive attributes should automatically be updated to include any operational attributes maintained by the Directory Server itself that may contain sensitive information. At present, this includes the `ds-sync-hist` operation attribute, which is used for data required for replication conflict resolution and may contain values from other attributes in the entry.
- **`allow-in-filter`** . Indicates whether sensitive attributes may be used in filters. This applies not only to the filter used in search requests, but also filters that may be used in other places, like the assertion and join request controls. The value of this property must be one of:
  - `Allow` (allow sensitive attributes to be used in filters over both secure and insecure connections)
  - `Reject` (reject any request which includes a filter targeting one or more sensitive attributes over both secure and insecure connections)
  - `Secure-only` (allow sensitive attributes to be used in filters over secure connections, but reject any such requests over insecure connections)
- **`allow-in-add`** . Indicates whether sensitive attributes may be included in entries created by LDAP add operations. The value of this property must be one of:
  - `Allow` (allow sensitive attributes to be included in add requests over both secure and insecure connections)
  - `Reject` (reject any add request containing sensitive attributes over both secure and insecure connections)
  - `Secure-only` (allow sensitive attributes to be included in add requests received over a secure connection, but reject any such requests over an insecure connection)
- **`allow-in-compare`** . Indicates whether sensitive attributes may be targeted by the assertion used in a compare operation. The value of this property must be one of:
  - `Allow` (allow sensitive attributes to be targeted by requests over both secure and insecure connections)
  - `Reject` (reject any compare request targeting a sensitive attribute over both secure and insecure connections)
  - `Secure-only` (allow compare requests targeting sensitive attributes over a secure connection, but reject any such requests over an insecure connection)
- **`allow-in-modify`** . Indicates whether sensitive attributes may be updated using modify operations. The value of this property must be one of:
  - `Allow` (allow sensitive attributes to be modified by requests over both secure and insecure connections)
  - `Reject` (reject any modify request updating a sensitive attribute over both secure and insecure connections)
  - `Secure-only` (only modify requests updating sensitive attributes over a secure connection, but reject any such request over an insecure connection)

The `allow-in-returned-entries`, `allow-in-filter`, `allow-in-add`, `allow-in-compare`, and `allow-in-modify` properties all have default values of `secure-only`, which prevents the possibility of exposing sensitive data in the clear to anyone able to observe network communication.

If a client connection policy references a sensitive attribute definition, then any restrictions imposed by that definition will be enforced for any clients associated with that client connection policy. If multiple sensitive attribute definitions are associated with a client connection policy, then the server will use the most restrictive combination of all of those sets.

Note that sensitive attribute definitions work in conjunction with other security mechanisms defined in the server and may only be used to enforce additional restrictions on clients. Sensitive attribute definitions may never be used to grant a client additional access to information that it would not have already had through other means. For example, if the `employeeSSN` attribute is declared to be a sensitive attribute and the `allow-in-returned-entries` property has a value of `Secure-only`, then the `employeeSSN` attribute will only be returned to those clients that have both been granted permission by the access control rules defined in the server and are communicating with the server over a secure connection. The `employeeSSN` attribute will be stripped out of entries returned to clients normally authorized to see it if they are using insecure connections, and it will also be stripped out of entries for clients normally not authorized to see it even if they have established secure connections.

Creating a sensitive attribute

Steps

1. To create a sensitive attribute, you must first create one or more sensitive attribute definitions.

   For example, to create a sensitive attribute definition that will only allow access to the `employeeSSN` attribute by clients using secure connections, the following configuration changes may be made:

   ```
   $ bin/dsconfig create-sensitive-attribute \
     --attribute-name "Employee Social Security Numbers" \
     --set attribute-type:employeeSSN \
     --set include-default-sensitive-operational-attributes:true \
     --set allow-in-returned-entries:secure-only \
     --set allow-in-filter:secure-only \
     --set allow-in-add:secure-only \
     --set allow-in-compare:secure-only \
     --set allow-in-modify:secure-only
   ```

2. Associate those sensitive attribute definitions with the client connection policies for which you want them to be enforced.

   ```
   $ bin/dsconfig set-client-connection-policy-prop --policy-name default \
     --set "sensitive-attribute:Employee Social Security Numbers"
   ```

Configuring global sensitive attributes

About this task

Administrators can assign one or more sensitive attribute definitions to a client connection policy. However, in an environment with multiple client connection policies, it could be easy to add a sensitive attribute definition to one policy but overlook it in another. The Directory Server supports the ability to define sensitive attributes as a global configuration option so that they will automatically be used across all client connection policies.

Steps

- Run **dsconfig** to add a global sensitive attribute across all client connection policies. The following command adds the `employeeSSN` as a global sensitive attribute, which is applied across all client connection policies.

```
$ bin/dsconfig set-global-configuration-prop --add "sensitive-
attribute:employeeSSN"
```

Excluding a global sensitive attribute on a client connection policy

About this task

Administrators can set a global sensitive attribute across all client connection policies. However, there may be cases when a specific directory server must exclude the sensitive attribute as it may not be needed for client connection requests. For example, in most environments it is good to declare the `userPassword` attribute to be a sensitive attribute in a manner that prevents it from being read by external clients. Further, this solution is more secure than protecting the `password` attribute using the server's default global ACI, which only exists for backwards compatibility purposes. If the Data Sync Server is installed, then it does need to be able to access passwords for synchronization purposes. In this case, the administrator can set `userPassword` to be a sensitive attribute in all client connection policies, but exclude it in a policy specifically created for use by the Data Sync Server. The Directory Server provides an `exclude-global-sensitive-attribute` property for this purpose.

Steps

1. Run **dsconfig** to remove the global ACI that limits access to the `userPassword` or `authPassword` attribute. This is present for backwards compatibility.

```
$ bin/dsconfig set-access-control-handler-prop \
  --remove 'global-aci:(targetattr="userPassword || authPassword")
  (version 3.0; acl "Prevent clients from retrieving passwords from the
 server";
  deny (read,search,compare) userdn="ldap:///anyone";)'
```

2. Run **dsconfig** to add the `userPassword` attribute as a global sensitive attribute, which is applied to all client connection policies. Do this by adding the built-in "Sensitive Password Attributes" Sensitive Attribute definition to the Global Configuration.

```
$ bin/dsconfig set-global-configuration-prop \
  --add "sensitive-attribute:Sensitive Password Attributes"
```

3. If the server is designated to synchronize passwords with a Sync Server, then it is necessary to configure a client connection policy for the Sync User to exclude the global sensitive attribute. The following is an example on how to create a new policy if the Data Sync Server binds with the default DN of `cn=Sync User,cn=Root DNs,cn=config`.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Requests by Sync Users" \
  --type simple \
  --set user-auth-type:internal \
  --set user-auth-type:sasl \
  --set user-auth-type:simple \
  --set "included-user-base-dn:cn=Sync User,cn=Root DNs,cn=config"

$ bin/dsconfig create-client-connection-policy \
  --policy-name "Data Sync Server Connection Policy" \
  --set enabled:true \
  --set evaluation-order-index:9998 \
  --set "connection-criteria:Requests by Sync Users" \
  --set "exclude-global-sensitive-attribute:Sensitive Password Attributes"
```

Working with the LDAP Changelog

The Directory Server provides a client-accessible LDAP changelog (based on the Changelog Internet Draft Specification) for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format. The LDAP changelog is typically used by external software to maintain application compatibility between client services.

Overview of the LDAP changelog

The Directory Server provides a client-accessible LDAP changelog (based on the Changelog Internet Draft Specification) for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format. The LDAP changelog is typically used by external software to maintain application compatibility between client services. For example, you can install the Data Sync Server that monitors the LDAP changelog for any updates that occur on a source directory server and synchronizes these changes to a target DIT or database server. The Directory Server provides an additional feature in that the LDAP changelog supports virtual attributes.

ⓘ **Note:** The LDAP Changelog should not be confused with the Replication Changelog. The main distinction is as follows:

- The LDAP Changelog (i.e., the external changelog that clients can access) physically resides at `<server-root>/db/changelog`.
- The Replication Changelog Backend (i.e., the changelog that replication servers use) physically resides at `<server-root>/changelogDB`.

Key changelog features

As of version 3.2, the Directory Server supports two new Changelog Backend properties that allow access control filtering and sensitive attribute evaluation for targeted entries. External client applications can change the contents of attributes they can see in the targeted entry based on the access control rules applied to the associated base DN.

- **apply-access-controls-to-changelog-entry-contents**. Indicates whether the contents of changelog entry attributes (i.e., `changes`, `deletedEntryAttrs`, `ds-changelog-entry-key-attr-values`, `ds-changelog-before-values`, and `ds-changelog-after-values`) are subject to access control and/or sensitive attribute evaluation to limit data that LDAP clients can see. The client must have the access control permissions to read changelog entries to retrieve them in any form. If this feature is enabled and the client does not have permission to read an entry at all, or if that client does not have permission to see any attributes that were targeted by the change, then the associated changelog entries targeted by those operations will be suppressed. If a client does not have permission to see certain attributes within the target entry, then references to those attributes in the changelog entry will also be suppressed. This property only applies to standard LDAP searches of the `cn=changelog` branch.
- **report-excluded-changelog-attributes**. Indicates whether to include additional information about any attributes that may have been removed due to access control filtering. This property only applies to content removed as a result of processing performed by the `apply-access-controls-to-changelog-entry-contents` property. Possible values are:
  - **none** - Indicates that changelog entries should not include any information about attributes that have been removed.
  - **attribute-counts** - Indicates that changelog entries should include a count of user and/ or operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, the number of the excluded user attributes will be reported in the `ds-changelog-num-excluded-user-attributes` attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the number of the excluded operational attributes will be reported in the `ds-changelog-num-excluded-operational-attributes`

attribute of the changelog entry. Both the `ds-changelog-num-excluded-user-attributes` and `ds-changelog-num-excluded-operational-attributes` are operational and must be explicitly requested by clients (or all operational attributes requested using "+") to be returned.

- **attribute-names** - Indicates that changelog entries should include the names of user and/or operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, then the names of the excluded user attributes will be reported in the `ds-changelog-excluded-user-attributes` attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the names of the excluded operational attributes will be reported in the `ds-change-log-excluded-operational-attribute` attribute of the changelog entry. Both the `ds- changelog-excluded-user-attribute` and `ds-changelog-excluded-operational-attribute` attributes are operational and must be explicitly requested by clients (or all operational attributes requested via "+") to be returned.

Enabling access control filtering in the LDAP changelog

About this task

To set up access control to the LDAP Changelog, use the **`dsconfig`** tool to enable the properties to the Changelog Backend. Only admin users with the `bypass-acl` privilege can read the changelog.

Steps

1. Enable the `apply-access-control-to-changelog-entry-contents` property to allow LDAP clients to undergo access control filtering using standard LDAP searches of the `cn=changelog` backend.

   ```
   $ bin/dsconfig set-backend-prop --backend-name "changelog" \
     --set "apply-access-controls-to-changelog-entry-contents:true"
   ```

   Access control filtering will be applied regardless of the value of the `apply-access-controls-to-changelog-entry-contents` setting when the Changelog Backend is servicing requests from an PingDataSync Server that has the `filter-changes-by-user` Sync Pipe property set.
2. Optional. Set the `report-excluded-changelog-attributes` property to include a count of users that have been removed through access control filtering. The count appears in the `ds-changelog-num-excluded-user-attributes` attribute for users and the `ds-changelog-num-excluded-operational-attributes` attribute for operational attributes.

   ```
   $ bin/dsconfig set-backend-prop --backend-name "changelog" \
     --set "report-excluded-changelog-attributes:attribute-counts"
   ```

Useful changelog features

The Directory Server provides two useful changelog configuration properties: `changelog-max-before-after-values` and `changelog-include-key-attribute`.

- **changelog-max-before-after-values**. Setting this property to a non-zero value causes all of the old values and all of the new values (up to the specified maximum) for each changed attribute to be stored in the changelog entry. The values will be stored in the `ds-change-log-before-values` and `ds-`

`changelog-after-values` attributes on the changelog entry. These attributes are not present by default.

> ⓘ **Note:** The `changelog-max-before-after-values` property can be expensive for attributes with hundreds or thousands of values, such as a group entry.

If any attribute has more than the maximum number of values, their names and number of before/after values will be stored in the `ds-changelog-attr-exceeded-max-values-count` attribute on the changelog entry. This is a multi-valued attribute whose format is:

```
attr=attributeName,beforeCount=100,afterCount=101
```

where "attributeName" is the name of the attribute and the "beforeCount" and "afterCount" are the total number of values for that attribute before and after the change, respectively. This attribute indicates that you need to reset the `changelog-max-before-after-values` property to a higher value. When this attribute is set, an alert will be generated.

> ⓘ **Note:** If the number of values for an attribute exceeds the maximum value set by the `changelog-max-before-after-values` property, then those values will not be stored.

- **changelog-include-key-attribute**. This property is used for correlation attributes that need to be synchronized across servers, such as `uid`. It causes the current (after-change) value of the specified attributes to be recorded in the `ds-changelog-entry-key-attr-values` attribute on the changelog entry. This applies for all change types. On a DELETE operation, the values are from the entry before they were deleted.

  The key values will be recorded on every change and override the settings configured in `changelog-include-attribute`, `changelog-exclude-attribute`, `changelog-deleted-entry-include-attribute`, or `changelog-deleted-entry-exclude-attribute`.

Example of the changelog features

After the `changelog-max-before-after-values` property is set, the before-and-after values of any change attribute will be recorded in the LDAP Changelog. For example, given a simple entry with two multi-valued mail attributes:

```
dn: uid=test,dc=example,dc=com
objectclass: inetorgperson
cn: test user
sn: user
description: oldDescription
mail: test@yahoo.com
mail: test@gmail.com
```

Then, apply the following changes to the entry:

```
dn: uid=test,dc=example,dc=com
changetype: modify
add: mail
mail: test@hotmail.com
-
delete: mail
mail: test@yahoo.com
-
replace: description
description: newDescription
```

The resulting changelog would record the following attribute values:

```
dn: changeNumber=1,cn=changelog
```

```
objectClass: top
objectClass: changeLogEntry
targetDN: uid=test,dc=example,dc=com
changeType: modify
changes::

changenumber: 1
```

You can run the **bin/base64** `decode -d` command-line tool to view the decoded value for the changes, `ds-changelog-before-values`, `ds-changelog-after-values` attributes:

After base64 decoding, the `changes` attribute reads:

```
add: mail
mail: test@hotmail.com
-
delete: mail
mail: test@yahoo.com
-
replace: description
description: newDescription
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z
-
```

After base64 decoding, the `ds-changelog-before-values` attribute reads:

```
description: oldDescription
mail: test@yahoo.com
mail: test@gmail.com
modifyTimestamp: 20131010020345.546Z
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
```

After base64 decoding, the `ds-changelog-after-values` attribute reads:

```
description: newDescription
mail: test@gmail.com
mail: test@hotmail.com
modifyTimestamp: 20131010020345.546Z
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
```

Viewing the LDAP changelog properties

You can view the LDAP changelog properties by running the **dsconfig** `get-backend-prop` command and specifying the changelog backend.

Viewing the LDAP changelog properties using dsconfig non-interactive mode

Steps

- Use **dsconfig** to view the changelog properties on the Directory Server. To view "advanced" properties that are normally hidden, add the `--advanced` option when running the command. For a specific description of each property, see the *PingDirectory Server Configuration Reference*.

```
$ bin/dsconfig get-backend-prop --backend-name changelog
```

```
Property                                    : Value(s)
--------------------------------------------:-------------
backend-id                                  : changelog
description                                 : -

use-reversible-form                         : false
je-property                                 : -
```

Enabling the LDAP changelog

By default, the LDAP changelog is disabled on the Directory Server. If you are using the **dsconfig** tool in interactive mode, the changelog appears in the Backend configuration as a Standard object menu item.

ⓘ **Note:** You can enable the feature using the **dsconfig** tool only if required as it can significantly affect LDAP update performance.

Enabling the LDAP changelog using dsconfig non-interactive mode

Steps

- Use **dsconfig** to enable the changelog property on the Directory Server.

```
$ bin/dsconfig set-backend-prop \
  --backend-name changelog --set enabled:true
```

Enabling the LDAP changelog using interactive mode

Steps

1. Use **dsconfig** to enable the changelog on each server in the network. Then, authenticate to the server by entering the host name, LDAP connection, port, bindDN and bind password.

   ```
   $ bin/dsconfig
   ```
2. On the Directory Server main menu, type `o` to change from the Basic object level to the Standard object level.
3. Enter the option to select the Standard Object level.
4. On the Directory Server main menu, type the number corresponding to Backend.
5. On the **Backend Management** menu, enter the option to view and edit an existing backend.
6. Next, you should see a list of the accessible backends on your system. For example, you may see options for the `changelog` and `userRoot` backends. Enter the option to work with the changelog backend.
7. On the **Changelog Backend properties** menu, type the number corresponding to the Enabled property.
8. On the **Enabled Property** menu, type the number to change the `Enabled` property to TRUE.
9. On the **Backend Properties** menu, type `f` to apply the change. If you set up the server in a server group, type `g` to update all of the servers in the group. Otherwise, repeat steps 1-10 on the other servers.
10. Verify that changes made to the data are recorded in the changelog.

Changing the LDAP changelog database location

In cases where disk space issues arise, you can change the on-disk location of the LDAP Change Log database. The changelog backend supports a `db-directory` property that specifies the absolute or relative path (relative to the local server root) to the file system directory that is used to hold the Oracle Berkeley DB Java Edition database files containing the data for this backend.

If you change the changelog database location, you must stop and then restart the Directory Server for the change to take effect. If the changelog backend is already enabled, then the database files must be manually moved or copied to the new location while the server is stopped.

Changing the LDAP changelog location using dsconfig non-interactive mode

Steps

1. Use **dsconfig** to change the database location for the LDAP Changelog, which by default is at `<server-root>/db`. The following command sets the LDAP changelog backend to `<server-root>/db2`. Remember to include the LDAP connection parameters (for example, host name, port, bindDN, bindPassword).

   ```
   $ bin/dsconfig set-backend-prop --backend-name changelog \
     --set "db-directory:db2" --set "enabled:true"
   ```

   The database files are stored under `<server-root>/db2/changelog`. The files for this backend are stored in a sub-directory named after the `backend-id` property.
2. Stop and restart the server. Since the LDAP changelog backend was previous disabled, there is no need to manually relocate any existing database files.

   ```
   $ bin/stop-server
   $ bin/start-server
   ```

Resetting the LDAP changelog location using dsconfig non-interactive mode

Steps

1. If you have changed the LDAP Changelog location, but want to reset it to its original location, use **`dsconfig`** to reset it. The following command resets the LDAP changelog backend to `<server-root>/db` location. Remember to include the LDAP connection parameters (for example, host name, port, bindDN, bindPassword).

   ```
   $ bin/dsconfig set-backend-prop --backend-name changelog \
     --reset "db-directory"
   ```

2. The server attempts to use whatever it finds in the configured location when it starts. If there is nothing there, it will create an empty database. If the LDAP changelog backend at the previous location is enabled at the time, stop the server, manually copy the database files to the new LDAP changelog location, and then restart the server.

Viewing the LDAP changelog parameters in the Root DSE

About this task

The Root DSE is a special entry that holds operational information about the server. The entry provides information about the LDAP controls, extended operations, and SASL mechanisms available in the server as well as the state of the data within the changelog. For changelog parameters, the attributes of interest include:

- **firstChangeNumber**. Change number for the first (oldest) change record contained in the LDAP changelog.
- **lastChangeNumber**. Change number for the last (most recent) change record contained in the LDAP changelog.
- **lastPurgedChangeNumber**. Change number for the last change that was purged from the LDAP changelog. It can be 0 if no changes have yet been purged.
- **firstReplicaChange**. Information about the first (oldest) change record for a change received from the specified replica. This is a multi-valued attribute and should include a value for each server in the replication topology.
- **lastReplicaChange**. Information about the last (most recent) change record for a change received from the specified replica.

The `firstReplicaChange` and `lastReplicaChange` attributes use the following syntax:

```
serverID:CSN:changeNumber
```

where:

- **serverID**. Specifies the unique identifier for the server updating the change log.
- **CSN**. Specifies the Change Sequence Number, which is the time when the update was made to the given replica.
- **changeNumber**. Specifies the order of the change that is logged to the LDAP changelog.

The `firstReplicaChange` and `lastReplicaChange` attributes can be used to correlate information in the local LDAP Change Log with data in the LDAP Change Log of other servers in the replication topology. The order of the individual changes in the LDAP Change Log can vary between servers based on the order in which they were received from a replica.

Steps

- Use **`ldapsearch`** to view the Root DSE.

  ```
  $ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" "+"
  ```

Viewing the LDAP changelog using ldapsearch

All records in the changelog are immediate children of the `cn=changelog` entry and are named with the `changeNumber` attribute. You can view changelog entries using **`ldapsearch`**. Changes are represented in the form documented in the *draft-good-ldap-changelog* specification with the targetDN attribute providing the DN of the updated entry, the `changeType` attribute providing the type of operation (add, delete, modify, or modDN), and the changes attribute providing a base64-encoded representation of the attributes included in the entry (for add operations) or the changes made (for modify operations) in LDIF form. You can view the changes by decoding the encoded value using the **`base64`** `decode` utility. The LDAP SDK for Java also provides support for parsing changelog entries.

Viewing the LDAP changelog using ldapsearch

Steps

1. Grant access to the `cn=changelog` backend to the `uid=admin` account using access control rules. By default, only the root user has access to this backend.

```
$ bin/ldapmodify
dn: cn=changelog
changetype: modify
add: aci
aci: (targetattr="*||+")
  (version 3.0; acl "Access to the changelog backend for the admin
 account";
  allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

2. Use **`ldapsearch`** to view the changelog.

```
$ bin/ldapsearch --baseDN cn=changelog --dontWrap "(objectclass=*)"
```

```
dn: cn=changelog
objectClass: top
objectClass: untypedObject
cn: changelog

dn: changeNumber=1,cn=changelog
objectClass: changeLogEntry
objectClass: top
targetDN: uid=user.0,ou=People,dc=example,dc=com
changeType: modify
changes::
 cmVwbGFjZTogbW9iaWxlCm1vYmlsZTogKzEgMDIwIDE1NCA5Mzk4Ci0KcmVwbGFjZToga

changenumber: 2
```

Viewing the LDAP change sequence numbers

Steps

- The changelog displays the server state information, which is important for failover between servers during synchronization operations. The server state information is exchanged between the servers in the network (LDAP servers and replication servers) as part of the protocol start message. It also helps the client application determine which server is most up-to-date. Make sure that the `uid=admin` account has the necessary access rights to the `cn=changelog` backend.

```
$ bin/ldapsearch --baseDN cn=changelog --dontWrap "(objectclass=*)" "+"
```

```
dn: cn=changelog

dn: changeNumber=1,cn=changelog
entry-size-bytes: 182
targetUniqueId: 68147342-1f61-3465-8489-3de58c532130
changeTime: 20111023002624Z
lastReplicaCSN: 0000011D27184D9E303000000001
replicationCSN: 0000011D27184D9E303000000001
replicaIdentifier: 12336

dn: changeNumber=2,cn=changelog
entry-size-bytes: 263
targetUniqueId: 4e9b7847-edcb-3791-b11b-7505f4a55af4
changeTime: 20111023002624Z
lastReplicaCSN: 0000011D27184F2E303000000002
replicationCSN: 0000011D27184F2E303000000002
replicaIdentifier: 12336
```

Viewing LDAP changelog monitoring information

About this task

The changelog contains a monitor entry that you can access over LDAP, JConsole, the Administrative Console, or SNMP. Make sure that the `uid=admin` account has the necessary access rights to the `cn=changelog` backend.

Steps

- Use **`ldapsearch`** to view the changelog monitor entry.

```
$ bin/ldapsearch --baseDN cn=changelog,cn=monitor "(objectclass=*)"
```

```
dn: cn=changelog,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: extensibleObject
cn: changelog
changelog: cn=changelog
firstchangenumber: 1
lastchangenumber: 8
lastpurgedchangenumber: 0
firstReplicaChange: 16225:0000011D0205237F3F6100000001:5
firstReplicaChange: 16531:0000011CFF334C60409300000002:1
lastReplicaChange: 16225:0000011D02054E8B3F6100000002:7
lastReplicaChange: 16531:0000011CFF334C60409300000002:1
oldest-change-time: 20081015063104Z
...(more data)...
```

Indexing the LDAP changelog

The Directory Server supports attribute indexing in the Changelog Backend to allow Get Changelog Batch requests to filter results that include only changes involving specific attributes. Normally, the directory server that receives a request must iterate over the whole range of changelog entries and then match entries based on search criteria for inclusion in the batch. The majority of this processing also involves determining whether the changelog entry includes changes to a particular attribute or set of attributes, or not. Using changelog indexing, client applications can dramatically speed up throughput when targeting the specific attributes.

Administrators can configure attribute indexing using the `index-include-attribute` and `index-exclude-attribute` properties on the Changelog Backend. The properties can accept the specific attribute name or special LDAP values "*" to specify all user attributes or "+" to specify all operational attributes.

To determine if the directory server supports this feature, administrators can view the Root DSE for the following entry:

```
supportedFeatures: 1.3.6.1.4.1.30221.2.12.3
```

Indexing a changelog attribute

Steps

1. Use **`dsconfig`** to set attribute indexing on an attribute in the Changelog Backend.

   The following command enables the Changelog Backend and sets the backend to include all user attributes ("*") for ADD or MODIFY operations using the `changelog-include-attribute` property. The `changelog-deleted-entry-include-attribute` property is set to all attributes ("*") to specify a set of attribute types that should be included in a changelog entry for DELETE operations. Attributes specified in this list will be recorded in the `deletedEntryAttrs` attribute on the changelog entry when an entry is deleted. The attributes `displayName` and `employeeNumber` are indexed using the `index-include-attribute` property.

   ```
   $ bin/dsconfig set-backend-prop --backend-name changelog \
     --set "enabled:true" \
     --set "changelog-include-attribute:*" \
     --set "changelog-deleted-entry-include-attribute:*" \
     --set "index-include-attribute:displayName" \
     --set "index-include-attribute:employeeNumber"
   ```

2. Add another attribute to index using the **`dsconfig`** `--add` option, which adds the attribute to an existing configuration setting.

   ```
   $ bin/dsconfig set-backend-prop --backend-name changelog \
     --add "index-include-attribute:cn"
   ```

Excluding attributes from indexing

Steps

- Use **`dsconfig`** to set attribute indexing on all user attributes in the Changelog Backend. The following command includes all user attributes except the description and location attributes.

  ```
  $ bin/dsconfig set-backend-prop --backend-name changelog \
    --set "index-include-attribute:*" \
    --set "index-exclude-attribute:description \
    --set "index-exclude-attribute:location
  ```

Tracking virtual attribute changes in the LDAP changelog

About this task

While the LDAP Changelog primarily tracks changes to real attributes, it can also provide information about virtual attributes included in created, updated, or deleted entries. The `include-virtual-attributes` property controls the virtual attribute information to include in changelog entries, and this property may include any or all of the following values:

add-attributes

Indicates that changelog entries for add operations should include a `ds-changelog-virtual-attributes` attribute that lists the virtual attribute values generated for the entry at the time it was created.

deleted-entry-attributes

Indicates that changelog entries for delete operations should include a `ds-changelog-virtual-attributes` attribute that lists the virtual attribute values generated for the entry at the time it was deleted.

before-and-after-values

Indicates that changelog entries for modify and modify DN operations should include `ds-changelog-before-virtual-values` and `ds-changelog-after-virtual-values` attributes that contain the values of virtual attributes that have been updated.

key-attribute-values

Indicates that changelog entries should include a `ds-changelog-entry-key-virtual-values` attribute that holds the values for any virtual attributes included in the set of key attributes, as defined by the `changelog-include-key-attribute` property.

The add-attributes and before-and-after-values options are selected by default.

Steps

- Use **`dsconfig`** to enable virtual attribute change tracking in the LDAP Changelog.

  The following command enables the LDAP changelog and sets `include-virtual-attributes` to `add-attributes`, which indicates that virtual attribute be included in the set of attributes listed for an add operation. The `delete-entry-attributes` option indicates that virtual attributes should be included in the set of deleted entry attributes listed for a delete operation. The `before-and-after-values` option indicates that virtual attributes should be included in the set of before and after values for attributes targeted by the changes. The `key-attribute-values` option indicates that virtual attributes should be included in the set of entry key attribute values.

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
  --set "enabled:true" \
  --set "include-virtual-attributes:add-attributes" \
  --set "include-virtual-attributes:deleted-entry-attributes" \
  --set "include-virtual-attributes: before-and-after-values" \
  --set "include-virtual-attributes: key-attribute-values"
```

Managing Access Control

The PingDirectory Server provides a fine-grained access control model to ensure that users are able to access the information they need, but are prevented from accessing information that they should not be allowed to see. It also includes a privilege subsystem that provides even greater flexibility and protection in many key areas.

This chapter presents the access control model and provides examples that illustrate the use of key access control functionality.

Overview of access control

The access control model uses access control instructions (ACIs), which are stored in the `aci` operational attribute, to determine what a user or a group of users can do with a set of entries, down to the attribute level. The operational attribute can appear on any entry and affects the entry or any subentries within that branch of the directory information tree (DIT).

Access control instructions specifies four items:

- **Resources**. *Resources* are the targeted items or objects that specifies the set of entries and/or operations to which the access control instruction applies. For example, you can specify access to certain attributes, such as the `cn` or `userPassword` password.
- **Name**. *Name* is the descriptive label for each access control instruction. Typically, you will have multiple access control instructions for a given branch of your DIT. The access control name helps describe its purpose. For example, you can configure an access control instructions labelled "ACI to grant full access to administrators."
- **Clients**. *Clients* are the users or entities to which you grant or deny access. You can specify individual users or groups of users using an LDAP URL. For example, you can specify a group of administrators using the LDAP URL: `groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com."`
- **Rights**. *Rights* are permissions granted to users or client applications. You can grant or deny access to certain branches or operations. For example, you can grant `read` or `write` permission to a `telephoneNumber` attribute.

Key access control features

The PingDirectory Server provides important access control features that provide added security for the Directory Server's entries.

Improved validation and security

The Directory Server provides an access control model with strong validation to help ensure that invalid ACIs are not allowed into the server. For example, the Directory Server ensures that all access control rules added over LDAP are valid and can be fully parsed. Any operation that attempts to store one or more invalid ACIs are rejected. The same validation is applied to ACIs contained in data imported from an LDIF file. Any entry containing a malformed `aci` value will be rejected.

As an additional level of security, the Directory Server examines and validates all ACIs stored in the data whenever a backend is brought online. If any malformed ACIs are found in the backend, then the server generates an administrative alert to notify administrators of the problem and places itself in lockdown mode. While in lockdown mode, the server only allows requests from users who have the `lockdown-mode` privilege. This action allows administrators to correct the malformed ACI while ensuring that no sensitive data is inadvertently exposed due to an access control instruction not being enforced. When the problem has been corrected, the administrator can use the **`leave-lockdown-mode`** tool or restart the server to allow it to resume normal operation.

Global ACIs

Global ACIs are a set of ACIs that can apply to entries anywhere in the server (although they can also be scoped so that they only apply to a specific set of entries). They work in conjunction with access control rules stored in user data and provide a convenient way to define ACIs that span disparate portions of the DIT.

In the PingDirectory Server, global ACIs are defined within the server configuration, in the `global-aci` property of configuration object for the access control handler. They can be viewed and managed using configuration tools like **`dsconfig`** and the Administrative Console.

The global ACIs available by default in the PingDirectory Server include:

- Allow anyone (including unauthenticated users) to access key attributes of the root DSE, including: `namingContexts`, `subschemaSubentry`, `supportedAuthPasswordSchemes`, `supportedControl`, `supportedExtension`, `supportedFeatures`, `supportedLDAPVersion`, `supportedSASLMechanisms`, `vendorName`, and `vendorVersion`.
- Allow anyone (including unauthenticated users) to access key attributes of the subschema subentry, including: `attributeTypes`, `dITContentRules`, `dITStructureRules`, `ldapSyntaxes`, `matchingRules`, `matchingRuleUse`, `nameForms`, and `objectClasses`.
- Allow anyone (including unauthenticated users) to include the following controls in requests made to the server: authorization identity request, manage DSA IT, password policy, real attributes only, and virtual attributes only.
- Allow anyone (including unauthenticated users) to request the following extended operations: get symmetric key, password modify request, password policy state, StartTLS, and Who Am I?

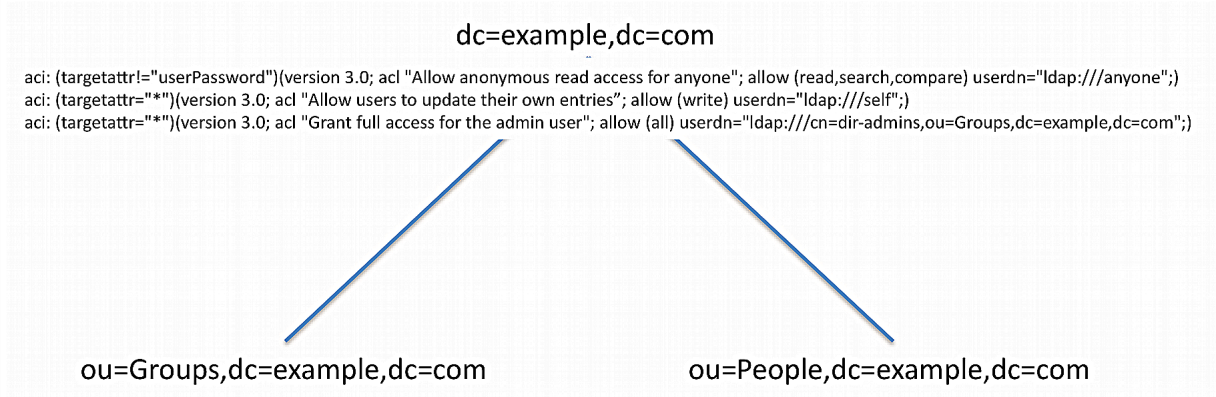
Access controls for public or private backends

The PingDirectory Server classifies backends as either public or private, depending on their intended purpose. A private backend is one whose content is generated by the Directory Server itself (for example, the root DSE, monitor, and backup backends), is used in the operation of the server (for example, the configuration, schema, task, and trust store backends), or whose content is maintained by the server (for example, the LDAP changelog backend). A public backend is intended to hold user-defined content, such as user accounts, groups, application data, and device data.

The PingDirectory Server access control model also supports the distinction between public backends and private backends. Many private backends do not allow writes of any kind from clients, and some of the private backends that do allow writes only allow changes to a specific set of attributes. As a result, any access control instruction intended to permit or restrict access to information in private backends should be defined as global ACIs, rather than attempting to add those instructions to the data for that private backend.

General format of the access control rules

Access control instructions (ACIs) are represented as strings that are applied to one or more entries within the Directory Information Tree (DIT). Typically, an ACI is placed on a subtree, such as `dc=example,dc=com`, and applies to that base entry and all entries below it in the tree. The Directory Server iterates through the DIT to compile the access control rules into an internally-used list of denied and allowed targets and their permissable operations. When a client application, such as **`ldapsearch`**, enters a request, the Directory Server checks that the user who binds with the server has the necessary access rights to the requested search targets. ACIs are cumulatively applied, so that a user who may have an ACI at an entry, may also have other access rights available if ACIs are defined higher in the DIT and are applicable to the user. In most environments, ACIs are defined at the root of a main branch or a subtree, and not on individual entries unless absolutely required.



MY TITLE ACI

An access control rule has a basic syntax as follows:

```
aci : (targets) (version 3.0; acl "name";
  permissions
  bind rules
  ;)
```

Access Control Components

Access Control Component	Description
targets	Specifies the set of entries and/or attributes to which an access control rule applies. Syntax: *(target keyword* = || *!= expression)*
name	Specifies the name of the ACI.
permissions	Specifies the type of operations to which an access control rule might apply. Syntax: *allow||deny (permission)*
bind rules	Specifies the criteria that indicate whether an access control rule should apply to a given requestor. Syntax: *bind rule keyword* = ||*!= expression;*. The bind rule syntax requires that it be terminated with a ";".

Summary of access control keywords

This section provides an overview of the keywords supported for use in the PingDirectory Server access control implementation.

Targets

A target expression specifies the set of entries and/or attributes to which an access control rule applies. The *keyword* specifies the type of target element. The *expression* specifies the items that is targeted by the access control rule. The operator is either the equal ("=") or not-equal ("!="). Note that the "!=" operator cannot be used with `targattrfilters` and `targetscope` keywords. For specific examples on each target keyword, see the section *Working with Targets*.

```
(keyword [=||!=]expression)
```

The following keywords are supported for use in the target portion of ACIs:

Summary of Access Control Target Keywords

Target Keyword	Description	Wildcards
extop	Specifies the OIDs for any extended operations to which the access control rule should apply.	No
target	Specifies the set of entries, identified using LDAP URLs, to which the access control rule applies.	**Yes**
targattrfilters	Identifies specific attribute values based on filters that may be added to or removed from entries to which the access control rule applies.	**Yes**
targetattr	Specifies the set of attributes to which the access control rule should apply.	**Yes**
targetcontrol	Specifies the OIDs for any request controls to which the access control rule should apply.	No

Target Keyword	Description	Wildcards
targetfilter	Specifies one or more search filters that may be used to indicate the set of entries to which the access control should apply.	**Yes**
targetscope	Specifies the scope of entries, relative to the defined target entries or the entry containing the ACI fi there is no target, to which the access control rule should apply.	No

Permissions

Permissions indicate the types of operations to which an access control rule might apply. You can specify if the user or group of users are allowed or not allowed to carry out a specific operation. For example, you would grant read access to a targeted entry or entries using "allow (read)" permission. Or you can specifically deny access to the target entries and/or attributes using the "deny (read)" permission. You can list out multiple permissions as required in the ACI.

```
allow (permission1 ...,
permission2
,...permissionN)
```

```
deny (permission1 ...,
permission2
,...permissionN)
```

The following keywords are supported for use in the permissions portion of ACIs:

Summary of Access Control Permissions

Permission	Description
add	Indicates that the access control should apply to add operations.
compare	Indicates that the access control should apply to compare operations, as well as to search operations with a base-level scope that targets a single entry.
delete	Indicates that the access control should apply to delete operations.
export	Indicates that the access control should only apply to modify DN operations in which an entry is moved below a different parent by specifying a new superior DN in the modify DN request. The requestor must have the `export` permission for operations against the entry's original DN. The requestor must have the `import` permission for operations against the entry's new superior DN. For modify DN operations that merely alter the RDN of an entry but keeps it below the same parent (i.e., renames the entry), only the `write` permission is required. This is true regardless of whether the entry being renamed is a leaf entry or has subordinate entries.
import	See the description for the `export` permission.
proxy	Indicates that the access control rule should apply to operations that attempt to use an alternate authorization identity (for example, operations that include a proxied authorization request control, an intermediate client request control with an alternate authorization identity, or a client that has authenticated with a SASL mechanism that allows an alternate authorization identify to be specified).

Permission	Description
read	Indicates that the access control rule should apply to search result entries returned by the server.
search	Indicates that the access control rule should apply to search operations with a non-base scope.
selfwrite	Indicates that the access control rule should apply to operations in which a user attempts to add or remove his or her own DN to the values for an attribute (for example, whether users may add or remove themselves from groups).
write	Indicates that the access control rule should apply to modify and modify DN operations.
all	An aggregate permission that includes all other permissions except “proxy.” This is equivalent to providing a permission of “add, compare, delete, read, search, selfwrite, write, export, and import.”

Bind rules

The Bind Rules indicate whether an access control rule should apply to a given requester. The syntax for the target keyword is shown below. The *keyword* specifies the type of target element. The expression specifies the items that is targeted by the access control rule. The operator is either equals ("=") or not-equals ("!="). The semi-colon delimiter symbol (";") is required after the end of the final bind rule.

```
keyword [=||!= ] expression;
```

Multiple bind rules can be combined using Boolean operations (AND, OR, NOT) for more access control precision. The standard Boolean rules for evaluation apply: innermost to outer parentheses first, left to right expressions, NOT before AND or OR. For example, an ACI that includes the following bind rule targets all users who are not `uid=admin,dc=example,dc=com` and use simple authentication.

```
(userdn!="ldap:///uid=admin,dc=example,dc=com" and authmethod="simple");
```

The following bind rule targets the `uid=admin,dc=example,dc=com` and authenticates using SASL EXTERNAL or accesses the server from a loopback interface.

```
(userdn="ldap:///uid=admin,dc=example,dc=com and (authmethod="SSL" or
 ip="127.0.0.1"));
```

The following keywords are supported for use in the bind rule portion of ACIs:

Summary of Bind Rule Keywords

Bind Rule Keyword	Description

authmethod	Indicates that the requester's authentication method should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are not allowed in this expression. The keyword's syntax is as follows:
	
	authmethod = *method*
	
	where *method* is one of the following representations:
	▪ none
	▪ simple. Indicates that the client is authenticated to the server using a bind DN and password.
	▪ ssl. Indicates that the client is authenticated with an SSL/TLS certificate (for example, via SASL EXTERNAL), and not just over a secure connection to the server.
	▪ sasl {sasl_mechanism}. Indicates that the client is authenticated to the server using a specified SASL Mechanism.
	
	The following example allows users who authenticate with an SSL/TLS certificate (for example., via SASL EXTERNAL) to update their own entries:
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow users to update their own entries";`
	`   allow (write) (userdn="ldap:///self" and authmethod="ssl");)`

dayofweek	Indicates that the day of the week should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are not allowed in this expression. Multiple day of week values may be separated by commas. The keyword's syntax is as follows:
	
	dayofweek = *day1, day2, ...*
	
	where *day* is one of the following representations:
	▪ sun
	▪ mon
	▪ tues
	▪ wed
	▪ thu
	▪ fri
	▪ sat
	
	The following example allows users who authenticate with an SSL/TLS certificate (for example., via SASL EXTERNAL) on weekdays to update their own entries:
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow users to update their own entries";`
	`   allow (write) (dayofweek!="sun,sat" and userdn="ldap:///`
	`self"`
	`   and authmethod="ssl");)`

Bind Rule Keyword	Description

dns	Indicates that the requester's DNS-resolvable host name should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are allowed in this expression. Multiple DNS patterns may be separated by commas. The keyword's syntax is as follows:
	
	dns = *dns-host-name*
	
	The following example allows users on host name `server.example.com` to update their own entries:
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow users to update their own entries";`
	`  allow (write) (dns="server.example.com" and userdn="ldap:///`
	`self");)`

groupdn	Indicates that the requester's group membership should be taken into account when determining whether the access control rule should apply to any operation. Wildcards are not allowed in this expression.
	
	groupdn [= || !=] "ldap:///groupdn [|| ldap:///groupdn] ..."
	
	The following example allows users in the managers group to update their own entries:
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow users to update their own entries";`
	`  allow (write)`
	`  (groupdn="ldap:///`
	`cn=managers,ou=groups,dc=example,dc=com");)`

Bind Rule Keyword	Description

ip	Indicates that the requester's IP address should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are allowed in this expression. Multiple IP address patterns may be separated by commas. The keyword's syntax is as follows:
	
	ip `[ = || != ]` *ipAddressList*
	
	where *ipAddressList* is one of the following representations:
	▪ A specific IPv4 address: 127.0.0.1
	▪ An IPv4 address with wildcards to specify a subnetwork: 127.0.0.*
	▪ An IPv4 address or subnetwork with subnetwork mask: 123.4.5.0+255.255.255.0
	▪ An IPv4 address range using CIDR notation: 123.4.5.0/24
	▪ An IPv6 address as defined by RFC 2373.
	
	The following example allows users on 10.130.10.2 and localhost to update their own entries:
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow users to update their own entries";`
	`   allow (write) (ip="10.130.10.2,127.0.0.1" and`
	` userdn="ldap:///self");)`

oauthscope	Indicates that the scopes associated with any OAuth 2.0 access token presented by a SCIMv2 client should be taken into account when determining whether the access control rule should apply to an operation. The keyword's syntax is as follows:
	
	`oauthscope [ = || != ] "scopeIdentifier"`
	
	where *scopeIdentifier* is one of the following:
	▪ The name of a single scope to match. The name will be treated as case-sensitive.
	▪ A substring assertion that contains one or more asterisks as wildcards.
	▪ A single asterisk by itself, which will match any scope.
	
	The following example will grant all rights to any client that presented an OAuth 2.0 token that is associated with the "scim_admin" scope:
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Full rights for users with the scim_admin`
	` OAuth 2.0 scope";`
	`    allow (all) oauthscope="scim_admin";)`

Bind Rule Keyword	Description

timeofday	Indicates that the time of day should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are not allowed in this expression. The keyword's syntax is as follows:
	
	`timeofday [ = || != || >= || > || <= || < ] time`
	
	where *time* is one of the following representations:
	
	▪ 4-digit 24-hour time format (0000 to 2359, where the first two digits represent the hour of the day and the last two represent the minute of the hour)
	▪ Wildcards are not allowed in this expression
	
	The following example allows users to update their own entries if the request is received before 12 noon.
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow users who authenticate before noon`
	`    to update their own entries";`
	`    allow (write) (timeofday<1200 and userdn="ldap:///self"`
	`    and authmethod="simple");)`

oauthscope	Indicates that the scopes associated with any OAuth 2.0 access token presented by a SCIMv2 client should be taken into account when determining whether the access control rule should apply to an operation. The keyword's syntax is as follows:
	
	`oauthscope [ = || != ] "scopeIdentifier"`
	
	where *scopeIdentifier* is one of the following:
	
	▪ The name of a single scope to match. The name will be treated as case-sensitive.
	▪ A substring assertion that contains one or more asterisks as wildcards.
	▪ A single asterisk by itself, which will match any scope.
	
	The following example will grant all rights to any client that presented an OAuth 2.0 token that is associated with the "scim_admin" scope:
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Full rights for users with the scim_admin`
	`OAuth 2.0 scope";`
	`    allow (all) oauthscope="scim_admin";)`

Bind Rule Keyword	Description

userattr	Indicates that the requester's relation to the value of the specified attribute should be taken into account when determining whether the access control rule should apply to an operation. A bindType value of `USERDN` indicates that the target attribute should have a value which matches the DN of the authenticated user. A bindType value of `GROUPDN` indicates that the target attribute should have a value which matches the DN of a group in which the authenticated user is a member. A bindType value of `LDAPURL` indicates that the target attribute should have a value that is an LDAP URL whose criteria matches the entry for the authenticated user. Any value other than `USERDN`, `GROUPDN`, or `LDAPURL` is expected to be present in the target attribute of the authenticated user's entry. The keyword's syntax is as follows:
	
	`userattr = attrName# [ bindType || attrValue ]`
	
	where:
	▪ *attrName* = name of the attribute for matching
	▪ *bindType* = USERDN, GROUPDN, LDAPURL
	▪ *attrValue* = an attribute value. Note that the *attrVALUE* of the attribute must match on both the bind entry and the target of the ACI.
	
	The following example allows a manager to change employee's entries. If the bind DN is specified in the *manager* attribute of the targeted entry, the bind rule is evaluated to TRUE.
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow a manager to change employee entries";`
	`   allow (write) userattr="manager#USERDN";)`
	
	The following example allows any member of a group to change employee's entries. If the bind DN is a member of the group specified in the *allowEditors* attribute of the targeted entry, the bind rule is evaluated to TRUE.
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow allowEditors to change employee entries";`
	`   allow (write) userattr="allowEditors#GROUPDN";)`
	
	The following example allows a user's manager to edit that user's entry and any entries below the user's entry up to two levels deep. You can specify up to five levels (0, 1, 2, 3, 4) below the targeted entry, with zero (0) indicating the targeted entry.
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow managers to change employees entries two levels below";`
	`   allow (write) userattr="parent[0,1,2].manager#USERDN";)`
	
	The following example allows any member of the engineering department to update any other member of the engineering department at or below the specified ACI.
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow any member of Eng Dept to update any other member of the`
	`   enginering department at or below the ACI";`
	`   allow (write) userattr="department#ENGINEERING";)`
	
	The following example allows an entry to be updated by any user whose entry matches the criteria defined in the LDAP URL contained in the `allowedEditorCriteria` attribute of the target entry.
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow a user that matches the filter to change entries";`

Bind Rule Keyword	Description

userdn	Indicates that the user's DN should be taken into account when determining whether the access control rule should apply to an operation. The keyword's syntax is as follows:
	
	`userdn [ = || != ] "ldap:///value [ || "ldap:///value ..."]`
	
	where *value* is one of the following representations:
	
	▪ The DN of the target user
	▪ A value of `anyone` to match any client, including unauthenticated clients.
	▪ A value of `all` to match any authenticated client.
	▪ A value of `parent` to match the client authenticated as the user defined in the immediate parent of the target entry.
	▪ A value of `self` to match the client authenticated as the user defined in the target entry.
	
	If the value provided is a DN, then that DN may include wildcard characters to define patterns. A single asterisk will match any content within the associated DN component, and two consecutive asterisks may be used to match zero or more DN components.
	
	The following example allows users to update their own entries:
	
	`aci: (targetattr="*")`
	`  (version 3.0; acl "Allow users to update their own entries";`
	`  allow (write) userdn="ldap:///self";)`

Access token validators

Access token validators verify the tokens that HTTP client applications submit when they request access to protected resources and associate each token with an identity stored in the directory server.

To authenticate to PingDirectory Server's HTTP services, clients use OAuth 2 bearer token authentication to present an access token in the HTTP Authorization request header. To process the incoming access tokens, PingDirectory Server uses access token validators, which determine whether to accept an access token and translate it into a set of properties, called *claims*, which PingDirectory Server's HTTP services use to make access control decisions.

Most access tokens identify a user as its subject using the sub claim. Access token validators can retrieve the token subject's attributes from the directory using an identity mapper, which correlates the access token subject to an LDAP entry.

Access token validators are used by the following services:

- Directory REST API
- SCIM 2
- Delegated Admin
- Consent API

In addition, PingDirectory Server can be configured to accept access tokens provided by LDAP clients using the OAUTHBEARER SASL authentication method.

About access token validator processing

You can configure any number of access token validators for PingDirectory Server.

Each access token validator possesses an evaluation order index, an integer that determines its processing priority when multiple access token validators are configured. Lower values are processed before higher values.

1. If an incoming HTTP request contains an access token, the token is sent to the access token validator with the lowest evaluation order index.
2. The access token validator validates the access token. Validation logic varies by access token validator type, but the validator generally verifies the following information:
   - A trusted source issued the token.
   - The token is not expired.
3. If the access token contains a subject, the access token validator uses its identity mapper to find a matching LDAP entry.
4. If the access token validator is unable to validate the access token, it passes the token to the access token validator with the next lowest evaluation order index, and the previous two steps are repeated.
5. HTTP request processing continues, and the policy request is sent to the HTTP service, such as the Directory REST API, for further evaluation.
6. Using either the access token claims parsed by the access token validator or the LDAP entry found by the identity mapper, the HTTP service determines whether the request should be accepted and which access control rules should be applied. This access control behavior varies by each HTTP service.

> ⓘ **Note:**
>
> Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by PingDirectory Server.

Access token validator types

PingDirectory Server works with a variety of access token validators.

PingFederate access token validator

To verify the access tokens that a PingFederate authorization server issues, the PingFederate access token validator uses HTTP to submit the tokens to PingFederate Server's token introspection endpoint.

This step allows the authorization server to determine whether a token is valid.

> ⓘ **Note:**
>
> Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by PingDirectory Server.

Because this step requires an outgoing HTTP request to the authorization server, the PingFederate access token validator might perform slower than other access token validator types. The validation result is guaranteed to be current, which is an important consideration if the authorization server permits the revocation of access tokens.

Before attempting to use a PingFederate access token validator, create a client that represents the access token validator in the PingFederate configuration. This client must use the Access Token Validation grant type.

Example configuration

In PingFederate, create a client with the following properties:

- Client ID: Ping Identity
- Client authentication: Client Secret
- Allowed grant types: Access Token Validation

Take note of the client secret that is generated for the client, and use the PingDirectory Server's **`dsconfig`** command to create an access token validator, as shown.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
 --mapper-name "User ID Identity Mapper" \
 --type exact-match \
 --set enabled:true \
 --set match-attribute:uid \
 --set match-base-dn:ou=people,dc=example,dc=com
# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031
# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "PingFederate Access Token Validator" \
  --type ping-federate \
  --set enabled:true \
  --set "authorization-server:PingFederate External Server" \
  --set client-id:PingDataGovernance \
  --set "client-secret:<client secret>"
  --set evaluation-order-index:2000
  --set "identity-mapper:User ID Identity Mapper"
```

Replace `<client secret>` with the client secret value generated by the PingFederate client.

JWT access token validator

The JWT access token validator verifies access tokens that are encoded in JSON Web Token (JWT) format, which can be signed in JSON web signature (JWS) format or signed and encrypted in JSON web encryption (JWE) format.

The JWT access token validator inspects the JWT token without presenting it to an authorization server for validation. Because the JWT access token validator does not make a token introspection request for every access token that it processes, it performs faster than the PingFederate access token validator. The access token is self-validated however, so the JWT access token validator cannot determine whether the token has been revoked.

Supported JWS/JWE features

For signed tokens, the JWT access token validator supports the following JWT web algorithm (JWA) types:

- RS256
- RS384
- RS512
- ES256
- ES384
- ES512

For encrypted tokens, the JWT access token validator supports the following key-encryption algorithms:

- RSA-OAEP
- ECDH-ES
- ECDH-ES+A128KW
- ECDH-ES+A192KW
- ECDH-ES+A256KW

For encrypted tokens, the JWT access token validator supports the following content-encryption algorithms:

- A128CBC-HS256
- A192CBC-HS384
- A256CBC-HS512

The JWT access token validator configuration defines three *allow lists* for the JWS/JWE signing and encryption algorithms that it will accept. You should customize these allow lists to reflect only the signing and encryption algorithms used by your access token issuer and no others. Doing so minimizes the access token validator's security threat surface.

Configure these allow lists using the following configuration properties:

- `allowed-signing-algorithm`

  Specifies the signing algorithms that the access token validator accepts.
- `allowed-key-encryption-algorithm`

  Specifies the key-encryption algorithms that the access token validator accepts.
- `allowed-content-encryption-algorithm`

  Specifies the content-encryption algorithms that the access token validator accepts.

Handling signed tokens
All access tokens the JWT access token validator handles must be cryptographically signed by the token issuer. The JWT access token validator validates a token's signature using a public signing key provided by the issuer.

Steps

- Configure the JWT access token validator with the issuer's public signing key in one of two ways:
  - Store the public key as a trusted certificate in PingDirectory Server's local configuration using the `trusted-certificate` property.
  - Provide the issuer's JWKS (JSON Web Key Set) endpoint using the `jwks-endpoint-path` property. The JWT access token validator then retrieves the issuer's public keys when it initializes. This method ensures that the JWT access token validator uses updated copies of the issuer's public keys.

Example: Use a locally configured trusted certificate
The following example configures a JWT access token validator to use a locally stored public signing certificate to validate access token signatures. The signing certificate is assumed to have been obtained out of band and must be a PEM-encoded X.509v3 certificate.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
 --mapper-name "User ID Identity Mapper" \
 --type exact-match \
 --set enabled:true \
 --set match-attribute:uid \
 --set match-base-dn:ou=people,dc=example,dc=com

# Add the public signing certificate to the server configuration
dsconfig create-trusted-certificate \
 --certificate-name "JWT Signing Certificate" \
 --set "certificate</path/to/signing-certificate.pem"

# Create the Access Token Validator
dsconfig create-access-token-validator \
 --validator-name "JWT Access Token Validator" \
 --type jwt \
 --set enabled:true \
 --set evaluation-order-index:1000 \
 --set allowed-signing-algorithm:RS256 \
 --set "trusted-certificate:JWT Signing Certificate"
 --set "identity-mapper:User ID Identity Mapper"
```

Example: Use the issuer's JWKS endpoint

The following example configures a JWT access token validator to retrieve public keys from a PingFederate authorization server's JWKS endpoint.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
 --mapper-name "User ID Identity Mapper" \
 --type exact-match \
 --set enabled:true \
 --set match-attribute:uid \
 --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
 --server-name "PingFederate External Server" \
 --type http \
 --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
 --validator-name "JWT Access Token Validator" \
 --type jwt \
 --set enabled:true \
 --set evaluation-order-index:1000 \
 --set allowed-signing-algorithm:RS256 \
 --set "authorization-server:PingFederate External Server" \
 --set jwks-endpoint-path:/ext/oauth/jwks
 --set "identity-mapper:User ID Identity Mapper"
```

Handling encrypted tokens

Optionally, you can configure the JWT access token validator to accept encrypted access tokens. To do this, you must configure the access token validator with a private/public key pair and provide the public key to the token issuer.

Steps

1. Create an encryption key pair.
2. Create the JWT access token validator.
3. Export the public encryption key from PingDataGovernance Server and provide it to your token issuer.

   Without this public encryption key, the issuer cannot encrypt tokens that can be decrypted by the JWT access token validator.

   You can run **`dsconfig`** to copy the public key to a file, or you can copy the value of the key pair's `certificate-chain` property in the Administrative Console.

Example

The following example configures a JWT access token validator to handle access tokens signed and encrypted using elliptic curve algorithms. For RSA signing and encryption algorithms, the configuration is very similar, but you would choose different values for the `allowed-signing-algorithm` and `allowed-encryption-algorithm` properties.

1. Create an encryption key pair.

```
# Create an encryption key pair
 dsconfig create-key-pair \
 --pair-name "JWT Elliptic Curve Encryption Key Pair" \
```

```
 --set key-algorithm:EC_256
```

2. Create the JWT access token validator.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
 --mapper-name "User ID Identity Mapper" \
 --type exact-match \
 --set enabled:true \
 --set match-attribute:uid \
 --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
 --server-name "PingFederate External Server" \
 --type http \
 --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
 --validator-name "JWT Access Token Validator" \
 --type jwt \
 --set enabled:true \
 --set evaluation-order-index:1000 \
 --set allowed-signing-algorithm:ES256 \
 --set "authorization-server:PingFederate External Server" \
 --set jwks-endpoint-path:/ext/oauth/jwks \
 --set "encryption-key-pair:JWT Elliptic Curve Encryption Key Pair" \
 --set allowed-key-encryption-algorithm:ECDH_ES
 --set "identity-mapper:User ID Identity Mapper"
```

3. Export the public encryption key from PingDataGovernance Server and provide it to your token issuer.

   The following command copies the key to a file.

```
 dsconfig get-key-pair-prop \
 --pair-name "JWT Elliptic Curve Encryption Key Pair" \
 --property certificate-chain \
 --no-prompt \
 --script-friendly > jwt-public-encryption-key.pem
```

Mock access token validator

A mock access token validator is a special access token validator type used for development or testing purposes.

A mock access token validator accepts arbitrary tokens without validating whether a trusted source issued them. This approach allows a developer or tester to make bearer token-authenticated requests without first setting up an authorization server.

Mock access tokens are formatted as plain-text JSON objects using standard JSON web token (JWT) claims.

Always provide the boolean `active` claim when creating a mock token. If this value is `true`, the token is accepted. If this value is `false`, the token is rejected.

If the `sub` claim is provided, a token owner lookup populates the `TokenOwner` policy request attribute, as with the other access token validator types.

The following example cURL command provides a mock access token in an HTTP request.

```
curl -k -X GET https://localhost:8443/scim/v2/Me -H 'Authorization:
 Bearer {"active": true, "sub":"user.3", "scope":"email profile",
 "client":"client1"}'
```

> ⓘ **Important:**
>
> Never use mock access token validators in a production environment because they do not verify whether a trusted source issued an access token.

Example configuration

The configuration for a mock access token validator resembles the configuration for a JWT access token validator. However, the JSON web signature (JWS) signatures require no configuration because mock tokens are not authenticated.

```
# Create an identity mapper that expects the token subject to be a uid
 dsconfig create-identity-mapper \
 --type exact-match \
 --set enabled:true \
 --set match-attribute:uid \
 --set match-base-dn:ou=people,dc=example,dc=com

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "Mock Access Token Validator" \
  --type mock --set enabled:true \
  --set evaluation-order-index:9999
  --set "identity-mapper:User ID Identity Mapper"
```

Third-party access token validator
Third-party access token validator

To create custom access token validators, use the Server SDK.

Working with targets

The following section presents a detailed look and examples of the target ACI keywords: `target`, `targetattr`, `targetfilter`, `targattrfilters`, `targetscope`, `targetcontrol`, and `extop`.

target

The `target` keyword indicates that the ACI should apply to one or more entries at or below the specified distinguished name (DN). The target DN must be equal or subordinate to the DN of the entry in which the ACI is placed. For example, if you place the ACI at the root of `ou=People,dc=example,dc=com`, you can target the DN, `uid=user.1,ou=People,dc=example,dc=com` within your ACI rule. The DN must meet the string representation specification of distinguished names, outlined in RFC 4514, and requires that special characters be properly escaped.

The `target` clause has the following format, where DN is the distinguished name of the entry or branch:

```
(target = ldap:///
                  DN
               )
```

For example, to target a specific entry, you would use a clause such as the following:

```
(target = ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

Note that, in general, specifying a target DN is not recommended. It is better to have the ACI defined in that entry and omit the `target` element altogether. For example, although you can have `(target="ldap:///uid=john.doe,ou=People,dc=example,dc=com)` in any of the `dc=example,dc=com` or `ou=People` entries, it is better for it to be defined in the `uid=john.doe` entry and not explicitly include the `target` element.

The expression allows for the "not equal" (!=) operator to indicate that all entries within the scope of the given branch that do NOT match the expression be targeted for the ACI. Thus, the following expression targets all entries within the subtree that do not match `uid=john.doe`.

```
(target != ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

The `target` keyword also supports the use of asterisk (*) characters as wildcards to match elements within the distinguished name. The following target expression matches all entries that contains and begins with "john.d, " so that entries like "`john.doe,ou=People,dc=example,dc=com`," and "`john.davies,ou=People,dc=example,dc=com`" would match.

```
(target = ldap:///uid=john.d*,ou=People,dc=example,dc=com)
```

The following target expression matches all entries whose DN begins with "john.d," and matches the `ou` attribute. Entries like "`john.doe,ou=People,dc=example,dc=com`," and "`john.davies,ou=asia-branch,dc=example,dc=com`" would match.

```
(target = ldap:///uid=john.d*,ou=*,dc=example,dc=com)
```

Another example of a complete ACI targets the entries in the `ou=People,dc=example,dc=com` branch and the entries below it, and grants the users the privilege to modify all of their user attributes within their own entries.

```
aci:(target="ldap:///ou=People,dc=example,dc=com")
  (targetattr="*")
  (version 3.0; acl "Allow all the ou=People branch to modify their own
 entries";
  allow (write) userdn="ldap:///self";)
```

targetattr

The `targetattr` keyword targets the attributes for which the access control instruction should apply. There are four general forms that it can take in the PingDirectory Server:

- **(targetattr="*")**. Indicates that the access control rule applies to all user attributes. Operational attributes will not automatically be included in this set.
- **(targetattr="+")**. Indicates that the access control rule applies to all operational attributes. User attributes will not automatically be included in this set.
- **(targetattr="attr1||attr2||attr3||...||attrN")**. Indicates that the access control rule applies only to the named set of attributes.
- **(targetattr!="attr1||attr2||attr3||...||attrN")**. Indicates that the access control rule applies to all user attributes except the named set of attributes. It will not apply to any operational attributes.

The targeted attributes can be classified as user attributes and operational attributes. User attributes define the actual data for that entry, while operational attributes provide additional metadata about the entry that can be used for informational purposes, such as when the entry was created, last modified and by whom. Metadata can also include attributes specifying which password policy applies to the user, or overrided default constraints like size limit, time limit, or look-through limit for that user.

The PingDirectory Server distinguishes between these two types of attributes in its access control implementation. The Directory Server does not automatically grant any access at all to operational attributes. For example, the following clause applies only to user attributes and not to operational attributes:

```
(targetattr="*")
```

You can also target multiple attributes in the entry. The following clause targets the common name (cn), surname (sn) and state (st) attribute:

```
(targetattr="cn||sn||st")
```

You can use the "+" symbol to indicate that the rule should apply to all operational attributes, as follows:

```
(targetattr="+")
```

To include all user and all operational attributes, you use both symbols, as follows:

```
(targetattr="*||+")
```

If there is a need to target a specific operational attribute rather than all operational attributes, then it can be specifically included in the values of the `targetattr` clause, as follows:

```
(targetattr="ds-rlim-size-limit")
```

Or if you want to target all user attributes and a specific operational attribute, then you can use them in the `targetattr` clause, as follows:

```
(targetattr="*||ds-rlim-size-limit")
```

The following ACIs are placed on the `dc=example,dc=com` tree and allows any user anonymous read access to all entries except the `userPassword` attribute. The second ACI allows users to update their own contact information. The third ACI allows the `uid=admin` user full access privileges to all user attributes in the `dc=example,dc=com` subtree.

```
aci: (targetattr!="userPassword")(version 3.0; acl "Allow anonymous
   read access for anyone"; allow (read,search,compare) userdn="ldap:///
anyone";)
aci: (targetattr="telephonenumber||street||homePhone||l||st")
  (version 3.0; acl "Allow users to update their own contact info";
   allow (write) userdn="ldap:///self";)
aci: (targetattr="*")(version 3.0; acl "Grant full access for the admin
 user";
  allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

An important note must be made when assigning access to user and operational attributes, which can be outlined in an example to show the implications of the Directory Server not distinguishing between these attributes. It can be easy to inadvertently create an access control instruction that grants far more capabilities to a user than originally intended. Consider the following example:

```
aci: (targetattr!="uid||employeeNumber")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)
```

This instruction is intended to allow a user to update any attribute in his or her own entry with the exception of `uid` and `employeeNumber`. This ACI is a very common type of rule and seems relatively harmless on the surface, but it has very serious consequences for a Directory Server that does not distinguish between user attributes and operational attributes. It allows users to update operational attributes in their own entries, and could be used for a number of malicious purposes, including:

- A user could alter password policy state attributes to become exempt from password policy restrictions.
- A user could alter resource limit attributes and bypass size limit, time limit, and look-through-limit constraints.
- A user could add access control rules to his or her own entry, which could allow them to make their entry completely invisible to all other users including administrators granted full rights by access control rules, but excluding users with the `bypass-acl` privilege, allow them to edit any other attributes in their

own entry including those excluded by rules like `uid` and `employeeNumber` in the example above, or add, modify, or delete any entries below his or her own entry.

Because the PingDirectory Server does not automatically include operational attributes in the target attribute list, these kinds of ACIs do not present a security risk for it. Also note that users cannot add ACIs to any entries unless they have the `modify-acl` privilege.

Another danger in using the `(targetattr!="x")` pattern is that two ACIs within the same scope could have two different `targetattr` policies that cancel each other out. For example, if one ACI has `(targetattr!="cn||sn")` and a second ACI has `(targetattr!="userPassword")`, then the net effect is `(targetattr="*")`, because the first ACI inherently allows `userPassword`, and the second allows `cn` and `sn`.

targetfilter

The `targetfilter` keyword targets all attributes that match results returned from a filter. The `targetfilter` clause has the following syntax:

```
(targetfilter =
                    ldap_filter
                )
```

For example, the following clause targets all entries that contain "ou=engineering" attribue:

```
(targetfilter = "(ou=engineering)")
```

You can only specify a single filter, but that filter can contain multiple elements combined with the OR operator. The following clause targets all entries that contain "ou=engineering," "ou=accounting," and "ou=marketing."

```
(targetfilter = "(|(ou=engineering)(ou=accounting)(ou=marketing)")
```

The following example allows the user, `uid=eng-mgr`, to modify the `departmentNumber`, `cn`, and `sn` attributes for all entries that match the filter `ou=engineering`.

```
aci:(targetfilter="(ou=engineering)")
  (targetattr="departmentNumber||cn||sn")
  (version 3.0; acl "example"; allow (write)
   userdn="ldap:///uid=eng-mgr,dc=example,dc=com";)
```

targattrfilters

The `targattrfilters` keyword targets specific attribute *values* that match a filtered search criteria. This keyword allows you to set up an ACI that grants or denies permissions on an attribute value if that value meets the filter criteria. The `targattrfilters` keyword applies to individual values of an attribute, not to the whole attribute. The keyword also allows the use of wildcards in the filters.

The keyword clause has the following formats:

```
(target = "add=attr1:Filter1 && attr2:Filter2... && attrn:FilterN,
del=attr1:Filter1 && attr2:Filter2 ... && attrN:FilterN" )
```

where

- **add** represents the operation of adding an attribute value to the entry
- **del** represents the operation of removing an attribute value from the entry
- **attr1, attr2... attrN** represents the targeted attributes
- **filter1, filter2 ... filterN** represents filters that identify matching attribute values

The following conditions determine when the attribute must satisfy the filter:

- When adding or deleting an entry containing an attribute targeted a `targattrfilters` element, each value of that attribute must satisfy the corresponding filter.

- When modifying an entry, if the operation adds one or more values for an attribute targeted by a `targattrfilters` element, each value must satisfy the corresponding filter. If the operation deletes one or more values for a targeted attribute, each value must satisfy the corresponding filter.
- When replacing the set of values for an attribute targeted by a `targattrfilters` element, each value removed must satisfy the delete filters, and each value added must satisfy the add filters.

The following example allows any user who is part of the `cn=directory server admins` group to add the `soft-delete-read` privilege.

```
aci:(targattrfilter="add=ds-privilege-name:(ds-privilege-name=soft-delete-
read)")
  (version 3.0; acl "Allow members of the directory server admins group to
 grant the
   soft-delete-read privilege"; allow (write)
   groupdn="ldap:///cn=directory server admins,ou=group,dc=example,dc=com";)
```

targetscope

The `targetscope` keyword is used to restrict the scope of an access control rule. By default, ACIs use a subtree scope, which means that they are applied to the target entry (either as defined by the target clause of the ACI, or the entry in which the ACI is define if it does not include a target), and all entries below it. However, adding the `targetscope` element into an access control rule can restrict the set of entries to which it applies.

The following `targetscope` keyword values are allowed:

- **base**. Indicates that the access control rule should apply only to the target entry and not to any of its subordinates.
- **onelevel**. Indicates that the access control rule should apply only to entries that are the immediate children of the target entry and not to the target entry itself, nor to any subordinates of the immediate children of the target entry.
- **subtree**. Indicates that the access control rule should apply to the target entry and all of its subordinates. This is the default behavior if no `targetscope` is specified.
- **subordinate**. Indicates that the access control rule should apply to all entries below the target entry but not the target entry itself.

The following ACI targets all users to view the operational attributes (`supportedControl`, `supportedExtension`, `supportedFeatures`, `supportedSASLMechanisms`, `vendorName`, and `vendorVersion`) present in the root DSE entry. The `targetscope` is base to limit users to view only those attributes in the root DSE.

```
aci: (target="ldap:///")(targetscope="base")
    (targetattr="supportedControl||supportedExtension||
     supportedFeatures||supportedSASLMechanisms||vendorName||vendorVersion")
    (version 3.0; acl "Allow users to view Root DSE Operational Attributes";
     allow (read,search,compare) userdn="ldap:///anyone")
```

targetcontrol

The `targetcontrol` keyword is used to indicate whether a given request control can be used by those users targeted in the ACI. Multiple OIDs can be provided by separating them with the two pipe characters (optionally surrounded by spaces). Wildcards are not allowed when specifying control OIDs.

The following ACI example shows the controls required to allow an administrator to use and manage the Soft-Delete feature. The Soft Delete Request Control allows the user to soft-delete an entry, so that it could be undeleted at a later time. The Hard Delete Request Control allows the user to permanently remove an entry or soft-deleted entry. The Undelete Request Control allows the user to undelete a currently soft-deleted entry. The Soft-Deleted Entry Access Request Control allows the user to search for any soft-deleted entries in the server.

```
aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.22||
```

```
   1.3.6.1.4.1.30221.2.5.23||1.3.6.1.4.1.30221.2.5.24")
  (version 3.0; acl "Allow admins to use the Soft Delete Request Control,
   Hard Delete Request Control,Undelete Request Control, and
   Soft-deleted entry access request control";
   allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

extOp

The `extop` keyword can be used to indicate whether a given extended request operation can be used. Multiple OIDs can be provided by separating them with the two pipe characters (optionally surrounded by spaces). Wildcards are not allowed when specifying extended request OIDs.

The following ACI allows the `uid=user-mgr` to use the Password Modify Request (i.e., OID=1.3.6.1.4.1.4203.1.11.1) and the StartTLS (i.e., OID=1.3.6.1.4.1.1466.20037) extended request OIDs.

```
aci:(extop="1.3.6.1.4.1.4203.1.11.1 || 1.3.6.1.4.1.1466.20037")
  (version 3.0; acl "Allows the mgr to use the Password Modify Request and
 StartTLS;
   allow(read) userdn="ldap:///uid=user-mgr,ou=people,dc=example,dc=com";)
```

Examples of common access control rules

This section provides a set of examples that demonstrate access controls that are commonly used in your environment. Note that to be able to alter access control definitions in the server, a user must have the `modify-acl` privilege as discussed later in this chapter.

Administrator access

The following ACI can be used to grant any member of the "`cn=admins,ou=groups,dc=example,dc=com`" group to add, modify and delete entries, reset passwords and read operational attributes such as `isMemberOf` and password policy state:

```
aci: (targetattr="+")(version 3.0; acl "Administrators can read, search or
 compare operational attributes";
allow (read,search,compare) groupdn="ldap:///
cn=admins,ou=groups,dc=example,dc=com";)
aci: (targetattr="*")(version 3.0; acl "Administrators can add, modify and
 delete entries";
allow (all) groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com";)
```

Anonymous and authenticated access

The following ACI allow anonymous read, search and compare on select attributes of `inetOrgPerson` entries while authenticated users can access several more. The authenticated user will inherit the privileges of the anonymous ACI. In addition, the authenticated user can change `userPassword`:

```
aci: (targetattr="objectclass || uid || cn || mail || sn || givenName")
(targetfilter="(objectClass=inetorgperson)")
(version 3.0; acl "Anyone can access names and email addresses of entries
 representing people";
allow (read,search,compare) userdn="ldap:///anyone";)
aci: (targetattr="departmentNumber || manager || isMemberOf")
(targetfilter="(objectClass=inetorgperson)")
(version 3.0; acl "Authenticated users can access these fields for entries
 representing people";
allow (read,search,compare) userdn="ldap:///all";)
aci: (targetattr="userPassword")(version 3.0; acl "Authenticated users can
 change password";
allow (write) userdn="ldap:///all";)
```

If no unauthenticated access should be allowed to the Directory Server, the preferred method for preventing unauthenticated, or anonymous access is to set the Global Configuration property `reject-unauthenticated-requests` to true.

Delegated access to a manager

The following ACI can be used to allow an employee's manager to edit the value of the employee's `telephoneNumber` attribute. This ACI uses the `userattr` keyword with a bind type of `USERDN`, which indicates that the target entry's manager attribute must have a value equal to the DN of the authenticated user:

```
aci: (targetattr="telephoneNumber")
(version 3.0; acl "A manager can update telephone numbers of her direct
 reports";
allow (read,search,compare,write) userattr="manager#USERDN";)
```

Proxy authorization

The following ACIs can be used to allow the application "`cn=OnBehalf,ou=applications,dc=example,dc=com`" to use the proxied authorization v2 control to request that operations be performed using an alternate authorization identity. The application user is also required to have the `proxied-auth` privilege as discussed later in this chapter:

```
aci: (version 3.0;acl "Application OnBehalf can proxy as another entry";
allow (proxy) userdn="ldap:///cn=OnBehalf,ou=applications,dc=example,dc=com";)
```

Validating ACIs before migrating data

Many directory servers allow for less restrictive application of their access control instructions, so that they accept invalid ACIs. For example, if Sun/Oracle encounters an access control rule that it cannot parse, then it will simply ignore it without any warning, and the server may not offer the intended access protection. Rather than unexpectedly exposing sensitive data, the PingDirectoryProxy Server rejects any ACIs that it cannot interpret, which ensures data access is properly limited as intended, but it can cause problems when migrating data with existing access control rules to a PingDirectoryProxy Server.

To validate an access control instruction, the PingDirectoryProxy Server provides a **`validate-acis`** tool in the `bin` directory (UNIX or Linux systems) or `bat` directory (Windows systems) that identifies any ACI syntax problems before migrating data. The tool can examine access control rules contained in either an LDIF file or an LDAP directory and write its result in LDIF with comments providing information about any problems that were identified. Each entry in the output will contain only a single ACI, so if an entry in the input contains multiple ACIs, then it may be present multiple times in the output, each time with a different ACI value. The entries contained in the output contains only ACI values, and all other attributes will be ignored.

Validating ACIs from a file

About this task

The **`validate-acis`** tool can process data contained in an LDIF file. It will ignore all attributes except `aci`, and will ignore all entries that do not contain the `aci` attribute, so any existing LDIF file that contains access control rules may be used.

Steps

1. Run the **`bin/validate-acis`** tool (UNIX or Linux systems) or **`bat\validate-acis`** (Win dows systems) by specifying the input file and output file. If the output file already exists, the existing contents will be re-written. If no output file is specified, then the results will be written to standard output.

```
$ bin/validate-acis --ldifFile test-acis.ldif --outputFile validated-
acis.ldif
```

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

2. Review the results by opening the output file. For example, the `validated-acis.ldif` file that was generated in the previous step reads as follows:

```
# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr!="userPassword")
  (version 3.0; acl "Allow anonymous read access for anyone";
    allow (read,search,compare) userdn="ldap:///anyone";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

3. If the input file has any malformed ACIs, then the generated output file will show what was incorrectly entered. For example, remove the quotation marks around `userPassword` in the original `test-acis.ldif` file, and re-run the command. The following command uses the `--onlyReportErrors` option to write any error messages to the output file only if a malformed ACI syntax is encountered.

```
$ bin/validate-acis --ldifFIle test-acis.ldif --outputFile validated-
acis.ldif \
  --onlyReportErrors
```

```
# Processing complete
# Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

The output file shows the following message:

```
# The following access control rule is malformed or contains an unsupported
# syntax: The provided string '(targetattr!=userPassword)(version 3.0; acl
# "Allow anonymous read access for anyone"; allow (read,search,compare)
# userdn="ldap:///anyone";)' could not be parsed as a valid Access Control
# Instruction (ACI) because it failed general ACI syntax evaluation
dn: dc=example,dc=com
aci: (targetattr!=userPassword)
  (version 3.0; acl "Allow anonymous read access for anyone";
    allow (read,search,compare) userdn="ldap:///anyone";)
```

```
# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

Validating ACIs in another Directory Server

About this task

The **validate-acis** tool also provides the ability to examine ACIs in data that exists in another Directory Server that you are planning to migrate to the PingDirectory Server. The tool helps to determine whether the Ping Identity Server accepts those ACIs.

Steps

- To use it in this manner, provide arguments that specify the address and port of the target Directory Server, credentials to use to bind, and the base DN of the subtree containing the ACIs to validate.

```
$ bin/validate-acis
```

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

Migrating ACIs from Sun/Oracle to PingDirectory Server

This section describes the most important differences in access control evaluation between Sun/Oracle and the PingDirectory Server.

Support for macro ACIs

Sun/Oracle provides support for macros ACIs, making it possible to define a single ACI that can be used to apply the same access restrictions to multiple branches in the same basic structure. Macros ACIs are infrequently used and can cause severe performance degradation, so support for macros ACIs is not included in the PingDirectory Server. However, you can achieve the same result by simply creating the same ACIs in each branch.

Support for the roleDN bind rule

Sun/Oracle roles are a proprietary, non-standard grouping mechanism that provide little value over standard grouping mechanisms. The PingDirectory Server does not support DSEE roles and does not support the use of the `roleDN` ACI bind rule. However, the same behavior can be achieved by converting the DSEE roles to standard groups and using the `groupDN` ACI bind rule.

Targeting operational attributes

The Sun/Oracle access control model does not differentiate between user attributes and operational attributes. With Sun/Oracle, using `targetattr="*"` will automatically target both user and operational attributes. Using an exclusion list like `targetattr!="userPassword"` will automatically target all operational attributes in addition to all user attributes except `userPassword`. This behavior is responsible for several significant security holes in which users are unintentionally given access to operational

attributes. In some cases, it allows users to do things like exempt themselves from password policy restrictions.

In the PingDirectory Server, operational attributes are treated differently from user attributes and operational attributes are never automatically included. As such, `targetattr="*"` will target all user attributes but no operational attributes, and `targetattr!="userPassword"` will target all users attributes except `userPassword`, but no operational attributes. Specific operational attributes can be targeted by including the names in the list, like `targetattr="creatorsName||modifiersName"`. All operational attributes can be targeted using the `"+"` character. So, `targetattr="+"` targets all operational attributes but no user attributes and `targetattr="*||+"` targets all user and operational attributes.

Specification of global ACIs

Both DSEE and PingDirectory Server support global ACIs, which can be used to define ACIs that apply throughout the server. In servers with multiple naming contexts, this feature allows you to define a rule once as a global ACI, rather than needing to maintain an identical rule in each naming context.

In DSEE, global ACIs are created by modifying the root DSE entry to add values of the `aci` attribute. In the PingDirectory Server, global ACIs are managed with **`dsconfig`** referenced in the `global-aci` property of the Access Control Handler.

Defining ACIs for non-user content

In DSEE, you can write to the configuration, monitor, changelog, and tasks backends to define ACIs. In the PingDirectory Server, access control for private backends, like configuration, monitor, schema, changelog, tasks, encryption settings, backups, and alerts, should be defined as global ACIs.

Limiting access to controls and extended operations

DSEE offers limited support for restricting access to controls and extended operations. To the extent that it is possible to control such access with ACIs, DSEE defines entries with a DN such as "`oid={oid},cn=features,cn=config`" where `{oid}` is the OID of the associated control or extended operation. For example, the following DSEE entry defines ACIs for the persistent search control: "`oid=2.16.840.1.113730.3.4.3,cn=features,cn=config`".

In the PingDirectory Server, the "`targetcontrol`" keyword can be used to define ACIs that grant or deny access to controls. The "`extop`" keyword can be used to define ACIs that grant or deny access to extended operation requests.

Tolerance for malformed ACI values

In DSEE, if the server encounters a malformed access control rule, it simply ignores that rule without any warning. If this occurs, then the server will be running with less than the intended set of ACIs, which may prevent access to data that should have been allowed or, worse yet, may grant access to data that should have been restricted.

The PingDirectory Server is much more strict about the access control rules that it will accept. When performing an LDIF import, any entry containing a malformed or unsupported access control rule will be rejected. Similarly, any add or modify request that attempts to create an invalid ACI will be rejected. In the unlikely event that a malformed ACI does make it into the data, then the server immediately places itself in lockdown mode, in which the server terminates connections and rejects requests from users without the `lockdown-mode` privilege. Lockdown mode allows an administrator to correct the problem without risking exposure to user data.

ⓘ **Note:** Consider running the **`import-ldif`** tool with the `--rejectFile` option so that you can review any rejected ACIs.

About the privilege subsystem

In DSEE, only the root user is exempt from access control evaluation. While administrators can create ACIs that give "normal" users full access to any content, they can also create ACIs that would make some portion of the data inaccessible even to those users. In addition, some tasks can only be accomplished by the root user and you cannot restrict the capabilities assigned to that root user.

The PingDirectory Server offers a privilege subsystem that makes it possible to control the capabilities available to various users. Non-root users can be granted limited access to certain administrative capabilities, and restrictions can be enforced on root users. In addition, certain particularly risky actions (such as the ability to interact with the server configuration, change another user's password, impersonate another user, or shutdown and restart the server) require that the requester have certain privileges in addition to sufficient access control rights to process the operation.

Identifying unsupported ACIs

The PingDirectory Server provides a **`validate-acis`** tool that can be used to examine content in an LDIF file or data in another directory server (such as a DSEE instance) to determine whether the access control rules contained in that data are suitable for use in the PingDirectory Server instance. When migrating data from a DSEE deployment into a PingDirectory Server instance, the **`validate-acis`** tool should first be used to determine whether ACIs contained in the data are acceptable. If any problems are identified, then the data should be updated to correct or redefine the ACIs so that they are suitable for use in the PingDirectory Server.

For more information about using this tool, see *Validating ACIs Before Migrating Data*.

Working with privileges

In addition to the access control implementation, the PingDirectory Server includes a privilege subsystem that can also be used to control what users are allowed to do. The privilege subsystem works in conjunction with the access control subsystem so that privileged operations are only allowed if they are allowed by the access control configuration and the user has all of the necessary privileges.

Privileges can be used to grant normal users the ability to perform certain tasks that, in most other directories, would only be allowed for the root user. In fact, the capabilities extended to root users in the PingDirectory Server are all granted through privileges, so you can create a normal user account with the ability to perform some or all of the same actions as root users.

Administrators can also remove privileges from root users so that they are unable to perform certain types of operations. Multiple root users can be defined in the server with different sets of privileges so that the capabilities that they have are restricted to only the tasks that they need to be able to perform.

Available privileges

The following privileges are defined in the PingDirectory Server.

Summary of Privileges

Privilege	Description
audit-data-security	This privilege is required to initiate a data security audit on the server, which is invoked by the **`audit-data-security`** tool.
backend-backup	This privilege is required to initiate an online backup through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
backend-restore	This privilege is required to initiate an online restore through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.

Privilege	Description
bypass-acl	This privilege allows a user to bypass access control evaluation. For a user with this privilege, any access control determination made by the server immediately returns that the operation is allowed. Note, however, that this does not bypass privilege evaluation, so the user must have the appropriate set of additional privileges to be able to perform any privileged operation (for example, a user with the `bypass-acl` privilege but without the `config-read` privilege is not allowed to access the server configuration).
bypass-pw-policy	This privilege allows a user entry to bypass password policy evaluation. This privilege is intended for cases where external synchronization might require passwords that violate the password validation rules. The privilege is also evaluated for bind operations, meaning password restrictions are also bypassed when binding as a user who has this privilege.
bypass-read-acl	This privilege allows the associated user to bypass access control checks performed by the server for bind, search, and compare operations. Access control evaluation may still be enforced for other types of operations.
config-read	This privilege is required for a user to access the server configuration. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to see.
config-write	This privilege is required for a user to alter the server configuration. The user is also required to have the `config-read` privilege. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to alter.
disconnect-client	This privilege is required for a user to request that an existing client connection be terminated. The connection is terminated through the disconnect client task. The server's access control configuration must also allow the user to add the corresponding entry to the tasks backend.
jmx-notify	This privilege is required for a user to subscribe to JMX notifications generated by the Directory Server. The user is also required to have the `jmx-read` privilege.
jmx-read	This privilege is required for a user to access any information provided by the Directory Server via the Java Management Extensions (JMX).
jmx-write	This privilege is required for a user to update any information exposed by the Directory Server via the Java Management Extensions (JMX). The user is also required to have the `jmx-read` privilege. Note that currently all of the information exposed by the server over JMX is read-only.
ldif-export	This privilege is required to initiate an online LDIF export through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, you can set up a global ACI that allows access to members of an Administrators group.
ldif-import	This privilege is required to initiate an online LDIF import through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, configure the global ACI as shown in the previous description of the **`ldif-export`** privilege.
lockdown-mode	This privilege allows the associated user to request that the server enter or leave lockdown mode, or to perform operations while the server is in lockdown mode.

Privilege	Description
modify-acl	This privilege is required for a user to add, modify, or remove access control rules defined in the server. The server's access control configuration must also allow the user to make the corresponding change to the `aci` operational attribute.
password-reset	This privilege is required for one user to be allowed to change another user's password. This privilege is not required for a user to be allowed to change his or her own password. The user must also have the access control instruction privilege to write the `userPassword` attribute to the target entry.
privilege-change	This privilege is required for a user to change the set of privileges assigned to a user, including the set of privileges, which are automatically granted to root users. The server's access control configuration must also allow the user to make the corresponding change to the `ds-privilege-name` operational attribute.
proxied-auth	This privilege is required for a user to request that an operation be performed with an alternate authorization identity. This privilege applies to operations that include the proxied authorization v1 or v2 control operations that include the intermediate client request control with a value set for the client identity field, or for SASL bind requests that can include an authorization identity different from the authentication identity.
server-restart	This privilege is required to initiate a server restart through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
server-shutdown	This privilege is required to initiate a server shutdown through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
soft-delete-read	This privilege is required for a user to access a soft-deleted-entry.
stream-values	This privilege is required for a user to perform a stream values extended operation, which obtains all entry DNs and/or all values for one or more attributes for a specified portion of the DIT.
unindexed-search	This privilege is required for a user to be able to perform a search operation in which a reasonable set of candidate entries cannot be determined using the defined index and instead, a significant portion of the database needs to be traversed to identify matching entries. The server's access control configuration must also allow the user to request the search.
update-schema	This privilege is required for a user to modify the server schema. The server's access control configuration must allow the user to update the operational attributes that contain the schema elements.

Privileges automatically granted to root users

The special abilities that root users have are granted through privileges. Privileges can be assigned to root users in two ways:

- By default, root users may be granted a specified set of privileges. Note that it is possible to create root users which are not automatically granted these privileges by including the `ds-cfg-inherit-default-root-privileges` attribute with a value of FALSE in the entries for those root users.
- Individual root users can have additional privileges granted to them, and/or some automatically-granted privileges may be removed from that user.

The set of privileges that are automatically granted to root users is controlled by the `default-root-privilege-name` property of the Root DN configuration object. By default, this set of privileges includes:

- audit-data-security
- backend-backup
- backend-restore
- bypass-acl
- config-read
- config-write
- disconnect-client
- ldif-export
- lockdown-mode
- manage-topology
- metrics-read
- modify-acl
- password-reset
- permit-get-password-policy-state-issues
- privilege-change
- server-restart
- server-shutdown
- soft-delete-read
- stream-values
- unindexed-search
- update-schema

The privileges not granted to root users by default includes:

- bypass-pw-policy
- bypass-read-acl
- jmx-read
- jmx-write
- jmx-notify
- permit-externally-processed-authentication
- permit-proxied-mschapv2-details
- proxied-auth

The set of default root privileges can be altered to add or remove values as necessary. Doing so will require the `config-read`, `config-write`, and `privilege-change` privileges, as well as either the `bypass-acl` privilege or sufficient permission granted by the access control configuration to make the change to the server's configuration.

Assigning additional privileges for administrators

To allow access to the Tasks backend, set up a global ACI that allows access to members of an Administrators group as follows:

```
$ dsconfig set-access-control-handler-prop \
  --add 'global-aci:(target="ldap:///cn=tasks")(targetattr="*||+")
        (version 5.0; acl "Access to the tasks backend for administrators";
         allow (all) groupdn="ldap:///
         cn=admins,ou=groups,dc=example,dc=com";)'
```

Assigning privileges to normal users and individual root users

Privileges can be granted to normal users on an individual basis. This can be accomplished by adding the `ds-privilege-name` operational attribute to that user's entry with the names of the desired privileges. For example, the following change will grant the `proxied-auth` privilege to the `uid=proxy,dc=example,dc=com` account:

```
dn: uid=proxy,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: proxied-auth
```

The user making this change will be required to have the `privilege-change` privilege, and the server's access control configuration must also allow the requester to write to the `ds-privilege-name` attribute in the target user's entry.

This same method can be used to grant privileges to root users that they would not otherwise have through the set of default root privileges. You can also remove default root privileges from root users by prefixing the name of the privilege to remove with a minus sign. For example, the following change grants a root user the `jmx-read` privilege in addition to the set of default root privileges, and removes the `server-restart` and `server-shutdown` privileges:

```
dn: cn=Sync Root User,cn=Root DNs,cn=config
changetype: modify
add: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: -server-restart
ds-privilege-name: -server-shutdown
```

Note that because root user entries exist in the configuration, this update requires the `config-read` and `config-write` privileges in addition to the `privilege-change` privilege.

Disabling privileges

Although the privilege subsystem in the PingDirectory Server is a very powerful feature, it might break some applications if they expect to perform some operation that requires a privilege that they do not have. In the vast majority of these cases, you can work around the problem by simply assigning the necessary privilege manually to the account used by that application. However, if this workaround is not sufficient, or if you need to remove a particular privilege (for example, to allow anyone to access information via JMX without requiring the `jmx-read` privilege), then privileges can be disabled on an individual basis.

The set of disabled privileges is controlled by the `disabled-privilege` property in the global configuration object. By default, no privileges are disabled. If a privilege is disabled, then the server behaves as if all users have that privilege.

Working with proxied authorization

The Directory Server supports the Proxied Authorization Control (RFC 4370) to allow an authorized LDAP client to authenticate to the server as another user. Typically, LDAP servers are deployed as backend authentication systems that store user credentials and authorization privileges necessary to carry out an operation. Single sign-on (SSO) systems can retrieve user credentials from the Directory Server and then issue permissions that allow the LDAP client to request operations under the identity as another user. The use of the proxied authorization control provides a means for client applications to securely process requests without the need to bind or re-authenticate to the server for each and every operation.

The Directory Server supports the proxied authorization V1 and V2 request controls. The proxied authorization V1 request control is based on early versions of the draft-weltman-ldapv3-proxy Internet draft and is available primarily for legacy systems. It is recommended that deployments use the proxied authorization V2 request control based on RFC 4370.

The proxied authorization V2 control is used to request that the associated operation be performed as if it has been requested by some other user. This control may be used in conjunction with add, delete, compare, extended, modify, modify DN, and search requests. In that case, the associated operation will be processed under the authority of the specified authorization identity rather than the identity associated with the client connection (i.e., the user as whom that connection is bound). The target authorization identity for this control is specified as an "authzid" value, which should be either "dn:" followed by the distinguished name of the target user, or "u:" followed by the user name.

Note that because of the inherent security risks associated with the use of the proxied authorization control, most directory servers that support its use enforce strict restrictions on the users that are allowed to request this control. If a user attempts to use the proxied authorization V2 request control and does not have sufficient permission to do so, then the server will return a failure response with the `AUTHORIZATION_DENIED` result code.

Configuring proxied authorization

About this task

Configuring proxied authorization requires a combination of access control instructions and the `proxied-auth` privilege to the entry that will perform operations as another user.

> ⓘ **Note:** You cannot use the `cn=Directory Manager` root DN as a proxying DN.

Steps

1. Open a text editor and create a user entry, such as `uid=clientApp`, which is the user entry that will request operations as another user, `uid=admin,dc=example,dc=com`. The client application entry also requires the `proxied-auth` privilege to allow it to run proxied authorization requests. Save the file as `add-user.ldif`.

```
dn: ou=Applications,dc=example,dc=com
objectClass: top
objectClass: organizationalUnit
objectClass: extensibleObject
ou: Admins
ou: Applications

dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
givenName: Client
uid: clientApp
cn: Client App
sn: App
userPassword: password
ds-privilege-name: proxied-auth
```

2. Add the file using **`ldapmodify`**.

```
$ bin/ldapmodify --defaultAdd --filename add-user.ldif
```

3. The client application targets a specific subtree in the Directory Information Tree (DIT) for its operations. For example, some client may need access to an accounts subtree to retrieve customer information. Another client may need access to another subtree, such as a subscriber subtree. In this example, we want the client application to target the `ou=People,dc=example,dc=com` subtree. To allow the target, open a text editor and create an LDIF file to assign an ACI to that branch so that the client app user can access it as a proxy auth user. Note that the ACI should be on a single line of text. The example shows the ACI over multiple lines for readability. Add the file using the **`ldapmodify`**.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci:  (version 3.0; acl "People Proxy Access"; allow(proxy)
  userdn="ldap:///uid=clientApp,ou=Applications,dc=example,dc=com";)
```

4. Run a search to test the configuration using the bind DN `uid=clientApp` and the `proxyAs` option, which requires that you prefix "dn:" to the proxying entry or "u:" to the user name. The `uid=clientApp`

binds to the server and proxies as `uid=admin` to access the `ou=People,dc=example,dc=com` subtree.

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)"
```

Restricting proxy users

The Directory Server provides a set of operational attributes that restricts the proxied authorization capabilities of a client application and its proxyable target entry. When present in an entry, the Directory Server evaluates each operational attribute together to form a whitelist of potential users that can be proxied. If none of those attributes is present, then the user may potentially proxy as anyone.

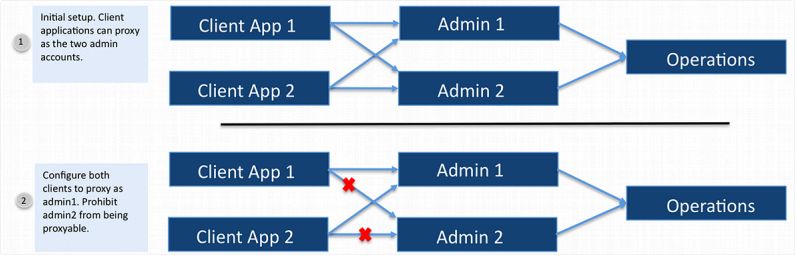
The Directory Server supports a two-tier provision system that, when configured, can restrict specific users for proxied authorization. The first tier is a set of `ds-auth-may-proxy-as-*` operational attributes on the client entry that will bind to the server and carry out operations under the identity of another user. The second tier is a set of `ds-auth-is-proxyable-*` operational attributes on the user entry that defines whether access is allowed, prohibited, or required by means of proxied authorization. If allowed or required, the attributes define which client entries can proxy as the user.

MY TITLE Proxying Operational Attributes

For example, if a client application, such as `uid=clientApp`, is requesting to search the `ou=People,dc=example,dc=com` branch as the user `uid=admin`, the command would look like this:

```
ldapsearch --bindDN uid=clientApp,dc=example,dc=com \
--bindPassword password \
--proxyAs uid=admin,dc=example,dc=com \
--baseDN ou=People,dc=example,dc=com \
"(object-class=*)
```

At bind, the Directory Server evaluates the list of users in the `uid=clientApp` entry based on the presence of any `ds-auth-may-proxy-as-*` attributes. In the figure below, the `uid=clientApp` entry has a `ds-auth-may-proxy-as` attribute with a value, `uid=admin`, which means that the client app user may proxy only as the `uid=admin` account. Next, the server confirms that `uid=admin` is in the list of proxyable users and then evaluates the `ds-auth-is-proxyable-*` attributes present in the `uid=admin` entry. These attributes determine the list of restricted users that either are allowed, prohibited, or required to proxy as the `uid=admin` entry. In this case, the `uid=admin` entry has the `ds-auth-is-proxyable` attribute with a value of "required", which indicates that the entry can only be accessed by means of proxied authorization. The `uid=admin` entry also has the `ds-auth-is-proxyable-by` attribute with a value of `uid=clientApp`, which indicates it can only be requested by the `uid=clientApp` entry. Once both sets of attributes have been confirmed, the `uid=clientApp` can bind to the server as the authenticated user. From this point, the Directory Server performs ACI evaluation on the branch to determine if the requested user has access rights to the branch. If the branch is accessible by the `uid=clientApp` entry, and then the search request is processed.



MY TITLE Proxying Operational Attributes Examples

About the ds-auth-may-proxy-as-* operational attributes

The Directory Server first evaluates the list of potential users that can be proxied for the authenticated user based on the presence of the `ds-auth-may-*` operational attributes in the entry. These operational attributes are multi-valued and are evaluated together if all are present in an entry:

- **ds-auth-may-proxy-as**. Specifies the user DNs that the associated user is allowed to proxy as. For instance, based on the previous example, you could specify in the `uid=clientApp` entry that it can proxy operations as `uid=admin` and `uid=agent1`.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as: uid=admin,dc=example,dc=com
ds-auth-may-proxy-as: uid=agent1,ou=admins,dc=example,dc=com
```

- **ds-auth-may-proxy-as-group**. Specifies the group DNs and its group members that the associated user is allowed to proxy as. For instance, you could specify that the potential users that the `uid=clientApp` entry can proxy as are those members who are present in the group `cn=Agents,ou=Groups,dc=example,dc=com`. This attribute is multi-valued, so that more than one group can be specified. Nested static and dynamic groups are also supported.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as-group: cn=Agents,ou=Groups,dc=example,dc=com
```

- **ds-auth-may-proxy-as-url**. Specifies the DNs that are returned based on the criteria defined in an LDAP URL that the associated user is allowed to proxy as. For instance, the attribute specifies that the client can proxy as those entries that match the criteria in the LDAP URL. This attribute is multi-valued, so that more than one LDAP URL can be specified.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as-url: ldap:///ou=People,dc=example,dc=com??sub?
(l=austin)
```

About the ds-auth-is-proxyable-* operational attributes

After the Directory Server has evaluated the list of users that the authenticated user can proxy as, the server checks to see if the requested authorized user is in the list. If the requested authorized user is present in the list, then the server continues processing the proxable attributes in the entry. If the requested authorized user is not present in the list, the bind will fail.

The operational attributes on the proxying entry are as follows:

- **ds-auth-is-proxyable**. Specifies whether the entry is proxyable or not. Possible values are: "allowed" (operation may be proxied as this user), "prohibited" (operations may not be proxied as this

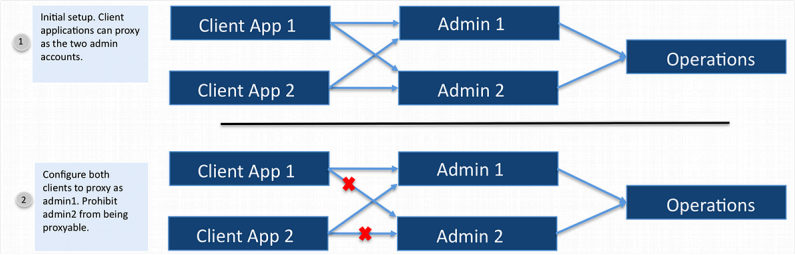
user), "required" (indicates that the account will not be allowed to authenticate directly but may only be accessed by some form of proxied authorization).

- **ds-auth-is-proxyable-as**. Specifies any users allowed to use this entry as a target of proxied authorization.
- **ds-auth-is-proxyable-as-group**. Specifies any groups allowed to use this entry as a target of proxied authorization. Nested static and dynamic groups are also supported.
- **ds-auth-is-proxyable-as-url**. Specifies the LDAP URLs that are used to determine any users that are allowed to use this entry as a target of proxied authorization.

Restricting proxied authorization for specific users

About this task

To illustrate how the proxied authorization operational attributes work, it is best to set up a simple example where two LDAP clients, `uid=clientApp1` and `uid=clientApp2` can freely proxy two administrator accounts, `uid=admin1` and `uid=admin2`. We will add the `ds-auth-may-proxy-as-*` and the `ds-auth-is-proxyable-*` attributes to these entries to restrict how each account can use proxied authorization. For example, the two client applications will continue to proxy the `uid=admin1` account but the `uid=admin2` account will no longer be able to be used as a proxied entry.



MY TITLE Proxy Users Example Scenario

Steps

1. For this example, set up two user entries, `uid=clientApp1` and `uid=clientApp2`, which will be proxying the `uid=admin1` and `uid=admin2` accounts to access the `ou=People,dc=example,dc=com` subtree. Both entries have the `proxied-auth` privilege assigned to it. Open a text editor and create an LDIF file. Add the file using the **`ldapmodify`** tool. Note that "..." indicates that other attributes present in the entry are not included in the example for readability purposes.

```
dn: uid=clientApp1,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth

dn: uid=clientApp2,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
```

2. Next, assign the ACI for each client application to the subtree, `ou=People,dc=example,dc=com`. Note that the ACIs should be on one line of text. The example displays the ACIs over multiple lines for readability.

```
dn: ou=People,dc=example,dc=com
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
       userdn="ldap:///uid=clientApp1,ou=Applications,dc=example,dc=com";)
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
       userdn="ldap:///uid=clientApp2,ou=Applications,dc=example,dc=com";)
```

3. Run a search for each entry. In this example, assume that there are two admin accounts: `admin1` and `admin2` that have full access rights to user attributes. You should be able to proxy as the `uid=admin1` and `uid=admin2` entries to access the subtree for both clients.

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp1,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin1,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)"

$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp2,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin2,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)"
```

4. Next, limit the proxied authorization capabilities for each client application. Update the `uid=clientApp1` entry to add the `ds-auth-may-proxy-as` attribute. In this example, the `ds-auth-may-proxy-as` attribute specifies that `uid=clientApp1` can proxy as the `uid=admin1` entry. Open a text editor, create the following LDIF file, save it, and add it using **`ldapmodify`**. Note that `ds-auth-may-proxy-as` is multi-valued:

```
dn: uid=clientApp1,ou=Applications,dc=example,dc=com
changetype: modify
add: ds-auth-may-proxy-as
ds-auth-may-proxy-as: uid=admin1,dc=example,dc=com
```

5. Repeat the previous step for the `uid=clientApp2` entry, except specify the `ds-auth-may-proxy-as-url`. The client entry may proxy as any DN that matches the LDAP URL.

```
dn: uid=clientApp2,ou=Applications,dc=example,dc=com
changetype: modify
add: ds-auth-may-proxy-as-url
ds-auth-may-proxy-as-url: ldap:///dc=example,dc=com??sub?(uid=admin*)
```

6. Next, we want to create a group of client applications that has `uid=clientApp1` and `uid=clientApp2` as its `uniquemembers` to illustrate the use of the `ds-auth-proxyable-by-group` attribute. In this example, set up a static group using the `groupOfUniqueNames` object class.

```
dn: ou=Groups,dc=example,dc=com
objectClass: top
objectClass: organizationalunit
ou: groups

dn: cn=Client Applications,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
cn: Client Applications
ou: groups
uniquemember: uid=clientApp1,ou=Applications,dc=example,dc=com
uniquemember: uid=clientApp2,ou=Applications,dc=example,dc=com
```

7. Update the `uid=admin1` entry to provide the DN that it may be proxied as. Add the `ds-auth-is-proxyable` and the `ds-auth-is-proxyable-by` attributes. For instance, we make the `uid=admin1` a required proxyable entry, which means that it can only be accessed by some form of proxied authorization. Then, specify each DN that can proxy as `uid=admin1` using the `ds-auth-is-proxyable-by`. Open a text editor, create the following LDIF file, save it, and add it using **`ldapmodify`**. Note that the example includes all three types of `ds-auth-is-proxable-by-*`

attributes as an illustration, but, in an actual deployment, only one type of attribute is necessary if they all target the same entries.

```
dn: uid=admin1,dc=example,dc=com
changetype: modify
add: ds-auth-is-proxyable
ds-auth-is-proxyable: required
-
add: ds-auth-is-proxyable-by
ds-auth-is-proxyable-by: ou=clientApp1,ou=Applications,dc=example,dc=com
ds-auth-is-proxyable-by: ou=clientApp2,ou=Applications,dc=example,dc=com
-
add: ds-auth-is-proxyable-by-group
ds-auth-is-proxyable-by-group: cn=Client
 Applications,ou=Groups,dc=example,dc=com
-
add: ds-auth-is-proxyable-by-url
ds-auth-is-proxyable-by-url: ldap:///ou=Applications,dc=example,dc=com??sub?
(uid=clientApp*)
```

8. Next, prohibit proxying for the `uid=admin2` entry by setting the `ds-auth-is-proxyable` to prohibited. Open a text editor, create the following LDIF file, save it, and add it using **`ldapmodify`**.

```
dn: uid=admin2,dc=example,dc=com
changetype: modify
add: ds-auth-is-proxyable
ds-auth-is-proxyable: prohibited
```

9. Run a search using the proxied account. For example, run a search first with `uid=clientApp1` or `uid=clientApp2` that proxies as `uid=admin1` to return a successful operation. However, if you run a search for `uid=clientApp1` that proxies as `uid=admin2`, as seen below, you will see an "authorization denied" message due to `uid=admin2` not matching the list of potential entries that can be proxied. The `ds-auth-may-proxy-as-*` attributes specify that the client can only proxy as `uid=admin1`:

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp1,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin2,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)"
```

```
One of the operational attributes (ds-auth-may-proxy-as,
ds-auth-may-proxy-as-group, ds-auth-may-proxy-as-url) in user entry
'uid=clientApp1,ou=Applications,dc=example,dc=com' does not allow
that user to be proxied as user 'uid=admin2,dc=example,dc=com'

Result Code:  123 (Authorization Denied)

Diagnostic Message:  One of the operational attributes (ds-auth-may-proxy-
as,
ds-auth-may-proxy-as-group, ds-auth-may-proxy-as-url) in user entry
'uid=clientApp1,ou=Applications,dc=example,dc=com' does not allow that
user to be proxied as user 'uid=admin2,dc=example,dc=com'
```

10. Run another search using `uid=clientApp2`, which attempts to proxy as `uid=admin2`.
You will see an "authorization denied" message due to the presence of the `ds-auth-is-proxyable:prohibited` operational attribute, which states that `uid=admin2` is not available for proxied authorization.

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp2,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
```

```
  --proxyAs "dn:uid=admin2,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)"
```

```
The 'ds-auth-is-proxyable' operational attribute
in user entry 'uid=admin2,dc=example,dc=com' indicates that
user may not be accessed via proxied authorization

Result Code:  123 (Authorization Denied)

Diagnostic Message: The 'ds-auth-is-proxyable' operational
attribute in user entry 'uid=admin2,dc=example,dc=com' indicates
that user may not be accessed via proxied authorization
```

Working with parameterized ACIs

The Directory Server supports the use of parameterized ACIs to control access to subtrees with homogenous administrative group or user patterns, which can be used in multi-tenant deployments. A single parameterized ACI can take the place of specifying identical ACIs on each tenant's subtree. For example, the following parameterized ACI:

```
(target="ldap:///o=($1),dc=example,dc=com")(version 3.0; acl \
"Subtree Admin Group members may search for and read entries in their
 subtree."; allow \
(search, read) groupdn="ldap:///cn=Subtree Admin
 Group,ou=groups,o=($1),dc=example,dc=com";)
```

Enables:

- Members of a group with DN **"cn=Subtree Admin Group,ou=groups,o=Customers, dc=example,dc=com"** to search for and read entries in the **"o=Customers, dc=example,dc=com"** subtree.
- Members of a group with DN **"cn=Subtree Admin Group,ou=groups,o=Partners, dc=example,dc=com"** to search for and read entries in the **"o=Partners, dc=example,dc=com"** subtree

The same access is granted for any substitution value for the **($1)** parameter variable. If an operation tried to read the **uid=user.1,o=acme,dc=example,dc=com** entry, this ACI would be considered. This ACI would allow a read action, if the operation's user is a member of the **cn=Subtree Admin Group,ou=groups,o=acme,dc=example,dc=com** group.

Attribute values from the target DN can be replaced with different variables **($#)** and then reference those variables in the group DN or user DN. The string representation of a parameter variable is constructed as follows:

- an open parenthesis
- a dollar sign
- a positive integer
- a closing parenthesis

In another example:

```
"population=($2),ou=Populations,environment=($1),ou=Environments,o=Acme"
```

The **($2)** variable is the population ID in the DN of the target entry, and **($1)** is the environment ID in the DN of the target entry. Those values from the target entry's DN are then substituted into the group DN or user DN value.

Parameter variables present in a parameterized ACI's target will be associated with the actual values from the resource DN. Each actual value will be substituted for its respective parameter variable in the ACI's target, and group bind rule DNs when performing access control on the resource entry. Parameter

variables can be used in multiple RDNs in a parameterized target. A given RDN may have at most one parameter variable as its attribute value, and a given parameter variable may appear only once in the parameterized target.

The following values are examples of valid parameterized target DNs:

- **`ou=($1),dc=example,dc=com`**
- **`population=($2),ou=Populations,environment=($1),ou=Environments,o=Acme`**
- **`o=($1)`** (for a global ACI)

An ACI on an entry can only apply to that entry's subtree. If an ACI with a parameterized target is stored on an entry, that entry's DN must appear in a non-parameterized form as the rightmost RDNs of the parameterized target's DN. For example, if an ACI with a parameterized target were stored on the **`dc=example,dc=com`** entry, that parameterized target must end in **`dc=example,dc=com`** in a non-parameterized form. Global ACIs do not have this restriction. Each global ACI can have parameter variables in any or all of its parameterized target's RDNs. Additional restrictions for parameterized targets include:

- They may not be pattern ACIs. That is, they may not contain wildcards ('*').
- RDNs that are parameterized must be single-valued. For example, a given parameterized RDN may not consist of two or more type-value pairs joined by '+'.

$attr.attrName macro

The ($attr.attrName) macro extracts a value from a specified attribute in the target entry rather than extracting a value from a field with the same number in the target DN. For example, ($attr.description) is replaced with the value of the description attribute in the target entry. If there are multiple values for the specified attribute then multiple actualized DNs are produced for the bind DN and the first matching actualized DN is used.

The ($attr.attrName) macro expands only the attribute's value so that you can extract values from the targe DN and build RDNs with different attribute names and types. Since the ($attr.attrName) macro extracts only the attribute's value, it is possible to combine it with a type that is different than what is present in the target DN.

Managing the Schema

This chapter presents a basic summary of the supported schema components on the PingDirectory Server and procedures to extend the schema with new element definitions. The chapter presents the following topics:

About the Schema

A schema is the set of directory server rules that define the structures, contents, and constraints of a Directory Information Tree (DIT). The schema guarantees that any new data entries or modifications meet and conform to these predetermined set of definitions. It also reduces redundant data definitions and provides a uniform method for clients or applications to access its Directory Server objects.

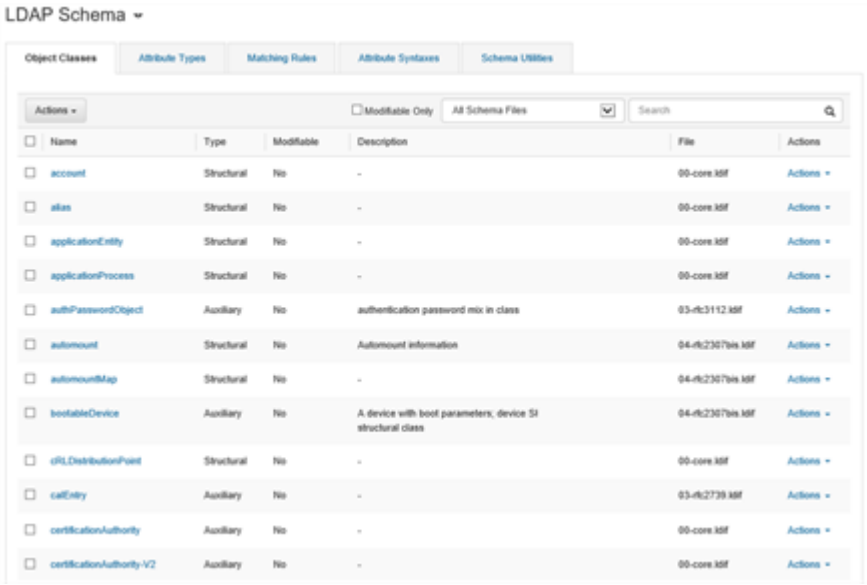
The PingDirectory Server ships with a default set of read-only schema files that define the core properties for the Directory Server. The Administrative Console provides a Schema Editor that administrators can use to view existing schema definitions and add new custom schema elements to their DIT. Any attempt to alter a schema element defined in a read-only file or add a new schema element to a read-only file will result in an "Unwilling to Perform" result.

About the Schema Editor

The Administrative Console provides a user-friendly graphical editor with tabs to manage any existing schema component related to the DIT: object classes, attributes, matching rules, attribute syntaxes, and

schema utilities. The **Object Classes** and **Attribute Types** tabs enable viewing existing definitions as well as adding, modifying, or removing custom schema elements.

The **Matching Rules** and **Attribute Syntaxes** tabs are read-only and provide a comprehensive listing of all of the elements necessary to define new schema elements. The **Schema Utilities** tab provides a schema validator that allows you to load a schema file or perform a cut-and-paste operation on the schema definition to verify that it meets the proper schema and ASN.1 formatting rules. The **Utilities** tab also supports schema file imports by first checking for proper syntax compliance and generating any error message if the definitions do not meet specification.



MY TITLE Example Schema Editor Screen

The Schema Editor provides two views for each definition: **Properties View** and **LDIF View**. The **Properties View** breaks down the schema definition by its properties and shows any inheritance relationships among the attributes. The **LDIF View** shows the equivalent schema definition in ASN.1 format, which includes the proper text spacing required for each schema element.

Default Directory Server Schema Files

The PingDirectory Server stores its schema as a set of LDIF files for a Directory Server instance in the `<server-root>/config/schema` directory. The Directory Server reads the schema files in alphanumeric order at startup, so that the `00-core.ldif` file is read first, then `01-pwpolicy.ldif`, and then the rest of the files. Custom schema files should be named so that they are loaded in last. For example, custom schema elements could be saved in a file labelled `99-user.ldif`, which loads after the default schema files are read at startup.

The Directory Server then uses the schema definitions to determine any violations that may occur during add, modify, or import requests. Clients applications check the schema (i.e., matching rule definitions) to determine the assertion value algorithm used in comparison or search operations.

The default set of schema files are present at installation and should not be modified. Modifying the default schema files could result in an inoperable server.

The schema files have the following descriptions:

Default Schema Files

Schema Files	Description
00-core.ldif	Governs the Directory Server's core functions.

Schema Files	Description
01-pwpolicy.ldif	Governs password policies.
02-config.ldif	Governs the Directory Server's configuration.
03-changelog.ldif	Governs the Directory Server's change log.
03-rfc2713.ldif	Governs Java objects.
03-rfc2714.ldif	Governs Common Object Request Broker Architecture (CORBA) object references.
03-rfc2739.ldif	Governs calendar attributes for vCard.
03-rfc2926.ldif	Governs Server Location Protocol (SLP) mappings to and from LDAP schemas.
03-rfc2985.ldif	Governs PKCS #9 public-key cryptography.
03-rfc3112.ldif	Governs LDAP authentication passwords.
03-rfc3712.ldif	Governs printer services.
03-uddiv3.ldif	Governs web services registries of SOA components.
04-rfc2307bis.ldif	Governs mapping entities from TCP/IP and UNIX into X.500 entries.

Extending the Directory Server Schema

The PingDirectory Server stores its schema as LDIF files in the `<server-root>/config/schema` directory. At startup, the Directory Server reads the schema files once in alphanumeric order starting with `00-core.ldif` and ending with any custom schema definition files, such as `99-user.ldif` if present.

You can extend the schema to include additional customizations necessary for your Directory Server data using one of the following methods:

- **Using the Schema Editor**. This method is the easiest and quickest way to set up a schema definition and have it validated for the correct ASN.1 formatting. The Editor lets you define your schema properties, load your custom file, or perform a cut-and-paste operation on a new schema element. If any errors exist in the file, the Schema Editor generates an error message if the schema definitions do not pass compliance.
- **Using a Custom Schema File**. You can create a custom schema file with your new definitions using a text editor, save it as `99-user.ldif`, and then import the file using the Schema Editor or the **`ldapmodify`** tool. You must name the custom LDIF file with a high two-digit number prefix, so that the Directory Server will read the file AFTER the core schema files are read at startup. For example, you can name the file, `99-myschema.ldif`, etc. See the next section, *General Tips on Extending the Schema* to see the requirements for naming each file.
- **Using the Command Line**. If you have a small number of additions, you can extend the schema over LDAP and from the command line using the **`ldapmodify`** tool. The Directory Server writes the new schema changes to a file `99-user.ldif` in the `<server-root>/config/schema` directory. However, this method can be cumbersome as schema definitions require strict adherence to text spacing and white space characters.

General Tips on Extending the Schema

You should consider the following points when extending the schema:

- Never modify the default schema files as doing so could damage the Directory Server’s processing capabilities.
- Define all attributes first before they can be used in an object class. If you are using the Schema Editor to add new schema elements, then you can use the Quick Add Attributes option when defining new objectclasses.

- Define the parent object class first before creating object classes that inherit from the parent.
- The schema file naming syntax requires that custom schema files must begin with exactly two digits followed by a non-digit character, followed by a zero or more characters and ending with ".ldif". Note that the two digits do not need to be followed by a dash ("-"). Any files that do not meet this criteria will be ignored and either a NOTICE or SEVERE_WARNING message will be logged.

  Any file in the `<server-root>/config/schema` directory with a name that starts with "." or with a name that ends with a tilde ('~'), ".swp", or ".tmp" will generate a NOTICE message indicating that temporary files will be ignored. Any other file that does not meet the naming criteria will generate a SEVERE_WARNING message indicating that it will be ignored.
- Define custom attributes and object classes in one file. Typically, this file will be the `99-user.ldif`. You can specify a different file name to which the Directory Server writes using the X-SCHEMA-FILE element and the file name in the definition. For example:

```
add: attributeTypes attributeTypes: ( 1.3.6.1.4.1.32473.3.1.9.1
  NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'Directory Server Example'
  X-SCHEMA-FILE '99-custom.ldif' )
```

- Pay special attention to the white space characters in the schema definitions, where WSP means zero or more space characters, and SP means one or more space characters. The LDIF specification states that LDIF parsers should ignore exactly one space at the beginning of each continuation line, since continuation lines must begin with a space character. Thus, if you define a new schema definition with each keyword on a separate continuation line, you should add two spaces before an element keyword to be safe. For example, the following attribute definition has two spaces before the keywords: NAME, SUP, and X-ORIGIN.

```
attributeTypes: ( 2.5.4.32 NAME 'owner' SUP distinguishedName X-ORIGIN 'RFC
 4519' )
```

- In a replicated topology, any new schema additions will be replicated to other replication servers to their respective Schema backend. The additions will be written to the file specified by the X-SCHEMA-FILE extension or written to `99-user.ldif` if no file is specified.

Managing Attribute Types

An attribute type determines the important properties related to an attribute, such as specifying the matching and syntax rules used in value comparisons. An attribute description consists of an attribute type and a set of zero or more options. Options are short, case-insensitive text strings that differentiate between attribute descriptions. For example, the LDAPv3 specification defines only one type of option, the tagging option, which can be used to tag language options, such as `cn;lang-de;lang-sp` or binary data, such as `userCertificate;binary`. You can also extend the schema by adding your own attribute definitions.

Attributes have the following properties:

- Attributes can be user attributes that hold information for client applications, or operational attributes that are used for administrative or server-related purposes. You can specify the purpose of the attribute by the `USAGE` element.
- Attributes are multi-valued by default. Multi-valued means that attributes can contain more than one value within an entry. Include the `SINGLE-VALUE` element if the attribute should contain at most one value within an entry.
- Attributes can inherit properties from a parent attribute as long as they both have the same USAGE, and the child attribute has the same `SYNTAX` or its `SYNTAX` allows values which are a subset of the values allowed by the `SYNTAX` of the parent attribute. For example, the surname (`sn`) attribute is a child of the name attribute.

Attribute Type Definitions

New attribute types do not require server code extensions if the provided matching rules and attribute syntaxes are used in the definitions. Administrators can create new attributes using the Schema Editor, which stores the definition in a file in the `<server-root>/config/schema` directory. See *Extending the Directory Server Schema* for more information.

The formal specification for attribute types is provided in RFC 4512, section 4.1.2 as follows:

```
AttributeTypeDescription = "(" wsp; Left parentheses followed by a white space
numericoid                      ; Required numeric object identifier
[ sp "NAME" sp qdescrs ]        ; Short name descriptor as alias for the OID
[ sp "DESC" sp qdstring ]       ; Optional descriptive string
[ sp "OBSOLETE" ]               ; Determines if the element is active
[ sp "SUP" sp oid ]             ; Specifies the supertype
[ sp "EQUALITY" sp oid ]        ; Specifies the equality matching rule
[ sp "ORDERING" sp oid ]        ; Specifies ordering matching rule
[ sp "SUBSTR" sp oid ]          ; Specifies substrings matching rule
[ sp "SYNTAX" sp oidlen ]       ; Numeric attribute syntax with minimum
 upper bound
                                ;  length expressed in {num}
[ sp "SINGLE-VALUE" ]           ; Specifies if the attribute is single
 valued in
                                ;  the entry
[ sp "COLLECTIVE" ]             ; Specifies if it is a collective attribute
[ sp "NO-USER-MODIFICATION" ]   ; Not modifiable by external clients
[ sp "USAGE" sp usage ]         ; Application usage
extensions wsp ")"              ; Extensions followed by a white space and
 ")"

usage = "userApplications" /    ; Stores user data
  "directoryOperation" /        ; Stores internal server data
  "distributedOperation" /      ; Stores operational data that must be
 synchronized
                                ; across servers
  "dSAOperation"                ; Stores operational data specific to a
 server and
                                ; should not be synchronized across servers
```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```
extensions = /
"X-ORIGIN" /                ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /           ; Specifies which schema file contains the definition
"X-APPROX" /                ; Specifies the approximate matching rule
"X-ALLOWED-VALUE" /         ; Explicitly specifies the set of allowed values
"X-VALUE-REGEX" /           ; Specifies the set of regular expressions to compare
 against
                            ;  attribute values to determine acceptance
"X-MIN-VALUE-LENGTH" /      ; Specifies the minimum character length for
 attribute values
"X-MAX-VALUE-LENGTH" /      ; Specifies the maximum character length for
 attribute values
"X-MIN-INT-VALUE" /         ; Specifies the minimum integer value for the
 attribute
"X-MAX-INT-VALUE" /         ; Specifies the maximum integer value for the
 attribute
"X-MIN-VALUE-COUNT" /       ; Specifies the minimum number of allowable values
 for the
                            ;  attribute
"X-MAX-VALUE-COUNT" /       ; Specifies the maximum number of allowable values
 for the
                            ;  attribute
```

```
"X-READ-ONLY"             ; True or False. Specifies if the file that contains
 the
                          ;  schema element is marked as read-only in the
 server
                          ;  configuration.
```

Basic Properties of Attributes

The Basic Properties section displays the standard elements in schema definition.

Basic Properties of Attributes

Attributes	Description
Name	Specifies the globally unique name.
Description	Specifies an optional definition that describes the attribute and its contents. The analogous LDIF equivalent is "DESC".
OID	Specifies the object identifier assigned to the schema definition. You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
Syntax	Specifies the attribute syntax used. For example, the `userPassword` attribute uses the User Password Syntax whereas the `authPassword` attribute uses the Authentication Password Syntax.
Parent	Specifies the schema definition's parent or supertype if any. The analogous LDIF equivalent is "SUP".
Multivalued	Specifies if the attribute can appear more than once in its containing object class.
Required By Class	Specifies any object classes that require the attribute.
Allowed By Class	Specifies any object classes that can optionally use the attribute.
Value Restrictions	Specifies any restriction on the value of the attribute.

The Extra Properties section provides additional auxiliary information associated with the attribute.

Basic Properties of Attributes

Attributes	Description
Aliases	Specifies any shortform alias names, if any. In theory, you could have any number of shortform names as long as they are all unique. The analogous LDIF equivalent appears as the secondary element with the NAME element. For example, NAME ('sn' 'surname').
Origin	Specifies the origin of the schema definition. Typically, it could refer to a specific RFC or company.
Stored in File	Specifies the schema file that stores the definition in the `<server-root>/config/schema` folder.
Usage	Specifies the intended use of the attribute. Choices are the following: ▪ userApplications ▪ directoryOperation ▪ distributedOperation ▪ dSAOperation
User-Modifiable	Specifies if the attribute can be modified by an authorized user.

Attributes	Description
Obsolete	Specifies if the schema definition is obsolete or not.
Matching Rules	Specifies the associated matching rules for the attribute.

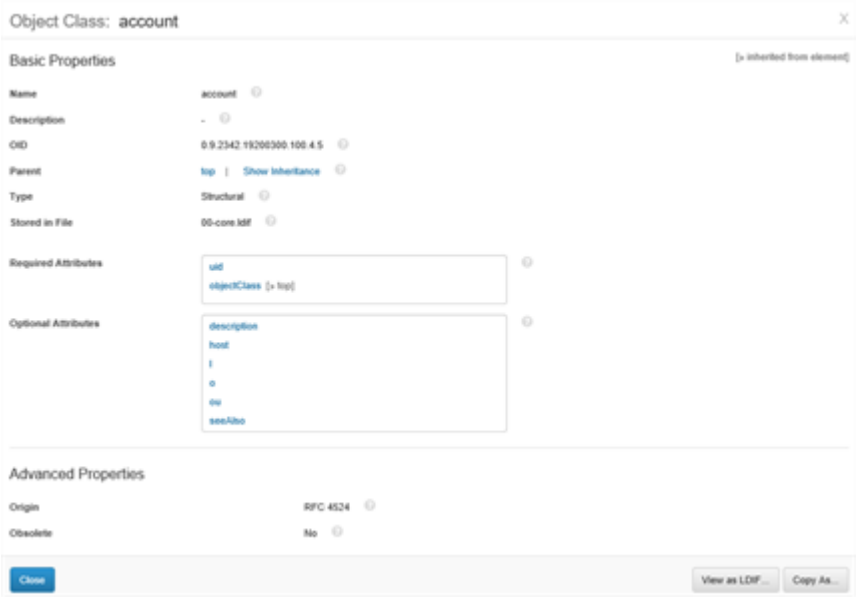
Viewing Attributes

The Schema Editor displays all of the attribute types on your directory server instance. It shows the basic properties that are required elements plus the extra properties that are allowed within the attribute definition.

To View Attribute Types Using the Schema Editor

Steps

1. Start the Administrative Console. Check that the Directory Server instance associated with the console is also running.
2. On the main menu, click **Schema**.
3. In the Administrative Console **Schema Editor**, click the **Attribute Types** tab.
4. Click a specific attribute to view its definition. In this example, click the `account` attribute. In the **Object Class** window, view the attribute properties.



5. Click the **View as LDIF** button to see the equivalent attribute definition in ASN.1 format.

To View Attribute Types over LDAP

Steps

- Use **`ldapsearch`** to view a multi-valued operational attribute `attributeTypes`, which publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" attributeTypes
```

To View a Specific Attribute Type over LDAP

Steps

- Use **ldapsearch** with the `--dontWrap` option and use the **grep** command to search for a specific attribute.

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base --dontWrap "(objectclass=*)" \
  attributeTypes | grep 'personalTitle'
```

Creating a New Attribute over LDAP

The following section shows how you can add the schema element from the previous section over LDAP. You can create your own schema file or type the schema from the command line. In either case, you must pay special attention to text spacing and ASN.1 formatting.

To Add an New Attribute to the Schema over LDAP

Steps

1. Create an LDIF file with the new attribute definition using a text editor. Save the file as `myschema.ldif`.

```
dn: cn=schema
changetype: modify
add: attributeTypes
attributeTypes: ( contractorStatus-OID NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ALLOWED-VALUES 'Y' 'N' 'y' 'n'
  X-ORIGIN 'PingDirectory Server Example' )
```

2. Use **ldapmodify** to add the attribute.

```
$ bin/ldapmodify --filename myschema.ldif
```

3. Verify the addition by displaying the attribute using **ldapsearch**.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  --dontwrap "(objectclass=*)" attributeTypes | grep 'contractorStatus'
```

4. You can view the custom schema file at `<server-root>/config/schema/99-user.ldif`. You should see the following:

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( contractorStatus-OID
  NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'PingDirectory Server Example' )
```

To Add Constraints to Attribute Types

Steps

- The Directory Server provides attribute type extensions that constrain the values for the associated attribute using the `DirectoryString` attribute syntax. The following schema definition includes two `attributeType` definitions for `myAttr1` and `myAttr2`. The first definition constrains the values for the attribute `myAttr1` to 'foo', 'bar', 'baz'. The second definition constrains the minimum allowable length for `myAttr2` to 1 and the maximum allowable length to 5.

```
attributeTypes: (1.2.3.4
  NAME 'myAttr1'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  X-ALLOWED-VALUES ( 'foo' 'bar' 'baz' ))
attributeTypes: ( 1.2.3.5
  NAME 'myAttr2'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  X-MIN-VALUE-LENGTH '1'
  X-MAX-VALUE-LENGTH '5' )
```

Managing Object Classes

Object classes are sets of related information objects that form entries in a Directory Information Tree (DIT). The Directory Server uses the schema to define these entries, to specify the position of the entries in a DIT, and to control the operation of the server. You can also extend the schema by adding your own schema definitions.

Object classes have the following general properties:

- Object classes must have a globally unique name or identifier.
- Object classes specify the required and allowed attributes in an entry.
- Object classes can inherit the properties and the set of allowed attributes from its parent object classes, which may also be part of a hierarchical chain derived from the top abstract object class.
- Object classes that are defined in the PingDirectory Server can be searched using the `objectClasses` operational attribute. The Directory Server also has a special entry called the subschema subentry, which provides information about the available schema elements on the server.

Object Classes Types

Based on RFC 4512, object classes can be a combination of three different types:

- **Abstract object classes** are used as the base object class, from which structural or auxiliary classes inherit its properties. This inheritance is a one-way relationship as abstract object classes cannot be derived from structural or auxiliary classes. The most common abstract object class is `top`, which defines the highest level object class in a hierarchical chain of object classes.
- **Structural object classes** define the basic attributes in an entry and define where an entry can be placed in a DIT. All entries in a DIT belong to one structural object class. Structural object classes can inherit properties from other structural object classes and from abstract object classes to form a chain of inherited classes. For example, the `inetOrgPerson` structural object class inherits properties from the `organizationalPerson` structural class, which inherits from another object class, person.
- **Auxiliary object classes** are used together with structural object classes to define additional sets of attributes required in an entry. The auxiliary object class cannot form an entry alone but must be present with a structural object class. Auxiliary object classes cannot derive from structural object classes or vice-versa. They can inherit properties from other auxiliary classes and from abstract classes.

Object Class Definition

New object classes can be specified with existing schema components and do not require additional server code extensions for their implementation. Administrators can create new object classes using the Schema

Editor, which manages schema in the `<server-root>/config/schema` directory. See *Extending the Directory Server Schema* for more information.

The object class definition is defined in RFC 4512, section 4.1.1, as follows::

```
ObjectClassDescription = "(" wsp; Left parenthesis followed by a white space
numericoid                      ; Required numeric object identifier
[ sp "NAME" sp qdescrs ]        ; Short name descriptor as alias for the OID
[ sp "DESC" sp qdstring ]       ; Optional descriptive string
[ sp "OBSOLETE" ]               ; Determines if the element is inactive
[ sp "SUP" sp oid ]             ; Specifies the direct superior object class
[ sp kind ]                     ; abstract, structural (default), auxiliary
[ sp "MUST" sp oids ]           ; Required attribute types
[ sp "MAY" sp oids ]            ; Allowed attribute type
extensions wsp ")"              ; Extensions followed by a white space and
 ")"

usage = "userApplications" /    ; Stores user data
  "directoryOperation" /        ; Stores internal server data
  "distributedOperation" /      ; Stores operational data that must be
 synchronized
                                ;   across servers
  "dSAOperation"                ; Stores operational data specific to a
 server and
                                ;   should not be synchronized across
 servers
```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```
extensions = /
"X-ORIGIN" /             ; Specifies where the object class is defined
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the definition
"X-READ-ONLY"            ; True or False. Specifies if the file that contains
                         ;   the schema element is marked as read-only
                         ;   in the server configuration.
```

ⓘ **Note:** Although RFC 4512 allows multiple superior object classes, the PingDirectory Server allows at most one superior object class, which is defined by the SUP element in the definition.

Basic Object Class Properties

The Basic Properties section displays the standard elements in schema definition.

Basic Properties of Attributes

Attributes	Description
Name	Specifies the globally unique name.
Description	Specifies an optional definition that describes the object class and its contents. The analogous LDIF equivalent is "DESC".
OID	Specifies the object identifier assigned to the schema definition. You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
Parent	Specifies the schema definition's hierarchical parent or superior object class if any. An object class can have one parent. The analogous LDIF equivalent
Type	Specifies the type of schema definition: abstract, structural, or auxiliary. The analogous LDIF equivalent is "ABSTRACT", "STRUCTURAL", or "AUX

Attributes	Description
Required Attributes	Specifies any required attributes with the object class. The Schema Editor also marks any inherited attributes from another object class. You can double-click an attribute value to take you to the Properties View for that particular attribute. The analogous LDIF equivalent is "MUST".
Optional Attributes	Specifies any optional attributes that could be used with the object class. The Schema Editor also marks any inherited attributes from another object class. You can double-click an attribute value to take you to the Properties View for that particular attribute. The analogous LDIF equivalent is "MAY".

The Extra Properties section provides additional auxiliary information associated with the object class.

Basic Properties of Attributes

Attributes	Description
Aliases	Specifies any shortform alias names, if any. In theory, you could have any number of shortform names as long as they are all unique. The analogous LDIF equivalent appears as the secondary element with the NAME element although most object classes do not have aliases.
Origin	Specifies the origin of the schema definition. Typically, it could refer to a specific RFC or company.
Obsolete	Specifies if the schema definition is obsolete or not.
Stored in File	Specifies the schema file that stores the definition in the `<server-root>/config/schema` folder.

Viewing Object Classes

You can view the object classes on your Directory Server by using the Administrative Console Schema Editor, over LDAP using the **`ldapsearch`** tool, or some third party tool. The Schema Editor displays all of the object classes on the directory server instance. It shows the basic properties that are required elements and the extra properties that are allowed within the object class.

To View Object Classes over LDAP

Steps

- Use **`ldapsearch`** tool to view a multi-valued operational attribute, `objectClasses`, which publishes the object class definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
--dontWrap "(objectclass=*)" objectClasses
```

```
dn: cn=schema
objectClasses: ( 2.5.6.0 NAME 'top' ABSTRACT MUST objectClass X-ORIGIN 'RFC
 4512' )
objectClasses: ( 2.5.6.1 NAME 'alias' SUP top STRUCTURAL MUST
 aliasedObjectName
  X-ORIGIN 'RFC 4512' )
objectClasses: ( 2.5.6.2 NAME 'country' SUP top STRUCTURAL MUST c
  MAY ( searchGuide $ description ) X-ORIGIN 'RFC 4519' )
...(more output)...
```

Managing an Object Class over LDAP

The following section shows how you can manage an object class schema element over LDAP by adding a new attribute element to an existing object class. You can create your own schema file or type the schema from the command line. In either case, you must pay special attention to text spacing and ASN.1 formatting. The following example procedure adds an attribute, `contractorAddress`, to the custom schema file, then adds it to the `contractor` objectclass.

To Manage an Object Class over LDAP

Steps

1. Assume that you have defined the `contractorAddress` attribute, create an LDIF file called `contractorAddress-attr.ldif` with the following content:

```
dn: cn=schema
changetype: modify

add: attributeTypes attributeTypes: ( contractor-OID NAME
 'contractorAddress'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'user defined'
  X-SCHEMA-FILE '98-custom-schema.ldif' )
  X-ORIGINS 'user defined'
  X-SCHEMA-FILE '98-custom-schema.ldif' )
```

2. Add the attribute using **`ldapmodify`**.

```
$ bin/ldapmodify --filename contractorAddress-attr.ldif
```

3. Next, create an LDIF file to modify the contractor objectclass to allow this attribute. When doing this, you are just re-adding the updated `objectClass` and the Directory Server will handle the proper replacement of the existing object class with the new one. Create a file called `contractor-oc.ldif`. Make sure that the lines are not wrapped, the `objectClasses` line should be one continuous line.

```
dn:cn=schema
changetype: modify
add: objectClasses
objectClasses: ( contractor-OID NAME 'contractor'
  DESC 'Contractor status information
  SUP top
  AUXILIARY MAY ( contractorStatus $ contractorAgency $ contractorAddress )
  X-ORIGIN 'Directory Server Example'
  X-SCHEMA-FILE '98-custom-schema.ldif' )
```

4. Update the `objectClass` using **`ldapmodify`** as follows:

```
$ bin/ldapmodify --filename contractor-oc.ldif
```

5. These schema changes will be replicated to all servers in the replication topology. Verify the change by looking at the `config/schema/98-custom-schema.ldif` file on the other servers in the replication topology to ensure that the changes are present.
6. If you need to add an index for this attribute, you can do so by using the **`dsconfig`** command-line utility. You will need to do this on each server in your topology unless you have server configuration groups set up. See *Configuring Server Groups* for more information.

```
$ bin/dsconfig create-local-db-index --backend-name userRoot \
  --index-name contractorAddress --set index-type:equality
```

7. Rebuild the index online. This will not affect other indexes or entries since there is no currently existing data for this attribute on any entry.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index contractorAddress
```

Creating a New Object Class Using the Schema Editor

The procedures to create a new object class are similar to that of creating a new attribute. Make sure that any attributes that are part of the new object class are defined prior to defining the object class.

To Create a New Object Class Using the Schema Editor

Steps

1. Start the Administrative Console.
2. On the main menu, click **LDAP Schema**.
3. On the **Schema Editor**, click the **Object Classes** tab, and then click **New** located in the bottom left of the window.
4. Enter the properties for the new objectclass. In the **Attributes** box, filter the types of attributes required for the new object class. Click the right arrow to move it into the **Required** or the **Optional** box. All custom attributes appear at the bottom of the list in the **Attributes** box.

Extending the Schema Using a Custom Schema File

You can add new attributes and object classes to your Directory Server schema by creating a custom schema file. You can import the file using the Schema Editor, over LDAP using the **`ldapmodify`** tool, or from the command line. Make sure to define the attributes first, then define the object classes.

To Extend the Schema Using a Custom Schema File

Steps

1. Create an LDIF file with the new attribute extensions using a text editor.

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
attributeTypes: ( contractorStatus-OID NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'Directory Server Example' )
attributeTypes: ( contractorAgency-OID NAME 'contractorAgency'
  EQUALITY caseIgnoreMatch
  SUBSTR caseIgnoreSubstringsMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.44{256}
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'PingDirectory Server Example' )
```

2. In the same LDIF file, add a new object class definition after the attribute types. In this example, create an auxiliary object class, `contractor`, that alone cannot be used as an entry. The object class will be used to add supplemental information to the `inetOrgPerson` structural object class. The attributes are all optional for the new object class.

```
objectClasses: ( contractor-OID
  NAME 'contractor'
  DESC 'Contractor status information'
```

```
  SUP top
  AUXILIARY
  MAY ( contractorStatus $ contractorAgency )
  X-ORIGIN 'PingDirectory Server Example' )
```

3. Save the file as `99-auxobjclass.ldif`. and place it in the `<server-root>/config/schema` directory.
4. At this stage, the schema extensions are not loaded into the Directory Server yet. You have four options to load them:
   - Create a task that loads the new extensions into the schema. We create a task labelled with the ID "add-schema-99-auxobjclass" and add it using **`ldapmodify`**. The server does not need to be restarted using this method.

     ```
     dn: ds-task-id=add-schema-99-auxobjclass,cn=Scheduled Tasks,cn=tasks
     objectClass: top
     objectClass: ds-task
     objectClass: ds-task-add-schema-file
     ds-task-id: add-schema-99-auxobjclass
     ds-task-class-name:
      com.unboundid.directory.server.tasks.AddSchemaFileTask
     ds-task-schema-file-name: 99-auxobjclass.ldif
     ```
   - Import the schema file using the Administrative Console Schema Editor. You do not need to restart the server when using this method.
   - Place the `99-auxobjclass.ldif` file in the `<server-root>/config/schema` directory and restart the Directory Server. The schema file is read at startup.
   - Add the schema file using **`load-ldap-schema-file`**. You do not need to restart the server when using this method.

     ```
     $ bin/load-ldap-schema-file --schemaFile config/schema 99-auxobjclass.ldif
     ```
5. Verify the addition by displaying the attribute using **`ldapsearch`**.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.9)" contractorStatus
   ```

   ```
   dn: uid=user.9,ou=People,dc=example,dc=com
   contractorStatus: TRUE
   ```

Managing Matching Rules

Matching rules determine how clients and servers compare attribute values during LDAP requests or operations. They are also used in evaluating search filter elements including distinguished names and attributes. Matching rules are defined for each attribute based on EQUALITY (e.g., two attributes are equal based on case, exact match, etc.), SUBSTR (e.g., assertion value is a substring of an attribute), and ORDERING (e.g., greater than or equal, less than or equal, etc.) properties.

ⓘ **Note:** The PingDirectory Server supports an `APPROXIMATE` matching rule that compares similar attributes based on fuzzy logic. Thus, attributes that are similar or "sound-like" each other are matched. For example, "petersen" would match "peterson".

Matching Rule Definition

New matching rules require additional server code extensions to be implemented on the PingDirectory Server. If you need new matching rules, contact your authorized support provider for assistance.

The formal specification for attribute types is provided in RFC 4512, section 4.1.3 as follows:

```
MatchingRuleDescription = "(" wsp    ; Left parentheses followed by a white
 space
numericoid                          ; Required numeric object identifier
 identifying
```

```
                                        ;   this matching rule
[ sp "NAME" sp qdescrs                  ; Short name descriptor
[ sp "DESC" sp qdstring                 ; Description
[ sp "OBSOLETE" ]                       ; Specifies if the rule is inactive
sp "SYNTAX" sp numericoid               ; Assertion syntax
extensions wsp ")"                      ; Extensions followed by a white space
 and ")"
```

Default Matching Rules

The PingDirectory Server provides a large set of matching rules, which support a variety of applications. The default matching rules available for the Directory Server are listed in the table below for each matching rule type: Equality, Substring, Ordering, and Approximate matches.

Default Matching Rules

Matching Rule/OID	Attribute Syntax/OID	Description
uuidMatch/ 1.3.6.1.1.16.2	UUID/ 1.3.6.1.1.16.1	Compares an asserted UUID with a stored UUID attribute value for equality. RFC 4530.
uuidOrderingMatch/ 1.3.6.1.1.16.3	UUID/ 1.3.6.1.1.16.1	Compares the collation order of an asserted UUID with a stored UUID attribute value for ordering RFC 4530.
caseExactIA5Match/ 1.3.6.1.4.1.1466.109.114.1	IA5 String/ 1.3.6.1.4.1.1466.115.121.1.26	Compares an asserted value with an attribute value of International Alphabet 5 syntax. RFC 4517.
caseIgnoreIA5Match/ 1.3.6.1.4.1.1466.109.114.2	IA5 String/ 1.3.6.1.4.1.1466.115.121.1.26	Compares an asserted value with an attribute value of International Alphabet 5 syntax. Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517.
caseIgnoreIA5SubstringsMatch/ 1.3.6.1.4.1.1466.109.114.3	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58	Compares an asserted substring with an attribute value of IA5 string syntax. Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517.
authPasswordExactMatch/ 1.3.6.1.4.1.4203.1.2.2	Authentication Password Syntax/ 1.3.6.1.4.1.4203.1.1.2	Authentication password exact matching rule.
authPasswordMatch/ 1.3.6.1.4.1.4203.1.2.3	Authentication Password Syntax/ 1.3.6.1.4.1.4203.1.1.2	Authentication password matching rule.
ds-mr-double-metaphone-approx/ 1.3.6.1.4.1.30221.1.4.1	Directory String/ 1.3.6.1.4.1.1466.115.121.1.15	Syntax based on the phonetic Double Metaphone algorithm for approximate matching.
ds-mr-user-password-exact/ 1.3.6.1.4.1.30221.1.4.2	User Password Syntax/ 1.3.6.1.4.1.30221.1.3.1	User password exact matching rule.

Matching Rule/OID	Attribute Syntax/OID	Description
ds-mr-user-password-equality/ 1.3.6.1.4.1.30221.1.4.3	User Password Syntax/ 1.3.6.1.4.1.30221.1.3.1	User password equality matching rule.
historicalCsnOrderingMatch/ 1.3.6.1.4.1.30221.1.4.4	1.3.6.1.4.1.30221.1.3.5	Compares the collation order of a historical change sequence number with a historical CSN attribute value.
caseExactIA5SubstringsMatch/ 1.3.6.1.4.1.30221.1.4.902	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58	Compares an asserted substring with an attribute value of IA5 string syntax. RFC 4517.
compactTimestampMatch/ 1.3.6.1.4.1.30221.2.4.1	Compact Timestamp/ 1.3.6.1.4.1.30221.2.3.1	Compact Timestamp matching rule.
compactTimestampOrderingMatch/ 1.3.6.1.4.1.30221.2.4.2	Compact Timestamp/ 1.3.6.1.4.1.30221.2.3.1	Compares the collation order of a compact timestamp number with an attribute value of Compact Timestamp syntax.
objectIdentifierMatch/ 2.5.13.0	OID/ 1.3.6.1.4.1.1466.115.121.1.38	Compares an asserted value with an attribute value of OID syntax. RFC 4517.
distinguishedNameMatch/ 2.5.13.1	DN/ 1.3.6.1.4.1.1466.115.121.1.12	Compares an asserted value with an attribute value of DN syntax. Spaces around commas and semicolons are ignored. Spaces around plus and equal signs around RDN components are ignored. RFC 4517.
caseIgnoreMatch/ 2.5.13.2	Directory String/ 1.3.6.1.4.1.1466.115.121.1.15	Compares an asserted value with an attribute value. Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517.
caseIgnoreOrderingMatch/ 2.5.13.3	Directory String/ 1.3.6.1.4.1.1466.115.121.1.15	Compares the collation order of the asserted string with an attribute value of Directory String syntax. Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517

Matching Rule/OID	Attribute Syntax/OID	Description
caseIgnoreSubstringsMatch/ 2.5.13.4	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58	Compares an asserted substring value with an attribute value of Directory String syntax. Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
caseExactMatch/ 2.5.13.5	Directory String/ 1.3.6.1.4.1.1466.115.121.1.15	Compares an asserted value with an attribute value of Directory String syntax. RFC 4517.
caseExactOrderingMatch/ 2.5.13.6	Directory String 1.3.6.1.4.1.1466.115.121.1.15	Compares the collation order of the asserted string with an attribute value of Directory String syntax. RFC 3698
caseExactSubstringsMatch/ 2.5.13.7	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58	Compares an asserted substring with an attribute value of Directory String syntax. RFC 3698
numericStringMatch/ 2.5.13.8	Numeric String/ 1.3.6.1.4.1.1466.115.121.1.36	Compares an asserted value with an attribute value of Numeric String syntax. Spaces are ignored when performing these comparisons. RFC 4517.
numericStringOrderingMatch/ 2.5.13.9	Numeric String/ 1.3.6.1.4.1.1466.115.121.1.36	Compares the collation order of the asserted string with an attribute value of Numeric String syntax. Spaces are ignored when performing these comparisons. RFC 4517.
numericStringSubstringsMatch/ 2.5.13.10	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58	Compares an asserted substring with an attribute value of Numeric String syntax. Spaces are ignored when performing these comparisons. RFC 4517.
caseIgnoreListMatch/ 2.5.13.11	Postal Address/ 1.3.6.1.4.1.1466.115.121.1.41	Compares an asserted value with an attribute value which is a sequence of Directory Strings. Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517.

Matching Rule/OID	Attribute Syntax/OID	Description
caseIgnoreListSubstringsMatch/ 2.5.13.12	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58	Compares the asserted substring with an attribute value, which is a sequence of Directory Strings. Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 3698.
booleanMatch/ 2.5.13.13	Boolean/ 1.3.6.1.4.1.1466.115.121.1.7	Compares an asserted boolean value with an attribute value of BOOLEAN syntax. Returns true if the values are both TRUE or both FALSE. RFC 3698.
integerMatch/ 2.5.13.14	Integer/ 1.3.6.1.4.1.1466.115.121.1.27	Compares an asserted value with an attribute value of INTEGER syntax. RFC 4517.
integerOrderingMatch/ 2.5.13.15	Integer/ 1.3.6.1.4.1.1466.115.121.1.27	Compares the collation order of the asserted integer with an attribute value of Integer syntax. Returns true if the attribute value is less than the asserted value. RFC 3698.
bitStringMatch/ 2.5.13.16	Bit String/ 1.3.6.1.4.1.1466.115.121.1.6	Compares an asserted Bit String value with an attribute value of Bit String syntax. RFC 4517.
octetStringMatch/ 2.5.13.17	Octet String/ 1.3.6.1.4.1.1466.115.121.1.40	Compares an asserted value with an attribute value of octet string syntax using a byte-for-byte comparison. RFC 4517.
octetStringOrderingMatch/ 2.5.13.18	Octet String/ 1.3.6.1.4.1.1466.115.121.1.40	Compares the collation order of the asserted octet string with an attribute value of Octet String syntax. Zero precedes a one bit. Shorter strings precede longer strings. RFC 3698.
octetStringSubstringsMatch/ 2.5.13.19	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58	Compares an asserted substring with an attribute value of octet string syntax using a byte-for-byte comparison. RFC 4517.
telephoneNumberMatch/ 2.5.13.20	Telephone Number/ 1.3.6.1.4.1.1466.115.121.1.50	Compares an asserted value with an attribute value of Telephone Number syntax. RFC 4517.

Matching Rule/OID	Attribute Syntax/OID	Description
telephoneNumberSubstringsMatch/ 2.5.13.21	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58	Compares an asserted value with the substrings of an attribute value of Telephone Number String syntax. RFC 4517.
presentationAddressMatch/ 2.5.13.22	Presentation Address/ 1.3.6.1.4.1.1466.115.121.1.43	Compares an asserted value with an attribute value of Presentation Address syntax. RFC 4517.
uniqueMemberMatch/ 2.5.13.23	Name and Optional UID/ 1.3.6.1.4.1.1466.115.121.1.34	Compares an asserted value with an attribute value of Unique Member syntax. RFC 4517.
protocolInformationMatch/ 2.5.13.24	Protocol Information/ 1.3.6.1.4.1.1466.115.121.1.42	Compares an asserted value with an attribute value of Protocol Information syntax. RFC 4517.
generalizedTimeMatch/ 2.5.13.27	Generalized Time/ 1.3.6.1.4.1.1466.115.121.1.24	Compares an asserted value with an attribute value of Generalized Time syntax. RFC 4517.
generalizedTimeOrderingMatch/ 2.5.13.28	Generalized Time 1.3.6.1.4.1.1466.115.121.1.24	Compares the collation order of the asserted string with an attribute value of Generalized Time String syntax and case is ignored. RFC 4517.
integerFirstComponentMatch/ 2.5.13.29	Integer/ 1.3.6.1.4.1.1466.115.121.1.27	Equality matching rules for subschema attributes between an Integer syntax and the value syntax. RFC 4517.
objectIdentifierFirstComponentMatch/ 2.5.13.30	OID/ 1.3.6.1.4.1.1466.115.121.1.38	Equality matching rules for subschema attributes between an OID syntax and the value syntax. RFC 4517.
directoryStringFirstComponentMatch/ 2.5.13.31	Directory String/ 1.3.6.1.4.1.1466.115.121.1.15	Compares an asserted Directory String value with an attribute value of type SEQUENCE whose first component is mandatory and of type Directory String. Returns true if the attribute value has a first component whose value matches the asserted Directory String using the rules of caseIgnoreMatch. RFC 3698.

Matching Rule/OID	Attribute Syntax/OID	Description
wordMatch/ 2.5.13.32	Directory String/ 1.3.6.1.4.1.1466.115.121.1.15	Compares an asserted word with any word in the attribute value for equality RFC 3698.
keywordMatch/ 2.5.13.33	Directory String/ 1.3.6.1.4.1.1466.115.121.1.15	Compares an asserted value with any keyword in the attribute value for equality. RFC 3698.

Basic Matching Rule Properties

The Properties section displays the standard elements in a matching rule schema definition.

Basic Properties of Matching Rules

Attributes	Description
Name	Specifies the descriptive and unique name of the element.
Description	Specifies an optional definition that describes the matching rule. The analogous LDIF equivalent is "DESC".
OID	Specifies the globally unique object identifier assigned to the schema definition. You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
Type	Specifies the type of type of matching rule: Equality, Ordering, Substring, or Approximate.
Syntax	Specifies the matching rule syntax.
Used by Attributes	Specifies any attributes that use the corresponding matching rule.

Viewing Matching Rules

You can view the matching rules on your Directory Server by using the Schema Editor on the Administrative Console, over LDAP using the **`ldapsearch`** tool, or some third party tool.

The Schema Editor displays all of the matching rules on your Directory Server instance. It shows the basic properties that are allowed within the matching rule.

To View Matching Rules Over LDAP

Steps

- Use **`ldapsearch`** to view a multi-valued operational attribute, `matchingRules`, which publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" matchingRules
```

Managing Attribute Syntaxes

The attribute type definition has a `SYNTAX` element, or attribute syntax, that specifies how the data values for the attribute are represented. The syntax can be used to define a large range of data types necessary for client applications. An attribute syntax uses the Abstract Syntax Notation One (ASN.1) format for its definitions.

Attribute Syntax Definition

New attribute syntaxes require additional code to be implemented on the PingDirectory Server. If you need new syntax definitions, contact your authorized support provider for assistance.

The formal specification for attribute types is provided in RFC 4512, section 4.1.5 as follows:

```
SyntaxDescription = "(" wsp
numericoid                ; Object identifier
[ sp "DESC" sp qdstring ] ; Description
extensions wsp ")"        ; Extensions followed by a white space and ")"
```

Default Attribute Syntaxes

The PingDirectory Server supports a large set of Attribute Syntax rules for applications. The default Attribute Syntax rules available for the directory server are listed in the table below.

Default Attribute Syntaxes

LDAP Syntax	OID	Description
UUID	1.3.6.1.1.16.1	128-bit (16 octets) Universally Unique Identifier (UUID) used for Uniform Resource Names as defined in RFC 4122. For example, a4028c1a-f36e-11da-ba1a-04112154bd1e.
Attribute Type Description	1.3.6.1.4.1.1466.115.121.1.3	Syntax for the AttributeTypeDescription rule based on RFC 4517.
Binary	1.3.6.1.4.1.1466.115.121.1.5	Strings based on Basic Encoding Rules (BER) or Distinguished Encoding rules (DER). For example, an X.509 digital certificate or LDAP messages are BER encoded.
Bit String	1.3.6.1.4.1.1466.115.121.1.6	Sequence of binary digits based on RFC 4517. For example, '0010111'B.
Boolean	1.3.6.1.4.1.1466.115.121.1.7	TRUE or FALSE.
Certificate	1.3.6.1.4.1.1466.115.121.1.8	BER/DER-encoded octet strings based on an X.509 public key certificate as defined in RFC 4523.
Certificate List	1.3.6.1.4.1.1466.115.121.1.9	BER/DER-encoded octet string based on an X.509 certificate revocation list as defined in RFC 4523.
Certificate Pair	1.3.6.1.4.1.1466.115.121.1.10	BER/DER-encoded octet string based on an X.509 public key certificate pair as defined in RFC 4523.
Country String	1.3.6.1.4.1.1466.115.121.1.11	Two character country code specified in ISO 3166. For example, US, CA, etc.
DN	1.3.6.1.4.1.1466.115.121.1.12	Distinguished name of an entry as defined in RFC4514.
Delivery Method	1.3.6.1.4.1.1466.115.121.1.14	Sequence of services in preference order by which an entity receives messages as defined in RFC4517. For example, videotext $ telephone.

LDAP Syntax	OID	Description
Directory String	1.3.6.1.4.1.1466.115.121.1.15	String of one or more characters from the Universal Character Set (UCS) using UCS Transformation Format 8 (UTF-8) encoding of the string.
DIT Content Rule Description	1.3.6.1.4.1.1466.115.121.1.16	DITContentRuleDescription as defined in RFC4517.
DIT Structure Rule Description	1.3.6.1.4.1.1466.115.121.1.17	DITStructureRuleDesciption as defined in RFC4517.
Enhanced Guide	1.3.6.1.4.1.1466.115.121.1.21	Combination of attribute types and filter operators to be used to construct search filters as defined in RFC4517. For example, person#(sn$EQ)#oneLevel.
Facsimile Telephone Number	1.3.6.1.4.1.1466.115.121.1.22	Fax telephone number on the public switched telephone network as defined in RFC4517.
Fax	1.3.6.1.4.1.1466.115.121.1.23	Image generated using Group 3 fax process as defined in RFC4517.
Generalized Time	1.3.6.1.4.1.1466.115.121.1.24	String representing data and time as defined in RFC4517. YYYYMMDDHHMMSS[.|,fraction][(+|-HHMM)|Z] For example, 201103061032, 201103061032-0500, or 201103061032Z ("Z" indicates Coordinated Universal Time).
Guide	1.3.6.1.4.1.1466.115.121.1.25	Attribute types and filter operators as defined in RFC4517.
IA5 String	1.3.6.1.4.1.1466.115.121.1.26	String of zero or more characters from the International Alphabet 5 (IA5) character set as defined in RFC4517.
Integer	1.3.6.1.4.1.1466.115.121.1.27	String representations of integer values. For example, the character string "1234" represents the number 1234 as defined in RFC4517.
JPEG	1.3.6.1.4.1.1466.115.121.1.28	Image in JPEG File Interchange Format (JFIF) as defined in RFC4517.
Matching Rule Description	1.3.6.1.4.1.1466.115.121.1.30	MatchingRuleDescription as defined in RFC4512.
Matching Rule Use Description	1.3.6.1.4.1.1466.115.121.1.31	Attribute types to which a matching rule is applied in an extensibleMatch search filter (RFC4511).
Name and Optional UID	1.3.6.1.4.1.1466.115.121.1.34	Distinguished name and an optional unique identifier that differentiates identical DNs as defined in RFC4517. For example, uid=jsmith,ou=People,dc=example,dc=com#'0111'B
Name Form Description	1.3.6.1.4.1.1466.115.121.1.35	NameFormDescription as defined in RFC4512.

LDAP Syntax	OID	Description
Numeric String	1.3.6.1.4.1.1466.115.121.1.36	Sequence of one or more numerals and spaces as defined in RFC4517. For example, 14 848 929 102.
Object Class Description	1.3.6.1.4.1.1466.115.121.1.37	ObjectClassDescription as defined in RFC 4512.
OID	1.3.6.1.4.1.1466.115.121.1.38	Object identifier as defined in RFC 4512.
Other Mailbox	1.3.6.1.4.1.1466.115.121.1.39	Specifies an electronic mailbox as defined in RFC 4517. For example, otherMailbox = google $ user@gmail.com
Octet String	1.3.6.1.4.1.1466.115.121.1.40	Sequence of zero or more octets (8-bit bytes) as defined in RFC4517.
Postal Address	1.3.6.1.4.1.1466.115.121.1.41	Strings of characters that form a multi-line address in a physical mail system. Each component is separated by a "$". For example, 1234 Main St.$Austin, TX 78744$USA.
Protocol Information	1.3.6.1.4.1.1466.115.121.1.42	Undefined.
Presentation Address	1.3.6.1.4.1.1466.115.121.1.43	String encoded OSI presentation address as defined in RFC 1278. For example, TELEX +00728722+RFC-1006+03+10.0.0.6
Printable String	1.3.6.1.4.1.1466.115.121.1.44	String of one or more printable ASCII alphabetic, numeric, and punctuation characters as defined in RFC 4517.
RFC3672 Subtree Specification	1.3.6.1.4.1.1466.115.121.1.45	Syntax based on subtree specification as defined as RFC 3672.
Supported Algorithm	1.3.6.1.4.1.1466.115.121.1.49	Octet string based on the LDAP-encoding for a supported algorithm value that results from the BER encoding of a SupportedAlgorithm ASN.1 value.
Telephone Number	1.3.6.1.4.1.1466.115.121.1.50	String of printable international telephone number representations in E.123 format as defined in RFC 4517. For example, +1 512 904 5525.
Teletex Terminal Identifier	1.3.6.1.4.1.1466.115.121.1.51	Identifier and telex terminal as defined in RFC 4517.
Telex Number	1.3.6.1.4.1.1466.115.121.1.52	String representing the telex number, country code, and answerback code as defined in RFC 4517. For example, 812374, ch, ehhg.
UTC Time	1.3.6.1.4.1.1466.115.121.1.53	Character string representing the data and time in UTC Time format as defined as RFC 4517: YYMMDDHHMM[SS][(+|-HHMM)|Z], where Z is the coordinated universal time. For example, 0903051035Z, 0903051035-0500.
LDAP Syntax Description	1.3.6.1.4.1.1466.115.121.1.54	SyntaxDescription as defined in RFC4512.

LDAP Syntax	OID	Description
Substring Assertion	1.3.6.1.4.1.1466.115.121.1.58	Syntax for assertion values in an extensible match as defined in RFC 4517.
Authentication Password Syntax	1.3.6.1.4.1.4203.1.1.2	Encoded password storage syntax as defined in RFC 3112. For example, the syntax specifies the storage scheme in brackets as follows: <storage-scheme> $<auth component>$<auth value> For example: SSHA$xdEZWRqgyJk= $egDEFDXvdeeEnXUEIDPnd39dkpe=
User Password Syntax	1.3.6.1.4.1.30221.1.3.1	Encoded password storage syntax as defined in RFC 2307. For example, the syntax specifies the storage scheme in brackets as follows: {SSHA}XaljOF0ii3fOwCrU1klgBpWFayqSYs +5W1pMnw==
Relative Subtree Specification	1.3.6.1.4.1.30221.1.3.2	Similar to the RFC 3672 subtree specification except it uses an LDAP search filter as the specification filter.
Absolute Subtree Specification	1.3.6.1.4.1.30221.1.3.3	Syntax for a subset of entries in a subtree based on RFC 3672.
Sun-defined Access Control Information	1.3.6.1.4.1.30221.1.3.4	Syntax for access control instructions used in Sun Directory Servers.
Compact Timestamp	1.3.6.1.4.1.30221.2.3.1	Syntax based on compact timestamp ISO 8601 format. For example, 20110306T102532.

Basic Attribute Syntax Properties

The Properties section displays the standard elements in an attribute syntax.

Basic Properties of Attribute Syntaxes

Attributes	Description
Name	Specifies the descriptive and unique name of the element.
Description	Indicates an optional definition that describes the attribute syntax. The analogous LDIF equivalent is "DESC".
OID	Specifies the globally unique object identifier assigned to the schema definition.
Used by Attributes	Indicates any attributes that use the corresponding attribute syntax.

Viewing Attribute Syntaxes

You can view the attribute syntaxes on your Directory Server by using the Schema Editor on the Administrative Console, over LDAP using the **`ldapsearch`** tool, or some third party tool.

The Schema Editor displays all of the attribute syntaxes on your Directory Server instance. It shows the properties that are allowed within the attribute syntax.

To View Attribute Syntaxes Over LDAP

Steps

- Use **`ldapsearch`** to view the Directory Server's published list of attribute syntaxes using the multi-valued operational attribute, `ldapSyntaxes`, which publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base "(objectclass=*)" ldapSyntaxes
```

Using the Schema Editor Utilities

The Schema Editor provides a **Schema Utilities** tab that enables importing new schema elements from a file and to checking schema compliance. If importing a schema file, the system automatically checks for compliance prior to the import. If the definition does not meet schema compliance, the system will display an error message. However, it is good practice to first check if your file is compliant with your schema prior to importing it.

To Check Schema Compliance Using the Schema Editor

Steps

1. Start the Administrative Console.
2. On the main menu, click **LDAP Schema**.
3. On the Schema Editor, click the **Schema Utilities** tab.
4. Click **Import Schema Elements** to read in an LDIF file, or copy-and-paste a new schema definition, and then click **Validate Entries**. If there is a problem, an error will be generated.

Modifying a Schema Definition

The Directory Server only allows schema definitions that are read-write to be edited. Schema elements indicated by the **Modifiable** column in the Schema Editor's tables can be modified.

To Modify a Schema Definition

Steps

1. Start the Administrative Console. Check that the Directory Server instance associated with the console is running.
2. On the main menu, click **Schema**.
3. On the Schema Editor, click the **Object Classes** tab.
4. Select the object class that you want to modify, and then click **Actions -> Edit**. The Edit dialog box appears.
5. Make your changes, and then click **OK**.

Deleting a Schema Definition

The Directory Server only allows schema definitions that are read-write to be deleted. In general, those schema definitions in the **Custom** folder of the Schema Editor can be removed from the system. You should make sure that the schema element is not currently in use.

To Delete a Schema Definition

Steps

1. Start the Administrative Console. Check that the Directory Server instance associated with the console is also running.
2. On the main menu, click **Schema**.
3. On the **Schema Editor**, click the **Object Classes** tab.
4. Select the object class that you want to remove, and then click **Actions -> Delete**.
5. On the **Confirmation** dialog, click **Yes** if you are sure that you want to delete the schema element.

Schema Checking

The PingDirectory Server provides full support for parsing all schema elements and provides access to all of its components. By default, the Directory Server enables schema checking for all operations, especially when importing data to the server or when modifying entries using the **`ldapmodify`** tool. Any schema violations will generate an error message to standard output.

To View the Schema Checking Properties

Steps

- Use **`dsconfig`** to view the schema checking property.

```
$ bin/dsconfig get-global-configuration-prop \
  --property check-schema
```

To Disable Schema Checking

About this task
Although not recommended, you can use the **`dsconfig`** tool to disable the schema checking. This feature only applies to public backends. Schema checking is enforced on private backends, such as changes to the Configuration, Schema, Task, and others. An admin action alert will be generated when attempting to disable schema checking using **`dsconfig`** interactive or non-interactive mode. The alert provides alternatives to disabling schema checking.

Steps

Run the **`dsconfig`** command and specify the `set-global-configuration-prop` subcommand to disable the `check-schema` property.

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
  --set check-schema:false
```

The system generates an admin action alert providing alternate options to disabling schema checking. Press **Enter** to continue the process or following one of the suggested tasks:

```
One or more configuration property changes require administrative action or
confirmation/notification.

Those properties include:

  *   check-schema: Schema checking should only be disabled as a last resort
      since disabling schema checking harms performance and can lead to
      unexpected behavior in the server as well as the applications that
      access it. There are less severe options for addressing schema issues:
```

```
 1.  Update the data to conform to the server schema.

 2.  Modify the server schema to conform to the data. Contact support before
     modifying the server's default schema.

 3.  Change the single-structural-objectclass-behavior property to allow
     entries to have no structural object class or multiple structural
object
     classes.

 4.  Change the invalid-attribute-syntax-behavior property to allow
attribute
     values to violate their attribute syntax.

 5.  Change the allow-zero-length-values property of the Directory String
     Attribute Syntax configuration to allow attributes with this syntax to
     have a zero length value.

Continue?  Choose 'no' to return to the previous step (yes / no) [yes]:
```

Managing Matching Rule Uses

Matching Rule Use definitions map certain attribute types with a matching rule definition for extensible match filters. Extensible match filters allows clients to search using DN components, for example, (`ou:dn:=engineering`) or using an OID number, for example, (`cn:1.2.3.4:=Sam Carter`). The matching rule use attribute publishes those attribute types and matching rule combinations, which can be used in extensible match assertions.

Typically, you define a matching rule use that is not normally specified in the attribute type definition. You can create new matching rule uses from the existing schema definitions by adding a custom schema file in the `<server-root>/config/schema` directory.

Matching Rule Use Definitions

Matching Rule Use can be specified with existing schema components and do not require additional code for its implementation.

The formal specification for attribute types is provided in RFC 4512, section 4.1.4 as follows:

```
MatchingRuleUseDescription = "(" wsp
numericoid                  ; Object identifier
[ sp "NAME" sp qdescrs ]    ; Short name descriptor
[ sp "DESC" sp qdstring ]   ; Description
[ sp "OBSOLETE" ]           ; Specifies if the rule use is inactive
sp "APPLIES" sp oid         ; Attribute types
extensions wsp ")"          ; Extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```
extensions = /
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the definition
"X-READ-ONLY"            ; True or False. Specifies if the file that contains
                         ;   the schema element is marked as read-only in the
                         ;   server configuration.
```

To View Matching Rule Uses

About this task

A matching rule use lists the attribute types that are suitable for use with an `extensibleMatch` search filter.

Steps

- Use **ldapsearch** to view the Directory Server's published list of matching rule uses using the multi-valued operational attribute, `matchingRuleUse`, which publishes the definitions on the Directory Server if any. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" matchingRuleUse
```

Managing DIT Content Rules

DIT Content Rules provide a way to precisely define what attributes may be present in an entry, based on its structural object class, without specifically creating a new object class definition. The DIT content rules can define the mandatory and optional attributes that entries contain, the set of auxiliary object classes that entries may be part of, and any optional attributes from the structural and auxiliary object classes that are prohibited from being present in the entries.

DIT Content Rule Definitions

DIT Content Rules can be specified with existing schema components and do not require additional code for its implementation. On the PingDirectory Server, only one DIT Content Rule may be defined for an entry in the structural object class.

The formal specification for attribute types is provided in RFC 4512, section 4.1.6 as follows:

```
DITContentRuleDescription = "(" wsp
numericoid                  ; Object identifier of the structural object class
 the rule applies to
[ sp "NAME" sp qdescrs ]    ; Short name descriptor
[ sp "DESC" sp qdstring ]   ; Description
[ sp "OBSOLETE" ]           ; Specifies if the rule is inactive
[ sp "AUX" sp oids ]        ; List of allowed auxiliary object classes
[ sp "MUST" sp oids ]       ; List of required attributes
[ sp "MAY" sp oids ]        ; List of allowed attributes in the entry
[ sp "NOT" sp oids ]        ; List of prohibited attributes in the entry
extensions wsp ")"          ; Extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```
extensions = /
"X-ORIGIN" /             ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the definition
"X-READ-ONLY"            ; True or False. Specifies if the file that contains
                         ;   the schema element is marked as read-only in
                         ;   the server configuration.
```

To View DIT Content Rules

Steps

- Use **ldapsearch** to view a multi-valued operational attribute `dITContentRules`, which publishes the definitions on the Directory Server if any. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" dITContentRules
```

Managing Name Forms

Name Forms define how entries can be named based on their structural object class. Specifically, name forms specify the structural object class to be named, as well as the mutually-exclusive set of required and allowed attributes to form the Relative Distinguished Names (RDNs) of the entries. Each structural object class may be associated with at most one name form definition.

Name Form Definitions

Name Forms can be specified with existing schema components and do not require additional code for its implementation.

The formal specification for attribute types is provided in RFC 4512, section 4.1.7.2 as follows:

```
NameFormDescription = "(" wsp
numericoid                  ; object identifier
[ sp "NAME" sp qdescrs ]    ; short name descriptor
[ sp "DESC" sp qdstring ]   ; description
[ sp "OBSOLETE" ]           ; not active
sp "OC" sp oid              ; structural object class
sp "MUST" SP oids           ; attribute types
[ sp "MAY" sp oids ]        ; attribute types
extensions wsp ")"          ; extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```
extensions = /
"X-ORIGIN" /             ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the definition
"X-READ-ONLY"            ; True or False. Specifies if the file that contains
                         ;   the schema element is marked as read-only in
                         ;   the server configuration.
```

To View Name Forms

Steps

- Use **`ldapsearch`** to view a multi-valued operational attribute `nameForms`, which publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

  ```
  $ bin/ldapsearch --baseDN cn=schema --searchScope base "(objectclass=*)"
   nameForms
  ```

Managing DIT Structure Rules

DIT Structure Rules define which entries may be superior or subordinate to other entries in the DIT. Together with name forms, DIT Structure Rules determine how RDNs are added together to make up distinguished names (DNs). Because DITs do not have a global standard and are specific to a company's implementation, each DIT structure rule associates a name form with an object class and specifies each structure rule with an integer rule identifier, instead of an OID number. The identifier defines its relationship, either superior or subordinate, to another object class. If no superior rules are specified, then the DIT structure rule applies to the root of the subtree.

DIT Structure Rule Definition

DIT Structure Rules can be specified with existing schema components and do not require additional code for its implementation.

The formal specification for attribute types is provided in RFC 4512, section 4.1.7.1 as follows:

```
DITStructureRuleDescription = "(" wsp
ruleid                      ; object identifier
[ sp "NAME" sp qdescrs ]    ; short name descriptor
[ sp "DESC" sp qdstring ]   ; description
[ sp "OBSOLETE" ]           ; specifies if the rule is inactive
sp "FORM" sp oid            ; OID or name form with which the rule is
 associated
[ sp "SUP" ruleids ]        ; Superior rule IDs
extensions wsp ")"          ; extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```
extensions = /
"X-ORIGIN" /             ; Specifies where the rule is defined
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the definition
"X-READ-ONLY"            ; True or False. Specifies if the file that contains
                         ;   the schema element is marked as read-only in
                         ;   the server configuration.
```

To View DIT Structure Rules

Steps

- Use **ldapsearch** to view a multi-valued operational attribute `dITStructureRules`, which publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" dITStructureRules
```

Managing JSON Attribute Values

The PingDirectory Server supports a JSON object attribute syntax, which can be used for attribute types whose values are JSON objects. The syntax requires that each value of this type is a valid JSON object. The following is an example schema definition:

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( jsonAttr1-OID NAME 'jsonAttr1' DESC 'test json attribute
 support' EQUALITY jsonObjectExactMatch SYNTAX 1.3.6.1.4.1.30221.2.3.4 USAGE
 userApplications )
objectClasses: ( jsonObjectClass-OID NAME 'jsonObjectClass' AUXILIARY MAY
 jsonAttr1 )
```

ⓘ **Note:** The EQUALITY matching rule should always be specified as `jsonObjectExactMatch` in the schema definition. Using the `jsonObjectFilterExtensibleMatch` is not valid in this case.

The `jsonObjectExactMatch` and `jsonObjectFilterExtensibleMatch` matching rules are provided to filter equality matching rule JSON object syntax. The following three additional matching rules are used in conjunction with the **jsonObjectExactMatch** and provide support for customizing the way that the server treats case sensitivity in JSON field names and in string values:

- **jsonObjectCaseSensitiveNamesCaseSensitiveValues**
- **jsonObjectCaseInsensitiveNamesCaseInsensitiveValues**
- **jsonObjectCaseInsensitiveNamesCaseSensitiveValues**

The `jsonObjectExactMatch` equality matching rule is used in evaluating equality filters in search operations, and for matching performed against JSON object attributes for add, compare, and modify operations. It determines whether two values are logically-equivalent JSON objects. The field names used in both objects must match exactly (although fields may appear in different orders). The values of each field must have the same data types. The order of elements in arrays is considered significant. Substring or approximate matching is not supported.

The `jsonObjectFilterExtensibleMatch` matching rule can perform more powerful matching against JSON objects. The assertion values for these extensible matching filters should be JSON objects that express the constraints for the matching. These JSON object filters are described in detail in the Javadoc documentation for the LDAP SDK for Java. Although the LDAP SDK can facilitate searches with this

matching rule, these searches can be issued through any LDAP client API that supports extensible matching.

The following are example searches using the `jsonObjectFilterExtensibleMatch` rule with available filter types.

Equals field filter type:

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com  -D "cn=Directory Manager"
 -w password '(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
 "equals", "field" : ["stuff", "onetype", "name"], "value" : "John Doe" })'
```

Contains field filter type:

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com  -D "cn=Directory Manager"
 -w password '(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
 "containsField", "field" : "age", "expectedType" : "number" })'
```

Greater than field filter type:

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com  -D "cn=Directory Manager"
 -w password '(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
 "greaterThan", "field" : "age", "value" : 26, "allowEquals" : true})'
```

Configuring JSON Attribute Constraints

The PingDirectory Server can define a number of constraints for the fields included in JSON objects stored in values of a specified attribute type. Constraints that can be placed on a JSON field include:

- Requiring values of the field to have a specified data type.
- Indicating whether the field is required or optional.
- Indicating whether the field can have multiple values in an array. If a field is permitted to have array values, restrictions can also be placed on the number of elements that can be present in the array.
- Indicating whether the field can have a value that is the null primitive as an alternative to values of the indicated data type.
- Restricting values of string fields to a predefined set of values, that match a given regular expression, or a specified length.
- Restricting values of numeric fields with upper and lower bounds.

Any existing data that doesn't match newly-defined JSON constraints can still be decoded and managed by the server. Only new entries are subject to the new constraints. Attempts to alter existing entries with non-compliant JSON objects may require fixing those objects to make them conform to the new constraints.

The two global configuration properties that define schema constraints for JSON objects are `create-json-attribute-constraints` and `create-json-field-constraints` in `dsconfig`. In `dsconfig` interactive under advanced settings, the menu options are JSON Attribute Constraints and JSON Field Constraints. Configuration properties for each include:

- **attribute-type**. The name or object identifier of the attribute type with which the definition is associated. This attribute type must have the JSON object syntax. This property will be the naming attribute for the configuration entry.
- **allow-unnamed-fields**. A boolean value that indicates whether JSON objects, used as the values of attributes of the associated type, can include fields that are not referenced in the `attribute-value-constraints` object. If this is `false`, JSON objects will only be permitted to have the defined fields. If this is `true` (which is the default behavior), JSON objects are permitted to have fields that are not referenced, and no constraints are imposed on those fields.

Unless a schema definition is configured with `allow-unnamed-fields` set to `false`, it is only necessary to include information about fields whose values should be indexed or tokenized. However, it may be

desirable to define other fields that are expected in order to ensure that clients will not be permitted to store invalid values. See the *Working with JSON Indexes* for information about indexing JSON attributes.

As with standard LDAP schema, JSON schema constraints are enforced for any changes made after the constraints are defined. If there are already JSON values in the data before a JSON schema is defined for that attribute type (or before changes are made), values that already exist may violate those constraints. JSON schema constraints will also be enforced for data provided in an LDIF import, so that entries containing JSON objects that violate these constraints will be rejected.

JSON Field Constraints

Property	Description
`field`	Specifies the path to the target field as a string, with periods to separate levels of hierarchy. If any field name in the hierarchy itself includes a period, that period should be escaped with a backslash.
`value-type`	Specifies the expected data type for the target field. Values can include: ▪ `any`. The target field can have any value. ▪ `boolean`. The target field must have a value of true or false. ▪ `integer`. The target field must have a number that can be exactly represented as an integer. ▪ `null`. The target field must have a value of null. ▪ `number`. The target field must have a value that represents a valid JSON number ▪ `object`. The target field must have a value that represents a valid JSON object. The `allowed-fields` array may contain additional elements that define constraints for the fields that may be present in the object. ▪ `string`. The target field must have a value that represents a valid JSON string.
`is-required`	Specifies whether the target field is required to be present. If it is present, its value must be either `true` or `false`. If it is absent, a default of `false` is assumed.
`is-array`	Indicates whether the target field can be an array. If the value can be an array, all of the elements of the array must be of the type specified in the `value-type` field. It can be present with a value that is one of the single strings listed below. If it is absent, a value of `prohibited` is assumed. Values include: ▪ `required`. The target field must be an array with zero or more values of the specified type, and must not be a single value of the specified type. ▪ `optional`. The target field may be an array with zero or more values of the specified type, or it may be a single value of the specified type. ▪ `prohibited`. The target field must not be an array and may only be a single value of the specified type.
`allow-null-value`	Specifies whether the target field can have a value of `null` as an alternative to the specified `value-type`. If present, its value must be either `true` or `false`. If it is absent, a default of `false` is assumed. This has no effect if the value-type is `null`.
`allow-empty-object`	If the value of the target field is a JSON object (or an array of JSON objects), specifies whether empty objects are permitted. If present, the value must be either `true` (the object may have zero or more fields) or `false` (the object may have one or more fields). If it is absent, a default of `false` is assumed.

Property	Description
`index-values`	Specifies whether values of the target field should be indexed in backends. If present, the value must be either `true` (the field should be indexed) or `false` (the field should not be indexed). If it is absent, a default of `false` is assumed. If `true`, the `value-type` must be `boolean`, `integer`, `null`, or `string`.
`index-entry-limit`	Specifies the maximum number of entries in which a particular value may appear before the entry ID list for that value is no longer maintained. If present, the value must be an integer greater than or equal to one. If it is absent, the server will use the default index entry limit for the associated backend. This is only applicable if `index-values` is `true`.
`prime-index`	Specifies whether backends should prime the contents of the JSON index database into memory when they are opened. This is ignored if the backend's `prime-all-indexes` property has a value of `true`.
`cache-mode`	Specifies the cache mode to use for the contents of the JSON index database. If the value is not specified, the backend's default cache mode will be used. If a cache mode of `cache-keys-only` is configured, priming will only load the internal nodes into memory for the index. If `no-caching` is configured, no priming is performed for the index.
`tokenize-values`	Specifies whether values of the target field should be tokenized in backends. If present, the value is either `true` (field values should be tokenized) or `false`. If it is absent, a value of `false` is assumed. If `true`, the `value-type` must be `string`.
`allowed-values`	Specifies an explicit set of values that the target field is permitted to have. If present, the value must be an array of strings. Any attempt to use a value not in this array for the associated field is rejected. This can only be used with a `value-type` of `string`. If not present, any value can be used as long as it satisfies all other defined constraints.
`allowed-value-regular-expression`	Specifies a regular expression that the target field will be required to match. If present, the value must be a single string or an array of strings representing valid regular expressions (which may require escaping to represent in JSON). Any attempt to use a value that does not match one of the provided regular expressions will be rejected. This can only be used with a `value-type` of `string`. If not present, values are not required to match any regular expression.
`minimum-numeric-value`	Specifies the lower bound for values of the target field. If present, the value must be a single number (it can be an integer). Any attempt to use a value that is less than this number is rejected. This can only be used with a `value-type` of `integer` or `number`. If not present, no minimum numeric value applies.
`maximum-numeric-value`	Specifies the upper bound for values of the target field. If present, the value must be a single number (it can be an integer). Any attempt to use a value that is more than this number is rejected. This can only be used with a `value-type` of `integer` or `number`. If not present, no maximum numeric value applies.
`minimum-value-length`	Specifies the minimum number of characters allowed for values of the target field. If present, the value must be an integer. Any attempt to use a value with fewer characters than this number is rejected. This can only be used with a `value-type` of `string`. If not present, no minimum length applies.

Property	Description
`maximum-value-length`	Specifies the maximum number of characters allowed for values of the target field. If present, the value must be an integer. Any attempt to use a value with more characters than this number is rejected. This can only be used with a `value-type` of `string`. If not present, no maximum length applies.
`minimum-value-count`	Specifies the minimum number of elements that must be present in an array. If present, the value must be an integer. Any attempt to use an array with fewer elements is rejected. This can only be used with an `is-array` value of `required` or `optional`. If not present, no minimum array value count applies.
`maximum-value-count`	Specifies the maximum number of elements that must be present in an array. If present, the value must be an integer. Any attempt to use an array with more elements is rejected. This can only be used with an `is-array` value of `required` or `optional`. If not present, no maximum array value count applies.

ⓘ **Note:** When writing JSON objects in a local DB backend, field names and JSON primitive values of `null`, `true`, and `false` are always tokenized. Integers are either tokenized or compacted using their two's complement representation (other numbers are stored using string representations). Array and object sizes are compacted, and their contents are compacted based on their data types. String values are tokenized that match a recognizable format, including:

- Dates and times in common generalized time and ISO 8601 formats.
- UUIDs in which the alphabetic characters are either all uppercase or all lowercase.
- Strings of at least 12 bytes that are a valid base64 encoding.
- Strings of at least 6 bytes that are a valid hexadecimal encoding, in which the alphabetic characters are either all uppercase or all lowercase.

To Add Constraints to JSON Attributes

Steps

- Use the `dsconfig` tool (interactive or command line) to create and configure JSON attribute constraints. The following is a sample command:

```
$ bin/dsconfig create-json-attribute-constraints \
  --attribute-type appjson \
  --set enabled:true \
  --set allow-unnamed-fields:false
```

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type appjson \
  --json-field email.verified \
  --set value-type:boolean \
  --set is-required:true \
  --set index-values:true \
  --set tokenize-values:false \
  --set allow-null-value:true
```

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type appjson \
  --json-field email.type \
  --set value-type:string \
  --set is-required:true \
  --set index-values:true \
```

```
  --set tokenize-values:true \
  --set allowed-value:home \
  --set allowed-value:other \
  --set allowed-value:work \
  --set allow-null-value:false \
  --set minimum-value-length:1
```

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type appjson \
  --json-field email.value \
  --set value-type:string \
  --set is-required:true \
  --set index-values:true \
  --set tokenize-values:true \
  --set prime-index:true \
  --set allow-null-value:true \
  --set maximum-value-length:256 \
  --set minimum-value-length:1 \
  --set allowed-value-regular-expression:[-_\+\.\w\d]+@\w+\.\w{2,5}
```

Managing Password Policies

The PingDirectory Server provides a flexible password policy system to assign, manage, or remove password policies for root and non-root users. The password policy contains configurable properties for password expiration, failed login attempts, account lockout and other aspects of password and account maintenance on the Directory Server. The Directory Server also provides a global configuration option and a per-user privilege feature that disables parts of the password policy evaluation for production environments that do not require a password policy.

Viewing password policies

Password policies enforce a set of rules that ensure that access to data is not compromised through negligent password practices. The PingDirectory Server provides mechanisms to create and maintain password policies that determine whether passwords should expire, whether users are allowed to modify their own passwords, or whether too many failed authentication attempts should result in an account lockout. Many other options are available to fully configure a password policy for your PingData Platform system.

The Directory Server provides three out-of-the-box password policies that can be applied to your entries or as templates for configuring customized policies. The Default Password Policy is automatically applied to all users although it is possible to use an alternate password policy on a per-user basis. The Root Password Policy is enforced for the default root user, which uses a stronger password storage scheme (PBKDF2 rather than the salted 256-bit SHA-2 scheme) and also requires that a root user provide his or her current password to select a new password.

The Secure Password Policy provides a more secure option than the default policy that makes use of a number of features, including password expiration, account lockout, last login time and last login IP address tracking, password history, and a number of password validators.

> ⓘ **CAUTION:**
>
> Using the Secure Password policy as-is may notably increase write load in the server by requiring updates to password policy state attributes in user entries and/or requiring users to change passwords more frequently. In environments in which write throughput is a concern (including environments spread across multiple data centers requiring replication over a WAN), it may be useful to consider whether the policy should be updated to reduce the number of entry updates that may be required.

Viewing password policies

Steps

- You can view the list of password policies configured on the Directory Server using the **dsconfig** tool, in either interactive or non-interactive mode, or the Administrative Console. The following example demonstrates the process for obtaining a list of defined password policies in non-interactive mode:

```
$ bin/dsconfig list-password-policies
```

```
Password Policy      : Type : password-attribute : default-password-storage-
scheme
-----------------------:---------:--------------------:----------------------------
Default Password Policy : generic : userpassword    : Salted 256-bit SHA-2
Root Password Policy : generic : userpassword    : PBKDF2
Secure Password Policy  : generic : userpassword       : PBKDF2
```

Viewing a specific password policy

Steps

- Use **dsconfig** or the Administrative Console to view a specific password policy. In this example, view the Default Password Policy that applies to all uses for which no specific policy has been configured.

```
$ bin/dsconfig get-password-policy-prop \
  --policy-name "Default Password Policy"
```

```
Property                                 : Value(s)
-----------------------------------------:--------------------------
description                              : -
password-attribute                       : userpassword
default-password-storage-scheme          : Salted SHA-1
deprecated-password-storage-scheme       : -
password-validator                       : -
account-status-notification-handler      : -
allow-user-password-changes              : true
password-change-requires-current-password : false
force-change-on-add                      : false
force-change-on-reset                    : false
password-generator                       : Random Password Generator
require-secure-authentication            : false
require-secure-password-changes          : false
min-password-age                         : 0s
max-password-age                         : 0s
max-password-reset-age                   : 0s
password-expiration-warning-interval     : 5d
expire-passwords-without-warning         : false
allow-expired-password-changes           : false
grace-login-count                        : 0s
lockout-failure-count                    : 0s
lockout-duration                         : 0s
lockout-failure-expiration-interval      : 0s
require-change-by-time                   : -
last-login-time-attribute                : ds-pwp-last-login-time
last-login-time-format                   : -
previous-last-login-time-format          : -
idle-lockout-interval                    : 0s
password-history-count                   : 0s
password-history-duration                : 0s
```

About the password policy properties

The Directory Server provides a number of configurable properties that can be used to control password policy behavior.

ⓘ **Note:** To view a description of each of the password policy properties, see the *Ping Identity Directory Server Configuration Reference* that is bundled with the PingDirectory Server.

Some of the most notable properties include:

- **allow-user-password-changes**. Specifies whether users can change their own passwords. If a user attempts to change his/her own password, then the server will consult this property for the user's password policy, and will also ensure that the access control handler allows the user to modify the configured password attribute.
- **default-password-storage-scheme**. Specifies the names of the password storage schemes that are used to encode clear-text passwords for this password policy.
- **enable-debug**. When enabled, is used to debug password policy interaction. This property should be used in addition to the server's debug framework with a relevant debug target.
- **force-change-on-add**. Specifies whether users are required to change their passwords upon first authenticating to the Directory Server after their account has been created.
- **force-change-on-reset**. Specifies whether users are required to change their passwords after they have been reset by an administrator. An administrator is a user who has the `password-reset` privilege and the appropriate access control instruction to allow modification of other users' passwords.
- **idle-lockout-interval**. Specifies the maximum length of time that an account may remain idle (the associated user does not authenticate to the server) before that user is locked out. For accounts that do not have a last login time value, the password changed time or the account creation time will be used. If that information is not available, then the user will not be allowed to authenticate. It is strongly recommended that the server be allowed to run for a period of time with last login time tracking enabled (i.e., values for both `last-login-time-attribute` and `last-login-time-format` properties) to ensure that users have a last login time before enabling idle account lockout.
- **lockout-duration**. Specifies the length of time that an account is locked after too many authentication failures. The value of this attribute is an integer followed by a unit of seconds, minutes, hours, days, or weeks. A value of 0 seconds indicates that the account must remain locked until an administrator resets the password.
- **lockout-failure-count**. Specifies the maximum number of times that a user may be allowed to attempt to bind with the wrong password before that user's account becomes locked either temporarily (in which case the account will automatically be unlocked after a configurable length of time) or permanently (in which case an administrator must reset the user's password before the account may be used again). For example, if the value is set to `3`, the user is locked out after three failed attempts, even if a fourth attempt is made with the correct password.
- **max-password-age**. Specifies the maximum length of time that a user can continue to use the same password before he or she is required to choose a new password. The value can be expressed in seconds (s), minutes (m), hours (h), days (d), or weeks (w). A minimum length of time can also be specified before the user is allowed to change the password.
- **password-change-requires-current-password**. Specifies whether users must include their current password when changing their password. This applies for both password changes made with the password modify extended operation as well as simple modify operations targeting the password attribute. In the latter case, if the current password is required then the password modification must remove the current value and add the desired new value (providing both the current and new passwords in the clear rather than using encoded representations).
- **password-expiration-warning-interval**. Specifies the length of time before a user's password expires that he or she receives notification about the upcoming expiration (either through the password policy or password expiring response controls). The value can be expressed in seconds (s), minutes (m), hours (h), days (d), or weeks (w).

- **password-retirement-behavior**. Specifies the behavior of a password that is allowed a retirement period before becoming invalid. This setting may be used by application service accounts that require a transition period while updating passwords. This is disabled by default.
- **password-validator**. Specifies the names of the password validators that are used with the associated password storage scheme. The password validators are invoked when a user attempts to provide a new password, to determine whether the new password is acceptable.
- **require-secure-authentication**. Indicates whether users with the associated password policy are required to authenticate in a secure manner. This might mean either using a secure communication channel between the client and the server, or using a SASL mechanism that does not expose the credentials.
- **require-secure-password-changes**. Indicates whether users with the associated password policy are required to change their password in a secure manner that does not expose the credentials.

ⓘ **Note:** As an alternative to account lockout, a **`failed-bind-response-delay`** configuration property can be set on the LDAP Connection handler to instruct the server to introduce a delay (such as one second) into the process of returning a response to an unsuccessful bind operation. Delaying the response to a failed bind only affects the connection on which the bind was attempted, and still limits the rate at which a malicious client can try to guess a user's password. However, it will not affect other attempts to authenticate as that user on other connections, so the legitimate user can still authenticate with the correct password.

Access log

You can configure the server to maintain a recent login history for both successful and failed login attempts. This history can be maintained by count or duration, and you can configure the history separately for sucessful and failed login attempts.Each record in the login history contains the following:

- The time of the login attempt.
- The client IP address.
- The authentication method.
- The reason for failure for failed attempts.

You can optionally collapse information about multiple similar attempts on the same date to avoid flooding the history for accounts that bind frequently. Records have an additional attempt count that tracks the number of attempts with the same client IP address, authentications method, and failure reason on the same date. You can also configure the server to maintain each attempt separately, or to only update the history at most once per day.

Recent login history is disabled by default. You can enable and configure the recent login history in password policy. Recent login history can be retrieved with the **`get recent login history`** control, available in the LDAP SDK or with the **`ldapsearch`** and **`ldapmodfy`** commands. The recent login history is also available in the ds-pwp-state-json JSON attribute and in the password policy state extended operation and the **`manage-account`** command-line tool.

The recent login history can be enabled and configured with the following password policy configuration properties:

- maximum-recent-login-history-successful-authentication-count - The maximum number of records that the server will maintain about recent successful authentications.
- maximum-recent-login-history-successful-authentication-duration - The maximum length of time for which the server will maintain information about recent successful authentications.
- maximum-recent-login-history-failed-authentication-count - The maximum number of records that the server will maintain about recent failed authentication attempts.
- maximum-recent-login-history-failed-authentication-duration - The maximum length of time for which the server will maintain information about recent failed authentication attempts.
- recent-login-history-similar-attempt-behavior - The behavior that the server will exhibit for cases in which a user makes multiple authentication attempts on the same date in which all of the fields in the

record other than the timestamp (client-ip-address, authentication-method, and potentially failure-reason) match. Possible values for this property include the following:

- collapse-similar-attempts-on-the-same-date - Indicates that the server will only maintain one record for any given date with the same values for all non-timestamp fields, and it will use the additional-attempt-count field to keep track of the number of additional attempts that were collapsed into the same record. The timestamp field for that record will reflect the most recent attempt on that date. This will be the default behavior.
- maintain-every-attempt - Indicates that the server will maintain a separate record for every attempt, regardless of how similar it is to a previous attempt although duplicate attempts within the same millisecond may not be preserved (see *Replication considerations* on page 644).
- update-at-most-once-per-day - Indicates that the server will only maintain one record for any given date with the same values for all non-timestamp fields. This can help reduce the number of writes needed to maintain a recent login history, but the value of the timestamp field may not accurately reflect the timestamp of the most recent attempt.

None of these properties are defined by default. If at least one of these properties is defined, the server maintains a recent login history within the specified constraints.

If both the maximum-recent-login-history-successful-authentication-count and maximum-recent-login-history-successful-authentication-duration properties are defined, the server uses the more-restrictive value that applies to a given user. This is also true for the maximum-recent-login-history-failed-authentication-count and maximum-recent-login-history-failed-authentication-duration properties. For example, if the password policy is configured to maintain a successful count of 10 and a successful duration of 30 days, then a user who successfully authenticates on more than ten dates in a 30-day period would be capped at ten records, while a user who authenticates less frequently would only have records for however many attempts they made within those 30 days.

The server can collapse multiple authentication attempts from the same date into a single record if other fields in the record (client-ip-address, authentication-method, and potentially failure-reason, match, this caps the number of records that will be maintained if you want to maintain records by duration rather than count. However, because multiple records may be generated for the same user on the same date if something is different (for example., a different IP address or authentication method), there is technically no limit to the number of records that may be generated when using only a duration-based cap. To help mitigate this, even if you generally want to maintain a duration-based cap, you can specify a maximum count to place an upper bound on what informatoin the server will maintain for a given user.

ⓘ **Note:** The password policy state for a given user is only updated when that user attempts to authenticate to the server. Therefore, a user might have records in their entry for authentication attempts that occurred outside of the maximum duration if they have not made any authentication attempt within that duration. Further, if the server is configured to maintain recent login history for successful authentication attempts, then it will always keep a record of the most recent attempt (or an attempt from the same date as the most recent attempt if the recent-login-history-similar-attempt-behavior is set to update-at-most-once-per-day), even if that attempt occurred outside of the maximum duration. Similarly, if the server is configured to maintain a history of failed attempts, then it will always provide information about the most recent failed attempt, even if it is older than the maximum duration.

If the password policy is configured to maintain a recent login history, the ds-pwp-state-json virtual attribute includes a recent-login-history field whose value is a JSON object with the same representation used in the get recent login history response control. It may also include the following additional fields that provide information about related configuration in the password policy:

- maximum-recent-login-history-successful-authentication-count
- maximum-recent-login-history-successful-authentication-duration-seconds
- maximum-recent-login-history-failed-authentication-count
- maximum-recent-login-history-failed-authentication-duration-seconds

The password policy state extended operation provides support for two additional operations:

- An operation that may be used to retrieve the recent login history. The value returned in this operation will be a JSON object in the same format as used in the get recent login history response control and the ds-pwp-state-json virtual attribute.
- An operation that may be used to clear the recent login history for a user.

Replication considerations

Each login attempt is maintained as a separate attribute value to avoid the potential for data loss as a result of replication propagation delay. If a record of all login attempts were maintained within a single JSON object, the object written on one server would not reflect concurrent attempts made on other servers, and replication would only use what it perceives to be the most recent value rather than attempting to merge the values.

It is still possible that information about one or more attempts made around the same time could be lost. This includes the following cases:

- If the server is not configured to collapse information about multiple similar attempts, then it will not be able to record information about multiple similar attempts made within the same millisecond, because that would result in duplicate attribute values.
- If the server is configured to collapse information about multiple similar attempts, then concurrent modifications (especially on different servers) could cause the additional-attempt-count value to be incremented to the same value on each of those servers. If the concurrent attempts happened within the same millisecond, then only one of them would be preserved and any others would be lost. If the attempts did not occur within the same millisecond, then we may be able to infer the correct value during internal processing, but there may still be corner cases in which the server could lose information about one or more attempts.

Get Recent Login History control

A pair of request and response controls can be used to obtain the recent login history. The request control, which has an OID of 1.3.6.1.4.1.30221.2.5.61 and no value, may be included in a bind request to indicate that the server should return the recent login history in the bind response. This is provided in the response control, which has an OID of 1.3.6.1.4.1.30221.2.5.62 and a value containing only the string representation of a JSON object with the recent login history. That object will have either or both of two top-level fields:

- successful-attempts - This field ispresent if the server is configured to maintain a history of successful attempts, and its value will be an array of JSON objects with information about those successful attempts. In particular, each of those objects will contain the timestamp, client-ip-address, authentication-method, and additional-attempt-count fields as used in the ds-pwp-recent-login-history-json attribute.
- failed-attempts - This field is present if the server is configured to maintain a history of failed attempts. Its value is an array of JSON objects with information about these failed attempts. In particular, each of those objects contains the timestamp, client-ip-address, authentication-method, failure-reason, and additional-attempt-count fields as used in the ds-pwp-recent-login-history-json attribute.

The response control is only returned if the server is configured to maintain a recent login history. When provided, the elements of the arrays are arranged in chronological order from most-recent to least-recent.

The UnboundID LDAP SDK for Java provides support for these controls, including enhanced support for retrieving information from the response control value. However, by ensuring that the request control does not have a value and that the response control value is a simple string, this information should be readily accessible to applications using other APIs.

Modifying an existing password policy

About this task

You can modify an existing password policy to suit your company's requirements.

ⓘ **Note:** Password policies should be kept synchronized across all PingDirectory Server and Directory Proxy Server instances.

Steps

- Use **dsconfigdsconfig** in non-interactive mode: (in interactive or non-interactive mode) or the Administrative Console to modify the configuration for any defined password policy. The following example sets some of the properties presented in the previous section for the default password policy using

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "max-password-age:90 days" \
  --set "password-expiration-warning-interval:14 days" \
  --set "lockout-failure-count:3" \
  --set "password-history-count:6"
```

Creating new password policies

You can create any number of password policies in the Directory Server using either the **dsconfig** tool (in interactive or non-interactive mode) or the Administrative Console.

Creating a new password policy

Steps

- Use **dsconfig** (in interactive or non-interactive mode) or the Administrative Console to create a new pasword policy. The following example demonstrates the process for creating a new policy using **dsconfig** in non-interactive mode.

```
$ bin/dsconfig create-password-policy \
  --policy-name "Demo Password Policy" \
  --set "password-attribute:userpassword" \
  --set "default-password-storage-scheme:Salted SHA-256" \
  --set "force-change-on-add:true" \
  --set "force-change-on-reset:true" \
  --set "password-expiration-warning-interval:2 weeks" \
  --set "max-password-age:90 days" \
  --set "lockout-duration:24 hours" \
  --set "lockout-failure-count:3" \
  --set "password-change-requires-current-password:true"
```

Assigning a password policy to an individual account

About this task

To indicate that a user should be subject to a particular password policy (rather than automatically inheriting the default policy), include the `ds-pwp-password-policy-dn` operational attribute in that user's entry with a value equal to the DN of the desired password policy for that user. This attribute can be explicitly included in a user's entry, or it can be generated by a virtual attribute, which makes it easy to apply a custom password policy to a set of users based on a flexible set of criteria.

Steps

1. Create a file (`assign.ldif`) with the following contents:

```
dn: uid=user.1,ou=People,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
```

```
ds-pwp-password-policy-dn: cn=Demo Password Policy,cn=Password
 Policies,cn=config
```

2. Use **ldapmodify** to apply the modification to the user's entry.

```
$ bin/ldapmodify --filename assign.ldif
```

Assigning a password policy using a virtual attribute

About this task

It is possible to automatically assign a custom password policy for a set of users using a virtual attribute. The virtual attribute can be configured so that it can use a range of criteria for selecting the entries for which the virtual attribute should appear.

Steps

1. Create an LDIF file, which may be used to add a group to the server.

```
dn: ou=Groups,dc=example,dc=com
objectClass: organizationalunit
objectClass: top
ou: Groups

dn: cn=Engineering Managers,ou=groups,dc=example,dc=com
objectClass: groupOfUniqueNames
objectClass: top
cn: Engineering Managers
uniqueMember: uid=user.0,ou=People,dc=example,dc=com ou: groups
```

2. Use **ldapmodify** to add the entries to the server.

```
$ bin/ldapmodify --defaultAdd --filename groups.ldif
```

3. Use **dsconfig** to create a virtual attribute that will add the `ds-pwp-pasword-policy-dn` attribute with a value of `cn=Demo Password Policy,cn=Password Policies,cn=config` to the entries for all users that are members of the `cn=Engineering Managers,ou=Groups,dc=example,dc=com` group.

```
$ bin/dsconfig create-virtual-attribute \
  --name "Eng Mgrs Password Policy" \
  --type user-defined \
  --set "description:Eng Mgrs Grp PWPolicy" \
  --set enabled:true \
  --set attribute-type:ds-pwp-password-policy-dn \
  --set "value:cn=Demo Password Policy,cn=Password Policies,cn=config" \
  --set "group-dn:cn=Engineering Managers,ou=Groups,dc=example,dc=com
```

4. Use **ldapsearch** to verify that a user in the group contains the assigned password policy DN.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
ds-pwp-password-policy-dn
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Demo Password Policy,cn=Password
 Policies,cn=config
```

Deleting a password policy

About this task

You can delete a password policy using either the **dsconfig** tool (in interactive or non-interactive mode) or the Administrative Console.

Steps

- Run the **dsconfig** command with the `delete-password-policy` subcommand to remove a password policy.

```
$ bin/dsconfig delete-password-policy \
  --policy-name "Demo Password Policy"
```

Modifying a user's password

There are two primary ways to change user passwords in the Directory Server:

- Perform a modify operation which replaces the value of the password attribute (often `userPassword`). Note that in some configurations, when a user attempts to change his or her own password it may be necessary to perform the modification by removing the password value and adding the desired new value to demonstrate that the user knows the current password value.
- Use the password modify extended operation to change the password. Note that if a user is changing his or her own password, it may be necessary to provide the current password value. The server will allow a new password to be provided (assuming that the new password is acceptable to all configured password validators), or it may automatically generate a new password for the user.

Note that regardless of the mechanism used to change the password, all password values should be provided in clear text rather than pre-encoded, and the user will be required to have sufficient access control rights to update the password attribute in the target user's entry. Further, when one user attempts to change the password for another user, then the requester will be required to have the `password-reset` privilege.

Validating a password

The requirements that the server will impose for a password change can be displayed to users. The get password quality requirements extended operation can be used to retrieve information about the requirements, which can then be sent to an end user before an attempted password change. These requirements can also be used to enable client-side validation, so that any password problems can be identified before it is sent to the server. The password validation details request control can be included in an add or modify request, or a password modify extended request, to identify which validation requirements were not met by the password provided in the request.

Password validators can be configured with user-friendly messages that describe the password requirements, and the messages that should be returned if a proposed password does not satisfy those requirements. The server will generate these messages if they are not provided in the configuration.

Password validator properties include **validator-requirement-description** and **validator-failure** message. The following is a simple password validator configuration that requires passwords to contain a minimum of five characters, and lists custom validator messages:

```
$ dsconfig create-password-validator \
  --validator-name "Minimum 5 Characters Password Validator" \
  --type length-based --set enabled:true \
  --set "validator-requirement-description:The password must contain
         at least 5 characters." \
  --set "validator-failure-message:The password did not contain
         at least 5 characters." \
  --set min-password-length:5
```

After the password validator is created, it should be assigned to a Password Policy to take affect:

```
$ dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Minimum 5 Characters Password Validator"
```

When a user authenticates, password validation processing is performed so that the server has access to the user's clear-text password. Password properties include the following:

- bind-password-validator - Specifies which validators to invoke on bind.
- password-validator - Specifies which validators to invoke during a password change.
- minimum-bind-password-validation-frequency — Specifies how frequently the server should validate a user's password during bind. Although you can specify that the password should be validated during each bind, it is probably sufficient to only do so periodically (for example, once a week or once a month).
- bind-password-validation-failure-action — Specifies the action the server should take if a user's password fails validation. By default, the account will be placed in a "must change password" state where the user is allowed to bind but any other operations the user attempts will fail until the user changes their password. Alternatively, the account can be locked so that the password needs to be reset by an administrator, or the server can generate an account status notification to recommend that the user choose a new password.

Retiring a password

An account password can be retired and rotated out of service, instead of immediately invalidated. This enables a new password to be assigned to an account while keeping the original password valid for a period of time to enable a transition. This is useful for application service accounts that require uninterrupted authentication with the server.

This behavior is disabled by default, but can be enabled in the password policy configuration by setting the **password-retirement-behavior** and **maximum-retired-password-age** properties.

To manually retire an account password or purge a password that has been retired, use the **ldapmodify** and **ldappasswordmodify** commands with options **-- retireCurrentPassword** and **--purgeCurrentPassword**. To use these commands on an account, the password policy that governs the account must have the **password-retirement-behavior** enabled.

Changing a user’s password using the Modify operation

Steps

- Use **ldapmodify** to change a user’s password by replacing the `userPassword` attribute.

```
$ bin/ldapmodify
dn: uid=user.0,ou=People,dc=example,dc=com
changetype: modify
replace: userPassword
userPassword: newpw
```

Changing a user's password using the Password Modify extended operation

Steps

- Use **ldappasswordmodify** to request that the Password Modify extended operation be used to modify a user’s password.

```
$ bin/ldappasswordmodify --authzID dn:uid=jdoe,ou=People,dc=example,dc=com
 \
  --newPassword newpw
```

Using an automatically-generated password

Steps

- Use **`ldappasswordmodify`** to automatically generate a new password for a user.

```
$ bin/ldappasswordmodify --authzID "u:user.1"

The LDAP password modify operation was successful
Generated Password: fbi27oqy
```

Enabling YubiKey authentication

Users can be enabled to authenticate with YubiKey devices (available from Yubico), which generate secure one-time passwords, with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. A YubiKey device generates a different password for every authentication attempt, and that one-time password is sent to a validation service to ensure that it is genuine and has not been used in an earlier authentication attempt. Although it is possible to use this one-time password as the only proof of identity, it is typically combined with a static password as a form of two-factor authentication.

YubiKey authentication requires server configuration and the addition of this capability to a user entry. Configuration of a client ID and API key to use when communicating with the validation service is also required. The API key is a shared secret between the YubiKey validation service and the client that is interacting with it, and is used when generating digital signatures so that both the server and the YubiKey validation service can ensure that the peer server is genuine.

All server and user entry configuration details are available in the *Security Guide*.

Enabling social login

Authentication involving credentials that do not reside in, or cannot be forwarded to or validated by the Directory Server (such as social login through Facebook, Google, or Twitter) can be enabled with the the UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION SASL mechanism. The bind request will not include any credentials, and authentication with this mechanism will not actually change the state of the underlying client connection. The server will behave as if the bind request included the retain identity request control, regardless of whether or not that control was included.

Bind requests using this mechanism can include any request controls that are permitted with other bind requests. If the externally-processed authentication is successful, the client can include the get password policy state issues request control in the bind request to obtain information about any password policy state issues that can cause the Directory Server authentication attempt to fail. The password policy request control can also be included to obtain certain password policy state warnings and errors, or to look for the password expired/password expiring controls in the bind response.

All server and user entry configuration details are available in the *PingDirectory Server Security Guide*.

Managing user accounts

The Directory Server provides a user management utility, the **`manage-account`** tool, that provides a means to quickly view and manipulate a number of password and account policy properties for a user or group of users.

> ⓘ **Note:** A disabled account status (for example, `account-is-disabled: true`) is different from an *account lockout* due to password policy. Unlocking a user account can be done with the **`manage-account`** tool. A disabled account requires the administrator to enable the account; password resets are not involved.

PingDirectory Server also hosts the Self Service Account Manager project at https://github.com/pingidentity/ssam, which is a customizable web application allowing users to perform their own account

registration, profile updates, and password changes. The project is for testing and development purposes, and is not a supported PingDirectory Server application.

Returning the password policy state information

Steps

- Use **manage-account** to get information about the account's password policy.

```
$ bin/manage-account get-all \
  --targetDN uid=user.1,ou=People,dc=example,dc=com
```

```
Password Policy DN: cn=Demo Password Policy,cn=Password Policies,cn=config
Account Is Disabled: false
Account Expiration Time:
Seconds Until Account Expiration:
Password Changed Time: 19700101000000.000Z
Password Expiration Warned Time:
Seconds Until Password Expiration: 1209600
Seconds Until Password Expiration Warning: 0
Authentication Failure Times:
Seconds Until Authentication Failure Unlock:
Remaining Authentication Failure Count: 3
Last Login Time:
Seconds Until Idle Account Lockout:
Password Is Reset: false
Seconds Until Password Reset Lockout:
Grace Login Use Times:
Remaining Grace Login Count: 0
Password Changed by Required Time:
Seconds Until Required Change Time:
Password History:
```

Determining whether an account is disabled

Steps

- Use **manage-account** to determine whether a user's account has been disabled.

```
$ bin/manage-account get-account-is-disabled \
  --targetDN uid=user.1,ou=People,dc=example,dc=com
```

```
Account Is Disabled: true
```

Disabling an account

Steps

- Use **manage-account** to disable a user's account.

```
$ bin/manage-account set-account-is-disabled \
  --operationValue true --targetDN uid=user.1,ou=People,dc=example,dc=com
```

```
Account Is Disabled: true
```

Enabling a disabled account

Steps

- Use **`manage-account`** to enable a user's account.

```
$ bin/manage-account clear-account-is-disabled \
  --targetDN uid=user.1,ou=People,dc=example,dc=com
```

```
Account Is Disabled: false
```

Assigning the manage-account access privileges to non-root users

About this task

Non-root users (e.g., `uid=admin`) with admin right privileges require access control permission to interact with certain password policy operational attributes when using the **`manage-account`** tool.

For example, the presence of the `ds-pwp-account-disabled` operational attribute in an entry determines that the entry is disabled. If the non-root admin user does not have the access privilege to read or interact with the `ds-pwp-account-disabled` operational attribute, the **`manage-account`** tool may report that the account is active. An account is considered active if the `ds-pwp-account-disabled` operational attribute does not exist in the entry or if the admin user does not have permission to see it.

Use the following procedure to give access rights to the non-root admin user.

Steps

1. Create a non-root user admin account, such as `uid=admin,dc=example,dc=com`. Grant the `password-reset` privilege to the account. See step 1 and 6 in the Configuring Administrators section for more information.
2. Run the **`manage-account`** tool to view the account status for an account.

```
$ bin/manage-account get-all \
  --targetDN uid=user.0,ou=People,dc=example,dc=com
```

```
Password Policy DN:  cn=Default Password Policy,cn=Password
 Policies,cn=config
Account Is Disabled:  false
Account Expiration Time:
Seconds Until Account Expiration:
Password Changed Time:  19700101000000.000Z
Password Expiration Warned Time:
Seconds Until Password Expiration:
Seconds Until Password Expiration Warning:
Authentication Failure Times:
Seconds Until Authentication Failure Unlock:
Remaining Authentication Failure Count:
Last Login Time:
Seconds Until Idle Account Lockout:
Password Is Reset:  false
Seconds Until Password Reset Lockout:
Grace Login Use Times:
Remaining Grace Login Count:  0
Password Changed by Required Time:
Seconds Until Required Change Time:
Password History:
```

3. Grant access control privileges to an account. The following allows access to manage accounts to a helpdesk user. Depending on the configuration requirements, this user may also need the `permit-get-password-policy-state-issues` and `password-reset` privileges.

```
dn: dc=example,dc=com
 changetype: modify
 add: aci
 aci: (targetattr="userPassword||ds-pwp-last-login-time||ds-pwp-password-
changed-by-required-time||ds-pwp-reset-time||ds-pwp-warned-time||
 ds-pwp-account-disabled||ds-pwp-account-expiration-time||ds-pwp-password-
policy-dn||ds-pwp-auth-failure||ds-pwp-last-login-ip-address||
 ds-pwp-retired-password||ds-pwp-account-activation-time||pwdReset||
pwdChangedTime||pwdAccountLockedTime")
 (version 3.0; acl "Grant full access to PWP related attributes to
 helpdesk"; allow (all) userdn="ldap:///uid=helpdesk,dc=example,dc=com";)
```

4. Run the **`manage-account`** tool to disable an account. The following command sets the `account-is-disabled` property to true for the `uid=user.0,dc=example,dc=com`.

```
$ bin/manage-account set-account-is-disabled \
  --targetDN uid=user.0,ou=People,dc=example,dc=com \
  --operationValue true
```

```
Account Is Disabled:  true
```

5. Run the **`ldapsearch`** tool to view the presence of the `ds-pwp-account-disabled` operational attribute in the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" "+"
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-account-disabled: true
```

Disabling password policy evaluation

The Directory Server provides a global configuration property (`disable-password-policy-evaluation`) that can be used to disable most password policy evaluation processing. This provides a convenience for those production environments that do not require password policy support. If the `disable-password-policy` property is set to true, passwords will still be encoded and evaluated, but only account expiration and account disabling will be in effect. All other password policy properties, such as password expiration, lockout, and force change on add or reset, are ignored.

The server also supports the use of a `bypass-pw-policy` privilege, which can be used to skip password policy evaluation for operations on a per-user basis. If a user has this privilege, then they will be allowed to perform operations on user entries that would normally be rejected by the password policy associated with the target entry. Note that this privilege will not have any effect for bind operations.

Globally disabling password policy evaluation

Steps

- Use **`dsconfig`** to set the `disable-password-policy-evaluation` property globally for the Directory Server.

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
  --set "disable-password-policy-evaluation:false"
```

Exempting a user from password policy evaluation

Steps

- Use **`ldapmodify`** to add the `bypass-pw-policy` privilege to a user entry.

```
$ bin/ldapmodify
dn: uid=user.1,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: bypass-pw-policy
```

About managing password validators

A password validator is a password policy component that is used to determine if a new password is acceptable. A password policy can be configured with any number of password validators. If a password policy is configured with multiple password validators, then all of them must consider a proposed new password acceptable before it will be allowed.

Password validators

The PingDirectory Server offers a number of types of password validators, including those listed in the following table. It is also possible to use the Server SDK to create custom password validators with whatever constraints are necessary for your environment.

Password Validators

Password Validators	Description
Attribute Value	Ensures that the proposed password does not match the value of another attribute in the user's entry. The validator can be configured to look in all attributes or in a subset of attributes. It can perform forward and reverse mapping, and it can also reject values which are substrings of another attribute.
Character Set	Ensures that the proposed password contains a sufficient number of characters from one or more user-defined character sets. For example, the validator can ensure that passwords must have at least one lowercase letter, one uppercase letter, one digit, and one symbol.
Commonly-Used Passwords Dictionary	Ensures that the proposed password is not one of 10,000 commonly used passwords. These are words that are common for attackers to use when trying to access user accounts. The Commonly-Used Passwords validator is invoked by the Secure Password Policy by default. The word list is located in `<server-root>/config/commonly-used-passwords.txt`, and can be used to create a custom validator, but should not be modified.
Dictionary	Ensures that the proposed password is not present in a specified dictionary file, optionally also testing the password with all characters in reverse order. A large dictionary file is provided with the server, but the administrator can supply an alternate dictionary. In this case, then the dictionary must be a plain-text file with one word per line.
Haystack Password Validator	Ensures that the proposed password is secure based on a combination of its length and the types of characters that it contains. For example, a longer password containing only lowercase letters may be stronger than a shorter password containing a mix of uppercase and lowercase letters, numbers, and symbols. This is based on the Gibson Research Corporation Password Haystacks concept.

Password Validators	Description
Length-Based Password Validator	Ensures that the number of characters in the proposed new password is within an acceptable range. Both a maximum and minimum number of characters may be specified.
Regular Expression Validator	Ensures that a proposed password either matches or does not match a given regular expression.
Repeated Characters	Ensures that a proposed password does not contain a substring in which the same character is repeated more than a specified number of times (for example, "aaaaa" or "aaabbb"). The validator can be configured to operated in a case-sensitive or case-insensitive manner, and you can also define custom sets of equivalent characters (for example, you could define all digits as equivalent, so the proposed password could not contain more than a specified number of consecutive digits.
Similarity-Based Password Validator	Ensures that the proposed new password is not too similar to the current password, using the Levenstein Distance algorithm, which calculates the number of characters that need to be inserted, removed, or replaced to transform one string into another. Note that for this password validator to be effective, it is necessary to have access to the user's current password. Therefore, if this password validator is to be enabled, the `password-change-requires-current-password` attribute in the password policy configuration must also be set to true.
Unique Characters	Ensures that the proposed password contains at least a specified minimum number of unique characters, optionally using case-insensitive validation.

Configuring password validators

You can use the **`dsconfig`** configuration tool or the Administrative Console to configure or modify any password validators. Once you have defined your password validators, you can add them to an existing password policy. The following example procedures show the dsconfig non-interactive commands necessary to carry out such tasks. If you use **`dsconfig`** in interactive command-line mode, you can access the Password Validator menu in the Basic Objects menu. For more details on the password validator properties, see the *PingDirectory Server Configuration Reference*.

Viewing the list of defined password validators

Steps

- Use **`dsconfig`** to view the set of password validators defined in the Directory Server.

Configuring the Attribute Value Password Validator

Steps

1. Use **`dsconfig`** to edit the existing default configuration for the Attribute Value Password Validator. For example, the following change configures the validator to only examine a specified set of attributes..

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Attribute Value" \
  --set match-attribute:cn \
  --set match-attribute:sn \
  --set match-attribute:telephonenumber \
  --set match-attribute:uid
```

2. Update an existing password policy to use the Attribute Value Password Validator.

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Attribute Value"
```

3. Test the Attribute Value Password Validator by submitting a password that is identical to one of the configured attributes (`cn`, `sn`, `telephonenumber`, `uid`).

```
$ bin/ldappasswordmodify --authzID "uid=user.0,ou=People,dc=example,dc=com"
 \
  --newPassword user.0
```

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
 defined in the
server: The provided password was found in another attribute in the user
 entry
```

Configuring the Character Set Password Validator

Steps

1. Use **`dsconfig`** to edit the existing default configuration. In this example, we change the requirement for special characters making them optional in a password, and add a requirement that at least two digits must be included in the password. Thus, in this example, all newly created passwords must have at least one lowercase letter, one uppercase letter, two digits, and optionally any special characters listed.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Character Set" \
  --remove character-set:1:0123456789 \
  --remove "character-set:1:~\!@#\$\%^&*()-_=+[]{}\|;:,.<>/?" \
  --add character-set:2:0123456789 \
  --add "character-set:0:~\!@#\$\%^&*()-_=+[]{}\|;:,.<>/?" \
  --set allow-unclassified-characters:false
```

2. Update an existing password policy to use the Character Set Password Validator.

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Character Set"
```

3. Test the Character Set Password Validator by submitting a password that meets the requirements (one lowercase letter, one uppercase letter, two digits). The following example should reject the given password because it does not pass the Character Set Password Validator.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword abab1
```

Configuring the Length-Based Password Validator

Steps

1. Use **`dsconfig`** to edit the existing default configuration. In this example, we set the required minimum number of characters in a password to five.

```
$ bin/dsconfig create-password-validator \
  --validator-name "Length-Based Password Validator" \
  --set max-password-length:5 --set min-password-length:5
```

2. Update an existing password policy to use the Length-Based Password Validator.

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
```

```
  --set "password-validator:Length-Based Password Policy"
```

3. Test the Length-Based Password Validator by submitting a password that has fewer than the minimum number of required characters.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword abcd
```

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
 defined in
the server: The provided password is shorter than the minimum required
 length of
5 characters
```

Configuring the Regular Expression Password Validator

Steps

1. Use **`dsconfig`** to create a Regular Expression password validator. The following password validator checks that the password contains at least one number, one lowercase letter, and one uppercase letter with no restrictions on password length. If the password matches the regular expression, then it will be accepted. When using the following command, remember to include the LDAP/LDAPS connection parameters (host name and port), bind DN, and bind password.

```
$ bin/dsconfig create-password-validator \
  --validator-name "Regular Expression" \
  --type regular-expression --set enabled:true \
  --set "match-pattern:^\\w*(?=\\w*\\d)(?=\\w*[a-z])(?=\\w*[A-Z])\\w*\$" \
  --set match-behavior:require-match
```

2. Update an existing password policy to use the Regular Expression validator.

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Regular Expression"
```

3. Test the Regular Expression Validator by submitting a password that meets the requirements (contains one number, one lowercase letter, and one uppercase letter), then run it again with a password that does not meet these requirements.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword baaA1
```

```
The LDAP password modify operation was successful
```

4. Try another password. The following password should fail, because no uppercase letter is present.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword baaa1
```

```
Error Message: The provided new password failed the validation checks
defined in the server: The provided password is not acceptable because it
 does
not match regular expression pattern '^\w*(?=\w*\d)(?=\w*[a-z])(?=\w*[A-
Z])\w*$'
```

Configuring the Repeated Character Password Validator

Steps

1. Use **dsconfig** to edit the existing default configuration.
   - In this example, we set the maximum consecutive length of any character to 3. For example, the following validator rejects any passwords, such as "baaaa1" or "4eeeeb", etc.

     ```
     $ bin/dsconfig set-password-validator-prop \
       --validator-name "Repeated Characters" \
       --set max-consecutive-length:3
     ```
   - Or, you can configure the validator to reject any character from a pre-defined character set that appears more than the specified number of times in a row (2). You can also specify more than one character set. For example, the following validator defines two characters sets: [abc] and [123]. It rejects any passwords with more than two consecutive characters from a character set. Thus, "aaa", "bbb", "ccc", "abc", or "123" and so on fails, but "12a3" is okay.

     ```
     $ bin/dsconfig set-password-validator-prop \
       --validator-name "Repeated Characters" \
       --set character-set:123 --set character-set:abc
     ```
2. Update an existing password policy to use the Repeated Character Password Validator.

   ```
   $ bin/dsconfig --no-prompt set-password-policy-prop \
     --policy-name "Default Password Policy" \
     --set "password-validator:Repeated Characters"
   ```
3. Test the Repeated Character Validator by submitting a password that has more than the maximum allowable length of consecutive characters.

   ```
   $ bin/ldappasswordmodify \
     --authzID "uid=user.0,ou=People,dc=example,dc=com" \
     --newPassword baaa1
   ```

   ```
   The LDAP password modify operation failed with result code 53
   Error Message: The provided new password failed the validation checks
    defined
   in the server: The provided password contained too many instances of the
    same
   character appearing consecutively. The maximum number of times the same
   character may appear consecutively in a password is 2
   ```

Configuring the Similarity-Based Password Validator

Steps

1. Use **dsconfig** to edit the existing default configuration. In this example, we set the minimum number of differences to 2.

   ```
   $ bin/dsconfig set-password-validator-prop \
     --validator-name "Similarity-Based Password Validator" \
     --set min-password-difference:2
   ```
2. Update an existing password policy to use the Similarity-Based Password Validator. The `password-change-requires-current-password` property must be set to TRUE, so that the password policy will ensure that the user's current password is available when that user is choosing a new password.

   ```
   $ bin/dsconfig set-password-policy-prop \
     --policy-name "Default Password Policy" \
     --set "password-validator:Similarity-Based Password Validator" \
     --set password-change-requires-current-password:true
   ```

3. Test the Similarity-Based Password Validator by submitting a password that has fewer than the minimum number of changes (e.g., 2). The **`ldappasswordmodify`** command requires the `--currentPassword` option when testing the Similarity-Based Password Validator.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" \
  --currentPassword abcde --newPassword abcdd

The LDAP password modify operation failed with result code 49
```

Configuring the Unique Characters Password Validator

Steps

1. Use **`dsconfig`** to edit the existing default configuration. In this example, we set the minimum number of unique characters that a password is allowed to contain to 3.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Similarity-Based" --set min-unique-characters:3
```

2. Update an existing password policy to use the Unique Characters Password Validator.

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Unique Characters"
```

3. Test the Unique Characters Password Validator by submitting a password that has fewer than the minimum number of unique characters (e.g., 3).

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" \
  --newPassword aaaaa

The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
 defined
in the server: The provided password does not contain enough unique
 characters.
The minimum number of unique characters that may appear in a user password
 is 3
```

Managing Replication

The PingDirectory Server provides a robust replication system to ensure high availability and fast failover in production environments. Write requests can be handled by every server in the topology with the replication component performing immediate synchronization with other members. The replicated server environment ensures that LDAP clients can seamlessly fail over to another server instance.

This chapter presents the architectural overview of replication, detailed configuration steps, ways to monitor replication as well as troubleshooting steps.

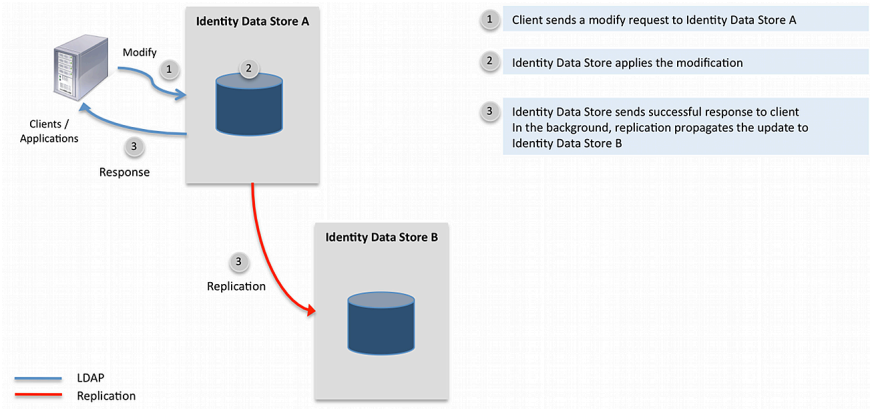
Overview of replication

Replication is a data synchronization mechanism that ensures that updates made to a database are automatically replayed to other servers. Replication improves data availability when unforeseen or planned outages occur, and improves search performance by allowing client requests to be distributed across multiple servers.

By default, all Directory Servers participating in replication are writable, so that LDAP clients can perform updates at any of these Directory Server instances. These updates will be propagated to the other servers automatically in the background and applied in the same order as the updates were entered. The

replication process flow is designed to immediately propagate changes to the other replicas in the topology with little or no latency.

The following figure demonstrates the basic flow of replication.



MY TITLE Replication Process Flow

The benefits of replication can be summarized as follows:

- **High-Availability**. Because the data is fully replicated on all other servers in the topology, replication allows participating servers to process all types of client requests. This mitigates any availability issues when a particular server is down due to a planned maintenance or unplanned outage. For those servers that are temporarily unavailable, they will receive updates when they become available again.
- **Improved Search Performance**. Search requests may be directed to any Directory Server participating in replication, which improves search performance over systems that only access single servers. Note, however, that replication does not improve write throughput since updates need to be applied at all servers.
- **WAN Friendly Data Synchronization**. The built-in compression feature in the replication protocol allows efficient propagation of updates over WAN links.

Replication versus synchronization

Replication is not a general purpose synchronization facility as it creates replicas with exact copies of the replicated data. Synchronization, on the other hand, can transform data between two different Directory Information Tree (DIT) structures, map attribute types, synchronize subsets of branches and specific object classes. The differences between replication and synchronization are illustrated as follows:

- **Replication cannot Synchronize between Different DIT Structures**. The DN of replicated entries must be the same on all servers. In some situations, it may be desirable to replicate entries with the help of DN mapping that are under different base DNs, but represent the same data, for example `uid=john.doe,ou=people,o=corp` on one server may represent the same user as `uid=john.doe,ou=people,dc=example,dc=com`. This is not supported by replication. Synchronization fully supports this feature.
- **Replication cannot Map Attribute Types or Transform Attribute Values**. In some situations, it may be necessary to map attribute types or transform attribute values when synchronizing data from one server to another. Replication does not support either attribute type mappings or attribute value transformations.
- **Replication does Not Support Fractional Replication**. Replication cannot be configured to replicate a subset of the attribute types from the replicated data set. Synchronization fully supports this feature.
- **Replication does Not Support Sparse Replication**. Replication cannot be configured to replicate entries with a particular object class only. Synchronization fully supports this feature.
- **Replication Requires Full Control of Replicated Data**. When two servers participate in replication, both servers implicitly trust each other using public key cryptography and apply all updates received via replication, which is considered an internal operation. While trust between servers is established

between two endpoint servers, synchronization does not require full control of the data. Disparate server system endpoints can be synchronized, such as a PingDirectory Server and a RDBMS database endpoint with each fully in control of its own data.

If replication does not meet your data synchronization requirements, consider using PingDataSync Server, which provides the versatility and robust performance required for most production environments.

Replication terminology

The following replication terms are used throughout this chapter.

Replication Terminology

Term	Description
Assured Replication	For applications that require immediate access to replicated data or require data consistency over response time, administrators can configure *assured replication*, where data is guaranteed to replicate *before* the response is returned to the client.
Change Number	A 64-bit number used to consistently order replication updates across the entire topology. It is composed of 3 fields: the timestamp of the update (measured in milliseconds since 00:00:00 UTC, January 1, 1970), the Replica ID, and the Sequence Number.
Conflict	Client updates made at different replicas affecting the same entry may be found in conflict when the updates are replayed at another replica. The Change Number of each update allows most of these conflicts to be resolved automatically. Certain updates, such as adding an entry with different attribute values at two servers simultaneously, result in conflicts that are flagged for required manual resolution.
Eventual Consistency	When not using assured replication, recent updates from LDAP clients are not immediately present at all servers. Out-of-sync data will be eventually synchronized and will be consistent on all servers. The network latency typically controls how long a given update takes to replicate.
Global Administrator	The administrative user with full rights to manage the replication topology. The user is created at the time of replication enable between two non-replicating servers and thereafter copied to newly enabled servers. The replication command-line utility expects the user name of the Global Administrator (by default, admin). The user is stored in `cn=Topology Admin Users,cn=Topology,cn=config`.
Historical Data	Historical Data are records of attribute value changes as a result of an LDAP Modify Operation. Historical Data is stored in the `ds-sync-hist` attribute of the target entry. This information allows replication to resolve conflicts from simultaneous LDAP Modify operations automatically.
Location	The collection of servers that may have similar performance characteristics when accessed from this Directory Server or reside in the same data center or city. A separate location setting may be defined for each data center, such as Austin, London, Chicago, etc. Location settings are used in the selection of the WAN Gateway server.
Modify Conflict	A conflict between two LDAP Modify operations. Conflicts arising from LDAP Modify operations are automatically resolved.

Term	Description
Naming Conflict	Any conflict other than Modify Conflicts. Naming conflicts typically include an operation that changes the DN of the target entry, creates an entry, or deletes an entry at one Replica.
Replica	The component in the Directory Server that handles interaction with a single replication domain, for example, the `dc=example,dc=com` replication domain within the `userRoot` backend.
Replica ID	The unique identifier of a replica that is set automatically in the corresponding Replication Domain configuration entry at each participating server. The replica ID identifies the source of each update in the replication topology.
Replica State	A list of the most recent change numbers of replication updates that have been applied to a replica. There can be at most one change number from each replica in the state. The replica state helps the Replication Server component to determine which updates the Replica has not received yet.
Replication	An automated background process that pushes directory server data changes to all other replicas.
Replication Changelog	A backend maintained by each replication server independently that records updates from each replica. This backend is distinct from the LDAP Changelog and the two should not be confused. The main distinction is as follows: ▪ The LDAP Changelog (i.e., the external changelog that clients can access) physically resides at `<server-root>/db/changelog`. ▪ The Replication Changelog Backend (i.e., the changelog that replication servers use) physically resides at `<server-root>/changelogDB` and is not accessible by clients and server extensions.
Replication Domain	The data configured for replication as defined by the base DN. Updates to entries at and below the base DN will be replicated.
Replication Replay	When a replica locally applies the update received via a replication server.
Replication Server	A component within the Directory Server process that is responsible for propagating directory server data changes to and from replicas. Each Directory Server instance participating in replication is also running a replication server.
Replication Server ID	The unique identifier of a replication server set automatically in its configuration object at each server in the replication topology. This identifier is used in the connection management code of the replication servers.
Replication Server State	A list of the most recent change numbers of replication updates that have been processed by a replication server. There can be at most one change number from each replica in the topology. The Replication Server State is used to determine which updates need to be sent to other replication servers. Similarly, the replica can use the Replication Server State to identify the set of updates to send to the replication server.
Sequence Number	A field in the change number that indicates the sequence of the client updates at a particular replica. For every update at the replica, the number is incremented. The initial value of the sequence number is 1. The number is stored as a 32-bit integer, but only positive values are used. The sequence number can roll over.

Term	Description
WAN Gateway	The designated replication server that assumes the WAN Gateway role within a collection of co-located replication servers (i.e., servers that are defined with identical location settings). Replication update messages between servers at different locations are routed through WAN gateways. The WAN Gateway role is assigned automatically by the protocol based on the server's WAN Gateway Priority setting. If the WAN Gateway server is down for any reason, the server with the next highest WAN Gateway Priority will dynamically assume the WAN Gateway role.
WAN Gateway Priority	The configuration setting that determines which replication server assumes the WAN Gateway role. The replication server with the lowest WAN Gateway Priority value in a location assumes the role of the WAN Gateway. The priority values can be set to 0 (never be a gateway), or any value from 1 (highest priority) to 10 (lowest priority).

Replication architecture

The major elements of replication in the PingDirectory Server are introduced in this section.

Eventual consistency

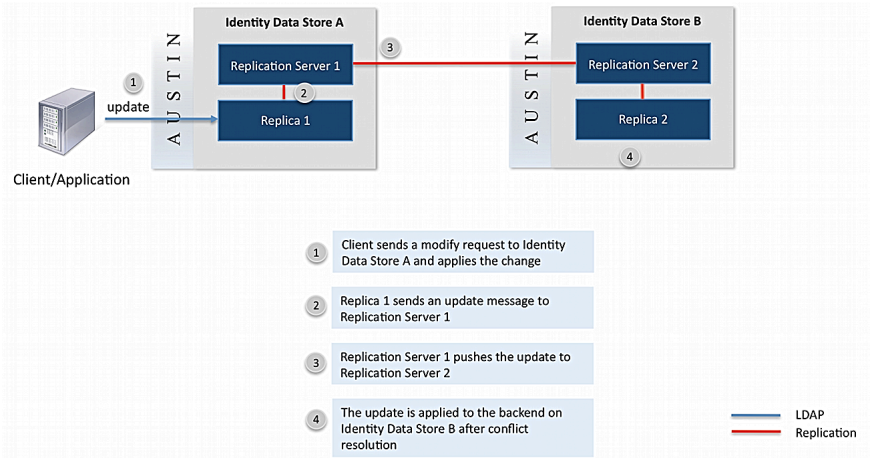
Replication is based on an eventual-consistency model, where updates that are propagated through a connected network of servers will eventually be consistent on all servers over a very short period of time. In a typical update operation, a client application updates an entry or group of entries on the PingDirectory Server with an ADD, DELETE, MODIFY, or MODIFY DN operation. After processing the operation, the Directory Server returns an LDAP response, while concurrently propagating the update to the other servers in the replicated topology. This concurrent processing model allows the client to continue submitting update requests without waiting for a replication completion response from the server. Alternatively, assured replication can be configured for specific write requests that requires local or global consistency, across datacenter locations, before a response is returned to the client. For more information, see *Configuring assured replication* on page 673.

To support this processing model, replication never locks the targeted entries at the other Directory Server instances before an update can be made locally. This means that the replicated Directory Servers may have an inconsistent view of the targeted entry for a very short period of time but will catch up as the propagated changes are applied. The eventual-consistency model also allows clients to complete update operations faster, since clients do not have to wait for replication to propagate the change. The rate of update operations remains the same no matter how many Directory Servers participate in replication.

Replicas and replication servers

Each Directory Server has an embedded replication server that is responsible for transmitting updates to other replication servers. There is a separate component, called a replica, for each replicating base DN, such as `cn=schema, dc=example,dc=com`. Each replica connects to the embedded replication server running within the Directory Server JVM process.

When a client application updates an entry on the Directory Server, the replica sends an update message to its embedded replication server. The replication server applies the change to the `replicationChangelog` backend repository and then sends an update message to the connected replication server on another directory server. The replication server on other directory servers then passes the change to the appropriate replica, which in turn applies the change to its backend after performing conflict resolution. This standard setup is seen in the figure below.



MY TITLE Replicas and Replication Servers

Authentication and authorization

The authentication in the Replication Protocol is based on public key cryptography using client certificate authentication via TLS. The certificate used for authentication is stored in the `ads-truststore` backend of the Directory Server. During replication setup, the command-line utility distributes public keys to all directory servers to establish trust between the Directory Servers and to enable client authentication via TLS.

The authorization model of replication is simple: once authenticated, the remote Directory Server is fully authorized to exchange replication messages with the local Directory Server. There is no other access control in place.

Logging

The access log messages in the Directory Server indicate if the update was received via replication and includes the corresponding change number. This allows the administrator to track which Directory Server the update originated from.

Replication deployment planning

The following should be considered before deploying in a production environment:

- **Minimizing Replication Conflicts**. Attention should be paid to the origin of client write requests to prevent a conflict. If two different clients attempt to create an entry with the same name, DN, at the same time against different servers, the possibility exists that both client requests will succeed. In this case, a conflict alert will be sent by the server. However, understand the client traffic pattern beforehand will minimize these occurrences. The Directory Server's Assured Replication feature and the PingDirectoryProxy Server can both assist in minimizing conflicts.
- **Replication Purge Delay**. Adjust the default one-day replication purge delay, consistently across all servers, to accommodate automatic catchup of changes when a server is offline for an extended period of time. The replication changes database, stored in `<server-root>/changelogDb`, grows larger as the replication purge delay is increased. A minimum value should be defined.

The rest of this section highlights other topics of consideration.

Location

In multi-site deployments, it is strongly recommended to configure the directory servers with location information using the **`dsconfig create-location`** command and **`dsconfig set-global-configuration-prop`** command. The Directory Server cannot determine LAN boundaries automatically, so incorrect location settings can result in undesired WAN communication. By default, replication also compresses all traffic between directory servers in different locations.

We recommend setting up the locations prior to enabling replication. The **`dsreplication enable`** command prompts for location information if you have forgotten to define the property.

User-defined LDAP

Directory Servers participating in replication are required to have a uniform user-defined schema. The **`dsreplication`** command-line utility sets up replication for the schema backend the first time replication is enabled to ensure that future schema changes are propagated to all directory servers.

Disk space

Replication increases the disk space required for the Directory Server. The Replication Changelog backend keeps changes from all directory servers for 24 hours by default. After this time period, also known as the purge delay, the backend is trimmed automatically.

In addition, within the `userRoot` and other local DN backends, attribute-level changes are recorded for a short period of time in the `ds-sync-hist` attribute of the entry targeted by an LDAP Modify operation. This attribute is used to resolve all conflicts resulting from LDAP Modify operations automatically.

The disk space impact of replication is highly dependent on the rate and size of changes in the replication topology, and the Replication Changelog purge delay.

Memory

Compared to a standalone directory server, replicated directory server instances require slightly more memory. All of the items discussed in the Disk Space section have an impact on the amount of memory the Directory Server is using. The additional replication overhead is typically less than 5%.

Time synchronization

Even though replication has a built-in mechanism to compensate for the potential clock skew between hosts, it is generally recommended to keep system clocks in sync within the deployment.

Communication ports

The replication server component in each directory server listens on a TCP/IP port for replication communication (the replication server port). This port, typically 8989, must be accessible from all directory servers participating in replication. The server-to-server communication channel is kept alive using a heartbeat, which occurs every 10 seconds. This traffic will prevent firewalls from closing connections prematurely.

The replication command-line utility (**`dsreplication`**) requires access to all directory servers participating in replication. This includes the LDAP or LDAPS port of the directory servers.

Keep these communication requirements in mind when configuring firewalls.

Hardware load balancers

Replication allows writes to be directed to any directory server in the topology. Distributing write operations in a round-robin fashion, however, may introduce conflicts. In particular, distributing a series of LDAP Add, Delete and Modify DN operations targeting the same DN in quick succession can result in conflicts that require manual intervention. The Assured Replication feature can help prevent conflicts created by the same client application.

If possible, consider using server affinity with the load balancer that either associates a client IP address or a client connection with a single directory server instance at a time. Also, consider using the PingDirectoryProxy Server for load balancing LDAP traffic. The Server Affinity feature in the Directory Proxy Server enables replication-friendly load balancing.

Directory Proxy Server

In addition, to facilitate replication-friendly load balancing, the PingDirectoryProxy Server should be considered in every replication deployment. The Directory Proxy Server can automatically adapt to

conditions in backend directory servers using health checks and route traffic accordingly. For example, traffic can be re-routed from directory servers with large backlog of replication updates.

Displaying the server information for a replication deployment

Steps

- Run the **`dsreplication status`** command with the `--displayServerTable` option.

```
$ bin/dsreplication status --displayServerTable
```

```
          --- Replication Status for dc=example,dc=com: ---
Server                          : Location : Priority (1) : Status
--------------------------------:----------:--------------:----------
austin-01.example.com:8989      : US       : 1 (*)        : Available
austin-02.example.com:8989      : US       : 2            : Available

```

Displaying all status information for a replication deployment

Steps

- Run the **`dsreplication status`** command with the `--showAll` option. You can also use the `--showAll` option together with the `--displayServerTable` option to see the server table information for the replication topology.

Enabling replication

Enabling replication between multiple Directory Servers means that any change within the replicated base DN is automatically propagated to all other Directory Servers in the topology. Configuration changes are not replicated, but can be through the use of Server Groups. Therefore, each Directory Server should be configured according to the deployment design.

Overview

To interface with the replication topology, the Directory Server provides a command-line utility, **`dsreplication`**, that must be used to manage and monitor replication.

The cluster name for an instance should be set to a unique name during install. The cluster-name controls a handle of configuration settings that are used cluster-wide; any changes to the configuration will always get pushed out to other members of the topology. If the cluster-name is set to a unique name for each server, any change to the configuration via the **dsconfig** command or the console needs to be done on every server in the topology. In a devops model, it is recommended that the cluster name be unique so that everything can be managed with server profiles. If you are doing an on-premise install, you may want to use a common cluster-name across the topology.

ⓘ **Note:** You should set a cluster name for the topology if you want cluster-wide settings to propagate across the topology in a single action.

Replication setup involves the following basic steps:

- **Set up the servers**. This is the basic installation steps to set up a Directory Server instance.
- **Import or restore data to one server**. After setting up the servers, at least one server should have the target data loaded through **import-ldif** or restore.
- **Enable replication between the servers**. Using the **dsreplication** tool, enable replication for each server to be included in the replication topology. The **dsreplication enable** subcommand should be run *N - 1* times for a topology of *N* servers. See *Command Line Interface* for more information.
- **Initialize data from source server to every server in the topology**. Run the **dsreplication initialize** subcommand for every target server that needs a copy of the data from the source server.
- **Verifying the replication topology**. Administrators can check the replication status after configuring the topology using the **dsreplication** status tool.

Command-line interface

Replication topologies are configured and maintained using the **dsreplication** command-line utility, which supports interactive and non-interactive modes. If you are running the server for the first time, we recommend using the **dsreplication** tool in interactive mode.

The **dsreplication** tool has the following format including some important subcommands listed in the section *The dsreplication Command-Line Utility*:

dsreplication `{subcommand} {connection parameters}`

The **dsreplication** tool keeps a history of invocations in the `logs/tools/dsreplication.history` file and keeps a log of up to 10 **dsreplication** sessions in the `logs/tools` directory.

What happens when you enable replication

The **dsreplication** `enable` subcommand is used to set up replication. The `enable` subcommand carries out the following functions:

- If it does not already exist, the global administrator user is created. The global administrator user has all the rights and privileges to update replication-related configuration objects. Most **dsreplication** subcommands require the global administrator.
- The server instances are registered in the `cn=topology,cn=config` tree. The registration includes basic host name, port information as well as the public key used during the replication authentication process.

  In case both servers are already participating in replication, the `cn=topology,cn=config` is merged to retain the server information from existing topologies.
- The embedded replication server is enabled. Servers already in replication will see their replication server configuration updated with the information of the new replication server.
- A replication domain is created for the requested base DNs. In case the first base DN is enabled, the replication domains for two additional base DNs are also enabled: `cn=topology,cn=config` and `cn=schema`.

- Initialization for the `cn=schema` base DN is executed. This will ensure that a uniform schema is present in the replication topology.
- Initialization must be performed for the enabled base DNs.

Initialization

Replica initialization transfers of a copy of the backend containing the replication domain to a target server. This should be performed after replication is enabled with the **`dsreplication initialize`** subcommand. There is no impact on the source server during this process.

ⓘ **Note:** When enabling or initializing servers, the **`--topologyFilePath`** option can be used with **`dsreplication`** to specify a file with a series of hosts and ports available in the topology that can be used as source servers. This option is used in place of specifying host 1, port1. When the hosts file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available for replication. This file is generated with the **`manage-topology export`** command.

- **dsreplication initialize**. The recommended approach for replica initialization. The **`dsreplication initialize`** subcommand performs the most efficient copy of data needed to initialize one or more replicas on a target server. Any existing data on the target server replica will be lost and the backend containing the base DN will be taken offline on the target server during the initialization.
- **Binary Copy**. The database copy method involves copying database backup files from the source directory server to one or more target servers. The Directory Server provides tools necessary for backing up and restoring backends. Using **`server-root/bin/backup`**, create a backup of the backend containing the replicated base DN. The backup files then need to be transferred to the target server(s) and restored individually with **`server-root/bin/restore`**. There are additional considerations when using database copy as the means to initialize a target replica:
  - If encryption is enabled on the servers, then a database **`bin/encryption-settings export`** then **`bin/encryption-settings import`**must be performed on the `encryption-settings` backend.
  - When using database copy to initialize a server which has been offline longer than the replication purge delay, the database copy of the `replicationChanges`, `schema`, and `adminRoot` backends are required.

Replica generation ID

Each replica has a generation ID, which is an integer that summarizes the replica. It provides replication with a quick and simple means of determining if two replicas contain the same data. If they do contain the same data, they'll have the same generation ID.

When replication is operating correctly, all of the replicas for each replicated base DN will have the same generation ID. The generation ID is stored on each replica as the operational attribute **`ds-sync-generation-id`**. For example:

```
ldapsearch -b 'dc=example,dc=com' -s base '(&)' ds-sync-generation-id
 dn: dc=example,dc=com
 ds-sync-generation-id: 2058329333
```

When the server starts, or when replication is enabled, the generation ID is computed for each affected replica that does not already have a generation ID stored as **`ds-sync-generation-id`**. The following is used to calculate the generation ID:

- The total number of entries in the replica. This is referred to as "the count."
- The first 1000 entries in the replica are converted to normalized LDIF, which is referred to as "the LDIF." Normalized LDIF only includes attributes **`objectclass`**, **`sn`**, **`cn`** and **`ds-entry-unique-id`**, and uses OIDs in place of attribute names.

- The Adler-32 checksum is calculated with the string produced by concatenating the count and the LDIF as input. This Adler-32 checksum is the generation ID.
- The generation ID is stored on the base DN as **`ds-sync-generation-id`**. This is so that the ID does not need to be computed the next time the replica is loaded.

Deploying a basic replication topology

About this task

This section describes how to set up a two-server replication topology. The example uses the LDAP and replication server ports 1389 and 8989 respectively.

Replica Ports

Host Name	LDAP Port	Replication Port
server1.example.com	1389	8989
server2.example.com	1389	8989

Steps

1. Install the first directory server with 2000 sample entries.

```
$ ./setup --cli --acceptLicense --baseDN "dc=example,dc=com" --ldapPort 1389
 \ --rootUserPassword pass --sampleData 10000 --no-prompt
```

2. Install the second directory server either on a separate host or the same host as the first, but with a different LDAP port.

```
$ ./setup --cli --acceptLicense --baseDN "dc=example,dc=com" --ldapPort 1389
 \ --rootUserPassword pass --no-prompt
```

3. From the first server, run the **`bin/dsreplication`** command in interactive mode to configure a replication topology:

```
$ bin/dsreplication
```

4. From the Replication Main menu, select the Manage the topology option.

```
>>>> Replication Main Menu

What do you want to do?

    1) Display replication status
    2) Manage the topology (add and remove servers)
    3) Initialize replica data over the network
    4) Initialize replica data manually
    5) Replace existing data on all servers

    q) quit

Enter choice: 2
```

5. From the Manage Replication Topology menu, choose the Enable Replication option.

```
>>>> Manage Replication Topology

Select an operation for more information.

    1)  Enable Replication -- add or re-attach a server to the topology
    2)  Disable Replication -- permanently remove a running replica from the
 topology
```

```
    3)  Remove Defunct Server -- permanently remove an unavailable server
 from the
          topology
    4)  Cleanup Server -- remove replication artifacts from an offline,
 local server
          (allowing it to be re-added to a topology)

    b)  back
    q)  quit

Enter choice [b]: 1
```

6. On the Enable Replication menu, read the brief introduction on what will take place during the setup, and then, enter "c" to continue the enable process.
7. Next, enter the LDAP connection parameters for the first of the two replicas that you are configuring. First, enter the host name or IP address of the first server.
8. Next, enter the type of LDAP connection to the first server: 1) LDAP, 2) LDAP with SSL, or 3) LDAP with StartTLS.
9. Type the LDAP listener port for the first replica. If you are a root user, you will see port 389 as the default. Others will see port 1389.
10. Authenticate as a root DN, such as **`cn=Directory Manager`**. You will be prompted later in the process to set up a global administrator and password. The global administrator is the user ID that manages the replication topology group.
11. Repeat steps 7–10 for the second replica.
12. Next, the **`dsreplication`** tool checks for the base DN on both servers. In order to enable replication, data must be present on at least one of the servers. For this example, press Enter to select the default base DN, `dc=example,dc=com`.

```
Choose one or more available base DNs for which to enable replication:

    1)  dc=example,dc=com

    c)  cancel

Enter one or more choices separated by commas [1]:
```

> ⓘ **Note:** If you see the following message:
>
> ```
> There are no base DNs available to enable replication between the two
>  servers.
> ```
>
> In most cases, a base DN was not set up on one of the directory servers or the backend is disabled.

13. Next, the prompt asks if you want to set up entry balancing using the Directory Proxy Server. Press Enter to accept the default (no), since we are not setting up replication in an entry-balanced environment in this scenario. For more information, see the *PingDirectoryProxy Server Administration Guide*.

```
Do you plan to configure entry balancing using the Directory Proxy Server?
 (yes / no) [no]:
```

14. Next, enter the replication port for the first replica (default, 8989). The port must be free.
15. If the first server did not have a pre-defined location setting, **`dsreplication`** will prompt you to enter a location. Press Enter to accept the default (yes) to set up a Location for the first server. Enter the name of the server's location.

```
The first server has not been configured with a location.
Assigning a location to each server in the replication topology reduces
network traffic in multi-site deployments. Would you like to set the
```

```
location in the first server? (yes / no) [yes]

The location of the first server: Austin
```

16. Repeat the previous steps for the second directory server. Again, if you did not pre-define a location setting for the second server, you will be prompted to enter this information.
17. At this time, set up the Global Administrator user ID (default is "admin") and a password for this account. The Global Administrator user ID manages the directory servers used in the replication topology.

```
Specify the user ID of the global administrator account
that will be used to manage the Ping Identity
                  Directory Server
instances to be replicated [admin]:

Password for the global administrator:
Confirm Password:
```

18. Return to the Replication Main Menu and enter the number corresponding to initializing data over the network.
19. On the Initialize Replica Data over the Network menu, select Initialize to initialize data on a single server, and then enter `c` to continue.
20. Next, specify a server in the replication topology. For this example, enter the host name or IP address, LDAP connection type, LDAP port, Global Admin user ID and password of the first server.
21. Next, select the source server that is hosting the data to which the target server will be initialized. For this example, select the first server, since the sample dataset has been loaded onto this server.
22. Next, select the base DN that will be initialized. In most cases, the base DN for the root suffix will be replicated. In this example, `dc=example,dc=com`.
23. Next, select the second server in this example that will have its data initialized, and then enter the Global Admin user ID and password for the target server. Any data present on the target server will be over-written.
24. Press Enter to confirm that you want to initialize data on the target server. When completed, you should see "Base DN initialized successfully."

```
Initializing the contents of a base DN removes all the existing contents of
that base DN. Do you want to remove the contents of the selected base DNs on
 server
server2.example.com:1389 and replace them with the contents of server
server1.example.com:1389? (yes / no) [yes]:
```

25. On the Initialize Replica Data Over Network menu, enter `b` to back out one level to the main menu. Then, on the Replication Main menu, enter the number to view the replication status.

```
     --- Replication Servers: dc=example,dc=com ---
Server                  : Location : Conflict Entries : Backlog : Recent
 Change Rate
------------------------:----------:------------------:---------:--------------------
ds1 (example.com:1389)   : austin   : 0                : 0       : 0
ds2 (example.com:1389)   : austin   : 0                : 0       : 0
```

Example deployment with non-interactive dsreplication

This example will create a four-server topology spanning two data centers. The four servers are already installed and have locations Austin and Budepest defined.

ⓘ **Note:** When enabling or initializing servers, the **`--topologyFilePath`** option can be used with **`dsreplication`** to specify a file with a series of hosts and ports available in the topology that can be used as source servers. This option is used in place of specifying host 1, port1. When the hosts file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is

successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available for replication. This file is generated with the **manage-topology export** command.

Deploying with non-interactive dsreplication

Steps

1. Generate the sample data using the **make-ldif** tool on the first server.

```
$ bin/make-ldif --templateFile config/MakeLDIF/example-10K.template \
  --ldifFile ldif/10K.ldif
```

2. Select a server from which to import data, and to be the source for future initialization to other servers. Stop this server, import the sample LDIF and start again, or perform a task-based **import-ldif** with the connection options.

```
$ bin/stop-server
$ bin/import-ldif --backendID userRoot --ldifFile ldif/10K.ldif
$ bin/start-server
```

3. Enable replication by choosing a specific server and running **dsreplication enable** three times. For the first invocation, create the replication topology administrator with the name **admin**.

```
$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
    --bindDN1 "cn=Directory Manager" --bindPassword1 password \
    --replicationPort1 8989 --host2 austin02.example.com --port2 1389 \
    --bindDN2 "cn=Directory Manager" --bindPassword2 password \
    --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
    --adminPassword password --no-prompt

$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
    --bindDN1 "cn=Directory Manager" --bindPassword1 password \
    --replicationPort1 8989 --host2 budapest01.example.com --port2 1389 \
    --bindDN2 "cn=Directory Manager" --bindPassword2 password \
    --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
    --adminPassword password --no-prompt

$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
    --bindDN1 "cn=Directory Manager" --bindPassword1 password \
    --replicationPort1 8989 --host2 budapest02.example.com --port2 1389 \
    --bindDN2 "cn=Directory Manager" --bindPassword2 password \
    --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
    --adminPassword password --no-prompt
```

4. Initialize the other servers (the dc=example,dc=com replicas) from the server that had the data imported with **import-ldif**. To minimize the WAN transfers, initialize **budapest02** from **budapest01**.

```
$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
  --hostDestination austin02.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --no-
prompt

$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
  --hostDestination budapest01.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --no-
prompt

$ bin/dsreplication initialize --hostSource budapest01.example.com --
portSource 1389 \
  --hostDestination budapest02.example.com --portDestination 1389 \
```

```
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --no-
prompt
```

5. View the state of replication.

```
$ bin/dsreplication status --adminPassword password --no-prompt --
displayServerTable --showAll
```

Using dsreplication with SASL GSSAPI (Kerberos)

Before you begin
This example procedure assumes that you have configured SASL GSSAPI on all servers in the replication topology and that they are working properly.

About this task
The Directory Server's utilities all support SASL GSSAPI options for systems using Kerberos as its main authentication mechanism. The following procedure shows how to use **`dsreplication`** with SASL GSSAP to set up a new **`replication.admin`** identity, while enabling replication on a server. The following are important points about the configuration:

- A separate Kerberos identity is required to manage replication. Existing Kerberos credentials can be used to interact with the server when enabling replication and creating the new identity.
- The new identity, such as replication.admin, must not exist as the cn or uid value under any public base DN.

Steps

1. Set the LDAP Connection Handler to explicitly listen on the server's host name address.

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --remove listen-address:0.0.0.0 --add listen-address:host.example.com
```

2. Update the identity mapper to have `cn=topology,cn=config` included in the list of base DNs and to add the `cn` attribute to match attributes. This step is required to map the admin account to the Kerberos realm.

```
$ bin/dsconfig set-identity-mapper-prop \
  --mapper-name "Regular Expression" \
  --add match-attribute:cn \
  --set "match-base-dn:cn=topology,cn=config" \
  --set match-base-dn:dc=example,dc=com
```

3. Invoke replication enable, authenticating as the existing kerberos `authid`. Note that no bind DNs and passwords are required to authenticate because we are using SASL binding. However, the new replication admin user requires a password at creation time, so we recommend using a strong random password. Once SASL is working, you will no longer have to provide this random password. Also note that we are forcing the use of the ticket cache, so make sure you have properly authenticated as `ds.admin` from your local host and the ticket is not expired in the cache.

```
$ kinit -p ds.admin
$ bin/dsreplication enable \
  --host1 server1.example.com --port1 1389 --replicationPort1 1989 \
  --host2 server2.example.com --port2 2389 --replicationPort2 2989 \
  --baseDN dc=example,dc=com \
  --adminUID replication.admin --adminPassword strongPassword \
  --saslOption1 mech=gssapi --saslOption1 authid=ds.admin@EXAMPLE.COM \
  --saslOption1 useTicketCache=true --saslOption1 requireCache=true \
  --saslOption2 mech=gssapi --saslOption2 authid=ds.admin@EXAMPLE.COM \
  --saslOption2 useTicketCache=true --saslOption2 requireCache=true
```

4. Use **`dsreplication initialize`** to initialize data on remote server.

```
$ kinit -p replication.admin
$ bin/dsreplication initialize \
  --hostSource server1.example.com --portSource 1389 \
  --hostDestination server2.example.com --portDestination 2389 \
  --baseDN dc=example,dc=com \
  --saslOption mech=GSSAPI \
  --saslOption authID=replication.admin@EXAMPLE.COM  \
  --no-prompt
```

5. The temporary **`userPassword`** can now be deleted from the **`replication.admin`** entry. Create a file called **`remove-password.ldif`** with these contents:

```
dn: cn=replication.admin,cn=Administrators,cn=topology,cn=config
changetype: modify
delete: userPassword
```

6. Apply the modifications using **`ldapmodify`**:

```
$ ./ldapmodify --filename remove-password.ldif -o mech=GSSAPI
-o authid=replication.admin@example.com \
  --saslOption useTicketCache=true \
  --hostname host.example.com --port 1389 \
  --noPropertiesFile
```

7. Check the topology's status by running **`dsreplication status`**. The `--saslOption useTicketCache=true` and `--saslOption requireCache=true` properties, instead of providing a password, for all **`dsreplication`** commands after properly creating the admin accounts and mappers.

```
$ bin/dsreplication status \
  --saslOption mech=gssapi \
  --saslOption authid=replication.admin@EXAMPLE.COM \
  --saslOption useTicketCache=true --saslOption requireCache=true \
  --hostname host.example.com --port 1389 \
  --no-prompt
```

Configuring assured replication

The PingDirectory Server's replication mechanism is based on the eventual-consistency model, which is a loosely-connected topology that propagates updates to other servers without waiting for their corresponding replication response messages. As a result, there is a small window of time where updates are not all present on the replicas as the changes are replicating through the system. There are, however, deployments that require *immediate* access to replicated data. In such cases, administrators can configure *Assured Replication*, which ensures that replication has completed *before* the update response is returned to the client.

From the LDAP client's perspective, assured replication has no bearing on the result code of the operation, just on the time in which it takes to receive the response for those requests in which replication assurance is applied. Detailed information regarding assurance processing is available to an LDAP client with awareness of the assured replication control.

The assured replication mechanism takes advantage of server location to distinguish between local and remote servers to allow different policies to apply. For example, a common assurance approach is to respond to a client update after all servers in the same location have applied the update, and one or more servers in remote locations have received the update. In addition, the level of assurance applied to each operation can be explicitly requested by the client and/or specified by the server configuration using the Replication Assurance Policy.

Assured replication is supported by client requests directly to PingDirectory Server and/or through a PingDirectoryProxy Server.

About the Replication Assurance Policy

Assured replication uses a *Replication Assurance Policy* to define the properties needed to ensure that replication has satisfactorily completed before the update response is returned to the client. Multiple policies can be defined but only one policy is matched with a client update request. Each policy contains an evaluation order index which, together with an optional request and connection criteria, provides flexibility in matching a policy to request.

The Replication Assurance Policy defines local and remote assurance *levels*. A *level* defines how rigorous the policy should be when waiting for propagation of updates, while *local* and *remote* distinguish servers in the same location versus servers in remote locations. Although optional, it is recommended that request or connection criteria be associated with a policy to apply replication assurance appropriately.

The Directory Server contains a Default Replication Assurance Policy that is enabled but has no assurance levels assigned. In addition to using the Default Replication Assurance Policy, any number of policies can be created and enabled. When a client request is received, the server iterates through the list of enabled policies according to each policy's *evaluation-order-index* property. A smaller *evaluation-order-index* value (e.g., 1) has precedence over policies with larger *evaluation-order-index* values (e.g., 2, 3, 4, etc.). The *evaluation-order-index* values do not need to be contiguous. The first policy that matches a request is associated with the operation.

The Replication Assurance Policy, which is defined on the PingDirectory Server and not on the PingDirectoryProxy Server, has the following properties:

- **evaluation-order-index**. Determines the evaluation order (the smaller value has precedence) among multiple Replication Assurance Policies that match against an operation.
- **local-level**. Specifies the assurance level used to replicate to local servers. A local server is defined as a server with the same `location` property value as set in the global configuration. The `local-level` property must be set to an assurance level as strict as the `remote-level` property. For example, if the `remote-level` is set to "`processed-all-remote-locations`," then the `local-level` property must be "`processed-all-servers`."
  - **None**. Replication to any local server is not assured.
  - **received-any-server**. At least one available local server must receive a replication update before a response is sent to the client.
  - **processed-all-servers**. All available local servers must complete replay of the replication update before the response is sent to the client. If a singular server is enabled, or only one server is available for a particular location, `processed-all-servers` will return a value of `false`.
- **remote-level**. Specifies the assurance level used to replicate to remote servers. A remote server is defined as a server that has a different `location` property value as set in the global configuration.
  - **None**. Replication to any remote server is not assured.
  - **received-any-remote-location**. At least one server at any available remote location must receive a replication update before a response is sent to the client.
  - **received-all-remote-locations**. All available remote servers must receive a replication update before the response is sent to the client.
  - **processed-all-remote-servers**. All available servers at all locations must complete replay of the replication update before the response is sent to the client. If a single server is enabled, or only one server is available for a particular location, `processed-all-remote-servers` will return a value of `false`.
- **timeout**. Specifies the maximum length of time to wait for the replication assurance requirements to be met before timeout and replying to the client.
- **connection-criteria**. Specifies connection criteria used to indicate which operations from clients matching this criteria use this policy. If both connection criteria and request criteria are specified for a policy, then both must match an operation for the policy to be assigned.
- **request-criteria**. Specifies request criteria used to indicate which operations from clients matching this criteria use this policy. If both connection criteria and a request criteria are specified for a policy, then both must match an operation for the policy to be assigned.

Servers in a replication topology are not required to share a homogeneous set of policies; you can configure the Replication Assurance Policies differently on the replicas in a topology. For example, if you configure server A to match add operations to a `processed-all-servers` assurance level, and server B to match add operations to a local `received-any-server` level, then add operations received on server A will have the assurance level of `processed-all-servers` and add operations received on server B will have the assurance level of `received-any-server`.

For more detailed information, see the *PingDirectory Server Configuration Reference Guide*.

Points about assured replication

The following are some points when implementing Assured Replication:

- **Client Controls**. The client may optionally include an assured replication request control with each operation. This control allows the client to specify bounds on assurance levels and/or override the timeout assigned by the matching replication assurance policy for the associated operation. The server always honors these request controls. See *About the Assured Replication Controls* for more information.
- **Directory Proxy Server**. Replication assurance policies are not supported on the PingDirectoryProxy Server. Replication client controls are passed through to the underlying Directory Server backend.
- **Schema backend Replication**. The schema backend is not supported by Assured Replication. Replication assurance policies that include criteria to match this backend will be rejected.
- **Backward Compatibility**. Server versions that support assured replication are backwards-compatible with prior versions that do not support assured replication.
- **WAN-Friendly Replication**. Assured replication functions independently from WAN-Friendly Replication and the notion of WAN Gateways.
- **Global Configuration Properties**. The Directory Server provides two configurable global configuration properties that determine the timing of the assurance source and maximum number of replication backup updates to be recognized as an available source.
  - **replication-assurance-source-timeout-suspend-duration**. Specifies the amount of time a replication assurance source will be suspended from assurance requirements if it experiences an assurance timeout. While suspended, the source will be excluded from assurance requirements for all operations originating on this Directory Server. This avoids the situation of repeated timeouts caused by degraded or offline servers. Default is 10 seconds.
  - **replication-assurance-source-backlog-fast-start-threshold**. Specifies the maximum number of replication backlog updates a replication assurance source can have and be immediately recognized as an available source. If a source connects to this server with more than the configured threshold backlog updates, it will be excluded from assurance requirements for all operations originating from this Directory Server until it completes at least one assurance successfully (i.e. this Directory Server receives an update acknowledgement message from it within the timeout window). Default is 1000.

Configuring assured replication

About this task

This example illustrates configuring a variety of assured replication policies. In practice it's common for all servers to have the same policy. The following example assumes that three servers are configured on localhost, on ports 1389, 2389 and 3389. Note that each server has a default Replication Assurance Policy with no assurance levels set.

Steps

1. On server 1, use **`dsconfig`** to create request criteria for add operations. This request criteria will be used to match any add operation with the Replication Assurance Policy that will be configured in the next step.

```
$ bin/dsconfig create-request-criteria \
```

```
  --criteria-name Adds \
  --type simple \
  --set operation-type:add
```

2. On server 1, set up the Replication Assurance Policy to make all add operations assured with a level of `processed-all-servers`, which indicates that all local servers in the topology must complete replay of the replication update before the response is sent to the client. Specify the Adds request criteria configured in the previous step.

```
$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Adds Processed All Locally" \
  --set evaluation-order-index:1 \
  --set local-level:processed-all-servers \
  --set "timeout:500ms" \
  --set request-criteria:Adds
```

3. On server 1, repeat the previous two steps for modify operations. The Replication Assurance Policy "Mods Received Any Locally" ensures that at least one available local server must receive a replication modify update before a response is sent to the client.

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Mods \
  --type simple \
  --set operation-type:modify

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Mods Received Any Locally" \
  --set evaluation-order-index:2 \
  --set local-level:received-any-server \
  --set "timeout:500ms" \
  --set request-criteria:Mods
```

4. On server 2, repeat steps 1-3 to set up the Adds and Mods request criteria and its respective Replication Assurance Policy.

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Adds \
  --type simple \
  --set operation-type:add

$ bin/dsconfig create-request-criteria \
  --criteria-name Mods \
  --type simple \
  --set operation-type:modify

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Adds Received Any Locally" \
  --set evaluation-order-index:1 \
  --set local-level:received-any-server \
  --set "timeout:500ms" \
  --set request-criteria:Adds

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Mods Processed All Locally" \
  --set evaluation-order-index:2 \
  --set local-level:processed-all-servers \
  --set "timeout:500ms" \
  --set request-criteria:Mods
```

5. Leave server 3 with the default Replication Assurance Policy configured with no assurance levels or criteria. In practice it is common for all servers to have the same assurance levels or criteria.

6. On server 1, list the policies on the server using the **dsconfig** command to confirm that they exist on the server.

```
$ bin/dsconfig list-replication-assurance-policies
```

```
Replication Assurance Policy         : Type    : enabled : evaluation-order-index : local-level           : remote-level
-------------------------------------:---------:---------:-------------------------:-----------------------:-------------
Adds Processed All Locally           : generic : true    : 1                       : processed-all-servers : none
Mods Received Any Locally            : generic : true    : 2                       : received-any-server   : none
Default Replication Assurance Policy : generic : true    : 9999                    : none                  : none
```

7. Repeat the previous step on server 2 and server 3. Server 3 should only show the Default Replication Assurance Policy.
8. Check the Replication Assurance counters on all servers before any add or modify operation using `ldapsearch`. They should be set to zero. These counters are on the replica server, which is where the policy is matched and assigned. On server 1, run the following command:

```
$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-local-completed-normally: 0
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

9. Check the Replication Summary table on all of the servers. For example, on server 1, run the following command:

```
$ bin/ldapsearch --baseDN "cn=Replication Summary
 dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 0
replication-assurance-local-completed-normally: 0
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

10. Add an entry to the server 1 Directory Server. Check that the counters matched the newly added entry to the "Adds Processed All Locally" Policy and that it completed assured.

```
$ bin/ldapmodify --filename add-user.ldif --defaultAdd

$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 1
replication-assurance-local-completed-normally: 1
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
```

```
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
replication-assurance-policy-matches: Adds Processed All Locally: 1
replication-assurance-policy-matches: Default Replication Assurance Policy:
 0
replication-assurance-policy-matches: Mods Received Any Locally: 0
replication-assurance-local-level-uses: processed-all-servers: 1
replication-assurance-remote-level-uses: none: 1

$ bin/ldapsearch --baseDN "cn=Replication Summary
 dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 1
replication-assurance-local-completed-normally: 1
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

11. Perform a modify of an entry under dc=example,dc=com on server 1. Check that the counters matched the modify operation to the "Mods Processed All Locally" policy and that the operations completed assured.

```
$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 2
replication-assurance-local-completed-normally: 2
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
replication-assurance-policy-matches: Adds Processed All Locally: 1
replication-assurance-policy-matches: Default Replication Assurance Policy:
 0
replication-assurance-policy-matches: Mods Received Any Locally: 1
replication-assurance-local-level-uses: processed-all-servers: 1
replication-assurance-local-level-uses: received-any-server: 1
replication-assurance-remote-level-uses: none: 2

$ bin/ldapsearch --baseDN "cn=Replication Summary
 dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 2
replication-assurance-local-completed-normally: 2
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
```

```
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

You have successfully configured Assured Replication.

About the assured replication controls

The LDAP SDK for Java provides an implementation of an LDAP control that can be included in add, bind, modify, modify DN, and certain extended requests to indicate the level of replication assurance desired for the associated operation. The OID for this control is 1.3.6.1.4.1.30221.2.5.28, and may have a criticality of either TRUE or FALSE.

For specific details, see the LDAP SDK javadoc for the `AssuredReplicationRequestControl` class.

Managing the topology

The following sections describe common topology management operations.

ⓘ **Note:** When enabling or disabling replication within a topology that contains multiple product versions, the tool must be run from the server root location of a member of the topology that has the oldest product version.

Adding a server to the topology

About this task
The following steps assume an existing directory server topology. The commands are identical for initial enable between two servers, where one server contains data for the replication domain stored in the **`userRoot`** backend. If database encryption is being used on the servers in the topology, it is important that the server being initialized has a copy of the `encryption-settings` backend from the source server.

Steps

1. A majority of servers (more than 50%) in the topology and the new server, should be online.
2. Enable replication for the base DN, or base DNs, using an existing server as **`host1`** and the new server as **`host2`**.

```
$ bin/dsreplication enable \
  --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 austin03.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt
```

3. Optionally, compare the configurations between the two hosts used in the **`dsreplication enable`** command. Make sure settings are consistent across the topology and are also consistent with the new system:

```
$ bin/config-diff --sourceLocal \
  --targetHost austin03.example.com \
  --targetBindDN "cn=directory manager" \
  --targetBindPassword pass --targetPort 1389
```

Disabling replication and removing a server from the topology

When removing a server from the topology, the remaining servers need to be made aware of the change. If the server to remove is online, only one invocation of **`dsreplication disable`** is necessary. If the server to remove is offline, the following steps are required:

1. Run **`remove-defunct-server`** from another server in the topology.
2. Run **`remove-defunct-server`** on the offline server to removed.

Similar to the **`enable`** command, more that 50% of servers not being removed from the topology must be online during the process.

If additional servers are offline and cannot be online while removing the server, you must distinguish between offline servers that are offline permanently and those that are offline temporarily. If servers are offline permanently, use **`remove-defunct-server`** to remove them. If servers are offline temporarily, they update automatically after they are online. The following examples show the steps in more detail:

- **Removing a server that is still online**. The **`dsreplication disable`** command can be run from any server, but a majority of servers in the topology need to be online.

  ```
  $ bin/dsreplication disable --hostname austin03.example.com --port 1389 \
    --baseDN dc=example,dc=com --adminUID admin --adminPassword password \
    --no-prompt
  ```

- **Removing a server that is offline**.The **`remove-defunct-server`** tool can be run against any server not being removed from the topology. More than 50% of servers in the topology must be online. The **`remove-defunct-server`** tool can be issued after setting the JVM property **`"com.unboundid.connectionutils.LdapResponseTimeoutMillis"`** to change the default ten-minute timeout for each server to take out of rotation. If multiple servers need to be removed, this approach speeds up the process.

  ```
  $ bin/remove-defunct-server --serverInstanceName austin01 \
    --bindDN "cn=Directory Manager" --bindPassword password
  ```

  To remove any topology references, run the **`remove-defunct-server`** tool on each server that is removed from the topology, as follows:

  ```
  $ bin/remove-defunct-server --no-prompt
  ```

The option **`--ignore-online`** removes an online server cleanly from the topology.

Replacing the data for a replicating domain

In the rare event that the data for the entire replication domain (such as the backend) needs to be replaced, perform the following steps:

Replacing the data

Steps

1. With all servers online, the **`dsreplication pre-external-initialization`** command must be run once against any server in the topology. This stops replication for the domain. No writes are made by clients to any of the servers.

   ```
   $ bin/dsreplication pre-external-initialization --hostname
    austin01.example.com \
     --port 1389 --baseDN dc=example,dc=com --adminUID admin \
     --adminPassword password --no-prompt
   ```

2. Using **`import-ldif`**, replace the data for **`dc=example,dc=com`**. Make sure that the input LDIF is free of any replication attributes by using the **`--excludeReplication`** option. The **`--overwriteExistingEntries`** option is necessary to overwrite the existing data for the domain. For example, to perform the **`import-ldif`** with the server offline:

   ```
   $ bin/import-ldif --ldifFile new-data.ldif --backendID userRoot --
   excludeReplication --overwriteExistingEntries
   ```

3. Initialize the other servers in the topology with **`dsreplication initialize`**, using the server which has the new data as the source host. For example:

```
$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
   --hostDestination budapest01.example.com --portDestination 1389 \
   --adminUID admin --adminPassword password --baseDN dc=example,dc=com \
   --no-prompt
```

4. Run **`dsreplication post-external-initialization`** once from any server in the topology. All servers in the topology must be online:

```
$ bin/dsreplication post-external-initialization --hostname
 austin01.example.com \
   --port 1389 --baseDN dc=example,dc=com --adminUID admin \
   --adminPassword password --no-prompt
```

Advanced configuration

The following sections are advanced configuration procedures that may be appropriate for your company's deployment.

Changing the replicationChanges DB Location

About this task

You can change the `replicationChanges` DB location if on-disk space issues arise. The replication changelog database can live outside `<server-root>` and be placed in another location on the file system. In that case, you must specify the absolute path of the replication changelog directory.

Steps

1. Use **`dsconfig`** to change the database location for the replication changelog, which by default is at `<server-root>/changelogDb`. The following command sets the replication changelog backend to `<server-root>/data/directory/changelogDB` . Remember to include the LDAP connection parameters (host name, port, bindDN, bindPassword).

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set "replication-db-directory:/data/directory/changelogDb" \
  --bindDN "cn=Directory Manager" --bindPassword secret --no-prompt
```

2. Stop the server, move the DB files, and then restart the server.

```
$ bin/stop-server
$ mv changelogDb /data/directory
$ bin/start-server
```

Modifying the replication purge delay

About this task

The replication purge delay specifies the period after which the directory server purges changes on the replication server database. Any change that is older than the purge delay is removed from the replication server database regardless of whether the change has been applied.

Currently, the PingDirectory Server sets the default purge delay to one day. Administrators can change the default purge delay using the **`dsconfig`** tool. To ensure proper replication processing, you must have the same purge delay value set for all replication servers in the topology.

Steps

- Use **dsconfig** to change the purge delay. The property accepts time units of seconds (s), minutes (m), hours (h), days (d), or weeks (w). The following command is entered on the command line and changes the purge delay from the default one day to two days.

  In **dsconfig** interactive mode, open the **Advanced objects** menu. Select **Replication Server**. Select the replication synchronization provider, and then select the option to change the replication purge delay.

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set "replication-purge-delay:2 d"
```

Configuring a single listener-address for the replication server

About this task

By default, the replication server binds the listening ports to all available interfaces of the machine. To bind the listener to a specific address, the address must be the host name provided when replication is enabled and the `listen-on-all-addresses` property must be set to `FALSE`.

The replication server's configuration entry already stores a host name for itself so that it can resolve the address and specify it during the socket bind. If the server information is missing from the system, an error message will be generated with instructions on specific address binding. You can use the **dsconfig** tool to change the value of the `listen-on-all-addresses` property from TRUE (default) to FALSE.

To configure a replication server to listen on a single address:

Steps

1. Create a new directory serverinstance with replication enabled on port 8989.
2. Run **netstat** to see the ports bound for listening on port 8989. Notice that *.8989 means that it is listening on all addresses.

```
$ netstat -an | grep LISTEN | grep 8989
```

3. Run **dsconfig** to disable listening on all addresses for the replication server.

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set listen-on-all-addresses:false
```

4. Run **netstat** again to see the ports bound for listening on port 8989. Notice that `<address>.8989` (for example, 10.8.1.211.8989) means that it is listening on the one address.

Monitoring replication

Replication in the PingDirectory Server can be monitored the following ways:

- The **dsreplication** `status` subcommand displays basic information about the replicated base DNs, the number of entries replicated as well as the approximate size of replication backlogs at each Directory Server.
- The more detailed information about the state of replication can be obtained via the information exposed in its monitoring framework under `cn=monitor`. Administrators can monitor their replication topologies using several tools and protocols: the PingDataMetrics Server, SNMP, LDAP, JMX, or through the Administrative Console. See Managing Logging and Monitoring.
- The Periodic Stats Logger plugin allows collecting replication statistics for profiling server performance. For more information, see Profiling Server Performance Using the Periodic Stats Logger.

Monitoring replication using cn=monitor

The `cn=monitor` branch has a number of entries that store the replication state of a topology.

- **Direct LDAP Server <baseDN> <host name:port> <serverID>**. Defines an LDAP server that is directly connected to the replication server that you are querying. The information in this entry applies to the replication server local to the `cn=monitor` entry. For detailed information, see *Summary of the Direct LDAP Monitor Information*.
- **Indirect LDAP Server <baseDN> <serverID>**. Defines an LDAP server that is connected to another replication server in the topology. While this server is connected to the same topology, it is not connected to the replication server being queried. For detailed information, see *Summary of the Indirect LDAP Server Monitor Information*.
- **Remote Repl Server <baseDN> <host name:port> <serverID>**. Defines a remote replication server that is connected to the local replication server. Information in this entry is in respect to the Replication Server local to the `cn=monitor` branch. For detailed information, see *Summary of the Remote Replication Server Monitor Information*.
- **Replica <baseDN>**. Stores information for an instance of the replicated naming context— also known as the replica—with respect to the Directory Server and its communication with a replication server. The Replica information is what is responsible for sending and receiving changes from the replication servers. For detailed information, see *Summary of the Replica Monitor Information*.
- **Replication Server <replPort> <serverID>**. Shows the information specific to the Replication Server running, for example, on the replication port <replPort> with a server ID of <serverID>. This entry defines the replication server. For detailed information, see *Summary of the Replication Server Monitor Information*.
- **Replication Server Database <baseDN> <serverID>**. Shows information for the changelog table of replica (suffix) in the replication server. As the Replication Server receives updates from the Directory Server, it records those changes in the changelog table. For detailed information, see *Summary of the Replication Server Database Monitor Information*.
- **Replication Server Database Environment <baseDN>**. Shows the information for the database environment for the replication server backend plus the total number of records added to and deleted from the database. For detailed information, see *Summary of the Replication Server Database Environment Monitor Information*.
- **Replication Summary <baseDN>**. Shows summary information on the replication topology and the state for a particular base DN. For detailed information, see *Summary of the Replication Summary Monitor Information*.
- **Replication Changes Backend**. Shows the backend information for all replication changes. For detailed information, see *Summary of the Replication Changes Backend Monitor Information*.
- **Replication Protocol Buffer**. Shows the state of the buffer (initially 4k) for protocol operations, which is stored in thread local storage. For detailed information, see *Summary of the Replication Protocol Buffer Monitor Information*.

Replication best practices

The following are recommended best practices related to replication based on our observations in actual production environments.

About the dsreplication command-line utility

The following points involve some security practices as applies to replication. For specific questions, please contact your authorized support provider.

- **Developing Scripts**. The **dsreplication** utility maintains the history of executed **dsreplication** commands with the full command-line arguments in the `logs/tools/dsreplication.history` file. The recorded commands may be used to develop scripts to set up and configure replication.

  Scripts invoking the **dsreplication** utility in non-interactive mode should check the return code from the dsreplication process. A non-zero return code indicates some sort of failure.

  If output messages from the **dsreplication** utility are not desired, use the `--quiet` option to suppress them.

  The utility, by default, fails if one or more warnings are issued during the command execution. Warnings can be suppressed using the `--ignoreWarnings` option. For example, this option is required when using **dsreplication** with non-fully-qualified host names (for example, localhost), otherwise **dsreplication** will fail. In production environments, use of this flag is strongly discouraged.

  The **dsreplication** utility also provides an `--ignoreLock` option that specifies that the tool should continue processing in non-interactive mode or in scripts even if the replication topology has been locked by another invocation of **dsreplication**. However, this option should be used with caution.
- **Concurrent Use**. With the exception of the **dsreplication** `status` subcommand, the **dsreplication** subcommands cannot be executed concurrently. The command-line utility locks the replication topology at one or more servers to prevent accidental configuration changes caused by multiple **dsreplication** subcommands running at the same time. It is best to avoid concurrent configuration changes in general.
- **Status**. The **dsreplication** `status` subcommand requires the Replication Servers to provide monitoring information. This can lead to a delay before the output of **dsreplication** `status` is displayed. By default, **dsreplication** will display the status for all replicated domains (with the exception of the special domains of the schema and the server registry).

  It is recommended to select a particular base DN for **dsreplication** `status` if multiple base DNs are configured for replication.

  It is also recommended to avoid invoking **dsreplication** `status` too often (more than once every 15 seconds) or from multiple locations at the same time. Some of the information displayed by **dsreplication** `status` is based on monitor information that is not refreshed every time the monitor is queried.

  The `status` subcommand should not be used for collecting performance metrics. It is best to rely on replication-related information captured by the Periodic Stats Logger plugin.
- **Topology Tasks**. The **dsreplication** tool allows specifying more than one server in a topology to act as the host for other servers for the enable and initialize actions. The **--topologyFilePath** option can be used to specify a file with a series of hosts and ports in the topology. When the hosts file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available. This file is generated with the **manage-topology export** command.

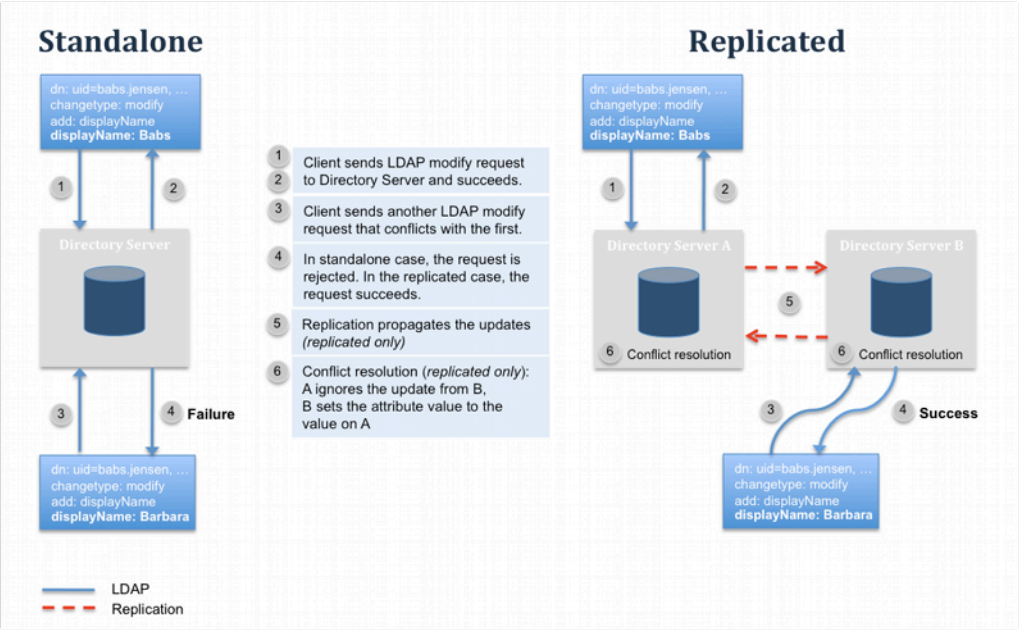
Replication conflicts

This section provides more in-depth information on replication conflicts than presented in earlier sections, so that administrators can understand the mechanisms and possible scenarios behind these conflicts.

Updates to Directory Server entries in a replication topology may happen independently, since replication guarantees only eventual consistency, not strong consistency. The eventual consistency model also means that conflicting changes can be applied at different directory server instances. In most cases, the Directory Server is able to resolve these conflicts automatically and in a consistent manner (i.e., all directory server instances in a replication topology will resolve each and every conflict the same way). However, in some scenarios, as seen below, manual administrative action is required. For any of these unresolved conflicts, the administrator is notified via administrative alerts.

On a high-level, the conflict resolution algorithm tries to resolve conflicts as if the operations causing the conflict in a distributed environment has been applied to a single directory server instance. For example, if

the same entry is added to two different directory server instances at about the same time, then once these operations have been replicated, both directory servers will keep only the entry that was added first. The following figure highlights the differences between standalone versus replicated environments.



MY TITLE Conflicting Operations in Standalone versus Replicated Environments

Types of replication conflicts

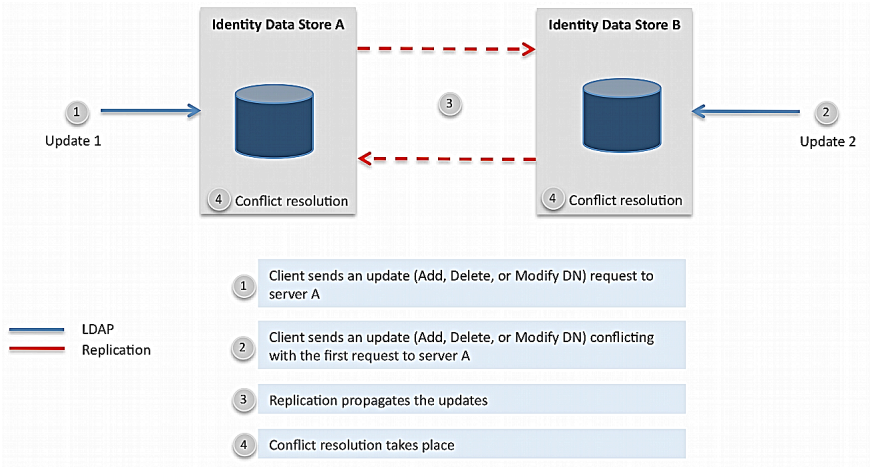
There are fundamentally two types of replication conflicts: naming and modification conflicts. Naming conflicts include operations that cause conflicts with the naming (DN) of the existing or new entries, while modification conflicts include operations that result in conflicts in the modification of attributes.

Naming conflict scenarios

For all of the naming conflict scenarios in the table below, assume the folloing:

- Update 1 was applied at Directory Server 1
- Update 2 was applied at Directory Server 2
- Update 1 occurred shortly before Update 2, so that Directory Server 2 received Update 1 after Update 2 was applied

The naming conflict scenario is illustrated in the following figure:



MY TITLE Naming Conflict Scenario

The following table shows the result of a modification conflict depending on the type of updates that occurs. The code does not compare change sequence numbers (CSNs) but applies operations in the order they were received. This may lead to inconsistent replays.

Naming Conflict Scenarios

Update 1	Update 2	Automatic Resolution?	Result of Conflict Resolution at Directory Server 2 When Update 1 is received
Modify	Delete	Yes	Modify is discarded.
Modify	Modify DN	Yes	New entry is located based on the entryUUID and Modify is applied to the renamed entry.
Delete	Delete	Yes	Delete operation is ignored.
Delete	Modify DN	Yes	Delete operation is applied to the renamed entry.
Delete of A	Add of B under A	Yes	Entry B is renamed and Entry A is deleted.
Modify DN	Delete of the same entry targeted by the Modify DN	Yes	Modify DN operation is ignored.
Modify DN with a new parent	Delete of parent	No	The entry targeted in the Modify DN operation is marked as a conflict entry.
Modify DN with a new parent	Modify DN of the parent	Yes	The entry will be moved under the new DN of the parent.
Modify DN of A with new DN B	Modify DN of C with new DN B	No	A and B will be conflict entries.
Add A	Modify DN of the parent of A	Yes	The entry is added under the new DN of the parent.
Add A	Delete of the parent of A	No	The added entry is marked as a conflict entry.

Update 1	Update 2	Automatic Resolution?	Result of Conflict Resolution at Directory Server 2 When Update 1 is received
Add A	Add A with same set of attributes	Yes	The entryUUID of the incoming Add operation applied to the existing entry.
Add A	Add A with different set of attributes (or values)	No	The existing entry is marked as a conflicting entry and the incoming Add is executed.

Modification conflict scenarios

Modification conflicts are always resolved automatically and no manual action is required. The LDAP Modify operation allows the following modification types:

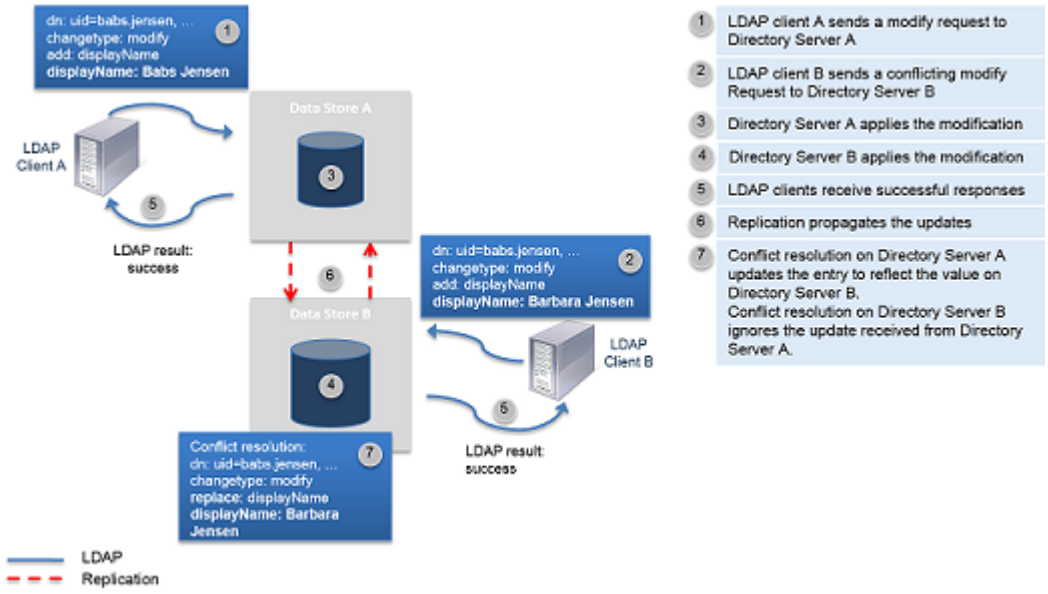
- Add of one or more values
- Delete of one or more values or the entire attribute
- Replacement of all values

Replication does not currently support the increment LDAP modification type.

For all of the operations in the table below, assume the following:

- LDAP Modify 1 was applied at Directory Server 1
- LDAP Modify 2 was applied at Directory Server 2
- LDAP Modify 1 occurred shortly before LDAP Modify 2, so that Directory Server 2 received LDAP Modify 1 after LDAP Modify 2 was applied.

The modification conflict scenario is illustrated in the figure below:



MY TITLE Modification Conflict Scenario

The following table shows the result of a modification conflict depending on the type of updates that occurs:

Modification Conflict Scenarios

Modify 1	Modify 2	Result of Conflict Resolution at Directory Server 2 When Modify 1 is received
Add of a single-value attribute	Add of the same attribute with a different value	Incoming Modify is ignored.
Delete of a single-valued attribute	Replacement of the value of the same attribute	Incoming Delete is ignored.
Replacement of a single-valued attribute	Delete of the same attribute	Incoming Replacement is ignored.
Delete some values from a multi-valued attribute	Delete some values from a multi-valued attribute	Incoming Delete is ignored.
Delete a multi-valued attribute	Delete of the same multi-valued attribute	Incoming Delete is ignored.
Delete a multi-valued attribute	Add the same multi-valued attribute	Incoming Delete is ignored.
Delete value X from a multi-valued attribute	Delete value X from the same multi-valued attribute	Incoming Delete is ignored.
Delete value X from a multi-valued attribute	Add value Y to the same multi-valued attribute	Delete of value X is applied.
Delete value X from a multi-valued attribute	Delete value Y from the same multi-valued attribute	Delete of value X is applied.
Delete value X from a multi-valued attribute	Replace all values of the same multi-valued attribute	Incoming Delete is ignored.
Add of values X and Y to a multi-valued attribute	Delete value X from the same multi-valued attribute	Only value Y is added.
Delete value X from a multi-valued attribute	Add of values X and Y to the same multi-valued attribute	Incoming Delete is ignored.

Troubleshooting replication

The following sections provide information to troubleshoot your replication deployment.

Recovering a replica with missed changes

If a server has been offline for a period of time longer than the replication purge delay, the **`dsreplication initialize`** command must be performed to bring the replica into sync with the topology.

Server startup is the only time missed changes are detected. A missed change is a change that the replica detects that it needs, but which cannot be found within any other replication server's replicationChanges backend (stored in the path server root **`/changelogDb`**). If missed changes are detected, the server enters lockdown mode, where only privileged clients can make requests. Any other server that is not missing changes can be used as a source for **`dsreplication initialize`**.

If a manual backup and restore of the server is required, then the following steps are equivalent to **`dsreplication initialize`**.

Performing a manual initialization

About this task
In the event that an online initialization is not possible, the following steps can be used to initialize a server.

Steps

1. From another server in the replication topology, back up the `userRoot`, `schema`, and `replicationChanges` backends to the `<server-root>/bak` directory. If data encryption is enabled, the `encryption-settings` backend should also be exported, as one or more encryption settings IDs may need to be imported into the new replica.

```
$ source-server-root>/bin/backup --backendID userRoot --backupDirectory \
   bak/userRoot
$ <source-server-root>/bin/backup --backendID schema --backupDirectory \
   bak/schema
$ <source-server-root>/bin/backup --backendID replicationChanges \
   --backupDirectory bak/replicationChanges
$ <source-server-root>/bin/encryption-settings export --id <id> \
   --output-file bak/exported-key
```

2. Copy the `bak` directory to the new replica.

```
$ scp -r <source-server-root>/bak/* \
    <user>@<destination-server>:<destination-server-root>/bak
```

3. Stop the server and restore the `userRoot`, `schema`, `changelog`, and `replicationChanges` backends. If the `encryption-settings` backend was exported, it should be be imported before restoring any of the backends.

```
$ <destination-server-root>bin/encryption-settings import --input-file \
   bak/exported-key --set-preferred
Enter the PIN used to encrypt the definition:
$ <destination-server-root>/bin/restore --backupDirectory bak/userRoot
$ <destination-server-root>/bin/restore --backupDirectory bak/schema
$ <destination-server-root>/bin/restore --backupDirectory \
   bak/replicationChanges
```

4. Start the server using **`bin/start-server`**.

Fixing replication conflicts

Replication conflicts can occur when an incompatible change to an entry is made on two replicas at the same time. The change is processed on one replica and then replicated to the other replica, which causes the conflict. While most conflicts are resolved automatically, some require manual action.

To fix replication conflicts, initialize the replica containing the conflicts with the data from another replica that does not have conflicts. If the database is large and the number of conflicts small, running **`ldapmodify`** against the server with the conflict will work if the command includes the Replication Repair Control specified by OID value 1.3.6.1.4.1.30221.1.5.2. The Replication Repair Control prevents the change from replicating. It also enables changing operational attribute values, which are not normally writable.

The following steps provide an example of using the Replication Repair Control to fix replication conflicts by applying change to only the server with the conflict. There are two examples: one for a modification conflict found by performing an **`ldap-diff`**, and the other for a naming conflict.

Fixing a modify conflict

Steps

1. The **bin/ldap-diff** tool can be used to isolate conflicting entries between two replicas. The following uses the tool to search across the entire base DN for any difference in user attributes, and reports the difference in **difference.ldif**. Replace the **sourceHost** value with the server that needs the adjustment.

```
$ bin/ldap-diff --sourceHost austin02.exmple.com --sourcePort 1389 \
                        --sourceBindDN "cn=Directory Manager" --
sourceBindPassword pass \
                        --targetHost austin01.example.com --targetPort 1389
 \
                        --targetBindDN "cn=Directory Manager" --
targetBindPassword
                        --baseDN "dc=example,dc=com" --outputLDIF
 difference.ldif \
                        --searchFilter "(objectclass=*)" --numPasses 3 "*"
 pass \
                        "^userPassword"
```

2. The **difference.ldif** file is in a format that can be used with **ldapmodify** to apply changes to the server that contains conflicts. The **ldap-diff** command must have been run with the **sourceHost** value as the server with conflicts. The following is an example of the contents of **difference.ldif**:

```
dn: uid=user.1,ou=people,dc=example,dc=com
                        changetype: modify
                        add: mobile
                        mobile: +1 568 232 6789
                        -
                        delete: mobile
                        mobile: +1 568 591 7372
                        -
```

3. Run **bin/ldapmodify** to correct the entries on only the server with conflicts.

```
$ bin/ldapmodify --bindPassword password -J "1.3.6.1.4.1.30221.1.5.2" \
                        --filename difference.ldif
```

Fixing a naming conflict

Steps

1. In this example, a naming conflict was encountered when the replica attempted to replay an ADD of **uid=user.200,ou=people,dc=example,dc=com**. In other words, two clients added the entry at the same time as an entry of the same name was added on another replica.

```
[18/Feb/2010:14:53:12 -0600] category=EXTENSIONS severity=SEVERE_ERROR
msgID=1880359005 msg="Administrative alert type=replication-unresolved-
conflict
id=bbd2cbaf-90a4-42af-94a8-c1a42df32fc6
class=com.unboundid.directory.server.replication.plugin.ReplicationDomain
msg='An unresolved conflict was detected for DN
 uid=user.200,ou=People,dc=example,dc=com.
The conflicting entry has been renamed to
entryuuid=69807e3d-ab27-43a3-8759-
ec0d8d6b3107+uid=user.200,ou=People,dc=example,dc=com'"
```

2. The Directory Server prepends the entryUUID to the DN of the conflicting attribute and adds a `ds-sync-conflict-entry` auxiliary object class to the entry to aid in search. For example, the following

command searches for any entry that has the `ds-sync-conflict-entry` objectclass and returns only the DNs that match the filter. You should see the conflicting entry for uid=user.200.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub \
  "(objectclass=ds-sync-conflict-entry)" "1.1"
```

```
dn: entryuuid=69807e3d-ab27-43a3-8759-
ec0d8d6b3107+uid=user.200,ou=People,dc=example,dc=com

dn: entryuuid=523c430e-
a870-4ebe-90f8-9cd811946420+uid=user.200,ou=People,dc=example,dc=com
```

ⓘ **Note:** Conflict entries are not returned unless the `objectclass=ds-sync-conflict-entry` is present in the search filter.

3. After comparing the conflict entry with the target entry, the difference can be applied in a manner similar to the previous example using **`ldapmodify`** with the Replication Repair Control. The conflict entry can also be deleted using this command. Run **`bin/ldapmodify`** with the Replication Repair Control to make the fix. When making changes using the Replication Repair Control, the updates will not be propagated via replication. You should examine each and every replica one by one, and apply the necessary modifications using the request control.

```
$ bin/ldapmodify -J "1.3.6.1.4.1.30221.1.5.2" \
  --filename difference.ldif
```

Fixing mismatched generation IDs

A warning that multiple generation IDs were detected for a specific suffix indicates that one or more replicas need to be re-initialized. If the warning is presented from a server after an initialization, it could be that **`post-external-initialization`** was not run as part of a global change in data. Running this command will fix the situation. The **`dsreplication`** `status` command will warn when any generation IDs are different across the topology.

Replication reference

The following section shows general reference information related to replication.

Summary of the dsreplication Subcommands

A summary of the **`dsreplication`** subcommands and functions is presented in the table below.

dsreplication subcommands

Subcommand	Description
`disable`	Disables replication on the specified server for the provided base DN and removes references to this server in the other servers with which it is replicating data.
`enable`	Updates the configuration of the servers to replicate the data under the specified base DN. If one of the servers is already replicating the data under the base DN with other servers, executing this subcommand will update the configuration of all the servers (so it is sufficient to execute the command line once for each server you add to the replication topology).
`initialize`	Initializes the data under the specified base DN on the destination server with the contents on the source server.

Subcommand	Description
initialize-all	Initializes the data under the specified base DN on all servers in the replication topology with the contents on the specified server.
post-external-initialization	Used with **pre-external-initialization**, the command resets the generation ID based on the newly-loaded data. This subcommand must be called after initializing the contents of all the replicated servers using the **import-ldif** tool or **dsreplication initialize**. Specify the list of base DNs that have been initialized and provide the credentials of any of the servers that are being replicated. See the usage of the `pre-external-initialization` subcommand for more information. This subcommand only needs to be run on one of the replicas once .
pre-external-initialization	Clears the existing generation ID and removes all accumulated changes of the replicated suffix from the replication changelog database at each and every replication server. This subcommand should be used when globally restoring the replicas on all of the servers in a topology. You must specify the list of base DNs that will be initialized and provide the credentials of any of the servers that are being replicated. After calling this subcommand, initialize the contents of all the servers in the topology, then call the `post-external-initialization` subcommand. This subcommand only needs to be run on one of the replicas once .
status	Displays the status of replication domains. If no base DNs are specified as parameters, the information for all base DNs is displayed. Available options with the status subcommand are: `--showAll`, `--displayServerTable`, `--location`.

Summary of the Direct LDAP Monitor information

The following table provides a description of the attributes in the `cn=Direct LDAP Server` monitor entry. The DN for the monitor entry is as follows:

```
dn: cn=Direct LDAP Server <baseDN> <host name:ldapPort> <serverID>,cn=monitor
```

Direct LDAP Monitor Information

Monitor Attribute	Description
replica-id:<serverID>	Replica ID number.
replication-backlog	Number of changes that the replication server has not seen from the server.
missing-changes	Number of missing changes.
approximate-delay	Difference between the time of the last change that the replication server has seen from the LDAP server and the most current timestamp on the latest change on the server.
base-dn	Base DN
ssl-encryption	Flag to indicate if SSL encryption is in use.
protocol-version	Displays the replication protocol version.

Monitor Attribute	Description
generation-id	Generation ID for the base DN on the Directory Server.
restricted	Boolean that indicates whether the replication domain is restricted in an Entry Balancing Configuration with the Directory Proxy Server.
ack-sent	Number of acknowledgement messages sent to this replica (not currently used).
ack-received	Number of acknowledgement messages received from this replica (not currently used).
add-sent	Number of protocol messages with an LDAP Add sent to this replica.
add-received	Number of protocol messages with an LDAP Add received from this replica.
delete-sent	Number of protocol messages with an LDAP Delete sent to this replica.
delete-received	Number of protocol messages with an LDAP Delete received from this replica.
done-sent	Number of done messages sent to this replica. A done message indicates an end of online initialization session. If the value is non-zero, then this replica has been initialized over the replication protocol.
done-received	Number of done messages received from this replica. A done message indicates an end of online initialization session. If the value is non-zero, then this replica has completed the initialization of other replicas over the replication protocol.
entry-sent	Number of entry messages sent to this replica. Entry messages carry replicated data to initialize replicas over the replication protocol.
entry-received	Number of entry messages received from this replica. Entry messages carry replicated data to initialize replicas over the replication protocol.
error-sent	Number of error messages sent to this replica.
error-received	Number of error messages received from this replica.
heartbeat-sent	Number of heartbeat messages sent to this replica.
heartbeat-received	Number of heartbeat messages received from this replica (should always be 0, since the replica never sends a heartbeat message to the server).
initialize-request-sent	Number of initialize-request messages sent to this replica. This message is sent when another replica requested initialization of its data using the replication protocol.
initialize-request-received	Number of initialize-request messages received from this replica. This message is sent when this replica requested initialization of its data using the replication protocol from another replica.
initialize-target-sent	Number of initialize-target messages sent to this replica. This message is sent before another replica has started the initialization of this replica.

Monitor Attribute	Description
initialize-target-received	Number of initialize-target messages received from this replica. This message is sent before this replica starts the initialization of one or more replicas.
ldap-server: <hostname:ldapPort>	The hostname and port of the local replication server.
modify-sent	Number of protocol messages with an LDAP Modify sent to this replica.
modify-received	Number of protocol messages with an LDAP Modify received from this replica.
modify-dn-sent	Number of protocol messages with an LDAP Modify DN sent to this replica.
modify-dn-received	Number of protocol messages with an LDAP Modify DN received from this replica.
repl-server-start-sent	Number of replication-server-start messages sent to this replica (should never be more than 1). The Replication Server responds with this message to the start message received from the replica.
repl-server-start-received	Number of replication-server-start messages received from this replica (should always be 0).
reset-generation-id-sent	Number of reset generation ID messages received from this replica.
reset-generation-id-received	Number of reset generation ID messages sent to this replica (should always be 0).
server-start-sent	Number of server-start messages sent to this replica (should always be 0).
server-start-received	Number of server-start messages received from this replica (should never be more than 1). Server-start is the first message the replica sends after establishing a replication connection.
window-sent	Number of window messages sent to this replica. Window messages are used for cumulative acknowledgement in the replication protocol.
window-received	Number of window messages received from this replica. Window messages are used for cumulative acknowledgement in the replication protocol.
window-probe-sent	Number of window probe messages sent to this replica (should always be 0).
window-probe-received	Number of window probe messages received from this replica. The replica sends a window probe message to the server if the send window in the replica is closed and the replica is unable to publish updates to the server.
update-sent	Number of changes sent to this server.
update-received	Number of changes received from this server.
internal-connection	Indicates if the replica is in the same process as the replication server.
server-state	Displays the state of the replica. Displays the latest change number that the replica has seen from all the other replicas including itself.

Monitor Attribute	Description
consumed-update-recent-rate	Rate that the connected Directory Server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last five seconds.
consumed-update-peak-rate	Highest rate that the connected Directory Server has consumed updates sent by this replication server, measured over a five second period since the replication server was started.
produced-update-recent-rate	Rate that the connected Directory Server has sent updates to this replication server, expressed as the number of updates per second and measured over the last five seconds.
produced-update-peak-rate	Highest rate that the connected Directory Server has sent updates to this replication server, measured over a five second period since the replication server was started.
max-send-window	Maximum number of changes that can be sent to the LDAP server before requiring an ACK.
current-send-window	Current number of changes remaining to be sent to the LDAP server before requiring an ACK.
max-rcv-window	Maximum number of changes that can be received by the LDAP server before sending an ACK.
current-rcv-window	Number of changes remaining to be received by the LDAP server before sending an ACK Server.
degraded	Indicates that the generation ID of the replica does not match the generation ID of the server. This is a temporary state, when loading data into the topology or the replica has not been initialized. Normally, it should be false.

Summary of the Indirect LDAP Server Monitor information

The following table provides a description of the attributes in the `cn=Indirect LDAP Server` monitor entry. These attributes provide information about a Directory Server that is connected to a different replication server in the topology.

```
dn: cn=Indirect LDAP Server <baseDN> <serverID>,cn=monitor
```

Indirect LDAP Server Monitor Information

Monitor Attribute	Description
replica-id: <serverID>	ID number identifying the replica.
base-dn: <baseDN>	Base DN
connected-to: Remote Repl Server <baseDN> <host name:replPort> <replID>	Replication server to which the directory server is connected.
replication-backlog	Number of changes that the replication server has not seen from the server.
approximate-delay	Amount of time between the last change seen by this Directory Server and the most recent change seen by the remote replication server. This value is the amount of time between the time stamps, not the amount of time required to synchronize the two servers.

Monitor Attribute	Description
generation-id	Generation ID for this suffix on this remote replication server.
consumed-update-recent-rate	Rate that the connected Replication Server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last five seconds.
consumed-update-peak-rate	Highest rate that the connected Replication Server has consumed updates sent by this replication server, measured over a five second period since the replication server was started.

Summary of the Remote Replication Server Monitor information

The following table provides a description of the attributes in the `cn=Remote Repl Server` monitor entry. The DN for the monitor entry is as follows:

```
dn: cn=Remote Repl Server <baseDN> <host name:replPort> <serverID>,cn=monitor
```

Remote Replication Server Monitor Information

Monitor Attribute	Description
replication-server: <host name>:<repl port>	Host name and replication port number of the Replication Server.
replication-server-id:<serverID>	Server ID for the Replication Server.
available	Indicates if the remote replication server is available or not. Values: true or false.
sending-paused	Indicates if sending is paused. Values: true or false.
receiving-paused	Indicates if receiving is paused. Values: true or false.
wan-gateway-priority	Specifies the WAN Gateway priority of the remote replication server.
is-wan-gateway	Indicates if the remote replication server is a WAN Gateway. Values: true or false.
wan-gateway-desired	Indicates if the remote replication server is a desired gateway. Values: true or false. This entry together with the `is-wan-gateway` property indicates the desired state. ▪ **is-wan-gateway=false, wan-gateway-desire=false**: Indicates another server with a higher gateway priority exists or the gateway priority is set to disabled. ▪ **is-wan-gateway=false, wan-gateway-desire=true**: Indicates that the remote replication server wants to be a WAN gateway. ▪ **is-wan-gateway=true, wan-gateway-desire=false**: Indicates that the remote replication server wants to give up its role as a WAN gateway. ▪ **is-wan-gateway=false, wan-gateway-desire=true**: Indicates the remote replication server wants to remain as a gateway server.
base-dn	base DN
ssl-encryption	Flag to indicate if SSL encryption is in use.
protocol-version	Replication protocol version.
generation-id	Generation ID for this suffix on this remote replication server.

Monitor Attribute	Description
restricted	Indicates that remote replication server is in an entry-balancing deployment.
add-sent	Number of protocol messages with an LDAP Add sent to the remote replication server.
add-received	Number of protocol messages with an LDAP Add received from the remote replication server.
delete-sent	Number of protocol messages with an LDAP Delete sent to the remote replication server.
delete-received	Number of protocol messages with an LDAP Delete received from the remote replication server.
done-sent	Number of done messages sent to the remote replication server. A done message indicates an end of online initialization session.
done-received	Number of done messages received from the remote replication server. A done message indicates an end of online initialization session.
entry-sent	Number of entry messages sent to the remote replication server. Entry messages carry replicated data to initialize replicas over the replication protocol.
entry-received	Number of entry messages received from the remote replication server. Entry messages carry replicated data to initialize replicas over the replication protocol.
error-sent	Number of error messages sent to the remote replication server.
error-received	Number of error messages received from the remote replication server.
heartbeat-sent	Number of heartbeat messages sent to the remote replication server.
heartbeat-received	Number of heartbeat messages received from the remote replication server.
initialize-request-sent	Number of initialize-request messages sent to the remote replication replication server. This message is used during online initialization from one replica to another.
initialize-request-received	Number of initialize-request messages received from the remote replication server. This message is used during online initialization from one replica to another.
initialize-target-sent	Number of initialize-target messages sent to the remote replication server. This message is used before online initialization from one replica to another.
initialize-target-received	Number of initialize-target messages received from the remote replication server. This message is used before online initialization from one replica to another.
modify-sent	Number of protocol messages with an LDAP Modify sent to the remote replication server.
modify-received	Number of protocol messages with an LDAP Modify received from the remote replication server.

Monitor Attribute	Description
modify-dn-sent	Number of protocol messages with an LDAP Modify DN sent to the remote replication server.
modify-dn-received	Number of protocol messages with an LDAP Modify DN received from the remote replication server.
monitor-sent	Number of monitor messages sent to the remote replication server. This message is primarily used when communicating with directory servers running a prior release.
monitor-received	Number of monitor messages received from the remote replication server. This message is primarily used when communicating with directory servers running a prior release.
monitor-request-sent	Number of monitor requests sent to the remote replication server. The receiving server will respond with a monitor message that includes server's information about the state of the topology.
monitor-request-received	Number of monitor requests received from the remote replication server. This server will respond with a monitor message that includes server's information about the state of the topology.
monitor-v2-sent	Number of monitor messages sent to the remote server. This monitor message is only used with Directory Server v3.5 or later.
monitor-v2-received	Number of monitor messages received from the remote server. This monitor message is only used with Directory Server v3.5 or later.
pause-sending-updates-sent	Number of pause-sending-updates messages sent to the remote server. The remote server must stop sending update messages to this server when receiving this message.
pause-sending-updates-received	Number of pause-sending-updates messages received from the remote server. This server will stop sending update messages to the remote server upon receiving this message.
repl-server-start-sent	Number of replication-server-start messages sent to the remote replication server (should never be more than 1). The Replication Server responds with this message to the replication-server-start message received from remote replication servers.
repl-server-start-received	Number of replication-server-start messages received from the remote replication server (should never be more than 1) window-sent: the number of window messages sent to the remote replication server. Window messages are used for cumulative acknowledgement in the replication protocol.
reset-generation-id-sent	Number of reset generation ID messages received from the remote replication server. This message is sent before and after the data is initialized in the topology.
reset-generation-id-received	Number of reset generation ID messages sent to the remote replication server. This message is sent before and after the data is initialized in the topology.
server-info-sent	Number of replication server information messages sent to the remote replication server. This message tells other replication servers about the replicas directly connected to the sending server. This message is also used to distribute information about the location of replicas.

Monitor Attribute	Description
server-info-received	Number of replication server information messages received from the remote replication server. This message tells other replication servers about the replicas directly connected to the sending server. This message is also used to distribute information about the location of replicas.
set-source-location-sent	Number of set-source-locations messages sent to the remote replication server. This message is used by WAN gateway servers to request update messages from additional locations.
set-source-location-received	Number of set-source-locations messages sent to the remote replication server. This message is used by WAN gateway servers to request update messages from additional locations.
start-sending-updates-sent	Number of start-sending-updates messages sent to the remote replication server. The remote server may only start sending updates to this server after receiving this message.
start-sending-updates-received	Number of start-sending-updates messages received from the remote server. Sending update messages to the remote server may only start after receiving this message.
window-sent	Number of window messages sent to the remote replication server. Window messages are used for cumulative acknowledgement in the replication protocol.
window-received	Number of window messages received from the remote replication server. Window messages are used for cumulative acknowledgement in the replication protocol.
messages-sent	Total number of messages sent.
messages-received	Total number of messages received.
update-sent	Total number of updates sent.
update-received	Total number of updates received.
server-state	Displays the server state of the remote replication server. It displays the last change seen on the remote replication server.
consumed-update-recent-rate	Rate that the connected Directory Server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last five seconds.
consumed-update-peak-rate	Highest rate that the connected Directory Server has consumed updates sent by this replication server, measured over a five second period since the replication server was started.
produced-update-recent-rate	Rate that the connected Directory Server has sent updates to this replication server, expressed as the number of updates per second and measured over the last five seconds.
produced-update-peak-rate	Highest rate that the connected Directory Server has sent updates to this replication server, measured over a five second period since the replication server was started.
max-send-window	Maximum number of changes that can be sent to the remote replication server before requiring an ACK.
current-send-window	Number of changes remaining to be sent to the remote replication server before requiring an ACK.

Monitor Attribute	Description
max-rcv-window	Maximum number of changes that can be received from the remote replication server before sending an ACK.
current-rcv-window	Number of changes remaining to be received from the remote replication server before sending an ACK.
degraded	Indicates that the generation ID of the replica does not match the generation ID of the remote replication server. This is a temporary state, when loading data into the topology or the replica has not been initialized. Normally, it should be false.

Summary of the Replica Monitor information

The following table provides a description of the attributes in the `cn=Replica` monitor entry for a specific base DN.

```
dn: cn=Replica <baseDN>,cn=monitor
```

Indirect LDAP Server Monitor Information

	Description
	Specified base DN. The monitor entries track your company's base DN (or base-DN: <baseDN>`dc=example,dc=com`), `cn=schema`base-DN: , and `cn=topology,cn=config`.
connected-to: Replication Server <replPort> <serverID>	Replication port number and server ID of the replication server to which this LDAP Server is connected. The first number is the replication server port number and the second number is the `server-id` of the replication server.
lost-connections	Number of times the Directory Server has lost connection to a replication server.
received-updates	Number of updates that the Directory Server Replica has received from the connected replication server.
sent-updates	Number of updates sent to the replication server.
pending-updates	Number of updates pending to send to the replication server.
replayed-updates	Total number of updates from the replication server that have been replayed for this replica.
replayed-updates-ok	Number of updates for this replica that have been successfully replayed with no conflicts.
replayed-update-failed	Number of updates for this replica that were successfully replayed after automatically resolving a modify conflict.
resolved-modify-conflicts	Number of updates for this replica that were successfully resolved after a modify conflict.
resolved-naming-conflicts	Number of updates for this replica that were successfully resolved after a naming conflict.
unresolved-naming-conflicts	Number of updates for this replica that could not be replayed due to an unresolvable naming conflict.
replica-id	Server ID for this replica.

	Description
max-rcv-window	Maximum number of changes that the Directory Server Replica can receive at a time before sending an acknowledgment back to the replication server.
current-rcv-window	Current received window size for this replica.
max-send-window	Maximum number of changes that the Directory Server Replica can send at a time to the replication server before requiring an ACK.
current-rcv-window	Number of changes remaining to be received from the replication server before it must send an ACK.
max-send-window	Maximum number of changes that the Directory Server Replica can send at a time to the replication server before requiring an ACK.
current-send-window	Number of changes remaining to be sent to the replication server before requiring an ACK.
ssl-encryption	Flag to indicate if SSL encryption is in use.
generation-id	Generation ID for this suffix on the Directory Server.
replication-backlog	Number of changes that are from this replica.

Summary of the Replication Server Monitor information

The following table provides a description of the attributes in the `cn=Replication Server` monitor entry.

```
dn: cn=Replication Server <baseDN> <replServerID>,cn=monitor
```

Replication Server Monitor Information

Monitor Attribute	Description
replication-server-id	Server ID for the Replication server ID.
replication-server-port	Port number on which the replication server listens for communication from other servers.
base-dn: <baseDN>	Indicates the suffix to which this replication server database applies.
Generation IDs by Base DN	List of generation IDs for each base DN on the server.
num-outgoing-replication-server-connections	Number of outgoing connections from the replication server.
num-incoming-replication-server-connections	Number of incoming connections into the replication server.
num-incoming-replica-connections	Number of incoming connections to the replica.

Summary of the Replication Server Database Monitor information

The following table provides a description of the attributes in the `cn=Replication Server database` monitor entry.

```
dn: cn=Replication Server database <baseDN> <replServerID>,cn=monitor
```

Replication Server Database Monitor Information

Monitor Attribute	Description
database-replica-id: <replicaID>	Specifies the replication server ID.
base-dn: <baseDN>	Indicates the suffix to which this replication server database applies.
first-change	First change number that is in this replication database table for this suffix from this `server-id`. For example, an example entry looks like the following: `0000012209EA622C390D00000002 Mon Jun 22 16:41:11 CDT 2011`
last-change	Last change number that is in this replication database table for this suffix from this `server-id`. For example, an example entry looks like the following: `0000012209EA622C390D00000002 Mon Jun 22 16:41:11 CDT 2011`
queue-size	Number of changes in the replication server queue waiting to be sent to this remote replication server database.
queue-size-bytes	Size in bytes of all the messages waiting in the queue.
records-added	Displays the number of records changed or added to the DIT.
records-removed	Displays the number of records removed from the DIT.

Summary of the Replication Server Database Environment Monitor information

The following table provides a description of the attributes in the `cn=Replication Server Database Environment` monitor entry, which includes the environment variables associated with the Oracle Berkeley Database Java Edition backend.

```
dn: cn=Replication Server Database Environment,cn=monitor
```

Replication Server Database Environment Monitor Information

Monitor Attribute	Description
je-version	Current version of the Oracle Berkeley Java Edition.
current-db-cache-size	Current DB cache size.
max-db-cache-size	Maximum DB cache size.
db-cache-percent-full	Percentage of the cache used by the Directory Server.
db-directory	Directory that holds the changelogDb file.
db-on-disk-size	Size of the DB on disk.
cleaner-backlog	Number of log files that must be cleaned for the cleaner to meet its target utilization.
random-read-count	Number of disk reads which required repositioning the disk head more than 1MB from the previous file position.
random-write-count	Number of disk writes which required repositioning the disk head by more than 1MB from the previous file position.

Monitor Attribute	Description
sequential-read-count	Number of disk reads which did not require repositioning the disk head more than 1MB from the previous file position.
sequential-write-count	Number of disk writes which did not require repositioning the disk head by more than 1MB from the previous file position.
nodes-evicted	Accumulated number of nodes evicted.
active-transaction-count	Number of currently active transactions.
num-checkpoints	Number of checkpoints. A checkpoint is a process that writes to your log files all the internal BTree nodes and structures modified as a part of write operations to your log files to facilitate a quick recovery.
checkpoint-in-progress: false	Indicates if a checkpoint is in progress.
total-checkpoint-duration-millis	Total time in milliseconds for all checkpoints.
average-checkpoint-duration-millis	Average time in milliseconds for all checkpoints.
last-checkpoint-duration-millis	Duration in milliseconds of the last checkpoint run.
last-checkpoint-start-time	Start time of the last checkpoint.
last-checkpoint-stop-time	Stop time of the last checkpoint.
millis-since-last-checkpoint	Time in milliseconds since the last checkpoint.
read-locks-held	Total read locks currently held.
write-locks-held	Total write locks currently held.
transactions-waiting-on-locks	Total transactions waiting for locks
je-env-stat-AdminBytes	Number of bytes of JE cache used for log cleaning metadata and other administrative structure.
je-env-stat-BufferBytes	Total memory currently consumed by log buffers, in bytes.
je-env-stat-CacheDataBytes	Total memory of cache used for data.
je-env-stat-CacheTotalBytes	Total amount of JE cache in use, in bytes.
je-env-stat-CleanerBacklog	Number of files to be cleaned to reach the target utilization.
je-env-stat-CursorsBins	Number of bottom internal nodes (BINs) encountered by the INCompressor that had cursors referring to them when the compressor ran. The compressor thread cleans up the internal BTree as records are deleted to ensure unused nodes are not present.
je-env-stat-DataBytes	Amount of JE cache used for holding data, keys and internal Btree nodes, in bytes.
je-env-stat-DbClosedBins	Number of bins encountered by the INCompressor that had their database closed between the time they were put on the compressor queue and when the compressor ran.
je-env-stat-EndOfLog	Location of the next entry to be written to the log.
je-env-stat-InCompQueueSize	Number of entries in the INCompressor queue when the getStats() call was made.
je-env-stat-LastCheckpointEnd	Location in the log of the last checkpoint end.
je-env-stat-LastCheckpointId	ID of the last checkpoint.

Monitor Attribute	Description
je-env-stat-lastCheckpointStart	Location in the log of the last checkpoint start.
je-env-stat-lockBytes	Number of bytes of JE cache used for holding locks and transactions.
je-env-stat-NBINsStripped	Number of BINS stripped by the evictor.
je-env-stat-NCacheMiss	Total number of requests for database objects which were not in memory.
je-env-stat-NCheckpoints	Total number of checkpoints run so far.
je-env-stat-NCleanerDeletions	Number of cleaner file deletions this session.
je-env-stat-NCleanerEntriesRead	Accumulated number of log entries read by the cleaner.
je-env-stat-NCleanerRuns	Number of cleaner runs this session.
je-env-stat-NClusterLNsProcessed	Accumulated number of leaf nodes (LNs) processed because they qualify for clustering.
je-env-stat-NDeltaINFlush	Accumulated number of delta internal nodes (INs) flushed to the log.
je-env-stat-NEvictPasses	Number of passes made to the evictor.
je-env-stat-NFSyncRequests	Number of fsyncs requested through the group commit manager. **`Fsync()`** synchronizes the file system after a write or a transaction.
je-env-stat-NFSyncTimeouts	Number of fsync requests submitted to the group commit manager which timed out.
je-env-stat-NFSyncs	Number of fsyncs issued through the group commit manager.
je-env-stat-NFileOpens	Number of times a log file has been opened.
je-env-stat-NFullBINFlush	Accumulated number of full bottom internal nodes (BINS) flushed to the log.
je-env-stat-NFullINFlush	Accumulated number of full INs flushed to the log.
je-env-stat-NINsCleaned	Accumulated number of INs cleaned.
je-env-stat-NINsDead	Accumulated number of INs that were not found in the tree anymore (deleted).
je-env-stat-NINsMigrated	Accumulated number of INs migrated.
je-env-stat-NINsObsolete	Accumulated number of INs obsolete.
je-env-stat-NLNQueueHits	Accumulated number of LNs processed without a tree lookup.
je-env-stat-NLNsCleaned	Accumulated number of LNs cleaned.
je-env-stat-NLNsDead	Accumulated number of LNs that were not found in the tree anymore (deleted).
je-env-stat-NLNsLocked	Accumulated number of LNs encountered that were locked.
je-env-stat-NLNsMarked	Accumulated number of LNs that were marked for migration during cleaning.
je-env-stat-NLNsMigrated	Accumulated number of LNs migrated.
je-env-stat-NLNsObsolete	Accumulated number of LNs obsolete.
je-env-stat-NLogBuffers	Number of log buffers currently instantiated.
je-env-stat-NMarkedLNsProcessed	Accumulated number of LNs processed because they were previously marked for migration.

Monitor Attribute	Description
je-env-stat-NNodesExplicitlyEvicted	Accumulated number of nodes evicted.
je-env-stat-NNodesScanned	Accumulated number of nodes scanned to select the eviction set.
je-env-stat-NNodesSelected	Accumulated number of nodes selected to evict.
je-env-stat-NNotResident	Number of requests for database objects not contained within the in memory data structures.
je-env-stat-NOpenFiles	Number of files currently open in the file cache.
je-env-stat-NPendingLNsLocked	Accumulated number of pending LNs that could not be locked for migration because of a long duration application lock.
je-env-stat-NPendingLNsProcessed	Accumulated number of LNs processed because they were previously locked.
je-env-stat-NRandomReadBytes	Number of bytes read which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomReads	Number of disk reads which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomWriteBytes	Number of bytes written which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomWrites	Number of disk writes which required repositioning the disk head by more than 1MB from the previous file position.
je-env-stat-NRepeatFaultReads	Number of reads which had to be repeated when faulting in an object from disk because the read chunk size controlled by `je.log.faultReadSize` is too small.
je-env-stat-NRepeatIteratorReads	Number of times we try to read a log entry larger than the read buffer size and can't grow the log buffer to accommodate the large object.
je-env-stat-NRootNodesEvicted	Accumulated number of database root nodes evicted.
je-env-stat-NSequentialReadBytes	Number of bytes read which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialReads	Number of disk reads which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialWriteBytes	Number of bytes written which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialWrites	Number of disk writes which did not require repositioning the disk head by more than 1MB from the previous file position.
je-env-stat-NSharedCacheEnvironments	Number of environments using the shared cache.
je-env-stat-NTempBufferWrites	Number of writes which had to be completed using the temporary marshalling buffer because the fixed size log buffers specified by `je.log.totalBufferBytes` and `je.log.numBuffers` were not large enough.
je-env-stat-NToBe-CleanedLNsProcessed	Accumulated number of LNs processed because they are soon to be cleaned.
je-env-stat-NonEmptyBins	Number of non-empty bins.

Monitor Attribute	Description
je-env-stat-ProcessedBins	Number of bins that were successfully processed by the INCompressor.
je-env-stat-RequiredEvictBytes	Number of bytes that must be evicted to get within the memory budget.
je-env-stat-SharedCacheTotalBytes	Total amount of the shared JE cache in use, in bytes.
je-env-stat-SplitBins	Number of bins encountered by the INCompressor that were split between the time they were put on the compressor queue and when the compressor ran.
je-env-stat-TotalLogSize	Approximation of the current total log size in bytes.
je-env-stat-NOwners	Total lock owners in the lock table.
je-env-stat-NReadLocks	Total read locks currently held.
je-env-stat-NRequests	Total number of lock requests to date.
je-env-stat-NTotalLocks	Total locks currently in the lock table.
je-env-stat-NWaiters	Total transactions waiting for locks.
je-env-stat-NWaits	Total number of lock waits to date.
je-env-stat-NWriteLocks	Total write locks currently held.
je-env-stat-LastCheckpointTime	Time of the last checkpoint.
je-env-stat-LastTxnId	Last transaction ID allocated.
je-env-stat-NAborts	Number of transactions that have aborted.
je-env-stat-NActive	Number of transactions that are currently active.
je-env-stat-NBegins	Number of transactions that have begun.
je-env-stat-NCommits	Number of transactions that have committed.
je-env-stat-NXAAborts	Number of XA transactions that have aborted.
je-env-stat-NXACommits	Number of XA transactions that have committed.
je-env-stat-NXAPrepares	Number of XA transactions that have been prepared.

Summary of the Replication Summary Monitor information

The following table provides a description of the attributes in the `cn=Replication Summary` monitor entry.

```
dn: cn=Replication Summary <baseDN>,cn=monitor
```

Replication Summary Monitor Information

Monitor Attribute	Description
base-dn:<baseDN>	Base DN summary.
replica: replica-id, ldap-server connected-to, generation-id, replication-backlog, recent-update-rate, peak-update-rate, age-of-oldest- backlog-change	Summary information for each replica in the topology. This entry appears for each replica in the topology with its own respective properties.

Monitor Attribute	Description
replication-server: server-id, server, generation-id, status, last-connected, last-failed, failed-attempts, attributes.	Summary information for each remote replication server only in the topology. This entry appears for each Replication Server in the topology with its own respective `serverID` and `server` properties.
update-queue: id, max-count, current-count, max-size, current-size, polling-source, polling-source-changed	Summary information for each update queue on a server: ▪ **id**. The ID of the receiving replica or replication server ▪ **max-count**. The maximum number of update messages that the sending replication server will keep in memory for the receiving replica or replication server. If the receiver cannot accept messages fast enough for any reason (high load, network latency, etc), then this queue will fill up. When that happens, the sending replication server will read update messages from the changelog backend. This slows down the update processing considerably. ▪ **current-count**. The number of update messages currently on the queue that have not been sent to the receiving replica or replication server. Every time the sending replication server sends an update to the receiving replica or replication server, this counter is decremented. ▪ **max-size**. The maximum total size (in bytes) of update messages that may be in the queue. This queue is capped by both the maximum count (`max-count`) and the `max-size` setting, whichever is reached first. ▪ **current-size**. The total size of update messages currently on the queue that have not been sent to the receiving replica or replication server. Every time the sending replication server sends an update to the receiving replica or replication server, this value is decremented by the size of the published update message. ▪ **polling-source**. Either 'memory' or 'db'. If set to 'memory', the sending replication server relies only on the in-memory queue to push update messages to the receiving replica or replication server. If set to 'db', update messages are read and sorted from the changelog database, which is significantly slower than publishing updates from the in-memory queue. ▪ **polling-source-changed**. The total number of times the polling-source attribute has changed value (either from 'db' to 'memory' or from 'memory' to 'db'). If this value changes very frequently, then the queue size setting is probably too low.

Summary of the replicationChanges Backend Monitor information

The following table provides a description of the attributes in the `cn=replicationChanges Backend` monitor entry.

```
dn: cn=replicationChanges Backend,cn=monitor
```

replicationChanges Backend Monitor Information

Monitor Attribute	Description
ds-backend-id	ID descriptor for the backend. Typically, this will be "replicationChanges".

Monitor Attribute	Description
ds-backend-base-dn	Base DN for the backend. Typically, this will be `cn=replicationChanges`.
ds-backend-is-private	Flag to indicate if the backend is private.
ds-backend-entry-count	Entry count for the backend.
ds-base-dn-entry-count	Entry count for the base DN and the specified base DN.
ds-backend-writability-mode	Flag to indicate if the backend is writable or not.

Summary of the Replication Protocol Buffer Monitor information

The following table provides a description of the attributes in the `cn=Replication Protocol` Buffer monitor entry. The monitors provide information on the state of the buffer for protocol operations, which is kept in the local storage.

```
dn: cn=Replication Protocol Buffer,cn=monitor
```

Replication Protocol Buffer Monitor Information

Monitor Attribute	Description
saved-buffers	Number of protocol buffers. Initial buffer size is 4k.
reallocations	Number of times the buffers had to be reallocated due to insufficient size.
large-buffer-creates	Number of times a buffer larger than 512k was requested.
large-buffer-evictions	Number of times a buffer was removed from the thread local storage, because it has grown above 512k.

Advanced topics reference

This chapter presents background reference information covering advanced replication topics.

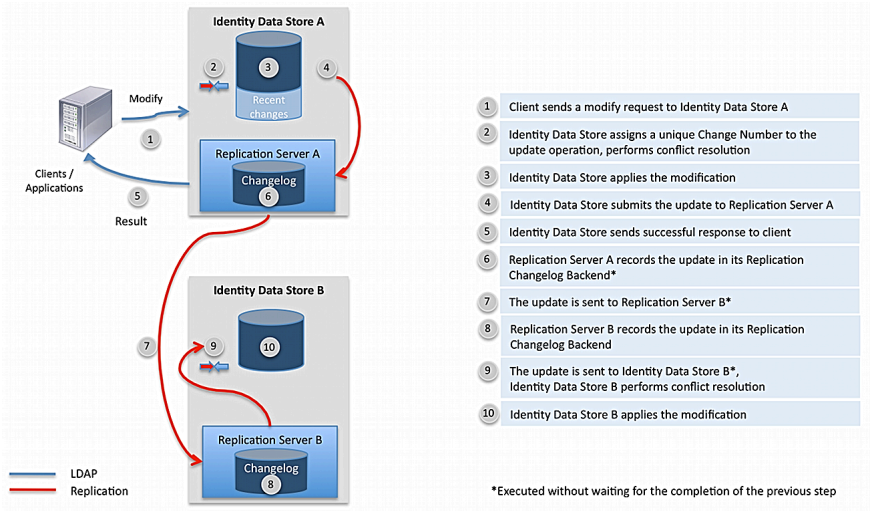
About the replication protocol

Replication communicates using a proprietary binary protocol that is implemented on top of the TCP/IP protocol using SSL encryption. Some protocol messages are used for administrative purposes (such as WAN Gateway server negotiation or flow control), some carry updates to replicated data, while others are directed to all servers for monitoring requests.

In a replicated topology, each participating Directory Server is connected to every other server via the replication server port in order to monitor health. Servers which share the same location setting are also connected to rapidly replicate changes and lastly the WAN Gateway servers are all interconnected to replicate changes across locations.

Directory Servers keep connections open as long as possible to reduce the communication latency when messages are exchanged. Heartbeat messages are transmitted on a regular basis to detect a network failure or an unresponsive directory server as early as possible. Heartbeat messages also prevent idle connections from being closed by firewalls.

The following detailed communication flow will be used to describe major components of replication. This illustration is the expanded view of figure shown in the Overview section.



MY TITLE Replication Communication Flow

Step 1. Client sends a Modify request to Directory Server A.

Step 2. Directory Server A assigns a unique change number to the operation. Conflict resolution is executed to see if the Modify request is in conflict with the existing attribute types or values in the existing entry. The change number is assigned before the Directory Server backend is updated so that the arrival order of client requests can be preserved. Historical data in the target entry is updated to reflect the change. Note that historical data is only updated for ADD and MODIFY operations.

Step 3. Directory Server applies the modifications in the corresponding backend.

Step 4. If the MODIFY operation successfully completes, then the Directory Server will submit the update to its embedded *Replication Server*. The Replication Server is a component within the Directory Server process responsible for propagating updates to and from the replication topology. The Directory Server itself only communicates with a single replication server, whereas the replication server component is connected to all other replication servers. If the Directory Server process exits unexpectedly and some updates have not been passed to the Replication Server, the backend has the ability to recover the last 50,000 recent changes that were processed at this server, guaranteeing that these changes can be replicated when the server starts up. The figure above also shows that replication protocol is used not just between replication servers but also between the Directory Server and the Replication Server.

Step 5. The response is sent to the client. In this example, a successful response is assumed.

Step 6. The Replication Server records the update in its own Changelog backend (i.e., backend ID of `replicationChanges`) and on disk with the path to `changelogDb` under the server root. The Replication Changelog backend keeps track of updates at each and every Directory Server in the replication topology. When a Directory Server joins the replication topology after being disconnected for some reason, updates from the Replication Changelog backend are re-sent to this Directory Server. Old records from the Replication Changelog backend are purged, which by default removes records older than 24 hours. If the backend does not contain all of the records that another Directory Server needed when rejoining the replication topology, then the replicated data set in the Directory Server must be re-initialized. In this case, the Directory Server enters lockdown mode and an administrative alert is sent.

Step 7. The Replication Server submits the update to the replication server component in Directory Server B. If there were more Directory Servers in this example, the Replication Server would submit the update to all the other replication servers in the same location.

Step 8. Just like in Step 6, the Replication Server component receiving an update inserts the change into its Replication Changelog backend.

Step 9. The update is forwarded to the Replica in Directory Server B. Conflict resolution is executed to see if the Modify request is in conflict with the existing attribute types or values in the existing entry.

Step 10. The Directory Server applies the modification in the corresponding backend. The Recent Changes database is not updated, because only updates that originated at this Directory Server are recorded in the Recent Changes database.

Change number

As seen in the previous Figure, the Directory Server assigns a unique change number to each update operation (specifically, ADD, DELETE, MODIFY, or MODIFY DN operations) to track each request when received from a client. The change number not only identifies each and every update, but it also allows ordering updates to the replicated data the same way on each Directory Server. The change number is composed of the following multiple fields:

- **Timestamp** that identifies when the update was made. The timestamp is time-zone-independent and recorded with millisecond resolution.
- **Server ID** that uniquely identifies the Directory Server where the update was made.
- **Sequence number** that defines the order of the updates received from external clients at a particular directory server.

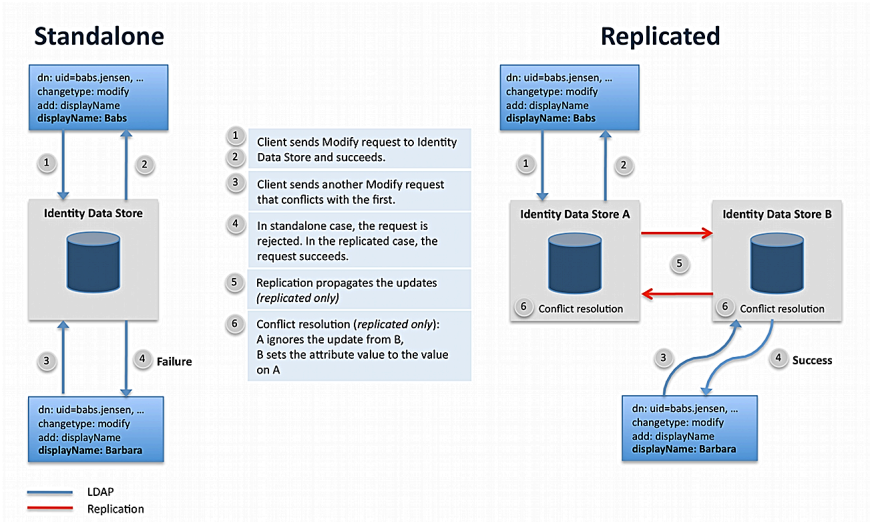
The replication protocol also sets a virtual clock that eliminates the need for synchronized time on servers. For troubleshooting purposes, however, it is still recommended to keep the system clocks synchronized.

Conflict resolution

The eventual-consistency model employed in replication introduces a window where conflicting updates targeting the same entry may be applied at two different Directory Servers. In general, two updates to the same Directory Server are in conflict if the update that arrived later fails. Conflict resolution, when possible, corrects conflicts introduced by clients automatically. There are some exceptions, however, when manual administrative action is required. For example, adding an entry in one replica and deleting the parent of this entry on another replica simultaneously will introduce a conflict that requires manual action. In a carefully implemented deployment, the risk of introducing conflicts that require manual action can be significantly reduced or even eliminated.

The conflict resolution algorithm in the PingDirectory Server uses a mechanism that orders all updates in the replication topology. Each update in the Directory Server is assigned a unique change number. The change number is attached to each update propagated via replication and allows each Directory Server to order updates exactly the same way.

Consider the following example that results in a conflict: add a single-valued attribute with different values to an entry concurrently at two Directory Servers (shown in the figure below). It is easy to see that the second operation would fail if a client attempted to add the same attribute to the same entry at the same Directory Server. In a replicated environment, the conflict is not immediately seen if these updates are applied concurrently at two different Directory Servers. The conflict is handled only after replication propagates the updates. The Directory Servers resolve the conflict independently of the other server. On one Directory Server, the entry will be updated to reflect the correct value; on the other Directory Server, the value will stay the same. As result, each Directory Server will independently resolve the conflict the same way based on the ordering of the updates. This example is illustrated below:



MY TITLE Conflict Resolution Process Flow

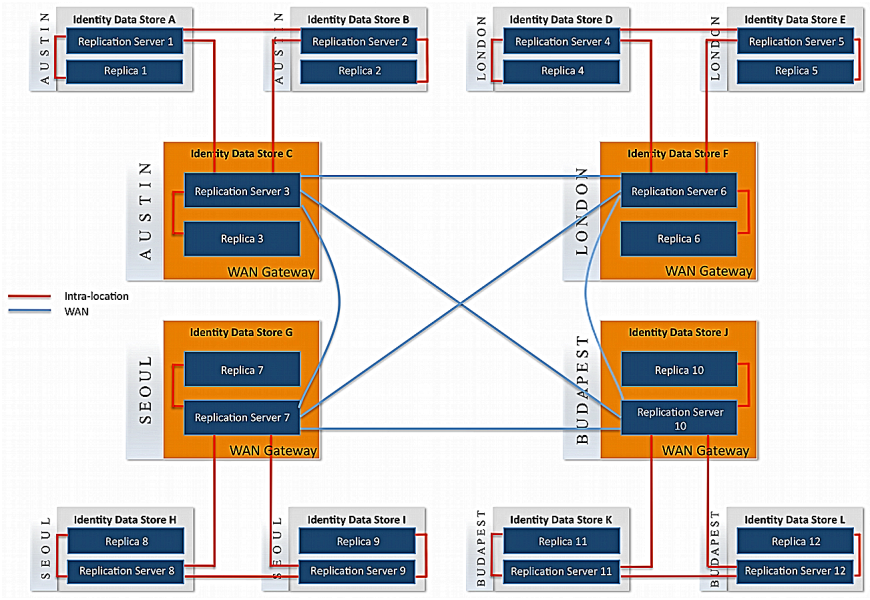
WAN-friendly replication

Many multi-national corporations that have data centers in different countries must minimize latency over WAN to ensure acceptable performance for their client applications. To minimize WAN latency, the Directory Server assigns one of two roles to the replication servers: the role of standard replication transmitting updates to the other co-located replication servers; the other role, a WAN-dedicated replication server designed to send updates to other WAN-designated replication servers in other locations. This two-role system minimizes WAN traffic by pushing all replication updates onto the connected replication servers that are designated as WAN Gateway Servers. Only the designated WAN Gateway Servers can transmit the update messages to other connected WAN Gateway servers at other locations.

WAN Gateway Server

The Directory Server's replication mechanism relies on the server's location information to reduce protocol traffic on WAN links. During protocol negotiation, the replication server with the highest WAN Gateway priority (priority 1 indicates the highest priority) automatically assumes the role as the WAN Gateway Server for that particular location. The Gateway Server's main function is to route update messages from other non-gateway servers at the same location to remote WAN Gateway servers at other locations. Similarly, at the destination point, the replication server with the WAN Gateway role will receive update messages from other WAN gateway servers at other locations and push them out to all replication servers at the current location. This setup ensures that all WAN communication flows through the WAN Gateway Servers.

The figure below shows a basic connection configuration for updates. Keep in mind that all of the replication servers are fully connected to each other for monitoring or server negotiation purposes.



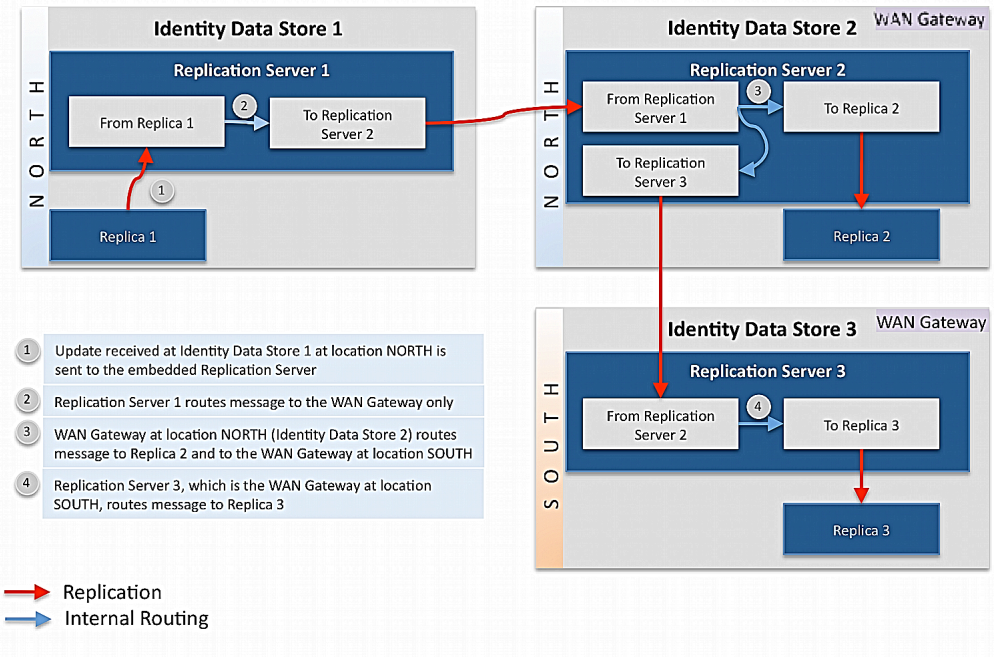
MY TITLE WAN Gateway Servers

If the WAN Gateway Server is temporarily unavailable due to a planned or unplanned downtime, the system will dynamically re-route updates to a newly designated WAN Gateway Server in the same location. The replication server with the next highest WAN Gateway priority number automatically assumes the WAN Gateway role. For deployments with entry-balancing Directory Proxy Servers, there will be one WAN Gateway Server per data set.

By default, all servers are enabled to serve as WAN Gateways and all are set to priority 5, which is simply a way to make them all equal. If necessary, the WAN Gateway priority can be changed using **`dsconfig`** after replication has been enabled.

WAN message routing

Non-gateway replication servers forward update messages from replicas to co-located replication servers only. It is the responsibility of the WAN gateway server to forward these messages to WAN gateway servers at other locations. The figure below illustrates how an update message is routed from a non-gateway server to a remote location.



MY TITLE WAN Message Routing

WAN Gateway Server selection

The WAN Gateway role is dynamically assigned to the most suitable server in a particular location. In most cases, the replication server with the higher WAN Gateway priority (e.g., priority 1 indicates the highest priority) assumes this role.

A replication server will not attempt to become a WAN Gateway if any of the following conditions exists:

- The WAN Gateway priority is set to 0
- The replication server is backlogged at server startup
- The current WAN Gateway has higher priority
- The WAN Gateway has not been elected yet, but higher priority replication servers are present in the location

The currently active WAN Gateway server will give up the gateway role in the following cases:

- The server has started the shutdown process
- The server is preparing for a scheduled maintenance cycle
- The server learns about a higher priority replication server in its location

Replication servers send WAN Gateway information to other servers at regular intervals using the replication protocol. This allows the replication servers to take the appropriate action, for example, to become a WAN Gateway, if necessary without any manual administrative action.

WAN replication in mixed-version environments

WAN Gateway Role assignment is only available on PingDirectory Servers version 3.5 or later. Legacy servers (i.e., pre-3.5) will never be selected as WAN Gateways. Updates from legacy replication servers are forwarded to all replication servers and not funneled to a single WAN Gateway. Also, updates from remote WAN Gateways will be forwarded to the legacy replication servers. Both of these actions will effectively increase WAN traffic during replication.

Recovering a replication changelog

About this task
In the event that the replication changelog is compromised (`<server-root>/changelogDb`), possibly due to a disk or NAS failure, perform the following steps.

Steps

1. Stop the server.
2. Backup **`replicationChanges`** from a remote server with the following command:

```
$ bin/backup --backupDirectory /app/backups/replicationChanges \
  --backendID replicationChanges
```

3. Copy the **`replicationChanges`** backup from the remote server and restore it on the local host as follows:

```
$ bin/restore --backupDirectory /app/tmp/replicationChanges
```

4. Start the server.

Disaster recovery

About this task
In the event that data is compromised across all systems and a restore is necessary, perform the following steps. These steps assume that no read or write operations are performed by any servers during this process.

> ⓘ **Note:**
>
> The following should be considered for disaster recovery:
>
> - With the default configuration, the server automatically exports all data nightly using the **`Export All Non-Administrative Backends`** recurring task. Up to seven days of exports are maintained. It is recommended that these be archived on another system.
> - The Data Recovery Log logs all changes in a reversible format to `logs/data-recovery/data-recovery`.
> - The **`bin/extract-data-recovery-log-changes`** tool provides the ability to redo or undo any changes from the `logs/data-recovery/data-recovery` logs.
> - The combination of these allows you to either rebuild the data set to any point in time or to revert specific changes on a live data set (for example, if an errant application mistakenly wipes out some data).

> ⓘ **Note:**
>
> See *LDIF export as a recurring task* on page 309 for information about LDIF exports.

Steps

1. Stop all servers.
2. Go to one of the servers and remove it from the topology:
   `bin/remove-defunct-server`

   This also cleans replication artifacts on this server instance as long as bind credentials are not provided. For this reason, don't provide `--bindDN` or `--bindPassword` with this.

3. The server might ask you to reconnect for each offline server, enter `no`.
4. Locate the backup or exported LDIF file that represents the last working copy of the database.
5. Restore the backup or import the LDIF file on a single server. If importing an LDIF file, use the `--excludeReplication` option with the **`bin/import-ldif`** command.
6. Start the restored server. The server can now receive client requests.
7. The server might ask you to reconnect for each offline server, enter `no`.
8. Clean up replication artifacts from the next server before starting it up:
   `bin/remove-defunct-server`
9. Start the server in lockdown mode with the following command:
   `bin/start-server --skipPrime --lockdownMode`
10. Enable replication from the first server to the second server.
    `bin/dsreplication enable`
11. Initialize the second server from the first with the following command:
    `bin/dsreplication initialize`
12. Restart the second server or use the **`bin/leave-lockdown-mode`** command to exit lockdown mode.

    The second server can now receive client requests.
13. Repeat steps 6 through 10 for any other servers.

Managing Logging

The PingDirectory Server supports a rich set of log publishers to monitor access, debug, and error messages that occur during normal server processing. Administrators can view the standard set of default log files as well as configure custom log publishers with pre-defined filtering with its own log rotation and retention policies.

Default Directory Server logs

The Directory Server provides a standard set of default log files to monitor the server activity. You can view this set of logs in the `PingDirectory/logs` directory. The following default log files are available on the Directory Server and are presented below.

Directory Server Logs

Log File	Description
access	File-based Access Log that records operations processed by the Directory Server. Access log records can be used to provide information about problems during operation processing (for example, unindexed searches, failed requests, etc.), and provide information about the time required to process each operation.
change-notifications.log	Records changes to data anywhere in the server, which match one or more configured change subscriptions.
config-audit.log	Records information about changes made to the Directory Server configuration in a format that can be replayed using the **`dsconfig`** tool
errors	File-based Error Log. Provides information about warnings, errors, and significant events that occur during server processing.
expensive-ops	Expensive Operations Log. Disabled by default. Provides only those operations that took longer than 1000 milliseconds to complete.
failed-ops	Failed Operations Log. Provides information on all operations that failed in single-line log format.

Log File	Description
replication	Records any replication errors and publishes them to the file system.
searches-returning-no-entries	Searches Returning No Entries Log. Disabled by default. Provides information only on operations that did not return any entries.
server.out	Records anything written to standard output or standard error, which includes startup messages. If garbage collection debugging is enabled, then the information will be written to server.out.
server.pid	Stores the server's process ID.
server.status	Stores the timestamp, a status code, and an optional message providing additional information on the server status.
setup.log	Records messages that occur during the initial configuration of a Directory Server with the **`setup`** tool.
tools	Directory that holds logs for long running utilities: **`import-ldif`**, **`export-ldif`**, **`backup`**, **`restore`**, **`verify-index`**. Current and previous copies of the log are present in the Directory Server.
update.log	Records messages that occur during a Directory Server update.

Types of log publishers

The PingDirectory Server provides several classes of log publishers for parsing, aggregating, and filtering information events that occur during normal processing in the server. There are three primary types of Log Publishers: access logs, debug logs, and error logs. Each type has multiple subtypes of log files based on the log server type:

Types of Log Publishers

Log Publisher Type	Description	
Access	Provides the requests received and responses returned by the Directory Server. The information can be used to understand the operations performed by clients and to debug problems with the client applications. It can also be used for collecting usage information for performance and capacity planning purposes. There are tools described later that can analyze the access log to provide summaries of the LDAP activity and performance.	
	File-based Audit Log	Special type of access logger that provides detailed information about changes processed within the server. Disabled by default. ▪ **Data Recovery Log**. Publishes information about each write operation processed in the server in a manner that allows those changes to be reverted or replayed (in conjunction with the extract-data-recovery-log-changes tool) if data recovery is needed.
	JDBC-based Access Log	Stores access log information using a JDBC database connection. Disabled by default.

Log Publisher Type	Description	
	File-based Access Logs	Provides a character-based stream used by TextWriter Publishers as a target for outputting log records. There are six types of file-based loggers: ▪ **Admin Alert Access Log**. Generates administrative alerts for any operations that match the criteria for this access logger. Disabled by default. ▪ **File-based Access Log**. Publishes access log messages to the file system. Enabled by default. ▪ **Syslog-based Access Log**. Publishes access log messages to a syslogd port. Disabled by default. ▪ **Expensive-Operations Access Log**. Publishes only those access log messages of operations that take longer than 1000 milliseconds. Disabled by default. ▪ **Failed-Operations Access Log**. Publishes only those access log messages of operations that failed for any reason. Enabled by default. ▪ **Successful Searches with No Entries Returned Log**. Publishes only those access log messages of search operations that failed to return any entries. Disabled by default. ▪ **JSON Access Logger**. Publishes JSON-formatted access log messages to the file system. ▪ **Console JSON Access Logger**. Publishes JSON-formatted access log messages to the JVM's standard output or standard error stream. This log publisher is only recommended when the server is run in no-detach mode and is best suited for use in Docker or other containers that can capture log content written to standard output or standard error. ▪ **Third-Party Access Log Publisher**. Publishes access log messages using a custom log publisher created using the Server SDK. ▪ **Third-Party File-Based Access Log Publisher**. Publishes access log messages to a file using a custom log publisher created using the Server SDK, including enhanced support for log file rotation and retention.
	HTTP Operation Log Publisherrs	▪ **Common Log File HTTP Operation Log Publisher**. Publishes information about HTTP requests in the W3C common log format. ▪ **HTTP Detailed Access**. Publishes detailed information about HTTP requests processed by the server.
Debug	Provides information about warnings, errors, or significant events that occur within the server.	

Log Publisher Type	Description	
	Debug Loggers	▪ **Debug ACI Logger**. Stores debug information on ACI evaluation for any request operations against the server. ▪ **Server SDK Extension Debug Logger** — Provides simplified access to debug messages generated by Server SDK extension
	File-based Error Logs	There are two types of File-based Error Logs: ▪ **Error log**. Publishes error messages to the file system. Enabled by default. ▪ **Replication log**. Publishes replication error messages to the file system. Enabled by default. ▪ **JSON Error Logger**. Publishes JSON-formatted error log messages to the file system. ▪ **Console JSON Access Logger**. Publishes JSON-formatted access log messages to the JVM's standard output or standard error stream. This log publisher is only recommended when the server is run in no-detach mode and is best suited for use in Docker or other containers that can capture log content written to standard output or standard error. ▪ **Third-Party Error Log Publisher**. Publishes error log messages using a custom log publisher created using the Server SDK. ▪ **Third-Party File-Based Error Log Publisher**. Publishes error log messages to a file using a custom log publisher created using the Server SDK, including enhanced support for log file rotation and retention.
	JDBC-based Error Logs	Stores error log information using a JDBC database connection. Disabled by default.
	Syslog-based Error Logs	Publishes error messages to a syslogd port.

Viewing the List of Log Publishers

You can quickly view the list of log publishers on the Directory Server using the **`dsconfig`** tool.

ⓘ **Note:** Initially, the JDBC, syslog, and Admin Alert log publishers must specifically be configured using **`dsconfig`** before they appear in the list of log publishers. Procedures to configure these types of log publishers appear later in this chapter.

To View the List of Log Publishers

Steps

- Use **`dsconfig`** to view the log publishers.

```
$ bin/dsconfig list-log-publishers
```

```
Log Publisher                                : Type              : enabled
---------------------------------------------:-------------------:--------
Debug ACI Logger                             : debug-access      : false
```

```
Expensive Operations Access Logger           : file-based-access : false
Failed Operations Access Logger              : file-based-access : true
File-Based Access Logger                     : file-based-access : true
File-Based Audit Logger                      : file-based-audit  : false
File-Based Debug Logger                      : file-based-debug  : false
File-Based Error Logger                      : file-based-error  : true
Replication Repair Logger                    : file-based-error  : true
Successful Searches with No Entries Returned : file-based-access : false
```

Enabling or Disabling a Default Log Publisher

You can enable or disable any log publisher available on the Directory Server using the **dsconfig** tool. By default, the following loggers are disabled and should be enabled only when troubleshooting an issue on the server:

- Expensive Operations Access Logger
- File-Based Audit Logger
- File-Based Debug Logger
- Successful Searches with No Entries Returned

To Enable a Default Access Log

Steps

- Use **dsconfig** to enable an Access Log Publisher. In this example, enable the Expensive-Ops log, which will record only those access log messages that take 1000 milliseconds or longer.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Expensive Operations Access Logger" --set enabled:true
```

Managing access and error log publishers

The Access Log records every request received and response returned by the Directory Server. The Access Log stores the IDs for the client connection, operation, the LDAP message involved with each client request, and the server response. The information can be used to debug any problems with a client application by correlating the numeric operation identifier to the client request or response.

The Directory Server supports multiple classes of access log publishers depending on your logging requirements. The following types of access log publishers are available on the system:

- **File-Based Access Log Publishers**. Provides a character-based TextWriter stream for outputting log records. There are three subclasses of TextWriter access logs:
  - **File-Based Access Logs**. Enabled by default. The File-based Access Log publishes access messages to the file system as `<server-root>/logs/access`. The Failed-Operations Log, Expensive-Operations Log, and the Searches with No Entries Returned Log are specialized types of the File-Based Access Log and shows only specific information necessary for troubleshooting purposes.
  - **Admin-Alert Access Logs**. Disabled by default. The Admin-Alert Access Log is specialized type of logger that automatically generates administrative alerts for any operations that match a criteria for this access log publisher.
  - **Syslog-Based Access Logs**. Disabled by default. The Syslog Access Log publishes access messages to a syslogd port.
- **File-Based Audit Logs**. Disabled by default. The Audit Log provides detailed information about modifications (writes) processed within the Directory Server. The File-based Audit Log publishes access messages to the file system as `<server-root>/logs/audit`.
- **JDBC-Based Access Logs**. Disabled by default. The JDBC-based Access Log provides information using a JDBC database connection.
- **JDBC-Based Error Logs**. Disabled by default. The JDBC-based Error Log provides information using a JDBC database connection.

Managing file-based access log publishers

The PingDirectory Server supports a flexible and configurable Access Logging system that provides a full set of customized components to meet your system's logging requirements. The default Access Log can be configured to write information to a log file with two records per operation, one for the request received and one for the response returned. It can also be configured to write one message per operation or configured to record information about a subset of operations processed by the server. In addition to modifying existing default log files, you can create custom log publishers to monitor specific properties or connection criteria. For more information, see *Creating New Log Publishers*.

The Directory Server can be configured to use multiple access log publishers writing logs to different files using different configurations. This approach makes it possible to have fine-grained logging for various purposes (for example, a log that contains only failed operations, a log that contains only operations requested by root users, or a log that contains only operations that took longer than 20ms to complete).

The Directory Server provides an additional mechanism to filter access logs to record only a subset of messages of one or more types. The access log filtering mechanism uses the operation criteria (connection, request, result, search-entry, search-reference) to determine whether a given message should be logged based on information associated with the client connection as well as information in the operation request/response messages. For more information, see *Configuring Filtered Logging*.

Access log format

The Access Log has a standard format that lists various elements identifying the connection and operation occurring within the Directory Server. By default, each operation generates one access log message.

The Access Log displays the following common properties:

- **Timestamp**. Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>
- **Connection Type**. Displays the connection type requested by the client and the response by the server. Examples include the following:
  - CONNECT
  - BIND REQUEST/RESULT
  - UNBIND REQUEST
  - DISCONNECT
  - SEARCH REQUEST/RESULT
  - MODIFY REQUEST/RESPONSE
  - others include: ABANDON, ADD, COMPARE, DELETE, EXTENDED OPERATION, MODIFY, MODIFY DN
- **Connection ID**. Numeric identifier, starting incrementally with 0, that identifies the client connection that is requesting the operation. The connection ID is unique for a span of time on a single server. Values of the connection ID will be re-used when the server restarts or when it has had enough connections to cause the identifier to wrap back to zero.
- **Operation ID**. Numeric identifier, starting incrementally with 0, that identifies the operation. The operation ID is unique for a span of time on a single server. Values of the operation ID will be re-used when the server restarts or when it has serviced enough operations to cause the identifier to wrap back to zero.
- **Result Code**. LDAP result code that determines the success or failure of the operation result. Result messages include a result element that indicates whether the operation was successful or if failed, the general category for the failure, and an etime element that indicates the length of time in milliseconds that the server spent processing the operation.

  The Directory Server provides a useful tool **`<server-root>/bin/ldap-result-code`** (UNIX, Linux) or **`<server-root>\bat\ldap-result-code`** (Windows), that displays all of the result codes used in

the system. You can use the utility if you are not sure what a result code means. For example, use the following:

- **`ldap-result-code`** `--list` displays all of the defined result codes in the Directory Server.
- **`ldap-result-code`** `--int-value 16654` displays the name of the result code with a numeric value of 16654.
- **`ldap-result-code`** `--search operation` displays a list of all result codes whose name includes the substring "operation".

- **Elapsed Time**. Displays the elapsed time (milliseconds) during which the operation completed its processing.
- **Message ID**. Numeric identifier, starting incrementally with 1, which identifies the LDAP message used to request the operation.

Access log example

The following example shows output from the Access Log in `<server-root>/logs/access`:

```
[01/Jun/2011:14:48:17 -0500] CONNECT conn=0 from="10.8.1.243" to="10.8.1.243"
 protocol="LDAP"
[01/Jun/2011:14:48:17 -0500] BIND REQUEST conn=0 op=0 msgID=1 version="3"
 dn="cn=Directory Manager"
  authType="SIMPLE"
[01/Jun/2011:14:48:17 -0500] BIND RESULT conn=0 op=0 msgID=1 resultCode=0
 etime=26.357
  authDN="cn=Directory Manager,cn=Root DNs,cn=config"
[01/Jun/2011:14:48:17 -0500] UNBIND REQUEST conn=0 op=1 msgID=2
[01/Jun/2011:14:48:17 -0500] DISCONNECT conn=0 reason="Client Unbind"
... (more output) ...
```

Modifying the access log using dsconfig interactive mode

About this task

The File-Based Access Log can be modified to include or exclude all log messages of a given type using the **`dsconfig`** tool in interactive or non-interactive mode.

Steps

1. Use **`dsconfig`** in interactive mode to modify the access log properties.

   ```
   $ bin/dsconfig
   ```
2. Follow the prompts to specify the LDAP connection parameters for host name or IP address, connection type (LDAP, SSL, or StartTLS), port number, bind DN and password.
3. On the Directory Server main menu, type the number corresponding to the Log Publisher.
4. On the **Log Publisher Management** menu, enter the option to view and edit an existing log publisher.
5. On the **Log Publisher** menu, type the number corresponding to File-based Access Logger.
6. On the **File-Based Access Log Publisher** menu, type the number corresponding to the property that you want to change, and then follow the prompts.
7. Type `f` to apply the changes.

Modifying the access log using dsconfig non-interactive mode

About this task

You can use the **`dsconfig`** tool in non-interactive mode to quickly modify a log publisher property on the command line or in a script. For information on each property, see the *Directory Server Configuration Reference Guide*, which is an HTML document listing the various properties for each Directory Server component.

Steps

- Use **dsconfig** with the `--no-prompt` option with the properties that you want to modify or set for your access log. In this example, enable the properties to include the instance name and startup ID.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Access
 Logger" \
  --set include-instance-name:true --set include-startup-id:true
```

Modifying the maximum length of log message strings

About this task

By default, the Directory Server sets the maximum length of log message strings to 2000 characters. This value is configurable for any access log publisher, except the Syslog publisher, which is set to 500 characters. You can change the maximum length of log message strings by setting the `max-string-length` configuration property. If any string has more than the configured number of characters, then that string will be truncated and a placeholder will be appended to indicate the number of remaining characters in the original string.

Steps

- Use **dsconfig** to set the `max-string-length` property for an access log. The following command configures the "File-based Access Logger" to include the instance name and the maximum length of the log message strings to 5000 characters.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set include-instance-name:true \
  --set max-string-length:5000
```

Disabling logging of inter-server periodic search requests

About this task

To disable the logging of inter-server periodic search requests and their results, perform the following steps:

Steps

1. Create a request criteria that matches all search requests with the inter-server request control.

```
dsconfig create-request-criteria --criteria-name "Inter-server Searches" \
        --type simple --set operation-type:search \
        --set any-included-request-control:1.3.6.1.4.1.30221.2.5.42
```

2. Create a request criteria that matches all requests that are not searches with the inter-server request control.

```
dsconfig create-request-criteria --criteria-name "Exclude Inter-server
 Searches" \
        --type aggregate --set "none-included-request-criteria:Inter-server
 Searches"
```

3. Configure the access logger to use the request criteria you created. This will disable the logging of internal search requests and their corresponding results to the access log.

```
dsconfig set-log-publisher-prop --publisher-name "File-Based Access Logger"
 \
        --set "request-criteria:Exclude Inter-server Searches"
```

Generating access logs summaries

About this task

The Directory Server provides a convenience tool, **summarize-access-log**, that generates a summary of one or more file-based access logs. The summary provides analytical metric information that could be useful for administrators. The following metrics are provided in each summary:

- Total time span covered by the log files.
- Number of connections established and the average rate of new connections per second.
- IP addresses of up to the top 20 of the clients that most frequently connect to the server, the number of connections by each address, and the percentage of connections of each.
- Total number of operations processed, the number of operations of each type, the percentage of each type out of the total number, and the average rate per second for each type of operation.
- Average processing time for all operations and for each type of operation.
- Histogram of the processing times for each type of operation.
- Up to the 20 most common result codes for each type of operation, the number of operations of that type with that result code, and the percentage of operations of that type with that result code.
- Number of unindexed searches processed by the server.
- Breakdown of the scopes used for search operations with the number of percentage of searches with each scope.
- Breakdown of the most common entry counts for search operations with the number and percentage of searches that returned that number of entries.
- Breakdown of the most commonly used filter types for searches with a scope other than "base" (that is, those searches for which the server will use es when processing the filter). These filters will be represented in a generic manner so that any distinct assertion values or substring assertion elements will be replaced with question marks and attribute names in all lowercase characters (for example, `(givenName=John)` would be represented as `(givenName=?)`).

Steps

- Use the **bin/summarize-access-log** with path to one or more access log files.

```
$ bin/summarize-access-log /path/to/logs/access
```

```
Examining access log /path/to/logs/access Examined 500 lines in 1 file
 covering a total duration of 1 day, 22 hours, 57 minutes, 31 seconds

Total connections established: 69 (0.000/second)
Total disconnects: 69 (0.000/second)

Most common client addresses:
127.0.0.1: 61 (88.406)
10.8.1.209: 8 (11.594)

Total operations examined: 181 ...
(metric for each operation examined) ...

Average operation processing duration: 22.727ms
Average add operation processing duration: 226.600ms
Average bind operation processing duration: 5.721ms
Average delete operation processing duration: 77.692ms
Average modify operation processing duration: 35.530ms
Average search operation processing duration: 4.017ms

Count of add operations by processing time:
... (histogram for add operations) ...

Count of bind operations by processing time:
```

```
... (histogram for bind operations) ...

Count of delete operations by processing time:
... (histogram for delete operations) ...

Count of modify operations by processing time:
... (histogram for modify operations) ...

Count of search operations by processing time:
... (histogram for search operations) ...

Most common add operation result codes:
success: 11 (84.615%)
entry already exists: 2 (15.385%)

Most common bind operation result codes:
success: 4 (50.000%)
invalid credentials: 4 (50.000%)

Most common delete operation result codes:
success: 1 (100.000%)

Most common modify operation result codes:
success: 9 (69.231%)
no such object: 4 (30.769%)

Most common search operation result codes:
success: 133 (91.724%)
no such object: 12 (8.276%)

Number of unindexed searches: 0

Most common search scopes:
BASE: 114 (78.621%)
SUB: 16 (11.034%)
ONE: 15 (10.345%)

Most common search entry counts:
1: 119 (82.069%)
0: 17 (11.724%)
2: 5 (3.448%)
10: 4 (2.759%)

Most common generic filters for searches with a non-base scope:
(objectclass=?): 19 (61.290%)
(ds-backend-id=?): 12 (38.710%)
```

About log compression

The Directory Server supports the ability to compress log files as they are written. This feature can significantly increase the amount of data that can be stored in a given amount of space, so that log information can be kept for a longer period of time.

Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled at the time the logger is created. Compression cannot be turned on or off once the logger is configured. Further, because of problems in trying to append to an existing compressed file, if the server encounters an existing log file at startup, it will rotate that file and begin a new one rather than attempting to append to the previous file.

Compression is performed using the standard gzip algorithm, so compressed log files can be accessed using readily-available tools. The **`summarize-access-log`** tool can also work directly on compressed log files, rather than requiring them to be uncompressed first. However, because it can be useful to have a small amount of uncompressed log data available for troubleshooting purposes, administrators using

compressed logging may wish to have a second logger defined that does not use compression and has rotation and retention policies that will minimize the amount of space consumed by those logs, while still making them useful for diagnostic purposes without the need to uncompress the files before examining them.

You can configure compression by setting the `compression-mechanism` property to have the value of "gzip" when creating a new logger.

About log signing

The Directory Server supports the ability to cryptographically sign a log to ensure that it has not been modified in any way. For example, financial institutions require audit logs for all transactions to check for correctness. Tamper-proof files are therefore needed to ensure that these transactions can be properly validated and ensure that they have not been modified by any third-party entity or internally by unscrupulous employees. You can use the **`dsconfig`** tool to enable the `sign-log` property on a Log Publisher to turn on cryptographic signing.

When enabling signing for a logger that already exists and was enabled without signing, the first log file will not be completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled will be considered completely valid. For the same reason, if a log file is still open for writing, then signature validation will not indicate that the log is completely valid because the log will not include the necessary "end signed content" indicator at the end of the file.

To validate log file signatures, use the **`validate-file-signature`** tool provided in the `bin` directory of the server (or the `bat` directory for Windows systems).

Once you have enabled this property, you must disable and then re-enable the Log Publisher for the changes to take effect.

About encrypting log files

The Directory Server supports the ability to encrypt log files as they are written. The **`encrypt-log`** configuration property controls whether encryption will be enabled for the logger. Enabling encryption causes the log file to have an **`.encrypted`** extension (and if both encryption and compression are enabled, the extension will be **`.gz.encrypted`**). Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption cannot be turned on or off once the logger is configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This will also reduce the overall size of the log file. The **`encrypt-file`** tool (or custom code, using the LDAP SDK's **`com.unboundid.util.PassphraseEncryptedInputStream`**) is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the **`encryption-settings create`** command. By default, the encryption will be performed with the server's preferred encryption settings definition. To explicitly specify which definition should be used for the encryption, the **`encryption-settings-definition-id`** property can be set with the ID of that definition. It is recommended that the encryption settings definition is created from a passphrase so that the file can be decrypted by providing that passphrase, even if the original encryption settings definition is no longer available. A randomly generated encryption settings definition can also be created, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data may remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it cannot write an incomplete block of data until the file is closed. This is not an issue for any log file that is not being actively written. To examine the contents of a log file that is being actively written, use the **`rotate-log`** tool to force the file to be rotated before attempting to examine it.

Configuring log signing

Steps

1. Use **dsconfig** to enable log signing for a Log Publisher. In this example, set the `sign-log` property on the File-based Audit Log Publisher.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
 Logger" \
  --set sign-log:true
```

2. Disable and then re-enable the Log Publisher for the change to take effect.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
 Logger" \
  --set enabled:false
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
 Logger" \
  --set enabled:true
```

Validating a signed file

About this task

The Directory Server provides a tool, **validate-file-signature**, that checks if a file has not been tampered with in any way.

Steps

- Run the **validate-file-signature** tool to check if a signed file has been tampered with. For this example, assume that the `sign-log` property was enabled for the File-Based Audit Log Publisher.

```
$ bin/validate-file-signature --file logs/audit

All signature information in file 'logs/audit' is valid
```

ⓘ **Note:** If any validations errors occur, you will see a message similar to the one as follows:

```
One or more signature validation errors were encountered
while validating the contents of file 'logs/audit':
* The end of the input stream was encountered without
  encountering the end of an active signature block.
  The contents of this signed block cannot be trusted
  because the signature cannot be verified
```

Configuring log file encryption

Steps

1. Use **dsconfig** to enable encryption for a Log Publisher. In this example, the File-based Access Log Publisher "Encrypted Access" is created, compression is set, and rotation and retention policies are set.

```
$ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted Access"
 \
  --type file-based-access \
  --set enabled:true \
  --set compression-mechanism:gzip \
  --set encryption-settings-definition-
id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
```

```
  --set encrypt-log:true \
  --set log-file:logs/encrypted-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "retention-policy:Size Limit Retention Policy"
```

2. To decrypt and decompress the file:

```
$ bin/encrypt-file --decrypt \
  --decompress-input \
  --input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
  --output-file decrypted-access
Initializing the server's encryption framework...Done
Writing decrypted data to file '/ds/PingDirectory/decrypted-access' using a
key generated from encryption settings definition
 '332c846ef0dcd1d5187c1592e4c74cad33fc1e5fc20b726cd301cdd2b3ffbc2b'
Successfully wrote 123,456,789 bytes of decrypted data
```

Creating new log publishers

The PingDirectoryProxy Server provides customization options to help you create your own log publishers with the **dsconfig** command.

When you create a new log publisher, you must also configure the log retention and rotation policies for each new publisher. For more information, see Configuring Log Rotation and Configuring Log Retention.

Creating a new log publisher

Steps

1. Use the **dsconfig** command in non-interactive mode to create and configure the new log publisher. This example shows how to create a logger that only logs disconnect operations.

```
$ bin/dsconfig create-log-publisher \
  --type file-based-access --publisher-name "Disconnect Logger" \
  --set enabled:true \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set log-connects:false \
  --set log-requests:false --set log-results:false \
  --set log-file:logs/disconnect.log
```

ⓘ **Note:** To configure compression on the logger, add the option to the previous command:

```
--set compression-mechanism: gzip
```

Compression cannot be disabled or turned off once configured for the logger. Therefore, careful planning is required to determine your logging requirements including log rotation and retention with regards to compressed logs.

2. If needed, view log publishers with the following command:

```
$ bin/dsconfig list-log-publishers
```

Creating a log publisher using dsconfig interactive command-line mode

Steps

1. On the command line, type **bin/dsconfig**.

2. Authenticate to the server by following the prompts.
3. On the main menu, select the option to configure the log publisher.
4. On the **Log Publisher** menu, select the option to create a new log publisher.
5. Select the Log Publisher type. In this case, select **File-Based Access Log Publisher**.
6. Type a name for the log publisher.
7. Enable it.
8. Type the path to the log file, relative to the Directory Server root. For example, `logs/disconnect.log`.
9. Select the rotation policy to use for this log publisher.
10. Select the retention policy to use for this log publisher.
11. On the Log Publisher Properties menu, select the option for `log-connects:false`, `log-disconnects:true`, `log-requests:false`, and `log-results:false`.
12. Type `f` to apply the changes.

Configuring log rotation

About this task

The Directory Proxy Server allows you to configure the log rotation policy for the server. When any rotation limit is reached, the Directory Proxy Server rotates the current log and starts a new log. If you create a new log publisher, you must configure at least one log rotation policy.

You can select the following properties:

- **Time Limit Rotation Policy**. Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every 7 days.
- **Fixed Time Rotation Policy**. Rotates the logs every day at a specified time (based on 24-hour time). The default time is 2359.
- **Size Limit Rotation Policy**. Rotates the logs when the file reaches the maximum size for each log. The default size limit is 100 MB.
- **Never Rotate Policy**. Used in a rare event that does not require log rotation.

Steps

- Use **`dsconfig`** to modify the log rotation policy for the access logger.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

Configuring log rotation listeners

The Directory Server provides two log file rotation listeners: the copy log file rotation listener and the summarize log file rotation listener, which can be enabled with a log publisher. Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file will be subject to deletion by a log file retention policy, but the copy will not be automatically removed. Use the following command to create a new copy log file rotation listener:

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Copy on Rotate" \
  --type copy \
```

```
  --set enabled:true \
  --set copy-to-directory:/path/to/archive/directory \
  --set compress-on-copy:true
```

The path specified by the **copy-to-directory** property must exist, and the file system containing that directory must have enough space to hold all of the log files that will be written there. The server automatically monitors free disk space on the target file system and generates administrative alerts if the amount of free space gets too low.

The summarize log file rotation listener invokes the **summarize-access-log** tool on a recently-rotated log file and writes its output to a file in a specified location. This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the **summarize-access-log** tool, including the **file-based-access** and **operation-timing-access** logger types. Use the following command to create a new summarize log file rotation listener:

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Summarize on Rotate" \
  --type summarize \
  --set enabled:true \
  --set output-directory:/path/to/summary/directory
```

The summary output files have the same name as the rotated log file, with an extension of **.summary**. If the **output-directory** property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.

As with the copy log file rotation listener, summary files are not automatically deleted. Although files are generally small in comparison to the log files themselves, make sure that enough space is available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

Configuring log retention

About this task

The Directory Server allows you to configure the log retention policy for each log on the server. When any retention limit is reached, the Directory Server removes the oldest archived log prior to creating a new log. Log retention is only effective if you have a log rotation policy in place. If you create a new log publisher, you must configure at least one log retention policy.

- **File Count Retention Policy**. Sets the number of log files you want the Directory Server to retain. The default file count is 10 logs. If the file count is set to 1, then the log will continue to grow indefinitely without being rotated.
- **Free Disk Space Retention Policy**. Sets the minimum amount of free disk space. The default free disk space is 500 MBytes.
- **Size Limit Retention Policy**. Sets the maximum size of the combined archived logs. The default size limit is 500 MBytes.
- **Time Limit Retention Policy**. Sets the maximum length of time that rotated log files should be retained.
- **Custom Retention Policy**. Create a new retention policy that meets your Directory Server's requirements. This will require developing custom code to implement the desired log retention policy.
- **Never Delete Retention Policy**. Used in a rare event that does not require log deletion.

Steps

- Use **dsconfig** to modify the log retention policy for the access logger.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
```

```
  --set "retention-policy:Free Disk Space Retention Policy"
```

Configuring filtered logging

About this task

The PingDirectory Server provides a mechanism to filter access log messages based on specific criteria. The filtered log can then be used with a custom log publisher to create and to generate your own custom logs. Adding new filtered logs and associate publishers does not change the behavior of any existing logs. For example, adding a new log that only contains operations that were unsuccessful does not result in those operations being removed from the default access log.

The following example shows how to create a set of criteria that matches any operation that did not complete successfully. It then explains how to create a custom access log publisher that logs only operations matching that criteria. Note that this log does not include messages for connects or disconnects, and only a single message is logged per operation. This message contains both the request and result details.

To run log filtering based on any operation result (for example, result code, processing time, and response controls), turn off request logging and set the `include-request-details-in-result-messages` property to TRUE. Since filtering based on the results of an operation cannot be done until the operation completes, the server has no idea whether to log the request. Therefore, it might log request messages but not log any result messages. Instead, if you can only log result messages and include request details in the result messages, then only messages for operations that match the result criteria are logged. All pertinent information about the corresponding requests are included.

Steps

1. Use the **`dsconfig`** command in non-interactive mode to create a result criteria object set to failure-result-codes, a predefined set of result codes that indicate when an operation did not complete successfully.

   ```
   $ bin/dsconfig create-result-criteria --type simple \
     --criteria-name "Failed Operations" --set result-code-criteria:failure-
   result-codes
   ```

2. Use **`dsconfig`** to create the corresponding log publisher that uses the result criteria. The log rotation and retention policies are also set with this command.

   ```
   $ bin/dsconfig create-log-publisher \
     --type file-based-access \
     --publisher-name "Filtered Failed Operations" \
     --set enabled:true \
     --set log-connects:false \
     --set log-disconnects:false \
     --set log-requests:false \
     --set "result-criteria:Failed Operations" \
     --set log-file:logs/failed-ops.log \
     --set include-request-details-in-result-messages:true \
     --set "rotation-policy:7 Days Time Limit Rotation Policy" \
     --set "retention-policy:Free Disk Space Retention Policy"
   ```

3. View the `failed-ops.log` in the `logs` directory. Verify that only information about failed operations is written to it.

Managing Admin Alert Access Logs

Admin Alert Access Logs are a specialized form of filtered log that automatically generates an administrative alert when criteria configured for the log publisher matches those messages in the access log.

About access log criteria

Configuring an Admin Alert Access Log requires that you configure the criteria for the access log messages. Each criteria can be either a Simple or an Aggregate type. The Simple type uses the set of properties for the client connection, operation request, and the contents of any operation-specific requests or results. The Aggregate type provides criteria that contains Boolean combination of other operation-specific criteria objects. For more information, see the *Ping Identity Directory Server Configuration Reference*.

The criteria can be one or more of the following:

- **Connection Criteria**. Defines sets of criteria for grouping and describing client connections based on a number of properties, including protocol, client address, connection security, and authentication state.
- **Request Criteria**. Defines sets of criteria for grouping and describing operation requests based on a number of properties, including properties for the associated client connection, the type of operation, targeted entry, request controls, target attributes, and other operation-specific terms.
- **Result Criteria**. Defines sets of criteria for grouping and describing operation results based on a number of properties, including the associated client connection and operation request, the result code, response controls, privileges missing or used, and other operation-specific terms.
- **Search Entry Criteria**. Defines sets of criteria for grouping and describing search result entries based on a number of properties, including the associated client connection and operation request, the entry location and contents, and included controls.
- **Search Reference Criteria**. Defines sets of criteria for grouping and describing search result references based on a number of properties, including the associated client connection and operation request, reference contents, and included controls.

Configuring an Admin Alert Access Log publisher

About this task

Prior to configuring an Admin Alert Access Log, you must establish an administrative alert handler in your system. For more information, see *Working with Administrative Alert Handlers*.

Steps

1. Use **dsconfig** to create a criteria object for the Admin Alert Access Log. For this example, we want to log only write operations that target user entries. The following command matches any of the specified operations whose target entry matches the filter "`(objectClass=person)`".

   If you are using the **dsconfig** tool in interactive mode, the menu items for the criteria operations are located in the Standard objects menu.

   ```
   $ bin/dsconfig create-request-criteria --type simple \
     --criteria-name "User Updates" \
     --set operation-type:add \
     --set operation-type:delete \
     --set operation-type:modify \
     --set operation-type:modify-dn \
     --set "any-included-target-entry-filter:(objectClass=person)"
   ```

2. Use **dsconfig** to create a log publisher of type `admin-alert-access`.

   ```
   $ bin/dsconfig create-log-publisher \
     --publisher-name "User Updates Admin Alert Access Log" \
     --type admin-alert-access \
     --set "request-criteria:User Updates" \
     --set include-request-details-in-result-messages:true \
     --set enabled:true
   ```

Managing the Syslog-Based Access Log Publishers

The Directory Server supports access logging using the syslog protocol that has been part of the Berkeley Software Distribution (BSD) operating systems for many years. Syslog provides a flexible, albeit simple, means to generate, store and transfer log messages that is supported on most UNIX and Linux operating systems.

The quasi-standard syslog message format cannot exceed 1 kbytes and has three important parts:

- **PRI**. Specifies the message priority based on its facility and severity. The message facility is a numeric identifier that specifies the type of log messages, such as kernel messages, mail system messages, etc. The severity is a numeric identifier that specifies the severity level of the operation that is being reported. Together, the facility and the severity determine the priority of the log message indicated by angled brackets and 1-3 digit priority number. For example, "<0>", "<13>", "<103>" are valid representations of the PRI.
- **Timestamp and Host Name**. The timestamp displays the current date and time of the log. The host name or IP address displays the source of the log.
- **Message**. Displays the actual log message.

Administrators can configure syslog to handle log messages using log priorities that are based on the message's facility and severity. This feature allows users to configure the logging system in such a way that messages with high severities can be sent to a centralized repository, while lower severity messages can be stored locally on a server.

ⓘ **Note:** Since the numeric values of the severity and facility are operating system-dependent, the central repository must only include syslog messages from compatible OS types, otherwise the meanings of the PRI field is ambiguous.

Before you begin

You will need to identify the host name and port to which you want to connect. Because the Syslog Protocol uses User Datagram Protocol (UDP) packets, we highly recommend that you use `localhost` and utilize some additional logging tools, such as `syslog-ng`. UDP is unreliable and unsecure means to transfer data packets between hosts.

Logging with syslog

The PingDirectory Server can write log messages using the syslog protocol, for both access and error logs.

This allows messages to be aggregated at the system level and potentially forwarded to a centralized system. The messages are written to syslog as they are generated, so attackers do not have a chance to alter these log messages.

If you want to use syslog-based logging, configure the server to log to a syslog server running on the local server over the loopback interface. The local syslog server can then forward the messages to a remote server over a secure connection.

Logging over TCP for improved reliability is now supported.

UDP-based communication is in the clear, so a network observer can see all of the log messages. Therefore, we recommend only using syslog to log to a local syslog server and having it forward messages to a remote server in a secure manner. TLS encryption for TCP-based communication is now optionally supported, so you can safely configure the server to log directly to a remote syslog server.

UDP does not provide any feedback in regard towhether messages are successfully delivered, but TCP does provide this feedback. When using TCP-based logging, you can optionally specify information about multiple syslog servers; if the primary syslog server becomes unavailable, the logger can fail over to an alternative syslog server.

Logging access and error log messages can be logged as JSON objects or in legacy space-delimited text format.

In addition to access and error logging over syslog, loggers that can write JSON-formatted audit and HTTP operation log messages are also provided.

Default access log severity level

All messages are logged at the syslog severity level of 6, which is `Informational: informational` messages. Note that this value is not standard across different types of UNIX or Linux systems. Please consult your particular operating system.

syslog-facility properties

When using syslog, specify a facility for the access log messages. As an advanced property, you can select a number that corresponds to the facility you wish to use. The default value for the `syslog-facility` property is 1 (one) for user-level messages. Note that these values are not standard across different types of UNIX or Linux systems. Please consult your particular operating system documentation for properties specific to that system.

Syslog Facility Properties

Facility	Description
0	kernel messages
1	user-level messages (default)
2	mail system
3	system daemons
4	security/authorization messages
5	messages generated internally by syslogd
6	line printer subsystem
7	network news subsystem
8	UUCP subsystem
9	clock daemon
10	security/authorization messages
11	FTP daemon
12	NTP subsystem
13	log audit
14	log alert
15	clock daemon
16	local use 0
17	local use 1
18	local use 2
19	local use 3
20	local use 4
21	local use 5
22	local use 6
23	local use 7

queue-size property

The maximum number of log records that can be stored in the asynchronous queue is determined by the `queue-size` property. The default queue size set is 10000, which means that the server will continuously flush messages from the queue to the log. The server does not wait for the queue to fill up before flushing to the log. Therefore, lowering this value can impact performance.

Configuring a Syslog-Based Access Log Publisher

About this task

You can configure a Syslog-based Access Log Publisher using the **`dsconfig`** tool. We recommend that you use syslog locally on localhost and use `syslog-ng` to send the syslog messages to remote syslog servers.

Because syslog implementations differ by vendor, please review your particular vendor's syslog configuration.

Steps

- Use **`dsconfig`** to create a log publisher of type syslog-based-access.

  If you are using the **`dsconfig`** tool in interactive mode, the menu item for Syslog Facility is an advanced property, which can be exposed by typing `a` (for "show advanced properties") on the Syslog-Based Access Log Publisher menu.

```
$ bin/dsconfig create-log-publisher \
--publisher-name "syslog-access" \
--type syslog-based-access \
--set syslog-facility:4 \
--set enabled:true
```

Managing the File-Based Audit Log Publishers

The Directory Server provides an audit log, a specialized version of the access log, for troubleshooting problems that may occur in the course of processing. The log records all changes to the data in LDIF format so that administrators can quickly diagnose the changes an application made to the data or replay the changes to another server for testing purposes.

The audit log does not record authentication attempts but can be used in conjunction with the access log to troubleshoot security-related issues. The audit log is disabled by default because it does adversely impact the server's write performance.

Audit log format

The audit log uses standard LDIF format, so that administrators can quickly analyze what changes occurred to the data. The audit log begins logging when enabled and should be used to debug any issues that may have occurred. Some common properties are the following:

- **Timestamp**. Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>
- **Connection ID**. Numeric identifier, starting incrementally with 0, that identifies the client connection that is requesting the operation.
- **Operation ID**. Numeric identifier, starting incrementally with 0, that identifies the operation.
- **Modifiers Name**. Displays the DN of the user who made the change.
- **Update Time**. Records the `modifyTimestamp` operational attribute.

Audit log example

The following example shows output from the Audit Log in the `<server-root>/ logs/audit`. The first entry shows when the audit log was enabled. The second entry show changes made to a user entry.

```
# 05/Jun/2011:10:29:04 -0500; conn=0; op=55

```

Enabling the File-Based Audit Log Publisher

About this task

You can enable the File-Based Audit Log Publisher using the **dsconfig** tool. The audit log can impact the Directory Server's write performance, so enable it only when troubleshooting any issues.

Steps

- Use **dsconfig** to enable the File-Based Audit Log Publisher. For this example, the instance name and startup ID is also enabled in the audit log.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
  --set include-instance-name:true \
  --set include-startup-id:true
```

Obscuring values in the audit log

You can obscure the values of specific attributes in the audit log using the `obscure-attribute` property. Each value of an obscured attribute is replaced in the audit log with a string of the form "***** OBSCURED VALUE *****". By default, attributes are not obscured, because the values of password attributes appear in hashed form rather than in the clear.

Managing the JDBC Access Log Publishers

The Directory Server supports the Java Database Connectivity (JDBCTM) API, which allows access to SQL datastores by means of its JDBC drivers. The JDBC 4.0 API, part of the Java SDK, provides a seamless method to interface with various database types in heterogeneous environments.

By easily connecting to a database, the Directory Server can be configured to implement a centralized logging system with different databases. Centralized logging simplifies log correlation and analysis tasks and provides security by storing data in a single repository. Some disadvantages of centralized logging

are that data flow asymmetries may complicate synchronization or network provisioning and may unduly burden the central repository with possibly heavy loads.

Before you begin

Before configuring the JDBC Access Log Publisher, you need to carry out two essential steps to set up the database.

- Install the database drivers in the Directory Server `lib` directory.
- Define the log mapping tables needed to map access log elements to the database column data. Only those elements in the log mapping table gets logged by the JDBC Log Publisher.

The following sections provide more information about these tasks.

Configuring the JDBC drivers

About this task

The Directory Server supports a number of JDBC drivers available in the market. We highly recommend using the JDBC 4 drivers supported in the Java platform. For example, for Oracle databases, you need to use the `ojdbc.jar` driver for Java and any associated JAR files (National Language Support jars, and others) required to connect with the particular database. The following databases are supported:

- DB2
- MySQL
- Oracle Call Interface (OCI)
- Oracle Thin
- PostgreSQL
- SQL Server

Steps

- Obtain the JAR file(s) for your particular database, and copy it into the `<server-root>/lib` directory.

Configuring the log field mapping tables

About this task

The log field mapping table associates access log fields to the database column names. You can configure the log field mapping table using the **`dsconfig`** tool, which then generates a DDL file that you can import into your database. The DDL file is generated when you create the JDBC Log Publisher.

To uniquely identify a log record, we recommend always mapping the following fields: `timestamp`, `startupid`, `message-type`, `connection-id`, `operation-type`, `instance-name`.

The table name is not part of this mapping.

The Directory Server also provides three options that you can quickly select for creating a log field mapping table:

- **Complete JDBC Access Log Field Mappings**. Maps all 52 object properties.
- **Complete JDBC Error Log Field Mappings**. Maps all 8 object properties.
- **Simple JDBC Access Log Field Mappings**. Maps a common set of object properties.
- **Custom JDBC Access Log Field Mappings**. Create a custom set of JDBC log field mappings.
- **Custom JDBC Error Log Field Mappings**. Create a custom set of JDBC error log field mappings.

Steps

1. Use **`dsconfig`** to create a log field mapping table. On the main menu, type `o` to change to the Standard Object menu, and type the number corresponding to Log Field Mapping.

2. On the **Log Field Mapping management** menu, enter the option to create a new Log Field Mapping.
3. On the **Log Field Mapping template** menu, enter the option to select a complete JDBC Access Log Field mapping to use as a template for your new field mapping.
4. Next, enter a name for the new field mapping. In this example, type `my-jdbc-test`.
5. On the **Access Log Field Mapping Properties** menu, select a property for which you want to change the value. Any property that is undefined will not be logged by the JDBC Access Log Publisher. When complete, type `f` to save and apply the changes.
6. On the **Log Field Mapping Management** menu, type `q` to exit the menu.
7. View the existing Log Mappings on the system.

```
$ bin/dsconfig list-log-field-mappings
```

```
Log Field Mapping                     : Type
--------------------------------------:-------
Complete JDBC Access Log Field Mappings : access
Complete JDBC Error Log Field Mappings  : error
my-jdbc-test                          : access
Simple JDBC Access Log Field Mappings   : access
```

Configuring the JDBC Access Log Publisher using dsconfig interactive mode

About this task

After setting up the drivers and the log mapping table, use the **`dsconfig`** utility to configure the JDBC Access Log Publisher on the Directory Server. The following example uses **`dsconfig`** interactive mode to illustrate the steps required to configure the log publisher and the external database server.

Steps

1. Copy the database JAR files to the `<server-root>/lib` directory, and then restart the Directory Server.
2. Launch the **`dsconfig`** tool in interactive command-line mode.

```
$ bin/dsconfig
```

3. Next, type the connection parameters to bind to the Directory Server. Enter the host name or IP address, type of LDAP connection (LDAP, SSL, or StartTLS) that you are using on the Directory Server, the LDAP listener port number, the user bind DN, and the bind DN password.
4. On the main menu, type the number corresponding to Log Publisher.
5. On the **Log Publisher management** menu, enter the option to create a new Log Publisher.
6. On the **Log Publisher template** menu, type n to create a new Log Publisher.
7. On the **Log Publisher Type** menu, enter the option to create a new JDBC-Based Access Log Publisher.
8. Type a name for the JDBC Access Log Publisher.
9. On the **Enabled Property** menu, enter the option to enable the log publisher.
10. On the **Server Property** menu, enter the option to create a new JDBC External Server.
11. Next, type the name for the JDBC External Server. This is a symbolic name used to represent the DBMS.
12. On the **JDBC Driver Type Property** menu, type the number corresponding to the type of JDBC database driver type.
13. Next, type a name for the `database-name` property. This is the DBMS database name. The database name must contain the table referred to in the generated DDL.
14. Next, type the host name or IP address (server-host-name) of the external server.

15. Type the server listener port. In this example, type `1541`.
16. Review the properties for the external server, and the type `f` to apply the changes.
17. If you need to supply your own JDBC URL, type a for advanced properties to open the `jdbc-driver-url` property and supply the appropriate URL. The example below shows how to access an Oracle Thin Client connection using a SID instead of a Service.

```
>>>> Configure the properties of the JDBC External Server

Property Value(s)
-----------------------------------------------------
1) description -
2) jdbc-driver-type oraclethin
3) jdbc-driver-url jdbc:oracle:thin@myhost:1541:my_SID
4) database-name jdbc-test
5) server-host-name localhost
6) server-port 1541
7) user-name -
8) password -

?) help
f) finish - create the new JDBC External Server
a) hide advanced properties of the JDBC External Server
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit

Enter choice [b]: f
```

```
JDBC External Server was created successfully
```

18. When the JDBC Log Publisher is created, the Directory Server automatically generates a DDL file of the Log Field Mappings in the `<server-root>/logs/ddls/<name-of-logger>.sql` file. Import the DDL file to your database.

Configuring the JDBC Access Log Publisher using dsconfig non-interactive mode

About this task

The following example uses **`dsconfig`** non-interactive mode to illustrate the steps to configure the log publisher and the external database server presented in the previous section.

Steps

1. Use **`dsconfig`** with the `--no-prompt` option to create the JDBC external server.

```
$ bin/dsconfig --no-prompt create-external-server \
  --server-name jdbc-external \ --type jdbc \
  --set jdbc-driver-type:oraclethin \
  --set database-name:ubid_access_log \
  --set server-host-name:localhost --set server-port:1541
```

2. Use **`dsconfig`** to create the log publisher.

```
$ bin/dsconfig --no-prompt create-log-publisher \
  --publisher-name jdbc-test \
  --type jdbc-based-access \
  --set enabled:true \
  --set server:jdbc-external \
  --set "log-field-mapping:Simple JDBC Access Log Field Mappings"
```

3. When the JDBC Log Publisher is created, the Directory Server automatically generates a DDL file of the Log Field Mappings in the `<server-root>/logs/ddls/<name- of-logger>.sql` file. Import the DDL file to your database.

   The procedure to configure the JDBC-Based Error Log Publisher is similar to creating a JDBC-Based Access Log Publisher. You can run the previous **`dsconfig`** command with the `--type jdbc-based-error` as follows:

```
$ bin/dsconfig --no-prompt create-log-publisher \
--publisher-name jdbc-error-test \
--type jdbc-based-error \
--set enabled:true \
--set server:jdbc-external \
--set "log-field-mapping:Simple JDBC Access Log Field Mappings"
```

Managing the File-Based Error Log Publisher

The Error Log reports errors, warnings, and informational messages about events that occur during the course of the Directory Server's operation. Each entry in the error log records the following properties (some are disabled by default and must be enabled):

- **Timestamp**. Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>
- **Category**. Specifies the message category that is loosely based on the server components.
- **Severity**. Specifies the message severity of the event, which defines the importance of the message in terms of major errors that need to be quickly addressed. The default severity levels are: `fatal-error`, `notice`, `severe-error`, `severe-warning`.
- **Message ID**. Specifies the numeric identifier of the message.
- **Message**. Stores the error, warning, or informational message.

Error log example

The following example displays the error log for the PingDataMetrics Server. The log is enabled by default and is accessible in the `<server-root>/logs/errors` file.

```
[21/Oct/2012:05:15:23.048 -0500] category=RUNTIME_INFORMATION severity=NOTICE

```

Modifying the File-Based Error Logs

Steps

- Use **dsconfig** to modify the default File-Based Error Log.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Error Logger" \
  --set include-product-name:true --set include-instance-name:true \
  --set include-startup-id:true
```

Managing the Syslog-Based Error Log Publisher

The Directory Server supports a Syslog-Based Error Log Publisher using the same mechanism as the Syslog-Based Access Log Publisher. You can easily configure the error logger using the **dsconfig** tool.

Syslog error mapping

The Directory Server automatically maps error log severities to the syslog severities. The following mappings are used:

Error to Syslog Severities Mappings to Syslog

Error Log Facility	Syslog Severity
FATAL_ERROR,0	Syslog Emergency
SEVERE_ERROR,1	Syslog Alert
SEVERE_WARNING,2	Syslog Critical
MILD_ERROR,3	Syslog Error
MILD_WARNING,4	Syslog Warn
NOTICE,5	Syslog Notice
INFORMATION,6	Syslog Info
DEBUG,7	Syslog Debug

Configuring a Syslog-Based Error Log Publisher

About this task

You can configure a Syslog-based Error Log Publisher using the **dsconfig** tool. Again, we recommend that you use syslog locally on `localhost` and use **syslog-ng** to send the data packets over the UDP protocol.

Because syslog implementations differ by vendor, please review your particular vendor's syslog configuration.

Steps

- Use **dsconfig** to create a log publisher of type `syslog-based-error`. In this example, set the syslog facility to 4 for security/authorization messages.

```
$ bin/dsconfig create-log-publisher --publisher-name "syslog-error" \
  --type syslog-based-error --set syslog-facility:4 --set enabled:true
```

Creating File-Based Debug Log Publishers

The Directory Server provides a File-Based Debug Log Publisher that can be configured when troubleshooting a problem that might occur during server processing. Because the debug data may be too large to maintain during normal operations, the Debug Log Publisher must be specifically configured and enabled. The Debug Log reports the following types of information:

- Exception data thrown by the server.
- Data read or written to network clients.
- Data read or written to the database.
- Access control or password policy data made within the server.

You can use the **dsconfig** tool to create a debug log publisher. You should only create a debug logger when troubleshooting a problem due to the voluminous output the Directory Server generates.

Creating a File-Based Debug Log Publisher

Steps

- Use **dsconfig** to create the debug log publisher. The `log-file` property (required) sets the debug log path. You must also specify the rotation and retention policy for the debug log.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "File-Based Debug Logger" \
  --type file-based-debug \
  --set enabled:true \
  --set log-file:/logs/debug \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy"
```

Deleting a File-Based Debug Log Publisher

Steps

- Use **dsconfig** to create the debug log publisher.

```
$ bin/dsconfig delete-log-publisher \
  --publisher-name "File-Based Debug Logger"
```

Managing Monitoring

The PingDirectory Server also provides a flexible monitoring framework that exposes its monitoring information under the `cn=monitor` entry and provides interfaces through the PingDataMetrics Server, the Administrative Console, SNMP, JMX, and over LDAP. The Directory Server also provides a tool, the Periodic Stats Logger, to profile server performance.

The monitor backend

The Directory Server exposes its monitoring information under the `cn=monitor` entry. Administrators can use various means to monitor the servers, including the PingDataMetrics Server, through SNMP, the Administrative Console, JConsole, LDAP command-line tools, and the Periodic Stats Logger. Use the **bin/status** tool to display server component activity and state.

The list of all monitor entries can be seen using ldapsearch as follows:

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
 --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
 --baseDN "cn=monitor" "(objectclass=*)" cn
```

The following table describes a subset of the monitor entries:

Directory Server Monitoring Components

Component	Description
Active Operations	Provides information about the operations currently being processed by the Directory Server. Shows the number of operations, information on each operation, and the number of active persistent searches.
Backends	Provides general information about the state of an a Directory Server backend, including the entry count. If the backend is a local database, there is a corresponding database environment monitor entry with information on cache usage and on-disk size.
Client Connections	Provides information about all client connections to the Directory Server. The client connection information contains a name followed by an equal sign and a quoted value (e.g., connID="15", connectTime="20100308223038Z", etc.)
Connection Handlers	Provides information about the available connection handlers on the Directory Server, which includes the LDAP and LDIF connection handlers. These handlers are used to accept client connections and to read requests and send responses to those clients.
Disk Space Usage	Provides information about the disk space available to various components of the Directory Server.
General	Provides general information about the state of the Directory Server, including product name, vendor name, server version, etc.
Index	Provides on each index. The monitor captures the number of keys preloaded, and counters for read/write/remove/open-cursor/read-for-search. These counters provide insight into how useful an index is for a given workload.
HTTP/HTTPS Connection Handler Statistics	Provides statistics about the interaction that the associated HTTP connection handler has had with its clients, including the number of connections accepted, average requests per connection, average connection duration, total bytes returned, and average processing time by status code.
JVM Stack Trace	Provides a stack trace of all threads processing within the JVM.
LDAP Connection Handler Statistics	Provides statistics about the interaction that the associated LDAP connection handler has had with its clients, including the number of connections established and closed, bytes read and written, LDAP messages read and written, operations initiated, completed, and abandoned, etc.
Processing Time Histogram	Categorizes operation processing times into a number of user-defined buckets of information, including the total number of operations processed, overall average response time (ms), number of processing times between 0ms and 1ms, etc.
System Information	Provides general information about the system and the JVM on which the Directory Server is running, including system host name, operation system, JVM architecture, Java home, Java version, etc.
Version	Provides information about the Directory Server version, including build ID, version, revision number, etc.

Component	Description
Work Queue	Provides information about the state of the Directory Server work queue, which holds requests until they can be processed by a worker thread, including the requests rejected, current work queue size, number of worker threads, and number of busy worker threads. The work queue configuration has a **`monitor-queue-time`** property set to **`true`** by default. This logs messages for new operations with a **`qtime`** attribute included in the log messages. Its value is expressed in milliseconds and represents the length of time that operations are held in the work queue. A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the **`ldapsearch`** command for example, use the **`--useAdministrativeSession`** option. The requester must have the **`use-admin-session`** privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the **`num-administrative-session-worker-threads`** property in the work queue configuration.

Monitoring disk space usage

The disk space usage monitor provides information about the amount of usable disk space available for Directory Server components. The disk space usage monitor evaluates the free space at locations registered through the `DiskSpaceConsumer` interface by various components of the server. Disk space monitoring excludes disk locations that do not have server components registered. However, other disk locations may still impact server performance, such as the operating system disk, if it becomes full. When relevant to the server, these locations include the server root, the location of the `/config` directory, the location of every log file, all JE backend directories, the location of the changelog, the location of the replication environment database, and the location of any server extension that registers itself with the DiskSpaceConsumer interface.

The disk space usage monitor provides the ability to generate administrative alerts, as well as take additional action if the amount of usable space drops below the defined thresholds.

Three thresholds can be configured for this monitor:

- **Low space warning threshold**. This threshold is defined as either a percentage or absolute amount of usable space. If the amount of usable space drops below this threshold, then the Directory Server will generate an administrative alert but will remain fully functional. It will generate alerts at regular intervals that you configure (such as once a day) unless action is taken to increase the amount of usable space. The Directory Server will also generate additional alerts as the amount of usable space is further reduced (e.g., each time the amount of usable space drops below a value 10% closer to the low space error threshold). If an administrator frees up disk space or adds additional capacity, then the server should automatically recognize this and stop generating alerts.
- **Low space error threshold**. This threshold is also defined as either a percentage or absolute size. Once the amount of usable space drops below this threshold, then the server will generate an alert notification and will begin rejecting all operations requested by non-root users with "UNAVAILABLE" results. The server should continue to generate alerts during this time. Once the server enters this mode, then an administrator will have to take some kind of action (e.g., running a command to invoke a task or removing a signal file) before the server will resume normal operation. This threshold must be less than or equal to the low space warning threshold. If they are equal, the server will begin rejecting requests from non-root users immediately upon detecting low usable disk space.
- **Out of space error threshold**. This threshold may also be defined as a percentage or absolute size. Once the amount of usable space drops below this threshold, then the PingDirectory Server will generate a final administrative alert and will shut itself down. This threshold must be less than or equal

to the low space error threshold. If they are equal, the server will shut itself down rather than rejecting requests from non-root users.

- **Disk space monitoring for tools**. The server monitors disk space consumption during processing for the `export-ldif`, `rebuild-index`, and `backup` tools. Space is monitored every 10 seconds if usable space for all monitored paths is greater than 15 percent of the capacity of those volumes. If usable space for any path drops below 15 percent, or below 10GB free, the space check frequency is increased to every second. Warning messages are generated if available space falls below 10 percent, or below 5GB free. If usable space for any path drops below two percent, or 1GB free, the tool processing is aborted and files may be removed to free up space.

The default configuration uses the same values for the low space error threshold and out of space error threshold. This is to prevent having the server online but rejecting requests, which will cause problems with applications trying to interact with the server. The low space warning threshold generates an alert before the problem becomes serious, well in advance of available disk space dropping to a point that it is critical.

The default values may not be suitable for all disk sizes, and should be adjusted to fit the deployment. Determining the best values should factor in the size of the disk, how big the database may become, how much space log files may consume, and how many backups will be stored.

The threshold values may be specified either as absolute sizes or as percentages of the total available disk space. All values must be specified as absolute values or as percentages. A mix of absolute values and percentages cannot be used. The low space warning threshold must be greater than or equal to the low space error threshold, the low space error threshold must be greater than or equal to the out of space error threshold, and the out of space error threshold must be greater than or equal to zero.

If the out of space error threshold is set to zero, then the server will not attempt to automatically shut itself down if it detects that usable disk space has become critically low. If the amount of usable space reaches zero, then the database will preserve its integrity but may enter a state in which it rejects all operations with an error and requires the server (or at least the affected backends) to be restarted. If the low space error threshold is also set to zero, then the server will generate periodic warnings about low available disk space but will remain fully functional for as long as possible. If all three threshold values are set to zero, then the server will not attempt to warn about or otherwise react to a lack of usable disk space.

Monitoring with the PingDataMetrics Server

The PingDataMetrics Server is an invaluable tool for collecting, aggregating and exposing historical and instantaneous data from the various Ping Identity servers in a deployment. The PingDataMetrics Server relies on a captive PostgreSQL datastore for the metrics, which it collects from internal instrumentation across the instances, replicas, and data centers in your environment. The data is available via a Monitoring API that can be used to build custom dashboards and monitoring applications to monitor the overall health of your PingData Platform system. For more information, refer to the *PingDataMetrics Server Administration Guide*.

About the collection of system monitoring data

All PingDirectory Servers have the capability to monitor the health of the server and host system they run on for diagnostic review and troubleshooting. Initially, the servers do not collect any performance data until they are prepared for monitoring by a Metrics Server using the `monitored-servers add-servers` tool or an administrator enables system health data collection for real-time inspection and querying. At a high level, all of the important server and machine metrics which can be monitored are available in the `cn=monitor` backend.

The Stats Collector plugin is the primary driver of performance data collection for LDAP, server response, replication, local JE databases, and host system machine metrics. Stats Collector configuration determines the sample and collection intervals, granularity of data (basic, extended, verbose), types of host system collection (cpu, disk, network) and what kind of data aggregation occurs for LDAP application statistics. The Stats Collector plugin ensures that a PingDataMetrics Server is able to gather all of the detailed data required for a comprehensive diagnostic review.

The Stats Collector plugin relies exclusively on entries in the `cn=monitor` backend to sample data using LDAP queries. The Stats Collector plugin is the primary driver of performance data collection for LDAP, server response, replication, local JE databases, and host system machine metrics. Stats Collector configuration determines the sample and collection intervals, granularity of data (basic, extended, verbose), types of host system collection (cpu, disk, network) and the type of data aggregation that occurs for LDAP application statistics. The Stats Collector plugin is configured with the `dsconfig` tool and collects data using LDAP queries. For example, the `--server-info:extended` option includes collection for the following:

- CPU
- JVM memory
- Memory
- Disk information
- Network information

Utilization metrics are gathered via externally invoked OS commands, such as `iostat` and `netstat`, using platform-specific arguments and version-specific output parsing.

Enabling the Host System monitor provider automatically gathers CPU and memory utilization but only optionally gathers disk and network information. Disk and network interfaces are enumerated in the configuration by device names (e.g., `eth0` or lo), and by disk device names (e.g., `sd1, sdab, sda2, scsi0`).

Monitoring key performance indicators by application

The PingDirectory Server can be configured to track many key performance metrics (for example, throughput and response-time) by the client applications requesting them. This feature is invaluable for measuring whether the Ping Identity identify infrastructure meets all of your service-level agreements (SLA) that have been defined for client applications.

When enabled, the per-application monitoring data can be accessed in the `cn=monitor` backend, the Periodic Stats Logger, and made available for collection by the Metrics Server. See the “Profiling Server Performance Using the Periodic Stats Logger” for more information on using that component. Also, see the Directory Server Configuration section of the *PingDataMetrics Server Administration Guide* for details on configuring the server to expose metrics that interest you. Tracked application information is exposed in the PingDataMetrics Server by metrics having the 'application-name' dimension. See the documentation under `docs/metrics` of the PingDataMetrics Server for information on which metrics are available with the 'application-name' dimension.

Configuring the external Servers

Before you install the PingDataMetrics Server, you need to configure the servers you will be monitoring: PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server. The PingDataMetrics Server requires all servers to be version 3.5.0 or later. See the administration guides for each product for installation instructions.

Once you have installed the Directory Server, you can use the **`dsconfig`** tool to make configuration changes for the PingDataMetrics Server. When using the **`dsconfig`** tool interactively, set the complexity level to Advanced, so that you can make all the necessary configuration changes.

Preparing the servers monitored by the PingDataMetrics Server

The Metrics Backend manages the storage of metrics and provides access to the stored blocks of metrics via LDAP. The Metrics Backend is configured to keep a maximum amount of metric history based on log retention policies. The default retention policy uses the Default Size Limit Retention Policy, Free Disk Space Retention Policy, and the File Growth Limit Policy, limiting the total disk space used to 500 MB. This amount of disk typically contains more than 24 hours of metric history, which is ample. The Directory Server keeps a metric history so that the PingDataMetrics Server can be down for a period and then catch up when it comes back online.

The following two commands create a Retention Policy that limits the number of files to 2000, and sets the Metrics Backend to flush data to a new file every 30 seconds.

```
$ bin/dsconfig create-log-retention-policy \
  --policy-name StatsCollectorRetentionPolicy \
  --type file-count --set number-of-files:2000

$ bin/dsconfig set-backend-prop \
  --backend-name metrics --set sample-flush-interval:30s \
  --set retention-policy:StatsCollectorRetentionPolicy
```

These commands configure the Metrics Backend to keep 16 hours of metric history, which consumes about 250 MB of disk, ensuring that captured metrics are available to the PingDataMetrics Server within 30 seconds of when the metric was captured. The value of the `sample-flush-interval` attribute determines the maximum delay between when a metric is captured and when it can be picked up by the PingDataMetrics Server.

The flush interval can be set between 15 seconds and 60 seconds, with longer values resulting in less processing load on the PingDataMetrics Server. However, this flush interval increases the latency between when the metric was captured and when it becomes visible in the Dashboard Application. If you change the `sample-flush-interval` attribute to 60 seconds in the example above, then the Directory Server keeps 2000 minutes of history. Because the number of metrics produced per unit of time can vary depending on the configuration, no exact formula can be used to compute how much storage is required for each hour of history. However, 20 MB per hour is a good estimate.

Configuring the Processing Time Histogram plugin

The Processing Time Histogram plugin is configured on each Directory Server and Directory Proxy Server as a set of histogram bucket ranges. When the bucket ranges for a histogram change, the PingDataMetrics Server notices the change and marks samples differently. This process allows for histograms with the same set of bucket definitions to be properly aggregated and understood when returned in a query. If different servers have different bucket definitions, then a single metric query cannot return histogram data from the servers.

You should try to keep the Processing Time Histogram bucket definitions the same on all servers. Having different definitions restricts the ability of the PingDataMetrics Server API to aggregate histogram data across servers and makes the results of a query asking "What percentage of the search requests took less than 12 milliseconds?" harder to understand.

For each server in your topology, you must set the separate-monitor-entry-per-tracked-application property of the processing time histogram plugin to true. This property must be set to expose per-application monitoring information under `cn=monitor`. When the separate-monitor-entry-per-tracked-application property is set to true, then the per-application-ldap-stats property must be set to per-application-only on the Stats Collector Plugin and vice versa.

For example, the following **`dsconfig`** command line sets the required properties of the Processing Time Histogram plugin:

```
$ bin/dsconfig set-plugin-prop --plugin-name “Processing Time Histogram” \
  --set separate-monitor-entry-per-tracked-application:true
```

The following **`dsconfig`** command line sets the per-application-ldap-stats property of the Stats Collector plugin to per-application-only:

```
$ bin/dsconfig set-plugin-prop --plugin-name “Stats Collector” \
 --set per-application-ldap-stats:per-application-only
```

Setting the connection criteria to collect SLA statistics by application

If you want to collect data about your SLAs, you need to configure connection criteria for each Service Level Agreement that you want to track. The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can also be used when the server needs to perform matching based on connection-level properties, such as filtered logging. For assistance using connection criteria, contact your authorized support provider.

For example, imagine that we are interested in collecting statistics on data that is accessed by clients authenticating as the Directory Manager. We need to create connection criteria on the Directory Server that identifies any user authenticating as the Directory Manager. The connection criteria name corresponds to the application-name dimension value that clients will specify when accessing the data via the API. When you define the Connection Criteria, change the included-user-base-dn property to include the Directory Manager's full LDIF entry.

The following **dsconfig** command line creates connection criteria for the Directory Manager:

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Directory Manager" \
  --type simple \
  --set "included-user-base-dn:cn=Directory Manager,cn=Root DNs,cn=config"
```

Proxy considerations for tracked applications

In a proxy environment, the criteria should be defined in the Directory Proxy Server since the Directory Proxy Server passes the application name through to the Directory Server in the intermediate client control. If a client of the Directory Proxy Server or Directory Server happens to use the intermediate client control, then the client name specified in the control will be used as the application name regardless of the criteria listed in the tracked-application property.

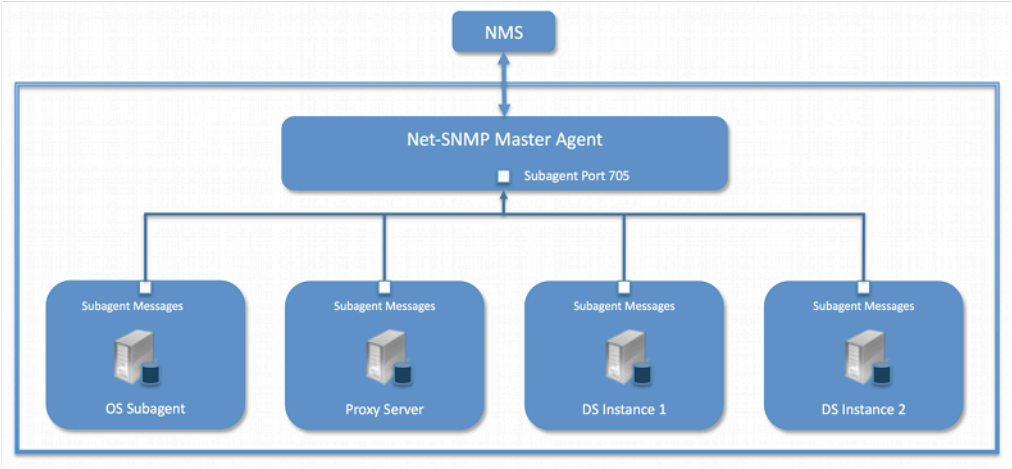
Monitoring using SNMP

The PingDirectoryProxy Server supports real-time monitoring using the Simple Network Management Protocol (SNMP). The Directory Proxy Server provides an embedded SNMPv3 subagent plugin that, when enabled, sets up the server as a managed device and exchanges monitoring information with a master agent based on the AgentX protocol.

SNMP implementation

In a typical SNMP deployment, many production environments use a network management system (NMS) for a unified monitoring and administrative view of all SNMP-enabled devices. The NMS communicates with a master agent, whose main responsibility is to translate the SNMP protocol messages and multiplex any request messages to the subagent on each managed device (for example, Directory Server instance, Directory Proxy Server, Data Sync Server, or OS Subagent). The master agent also processes responses or traps from the agents. Many vendors provide commercial NMS systems. Consult with your NMS system for specific information.

The PingDirectory Server contains an SNMP subagent plugin that connects to a Net-SNMP master agent over TCP. The main configuration properties of the plugin are the address and port of the master agent, which default to localhost and port 705, respectively. When the plugin is initialized, it creates an AgentX subagent and a managed object server, and then registers as a MIB server with the Directory Server instance. Once the plugin's startup method is called, it starts a session thread with the master agent. Whenever the connection is lost, the subagent automatically attempts to reconnect with the master agent. The Directory Server's SNMP subagent plugin transmits only read-only values for polling or trap purposes. (Set and inform operations are not supported). SNMP management applications cannot perform actions on the server on their own or by means of an NMS system.



MY TITLE Example SNMP Deployment

One important note is that the PingDirectory Server was designed to interface with a Net-SNMP (version 5.3.2.2 or later) master agent implementation with AgentX over TCP. Many operating systems provide their own Net-SNMP module. However, SMA disables some features present in the Net-SNMP package and only enables AgentX over UNIX Domain Sockets, which cannot be supported by Java. If your operating system has a native Net-SNMP master agent that only enables UNIX Domain Sockets, you must download and install a separate Net-SNMP binary from its web site.

Configuring SNMP

About this task

Because all server instances provide information for a common set of MIBs, each server instance provides its information under a unique SNMPv3 context name, equal to the server instance name. The server instance name is defined in the Global Configuration, and is constructed from the host name and the server LDAP port by default. Consequently, information must be requested using SNMPv3, specifying the context name that pertains to the desired server instance. This context name is limited to 30 characters or less. Any context name longer than 30 characters will result in an error message. Since the default context name is limited to 30 characters or less, and defaults to the server instance name and the LDAP port number, pay special attention to the length of the fully-qualified (DNS) host name.

ⓘ **Note:** The Directory Server supports SNMPv3, and only SNMPv3 can access the MIBs. For systems that implement SNMP v1 and v2c, Net-SNMP provides a proxy function to route requests in one version of SNMP to an agent using a different SNMP version.

Steps

1. Enable the Directory Server's SNMP plugin by using the **`dsconfig`** tool. Make sure to specify the address and port of the SNMP master agent. On each Directory Server instance, enable the SNMP subagent. Note that the SNMPv3 context name is limited to 30 bytes maximum. If the default dynamically-constructed instance name is greater than 30 bytes, there will be an error when attempting to enable the plugin. Enable the SNMP Subagent Alert Handler so that the sub-agent will send traps for administrative alerts generated by the server.

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" --set enabled:true
```

2. View the error log. You will see a message that the master agent is not connected, because it is not yet online.

```
The SNMP sub-agent was unable to connect to the master
agent at localhost/705: Timeout
```

3. Edit the SNMP agent configuration file, `snmpd.conf`, which is often located in `/etc/snmp/snmpd.conf`. Add the directive to run the agent as an AgentX master agent:

```
master agentx agentXSocket tcp:localhost:705
```

   Note that the use of `localhost` means that only sub-agents running on the same host can connect to the master agent. This requirement is necessary since there are no security mechanisms in the AgentX protocol.

4. Add the trap directive to send SNMPv2 traps to `localhost` with the community name, public (or whatever SNMP community has been configured for your environment) and the port.

```
trap2sink localhost public 162
```

5. To create a SNMPv3 user, add the following lines to the `/etc/snmp/snmpd.conf` file.

```
rwuser initial
createUser initial MD5 setup_passphrase DES
```

6. Run the following command to create the SNMPv3 user.

```
snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
localhost create snmpuser initial
```

7. Start the **`snmpd`** daemon and after a few seconds you should see the following message in the Directory Server error log:

```
The SNMP subagent connected successfully to the master agent
at localhost:705. The SNMP context name is host.example.com:389
```

8. Set up a trap client to see the alerts that are generated by the Directory Server. Create a config file in `/tmp/snmptrapd.conf` and add the directive below to it. The directive specifies that the trap client can process traps using the public community string, and can log and trigger executable actions.

```
authcommunity log, execute public
```

9. Install the MIB definitions for the Net-SNMP client tools, usually located in the `/usr/share/snmp/mibs` directory.

```
$ cp resource/mib/* /usr/share/snmp/mibs
```

10. Then, run the trap client using the **`snmptrapd`** command. The following example specifies that the command should not create a new process using **`fork()`** from the calling shell (`-f`), do not read any configuration files (`-C`) except the one specified with the `-c` option, print to standard output (`-Lo`), and then specify that debugging output should be turned on for the User-based Security Module (`-Dusm`). The path after the `-M` option is a directory that contains the MIBs shipped with our product (i.e., `server-root/resource/mib`) .

```
$ snmptrapd -f -C -c /tmp/snmptrapd.conf -Lf /root/trap.log -Dusm \
  -m all -M +/usr/share/snmp/mibs
```

11. Run the Net-SNMP client tools to test the feature. The following options are required: `-v <SNMP version>`, `-u <user name>`, `-A <user password>`, `-l <security level>`, `-n <context name (instance name)>` . The `-m` all option loads all MIBs in the default MIB directory in `/usr/share/snmp/mibs` so that MIB names can be used in place of numeric OIDs.

```
$ snmpget -v 3 -u snmpuser -A password -l authNoPriv -n host.example.com:389
 \
-m all localhost localDBBackendCount.0
```

```
$ snmpwalk -v 3 -u snmpuser -A password -l authNoPriv -n
 host.example.com:389 \
-m all localhost systemStatus
```

MIBS

The Directory Server provides SMIv2-compliant MIB definitions (RFC 2578, 2579, 2580) for distinct monitoring statistics. These MIB definitions are to be found in text files under `resource/mib` directory under the server root directory.

Each MIB provides managed object tables for each specific SNMP management information as follows:

- **LDAP Remote Server MIB**. Provides information related to the health and status of the LDAP servers that the Directory Proxy Server connects to, and statistics about the operations invoked by the Directory Proxy Server on those LDAP servers.
- **LDAP Statistics MIB**. Provides a collection of connection-oriented performance data that is based on a connection handler in the Directory Server. A server typically contain only one connection handler and therefore supplies only one table entry.
- **Local DB Backend MIB**. Provides key metrics related to the state of the local database backends contained in the server.
- **Processing Time MIB**. Provides a collection of key performance data related to the processing time of operations broken down by several criteria but reported as a single aggregated data set.
- **Replication MIB**. Provides key metrics related to the current state of replication, which can help diagnose how much outstanding work replication may have to do.
- **System Status MIB**. Provides a set of critical metrics for determining the status and health of the system in relation to its work load.

For information on the available monitoring statistics for each MIB available on the Directory Server and the Directory Proxy Server, see the text files provided in the `resource/mib` directory below the server installation.

The Directory Server generates an extensive set of SNMP traps for event monitoring. The traps display the severity, description, name, OID, and summary. For information about the available alert types for event monitoring, see the `resource/mib/UNBOUNDID-ALERT-MIB.txt` file.

Monitoring with the Administrative Console

About this task

Ping Identity has an Administrative Console for administrators to configure the directory server. The console also provides a status option that accesses the server's monitor content.

To view the Monitor Dashboard:

Steps

1. Ensure that the Directory Server is running.
2. Open a browser to `http://server-name:8443/console`.
3. Type the root user DN and password, and then click **Login**.
4. Use the top level navigation dropdown and select 'Status.'
5. On the Administrative Console's Status page, select the Monitors tab.

Accessing the Processing Time Histogram

About this task

The PingDirectory Server provides a processing time histogram that classifies operation response time into user-defined buckets. The histogram tracks the processing on a per operation basis and as a percentage of the overall processing time for all operations. It also provides statistics for each operation type (add, bind, compare, delete, modify, modify DN, search).

Steps

1. On the Administrative Console, click **Configuration > Status > Monitors tab**.
2. Select **Processing Time Histogram**. Other monitor entries can be accessed in similar ways.

Monitoring with JMX

The PingDirectory Server supports monitoring the JVM™ through a Java Management Extensions (JMX™) management agent, which can be accessed using JConsole or any other kind of JMX client. The JMX interface provides JVM performance and resource utilization information for applications running Java. You can monitor generic metrics exposed by the JVM itself, including memory pools, threads, loaded classes, and MBeans, as well as all the monitor information that the Directory Server provides. You can also subscribe to receive JMX notifications for any administrative alerts that are generated within the server.

Running JConsole

About this task

Before you can access JConsole, you must configure and enable the JMX Connection Handler for the Directory Server using the **dsconfig** tool. See Configuring the JMX Connection Handler and Alert Handler.

To invoke the JConsole executable, type `jconsole` on the command line. If *JDK_HOME* is not set in your path, you can access JConsole in the `bin` directory of the `JDK_HOME` path.

To run JConsole:

Steps

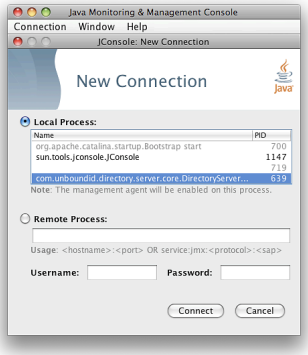
1. Use **JConsole** to open the Java Monitoring and Management Console. You can also run JConsole to monitor a specific process ID for your application: **jconsole PID**. Or you can run JConsole remotely using: **jconsole hostname:port**.

```
$ jconsole
```

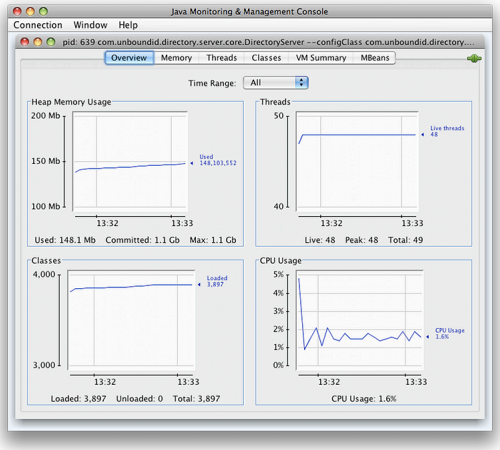
ⓘ **Note:** If SSL is configured on the JMX Connection Handler, you must specify the Directory Server jar file in the class path when running **jconsole** over SSL. For example, run the following **jconsole** command:

```
$ jconsole \
  -J-Djavax.net.ssl.trustStore=/path/to/certStores/truststore \
  -J-Djavax.net.ssl.trustStorePassword=secret \
  -J-Djava.class.path=$SERVER_ROOT/lib/PingDirectory.jar:/Library/Java/
JavaVirtualMachines/jdk-version.jdk/Contents/Home/lib/jconsole.jar
```

2. On the **Java Monitoring & Administrative Console**, click **Local Process**, and then click the **PID** corresponding to the directory server.



3. Review the resource monitoring information.



Monitoring the Directory Server using JConsole

About this task

You can set up JConsole to monitor the Directory Server using a remote process. Make sure to enable the JMX Connection Handler and to assign at least the `jmx-read` privilege to a regular user account (the `jmx-notify` privilege is required to subscribe to receive JMX notifications). Do not use a root user account, as this would pose a security risk.

Steps

1. Start the Directory Server.

```
$ bin/start-server
```

2. Enable the JMX Connection handler using the **`dsconfig`** tool. The handler is disabled by default. Remember to include the LDAP connection parameters (host name, port, bindDN, bindPassword).

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "JMX Connection Handler" --set enabled:true
```

3. Assign `jmx-read`, `jmx-write`, and `jmx-notify` (if the user receives notifications) to the user.

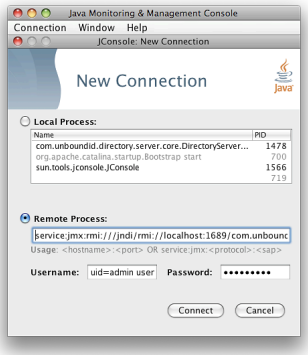
```
$ bin/ldapmodify --hostname server1.example.com --port 1389 \
  --bindDN "cn=Directory Manager" --bindPassword secret
dn: uid=admin,dc=example,dc=com
changetype: modify
```

```
replace: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: jmx-write
ds-privilege-name: jmx-notify
```

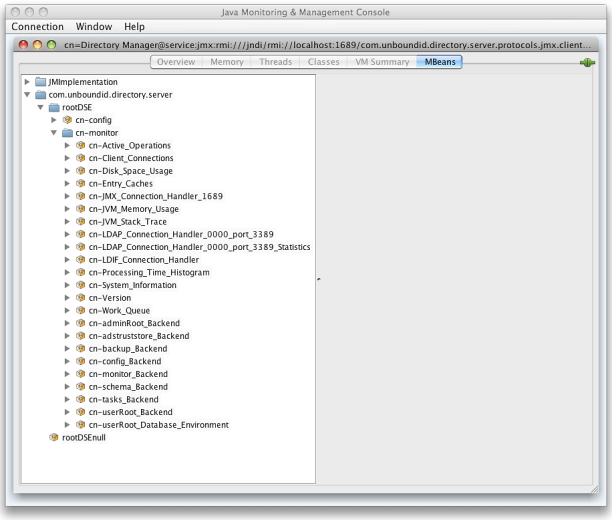
4. On the **Java Monitoring & Administrative Console**, click **Remote Process**, and enter the following JMX URL using the host and port of your Directory Server.

   ```
   service:jmx:rmi:///jndi/rmi://<host>:<port>/
   com.unboundid.directory.server.protocols.jmx.client-unknown
   ```

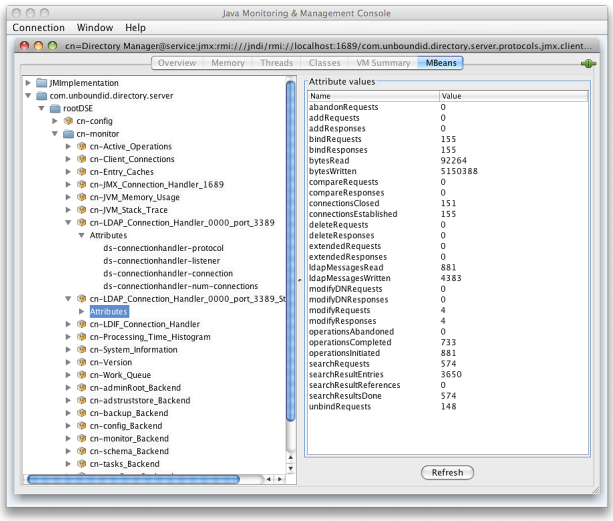
5. In the **Username** and **Password** fields, type the bind DN and password for a user that has at least the `jmx-read` privilege. Click **Connect**.



6. Click **com.unboundid.directory.server**, and expand the `rootDSE` node and the `cn-monitor` sub-node.



7. Click a monitoring entry. In this example, click the **LDAP Connection Handler** entry.



Monitoring Using the LDAP SDK

You can use the monitoring API to retrieve monitor entries from the Directory Proxy Server as well as to retrieve specific types of monitor entries.

For example, you can retrieve all monitor entries published by the Directory Server and print the information contained in each using the generic API for accessing monitor entry data as follows:

```
for (MonitorEntry e : MonitorManager.getMonitorEntries(connection))
  {
    System.out.println("Monitor Name: " + e.getMonitorName());
    System.out.println("Monitor Type: " + e.getMonitorDisplayName());
    System.out.println("Monitor Data:");
    for (MonitorAttribute a : e.getMonitorAttributes().values())
    {
      for (Object value : a.getValues())
      {
        System.out.println(" " + a.getDisplayName() + ": " +
 String.valueOf(value));
      }
     }
     System.out.println();
  }
```

For more information about the LDAP SDK and the methods in this example, see the *LDAP SDK* documentation.

Monitoring over LDAP

The PingDirectory Server exposes a majority of its information under the `cn=monitor` entry. You can access these entries over LDAP using the **`ldapsearch`** tool.

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --baseDN "cn=monitor" "(objectclass=*)"
```

Profiling Server Performance Using the Stats Logger

The Directory Proxy Server ships with a built-in Stats Logger that is useful for profiling server performance for a given configuration. At a specified interval, the Stats Logger can write server statistics to a JSON file or to a log file in a comma-separated format (.csv), which can be read by spreadsheet applications. The

logger has a negligible impact on server performance unless the `log-interval` property is set to a very small value (less than 1 second). The statistics logged and their verbosity can be customized.

The Stats Logger can also be used to view historical information about server statistics including replication, LDAP operations, host information, and gauges. Either update the configuration of the existing Stats Logger Plugin to set the advanced `gauge-info` property to `basic/extended` to include this information, or create a dedicated Periodic Stats Logger for information about statistics of interest.

For information about how to enable this logging and where to find the log file, see *To Enable the Stats Logger* on page 755.

To Enable the Stats Logger

About this task
By default, the Directory Proxy Server ships with the built-in "Stats Logger' disabled. To enable it using the **`dsconfig`** tool or the Administrative Console, go to **Plugins** menu (available on the Advanced object menu), and then, select .

Steps

1. Run **`dsconfig`** in interactive mode. Enter the LDAP or LDAPS connection parameters when prompted.

```
$ bin/dsconfig
```

2. Enter `o` to change to the Advanced Objects menu.
3. On the main menu, enter the number for Plugins.
4. On the **Plugin** menu, enter the number corresponding to view and edit an existing plugin.
5. On the **Plugin selection** list, enter the number corresponding to the Stats Logger.
6. On the **Stats Logger Plugin** menu, enter the number to set the `enabled` property to `TRUE`. When done, enter `f` to save and apply the configuration. The default logger will log information about the server every second to `<server-root>/logs/dsstats.csv`. If the server is idle, nothing will be logged, but this can be changed by setting the `suppress-if-idle` property to `FALSE` (`suppress-if-idle=false`).

```
>>>> Configure the properties of the Stats Logger Plugin

Property                Value(s)
-------------------------------------------------------------------------
1)   description        Logs performance stats to a log file
                        periodically.
2)   enabled                      false
3)   local-db-backend-info       basic
4)   replication-info             basic
5)   entry-cache-info             -
6)   host-info                    -
7)   included-ldap-application    If per-application LDAP stats is enabled,
                                  then stats will be included for all
                                  applications.
8)   log-interval                 1 s
9)   collection-interval         200 ms
10)  suppress-if-idle             true
11)  header-prefix-per-column     false
12)  empty-instead-of-zero        true
13)  lines-between-header         50
14)  included-ldap-stat           active-operations, num-connections,
                                  op-count-and-latency, work-queue
15)  included-resource-stat       memory-utilization
16)  histogram-format             count
17)  histogram-op-type            all
18)  per-application-ldap-stats   aggregate-only
```

```
19)  ldap-changelog-info          -
20)  gauge-info                   none
21)  log-file                     logs/dsstats.csv
22)  log-file-permissions         640
23)  append                       true
24)  rotation-policy              Fixed Time Rotation Policy, Size Limit
                                  Rotation Policy
25)  retention-policy             File Count Retention Policy

?)   help
f)   finish - apply any changes to the Periodic Stats Logger Plugin
a)   hide advanced properties of the Periodic Stats Logger Plugin
d)   display the equivalent dsconfig command lines to either re-create this
           object or only to apply pending changes
b)   back
q)   quit

Enter choice [b]:
```

7. Run the Directory Proxy Server. For example, if you are running in a test environment, you can run the **`search-and-mod-rate`** tool to apply some searches and modifications to the server. You can run **`search-and-mod-rate`** `--help` to see an example command.
8. View the Stats log output at `<server-root>/logs/dsstats.csv`. You can open the file in a spreadsheet.

To Configure Multiple Periodic Stats Loggers

About this task

Multiple Periodic Stats Loggers can be created to log different statistics, view historical information about gauges, or to create a log at different intervals (such as logging cumulative operations statistics every hour). To create a new log, use the existing Stats Logger as a template to get reasonable settings, including rotation and retention policy.

Steps

1. Run **`dsconfig`** by repeating steps 1–3 in *To Enable the Stats Logger*.
2. From the **Plugin management** menu, enter the number to create a new plugin.
3. From the **Create a New Periodic Stats Logger Plugin** menu, enter `t` to use an existing plugin as a template.
4. Enter the number corresponding to the existing stats logger as a template.
5. Next, enter a descriptive name for the new stats logger. For this example, type `Stats Logger-10s`.
6. Enter the log file path to the file. For this example, type `logs/dsstats2.csv`.
7. On the menu, make any other change to the logger. For this example, change the `log-interval` to 10s, and the `suppress-if-idle` to false. When finished, enter `f` to save and apply the configuration.
8. You should now see two loggers `dsstats.csv` and `dsstats2.csv` in the `logs` directory.

StatsD monitoring endpoint

The Monitoring Endpoint configuration type provides the StatsD Endpoint type that you can use to transfer metrics data in the StatsD format.

Examples of metrics you can send are:

- Busy worker thread count
- Garbage collection statistics
- Host system metrics such as CPU and memory

For a list of available metrics, use the interactive **dsconfig** menu for the Stats Collector Plugin or in the Administrative Console, edit the **Stats Collector** plugin as explained in the second example.

You configure the Monitoring Endpoint using the **dsconfig** command. When you configure Monitoring Endpoint, you include:

- The endpoint's hostname
- The endpoint's port
- A toggle to use TCP or UDP
- A toggle to use SSL if you use TCP

For example, to configure a new StatsD Monitoring Endpoint to send UDP data to localhost port 8125 using **dsconfig**:

```
dsconfig create-monitoring-endpoint \
    --type statsd \
    --endpoint-name StatsDEndpoint \
    --set enabled:true \
    --set hostname:localhost \
    --set server-port:8125 \
    --set connection-type:unencrypted-udp
```

If you are using the Administrative Console:

1. Click **Show Advanced Configuration**.
2. In the **Logging, Monitoring, and Notifications** section, click **Monitoring Endpoints**.
3. Click **New Monitoring Endpoint**.

You can send data to any number of monitoring endpoints.

The Stats Collector Plugin controls the metrics used by the StatsD monitoring endpoint. To send metrics with the StatsD monitoring endpoint, you must enable the Stats Collector Plugin. Also, you must configure the Stats Collector Plugin to indicate the metrics to send.

To enable the Stats Collector Plugin or to configure the type of data sent, use the **dsconfig** command or the Administrative Console. For example, to enable the Stats Collector Plugin to send host CPU metric, memory metrics, and server status metrics using **dsconfig**:

```
dsconfig set-plugin-prop \
    --plugin-name "Stats Collector" \
    --set enabled:true \
    --set host-info:cpu \
    --set host-info:disk \
    --set status-summary-info:basic
```

If you are not using Data Metrics Server to monitor your server, you can disable the generation of some metrics files that are not necessary for the StatsD Monitoring Endpoint. To do this, set the `generate-collector-files` property on the Stats Collector Plugin to `false`.

If you are using the Administrative Console:

1. Click **Show Advanced Configuration**.
2. In the **LDAP (Administration and Monitoring)** section, click **Plugin Root**
3. Edit the **Stats Collector** plugin.

After you enable the Stats Collector and create the StatsD monitoring endpoint, you can:

- Use the data with Splunk as explained in *Sending Metrics to Splunk with StatsD* on page 758.
- Configure other tools that support StatsD, such as CloudWatch or a Prometheus StatsD exporter, to use the data. For more information about this configuration, see your tool's StatsD documentation. Configure the StatsD monitoring endpoint to use the correct host and port. The `dsconfig create-`

`monitoring-endpoint` example above uses a host of localhost and a port of 8125. You can also set these values in the Administrative Console.

Sending Metrics to Splunk with StatsD

About this task

With the StatsD Endpoint type, you can send metric data to a Splunk installation.

In Splunk, you can use SSL to secure ports that are open for StatsD.

> ⓘ **Note:**
>
> StatsD metrics are typically sent over UDP. By using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost.

You can configure open UDP (or TCP) ports in Splunk to accept only connections from a certain hostname or IP address.

To securely send UDP (or TCP) data to Splunk, you can:

Steps

1. Send the data to a Splunk Universal Forwarder.
2. Have the forwarder communicate with the Splunk Indexer over SSL.

Adding custom logged statistics to a Periodic Stats Logger

Add custom statistics based on any attribute in any entry under `cn=monitor` using the Custom Logged Stats object. This configuration object provides powerful controls for how monitor attributes are written to the log. For example, you can extract a value from a monitor attribute using a regular expression. Newly created Custom Logged Stats will automatically be included in the Periodic Stats Logger output.

Besides allowing a straight pass-through of the values using the 'raw' statistic-type, you can configure attributes to be treated as a counter (where the interval includes the difference in the value since the last interval), an average, a minimum, or a maximum value held by the attribute during the specified interval. The value of an attribute can also be scaled by a fixed value or by the value of another monitor attribute.

> ⓘ **Note:** Custom third-party server extensions that were written using the Server SDK can also expose interval statistics using a Periodic Stats Logger. The extension must first implement the SDK's `MonitorProvider` interface and register with the server. The monitor attributes produced by this custom `MonitorProvider` are then available to be referenced by a Custom Logged Stats object.

To illustrate how to configure a Custom Logged Statistics Logger, the following procedure reproduces the built-in "Consumer Total GB" column that shows up in the output when the `included-resource-stat` property is set to memory-utilization on the Periodic Stats Logger. The column is derived from the `total-bytes-used-by-memory-consumers` attribute of the `cn=JVM Memory Usage,cn=monitor` entry as follows:

```
dn: cn=JVM Memory Usage,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-memory-usage-monitor-entry
objectClass: extensibleObject
cn: JVM Memory Usage
...
total-bytes-used-by-memory-consumers: 3250017037
```

Configuring a custom logged statistic using dsconfig interactive

Steps

1. Run **dsconfig** and enter the LDAP/LDAPS connection parameters when prompted.

```
$ bin/dsconfig
```

2. On the Directory Server configuration main menu (Advanced Objects menu), enter the number corresponding to Custom Logged Stats.
3. On the Custom Logged Stats menu, enter the number corresponding to Create a new Custom Logged Stats.
4. Select the Stats Logger Plugin from the list if more than one is present on the system. If you only have one stats logger, press **Enter** to confirm that you want to use the existing plugin.
5. Enter a descriptive name for the Custom Logged Stats. For this example, enter `Memory Usage`.
6. From the `monitor-objectclass` property menu, enter the objectclass attribute to monitor. For this example, enter `ds-memory-usage-monitor-entry`. You can run **ldapsearch** using the base DN "cn=JVM Memory Usage,cn=monitor" entry to view the entry.
7. Next, specify the attributes of the monitor entry that you want to log in the stats logger. In this example, enter `total-bytes-used-by-memory-consumers`, and then press **Enter** again to continue.
8. Next, specify the type of statistics for the monitored attribute that will appear in the log file. In this example, enter the option for raw statistics as recorded by the logger.
9. In the Custom Logged Stats menu, review the configuration. At this point, we want to set up a column name that lists the Memory Usage. Enter the option to change the `column-name` property.
10. Next, we want to add a specific label for the column name. Enter the option to add a value, and then enter **Memory Consumer Total (GB)**, and press **Enter** again to continue.
11. Confirm that you want to use the `column-name` value that you entered in the previous step, and then press `Enter` to use the value.
12. Next, we want to scale the Memory Consumer Totals by one gigabyte. On the **Custom Logged Stats** menu, enter the option to change the `divide-value-by` property.
13. On the `divide-value-by` property menu, enter the option to change the value, and then enter 1073741824 (i.e., 1073741824 bytes = 1 gigabytes).
14. On the **Custom Logged Stats** menu, review your configuration. When finished, enter `f` to save and apply the settings.

```
>>>> Configure the properties of the Custom Logged Stats
 >>>> via creating 'Memory Usage' Custom Logged Stats

         Property                    Value(s)
         ----------------------------------------------------------------
    1)   description                 -
    2)   enabled                     true
    3)   monitor-objectclass         ds-memory-usage-monitor-entry
    4)   include-filter              -
    5)   attribute-to-log            total-bytes-used-by-memory-consumers
    6)   column-name                 Memory Consumer Total (GB)
    7)   statistic-type              raw
    8)   header-prefix               -
    9)   header-prefix-attribute     -
    10)  regex-pattern               -
    11)  regex-replacement           -
    12)  divide-value-by             1073741824
    13)  divide-value-by-attribute   -
    14)  decimal-format              #.##
    15)  non-zero-implies-not-idle   false

    ?)   help
```

```
    f)   finish - create the new Custom Logged Stats
    a)   hide advanced properties of the Custom Logged Stats
    d)   display the equivalent dsconfig arguments to create this object
    b)   back
    q)   quit

Enter choice [b]:
```

```
The Custom Logged Stats was created successfully
```

When the Custom Logged Stats configuration change is completed, the new stats value should immediately show up in the Stats Logger output file.

Configuring a custom stats logger using dsconfig non-interactive

Steps

- Use the **`dsconfig`** non-interactive command-line equivalent to create your custom stats logger. The following one-line command replicates the procedure in the previous section. This command produces a column named "Memory Consumer Total (GB)" that contains the value of the of `total-bytes-used-by-memory-consumers` attribute pulled from the entry with the `ds-memory-usage-monitor-entry` objectclass. This value is scaled by 1073741824 to get to a value represented in GBs.

```
$ bin/dsconfig create-custom-logged-stats --plugin-name "Stats Logger" \
  --stats-name "Memory Usage" --type custom \
  --set monitor-objectclass:ds-memory-usage-monitor-entry \
  --set attribute-to-log:total-bytes-used-by-memory-consumers \
  --set "column-name:Memory Consumer Total (GB)" --set statistic-type:raw \
  --set divide-value-by:1073741824
```

Updating the Global Configuration

You also need to create Global Configuration-tracked applications for each app (connection criteria) you intend to track. The `tracked-application` property allows individual applications to be identified in the server by connection criteria. The name of the tracked application is the same as the name you defined for the connection criteria.

For example, the following **`dsconfig`** command line adds the connection criteria we created in the previous step to the list of tracked applications:

```
$ bin/dsconfig set-global-configuration-prop \
  --set "tracked-application:Directory Manager”
```
