Example:

The following allows access to manage accounts to a helpdesk user. Depending on the configuration requirements, this user might also need the `permit-get-password-policy-state-issues` and `password-reset` privileges.

```
dn: dc=example,dc=com
```

```
changetype: modify
add: aci
aci: (targetattr="userPassword|ds-pwp-last-login-time|ds-pwp-password-
changed-by-required-time|ds-pwp-reset-time|ds-pwp-warned-time|
ds-pwp-account-disabled|ds-pwp-account-expiration-time|ds-pwp-
password-policy-dn|ds-pwp-auth-failure|ds-pwp-last-login-ip-address|
ds-pwp-retired-password|ds-pwp-account-activation-time|pwdReset|
pwdChangedTime|pwdAccountLockedTime")
(version 3.0; acl "Grant full access to PWP related attributes to
helpdesk"; allow (all) userdn="ldap:///uid=helpdesk,dc=example,dc=com";)
```

4. To disable an account, run the **manage-account** tool.

Example:

The following command sets the `account-is-disabled` property to true for the `uid=user.0,dc=example,dc=com`.

```
$ bin/manage-account set-account-is-disabled \
--targetDN uid=user.0,ou=People,dc=example,dc=com \
--operationValue true
```

Result:

You receive the following message.

```
Account Is Disabled: true
```

5. To view the presence of the `ds-pwp-account-disabled` operational attribute in the entry, run the **ldapsearch** tool.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" "+"
```

Result:

The system displays the following information.

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-account-disabled: true
```

## Disabling password policy evaluation

You can disable and bypass password policy evaluations.

The Directory Server provides a global configuration property (`disable-password-policy-evaluation`) that can disable most password policy evaluation processing, which is convenient for those production environments that do not require password policy support. If the `disable-password-policy` property is set to true, passwords are still encoded and evaluated, but only account expiration and account disabling is in effect. All other password policy properties, such as password expiration, lockout, and force change on add or reset, are ignored.

The server also supports the use of a `bypass-pw-policy` privilege, which can skip password policy evaluation for operations on a per-user basis. If a user has this privilege, then they are allowed to perform operations on user entries that would normally be rejected by the password policy associated with the target entry.

### Note:

This privilege does not have any effect for bind operations.

## Globally disabling password policy evaluation

### Steps

- To set the `disable-password-policy-evaluation` property globally for the Directory Server, run the `dsconfig` tool.

Example:

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
  --set "disable-password-policy-evaluation:false"
```

## Exempting a user from password policy evaluation

### Steps

- To add the `bypass-pw-policy` privilege to a user entry, run the `ldapmodify` tool with the `bypass-pw-policy` subcommand.

Example:

```
$ bin/ldapmodify
dn: uid=user.1,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: bypass-pw-policy
```

## About managing password validators

A password validator is a password policy component you can use to determine if a new password is acceptable.

A password policy can be configured with any number of password validators. If a password policy is configured with multiple password validators, then they all must consider a proposed new password acceptable before it is allowed.

### Password validators

The PingDirectory Server offers several types of password validators.

You can use the Server SDK to create custom password validators with the constraints necessary for your environment.

### Password Validators

Password Validators	Description
Attribute Value	Ensures that the proposed password does not match the value of another attribute in the user's entry. You can configure the validator to look in all attributes or in a subset of attributes. It can perform forward and reverse mapping and reject values that are substrings of another attribute.
Character Set	Ensures that the proposed password contains a sufficient number of characters from one or more user-defined character sets. For example, the validator can ensure that passwords must have at least one lowercase letter, one uppercase letter, one digit, and one symbol.

Password Validators	Description
Commonly-Used Passwords Dictionary	Ensures that the proposed password is not one of 10,000 commonly used passwords. These are words that are common for attackers to use when trying to access user accounts. The Commonly-Used Passwords validator is invoked by the Secure Password Policy by default. The word list is located in <code>&lt;server-root&gt;/config/commonly-used-passwords.txt</code> . While it can be used to create a custom validator, it should not be modified.
Dictionary	Ensures that the proposed password is not present in a specified dictionary file, optionally also testing the password with all characters in reverse order. A large dictionary file is provided with the server, but the administrator can supply an alternate dictionary. In this case, the dictionary must be a plain-text file with one word per line.
Haystack Password Validator	Ensures that the proposed password is secure based on a combination of its length and the types of characters that it contains. For example, a longer password containing only lowercase letters might be stronger than a shorter password containing a mix of uppercase and lowercase letters, numbers, and symbols. This is based on the Gibson Research Corporation Password Haystacks concept.
Length-Based Password Validator	Ensures that the number of characters in the proposed new password is within an acceptable range. Both a maximum and minimum number of characters can be specified.
Regular Expression Validator	Ensures that a proposed password either matches or does not match a given regular expression.
Repeated Characters	Ensures that a proposed password does not contain a substring in which the same character is repeated more than a specified number of times (for example, "aaaaa" or "aaabbb"). You can configure the validator to operate in a case-sensitive or case-insensitive manner, and you can also define custom sets of equivalent characters, such as defining all digits as equivalent so the proposed password could not contain more than a specified number of consecutive digits.
Similarity-Based Password Validator	<p>Ensures that the proposed new password is not too similar to the current password, using the Levenstein Distance algorithm, which calculates the number of characters that need to be inserted, removed, or replaced to transform one string into another.</p> <div data-bbox="626 1524 1468 1766" style="border: 1px solid black; padding: 5px;"> <p> <b>Note:</b></p> <p>For this password validator to be effective, you must have access to the user's current password. If this password validator is enabled, the <code>password-change-requires-current-password</code> attribute in the password policy configuration must also be set to true.</p> </div>
Unique Characters	Ensures that the proposed password contains at least a specified minimum number of unique characters, optionally using case-insensitive validation.

## Configuring password validators

You can use the `dsconfig` configuration tool or the administrative console to configure or modify any password validators.

After you define your password validators, you can add them to an existing password policy. The following example procedures show the `dsconfig` non-interactive commands necessary to carry out such tasks.

If you use `dsconfig` in interactive command-line mode, you can access the `Password Validator` menu in the `Basic Objects` menu. For more details on the password validator properties, see the [PingDirectory Server Configuration Reference](#).

## Viewing the list of defined password validators

### Steps

- To view the set of password validators defined in the Directory Server, run the `dsconfig` tool.

## Configuring the Attribute Value Password Validator

### Steps

- To edit the existing default configuration for the Attribute Value Password Validator, run the `dsconfig` tool.

Example:

In this example, the configuration change configures the validator to only examine a specified set of attributes.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Attribute Value" \
  --set match-attribute:cn \
  --set match-attribute:sn \
  --set match-attribute:telephonenumber \
  --set match-attribute:uid
```

- Update an existing password policy to use the Attribute Value Password Validator.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Attribute Value"
```

- Test the Attribute Value Password Validator by submitting a password that is identical to one of the configured attributes (`cn`, `sn`, `telephonenumber`, `uid`).

Example:

```
$ bin/ldappasswordmodify --authzID
"uid=user.0,ou=People,dc=example,dc=com" \
  --newPassword user.0
```

Result:

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
defined in the
server: The provided password was found in another attribute in the user
entry
```

## Configuring the Character Set Password Validator

### Steps

1. To edit the existing default configuration, run the **dsconfig** tool.

Example:

This example changes the requirement for special characters by making them optional in a password and adds a requirement to include at least two digits in the password. In this example, all newly created passwords must have at least one lowercase letter, one uppercase letter, two digits, and optionally any special characters listed.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Character Set" \
  --remove character-set:1:0123456789 \
  --remove "character-set:1::~~\!@#\$\%^&*()-_+=[]{}|\|;:,.<>/?" \
  --add character-set:2:0123456789 \
  --add "character-set:0::~~\!@#\$\%^&*()-_+=[]{}|\|;:,.<>/?" \
  --set allow-unclassified-characters:false
```

2. Update an existing password policy to use the Character Set Password Validator.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Character Set"
```

3. Test the Character Set Password Validator by submitting a password that meets the requirements (one lowercase letter, one uppercase letter, two digits).

Example:

This example should reject the given password because it does not pass the Character Set Password Validator.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword abab1
```

## Configuring the Length-Based Password Validator

### Steps

1. To edit the existing default configuration, run the **dsconfig** tool.

Example:

In this example, the required minimum number of characters in a password is set to five.

```
$ bin/dsconfig create-password-validator \
  --validator-name "Length-Based Password Validator" \
  --set max-password-length:5 --set min-password-length:5
```

2. Update an existing password policy to use the Length-Based Password Validator.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Length-Based Password Policy"
```

3. Test the Length-Based Password Validator by submitting a password that has fewer than the minimum number of required characters.

Example:

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword abcd
```

Result:

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
defined in
the server: The provided password is shorter than the minimum required
length of
5 characters
```

## Configuring the Regular Expression Password Validator

About this task

Use the `dsconfig` tool to configure the Regular Expression Password Validator.

Steps

1. Use `dsconfig` to create a regular expression password validator.

Example:

The following password validator checks that the password contains at least one number, one lowercase letter, and one uppercase letter with no restrictions on password length. If the password matches the regular expression, then it is accepted. When using the following command, remember to include the LDAP/LDAPS connection parameters (host name and port), bind DN, and bind password.

```
$ bin/dsconfig create-password-validator \
  --validator-name "Regular Expression" \
  --type regular-expression --set enabled:true \
  --set "match-pattern:^(\\w*(?=\w*\d)(?=\w*[a-z])(?=\w*[A-Z])\\w*$" \
  --set match-behavior:require-match
```

2. Update an existing password policy to use the regular expression password validator.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Regular Expression"
```

3. Test the regular expression password validator by submitting a password that meets the requirements.

### Note:

To meet the password requirements, make sure your password contains one number, one lowercase letter, and one uppercase letter.

Example:

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword baaA1
```

Result: The LDAP password modify operation was successful

4. Test a password that does not meet the password requirements.

Example:

The following password should fail because no uppercase letter is present.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword baaa1
```

Result:

```
Error Message: The provided new password failed the validation checks
defined in the server: The provided password is not acceptable because it
does
not match regular expression pattern '^\\w*(?=\w*\d)(?=\w*[a-z])(?=\w*[A-
Z])\w*$'
```

### Configuring the Repeated Character Password Validator

Configure the Repeated Character Password Validator with the `dsconfig` tool.

Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

Choose from:

- Set the maximum consecutive length of any character.

#### Note:

For the following example, the maximum consecutive length of any character is set to 3. The validator rejects any passwords with 4 or more consecutive characters, such as "baaaa1" or "4eeeeb", etc.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Repeated Characters" \
  --set max-consecutive-length:3
```

- Configure the validator to reject any character from a pre-defined character set that appears more than the specified number of times in a row (2).

#### Note:

You can specify more than one character set. For example, the following validator defines two characters sets: `abc` and `123`. It rejects any passwords with more than two consecutive characters from a character set, such as "aaa", "bbb", "ccc", "abc", or "123". However, a password, such as "12a3", is acceptable.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Repeated Characters" \
  --set character-set:123 --set character-set:abc
```

2. Update an existing password policy to use the Repeated Character Password Validator.

Example:

```
$ bin/dsconfig --no-prompt set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Repeated Characters"
```

3. To test the Repeated Character Validator, submit a password that has more than the maximum allowable length of consecutive characters.

Example:

For this example, the faulty password submitted is `baaa1`.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" \
  --newPassword baaa1
```

**Result:** The LDAP password modify operation failed with result code 53 Error Message: The provided new password failed the validation checks defined in the server: The provided password contained too many instances of the same character appearing consecutively. The maximum number of times the same character may appear consecutively in a password is 2

### Configuring the Similarity-Based Password Validator

Use the `dsconfig` tool to configure the Similarity-Based Password Validator.

#### Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

Example:

In this example, we set the minimum number of differences to 2.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Similarity-Based Password Validator" \
  --set min-password-difference:2
```

2. Update an existing password policy to use the Similarity-Based Password Validator.

#### Note:

The `password-change-requires-current-password` property must be set to `true` so that the password policy will ensure that the user's current password is available when that user is choosing a new password.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Similarity-Based Password Validator" \
  --set password-change-requires-current-password:true
```

3. Test the Similarity-Based Password Validator by submitting a password that has fewer than the minimum number of changes, such as 2.

#### Note:

The `ldappasswordmodify` command requires the `--currentPassword` option when testing the Similarity-Based Password Validator.

Example:

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" \
```

```
--currentPassword abcde --newPassword abcdd
```

**Result:** The LDAP password modify operation failed with result code 49.

### Configuring the Unique Characters Password Validator

Use the `dsconfig` tool to configure, update, and test the Unique Characters Password Validator.

#### Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

Example:

In this example, we set the minimum number of unique characters that a password is allowed to contain to 3.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Similarity-Based" --set min-unique-characters:3
```

2. Update an existing password policy to use the Unique Characters Password Validator.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Unique Characters"
```

3. Test the Unique Characters Password Validator by submitting a password that has fewer than the minimum number of unique characters, such as 3.

Example:

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" \
  --newPassword aaaaa
```

**Result:** The LDAP password modify operation failed with result code 53 Error Message: The provided new password failed the validation checks defined in the server: The provided password does not contain enough unique characters. The minimum number of unique characters that may appear in a user password is 3

## Managing Replication

---

PingDirectory Server provides a robust replication system to ensure high availability and fast failover in production environments.

Every server in the topology can handle write requests, with the replication component performing immediate synchronization with other members. The replicated server environment ensures that LDAP clients can seamlessly fail over to another server instance.

### Overview of replication

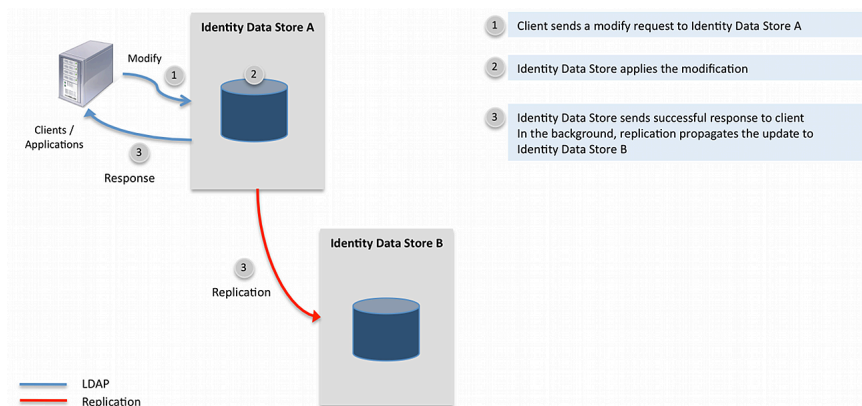

Replication is a data synchronization mechanism that ensures that updates made to a database are automatically duplicated to other servers.

Replication improves data availability when unforeseen or planned outages occur and improves search performance by allowing client requests to be distributed across multiple servers.

By default, all Directory Server instances participating in replication are writable so that LDAP clients can perform updates at any of these Directory Server instances. These updates are automatically propagated to the other servers in the background in the same order as the updates were entered. The replication

process flow is designed to immediately propagate changes to the other replicas in the topology with little or no latency.

The following figure demonstrates the basic flow of replication.

The benefits of replication can be summarized as follows:

#### High-Availability

Because the data is fully replicated on all other servers in the topology, replication allows participating servers to process all types of client requests. This mitigates any availability issues when a particular server is down due to a planned maintenance or unplanned outage. Servers that are temporarily unavailable receive updates when they become available again.

#### Improved Search Performance

Search requests can be directed to any Directory Server participating in replication, which improves search performance over systems that only access single servers.

#### Note:

Replication does not improve write throughput because updates need to be applied at all servers.

#### WAN Friendly Data Synchronization

The built-in compression feature in the replication protocol allows efficient propagation of updates over WAN links.

## Replication versus synchronization

Replication and synchronization are distinct functions from one another and are not interchangeable.

Replication is not a general purpose synchronization function because it creates replicas with exact copies of the replicated data. By contrast, synchronization can:

- Transform data between two different directory information tree (DIT) structures
- Map attribute types
- Synchronize subsets of branches and specific object classes

The differences between replication and synchronization are as follows:

#### Replication cannot synchronize between different DIT structures

The distinguished name (DN) of replicated entries must be the same on all servers. In some situations, you might want to replicate entries with the help of DN mapping that are under different base DNs, but represent the same data, for example `uid=john.doe,ou=people,o=corp` on one server could represent the same user as `uid=john.doe,ou=people,dc=example,dc=com`.

This is not supported by replication. Synchronization fully supports this feature.

Replication cannot map attribute types or transform attribute values

Some situations might require you to map attribute types or transform attribute values when synchronizing data from one server to another. Replication does not support attribute type mappings or attribute value transformations.

Replication does not support fractional replication

Replication can't be configured to replicate a subset of the attribute types from the replicated data set. Synchronization fully supports this feature.

Replication does not support sparse replication

Replication can't be configured to replicate only entries with a particular object class. Synchronization fully supports this feature.

Replication requires full control of replicated data

When two servers participate in replication, both servers implicitly trust each other using public key cryptography and apply all received updates by replication, which is considered an internal operation. While trust between servers is established between two endpoint servers, synchronization doesn't require full control of the data. Disparate server system endpoints can be synchronized, such as a PingDirectory Server and a relational database management system (RDBMS) database endpoint with each fully in control of its own data.

If replication does not meet your data synchronization requirements, consider using PingDataSync Server instead, which provides the versatility and robust performance required for most production environments.

## Replication terminology

The following terms have specific definitions as they apply to replication.

### Replication Terminology

Term	Description
Assured Replication	Data is guaranteed to replicate before the response is returned to the client. This is useful for applications that require immediate access to replicated data or require data consistency over response time.
Change Number	A 64-bit number used to consistently order replication updates across the entire topology. It is composed of 3 fields: <ul style="list-style-type: none"> <li>▪ The timestamp of the update in milliseconds since 00:00:00 UTC, January 1, 1970</li> <li>▪ The replica ID</li> <li>▪ The sequence number</li> </ul>
Conflict	Client updates made at different replicas affecting the same entry may be found in conflict when the updates are replayed at another replica. The Change Number of each update allows most of these conflicts to be resolved automatically. Certain updates, such as adding an entry with different attribute values at two servers simultaneously, result in conflicts that are flagged for manual resolution.

Term	Description
Eventual Consistency	<p>When not using assured replication, recent updates from LDAP clients are not immediately present at all servers.</p> <p>Out-of-sync data will eventually be synchronized and will be consistent on all servers. The network latency typically controls how long a given update takes to replicate.</p>
Global Administrator	<p>The administrative user with full rights to manage the replication topology.</p> <p>The user is created at the time of replication enablement between two non-replicating servers and thereafter copied to newly-enabled servers. The replication command-line utility expects the user name of the Global Administrator (by default, admin).</p> <p>The user is stored in <code>cn=Topology Admin Users, cn=Topology, cn=config</code>.</p>
Historical Data	<p>Historical Data are records of attribute value changes as a result of an LDAP Modify operation.</p> <p>Historical data are stored in the <code>ds-sync-hist</code> attribute of the target entry. This information allows replication to resolve conflicts from simultaneous LDAP Modify operations automatically.</p>
Location	<p>The collection of servers that may have similar performance characteristics when accessed from this Directory Server or reside in the same data center or city.</p> <p>A separate location setting may be defined for each data center, such as Austin, London, Chicago, and so forth. Location settings are used in the selection of the WAN Gateway server.</p>
Modify Conflict	<p>A conflict between two LDAP Modify operations.</p> <p>Modify conflicts are automatically resolved.</p>
Naming Conflict	<p>Any conflict other than Modify Conflicts.</p> <p>Naming conflicts typically include an operation that changes the DN of the target entry, creates an entry, or deletes an entry at one replica.</p>
Replica	<p>The component in the Directory Server that handles interaction with a single replication domain.</p> <p>For example, the <code>dc=example, dc=com</code> replication domain within the <code>userRoot</code> backend is a replica.</p>
Replica ID	<p>The unique identifier of a replica.</p> <p>Replica ID is automatically set in the corresponding Replication Domain configuration entry at each participating server. The replica ID identifies the source of each update in the replication topology.</p>

Term	Description
Replica State	<p>A list of the most recent change numbers of replication updates that have been applied to a replica.</p> <p>Each replica in the state can have a maximum of one change number. The Replication Server component uses the replica state to determine which updates the Replica has not yet received.</p>
Replication	<p>An automated background process that pushes directory server data changes to all other replicas.</p>
Replication Changelog	<p>A backend maintained independently by each replication server that records updates from each replica.</p> <p>This backend is distinct from the LDAP Changelog, and the two should not be confused. The main distinction is as follows:</p> <ul style="list-style-type: none"> <li>▪ The LDAP Changelog is the external changelog that clients can access. It is located at <code>&lt;server-root&gt;/db/changelog</code>.</li> <li>▪ The Replication Changelog Backend is the changelog that replication servers use. It is located at <code>&lt;server-root&gt;/changelogDB</code>, and is not accessible by clients or server extensions.</li> </ul>
Replication Domain	<p>The data configured for replication as defined by the base DN.</p> <p>Updates to entries at and below the base DN will be replicated.</p>
Replication Replay	<p>When a replica locally applies the update received via a replication server.</p>
Replication Server	<p>A component within the Directory Server process that is responsible for propagating directory server data changes to and from replicas.</p> <p>Each Directory Server instance participating in replication is also running a replication server.</p>
Replication Server ID	<p>The unique identifier of a replication server.</p> <p>The replication server ID is set automatically in its configuration object at each server in the replication topology.</p> <p>This identifier is used in the connection management code of the replication servers.</p>
Replication Server State	<p>A list of the most recent change numbers of replication updates that have been processed by a replication server.</p> <p>Each replica in the topology can have a maximum of one change number.</p> <p>The Replication Server State is used to determine which updates need to be sent to other replication servers. Similarly, the replica can use the Replication Server State to identify the set of updates to send to the replication server.</p>
Sequence Number	<p>A field in the change number that indicates the sequence of the client updates at a particular replica.</p> <p>The sequence number increases incrementally for every update at the replica. The initial value of the sequence number is 1. The number is stored as a 32-bit integer, but only positive values are used. The sequence number can roll over.</p>

Term	Description
WAN Gateway	<p>The designated replication server that assumes the WAN Gateway role within a collection of servers that are defined with identical location settings.</p> <p>Replication update messages between servers at different locations are routed through WAN gateways.</p> <p>The WAN Gateway role is assigned automatically by the protocol based on the server's WAN Gateway Priority setting. If the WAN Gateway server is down for any reason, the server with the next highest WAN Gateway Priority will dynamically assume the WAN Gateway role.</p>
WAN Gateway Priority	<p>The configuration setting that determines which replication server assumes the WAN Gateway role.</p> <p>The replication server with the highest WAN Gateway Priority in a location assumes the role of the WAN Gateway.</p> <p>Servers can have a WAN Gateway Priority value from 1 to 10, with 1 being the highest priority. A server with a WAN Gateway priority value of 0 will never be a gateway.</p>

## Replication architecture

This section introduces the major elements of replication in PingDirectory Server.

### Eventual consistency

Replication is based on an eventual-consistency model where the updates propagated through a connected network of servers will eventually be consistent on all servers over a short period of time.

In a typical update operation, a client application updates an entry or group of entries on a PingDirectory Server with an **ADD**, **DELETE**, **MODIFY**, or **MODIFY DN** operation. After processing the operation, the Directory Server returns an LDAP response while simultaneously propagating the update to the other servers in the replicated topology. This simultaneous processing model allows the client to continue submitting update requests without waiting for a replication completion response from the server.

To support this processing model, replication never locks the targeted entries at the other Directory Server instances before an update can be made locally. This means that the replicated Directory Servers might have an inconsistent view of the targeted entry for a short period of time, but will catch up as the propagated changes are applied.

The eventual-consistency model also allows clients to complete update operations faster because clients can propagate a change without having to wait for replication. The rate of update operations remains the same no matter how many Directory Servers participate in replication.

Alternatively, you can configure assured replication for specific write requests to require local or global consistency, across data center locations, before a response is returned to the client. For more information, see [Configuring assured replication](#) on page 857.

### Replicas and replication servers

Each Directory Server has an embedded replication server that is responsible for transmitting updates to other replication servers. Each replicating base distinguished name (DN), such as `cn=schema,dc=example,dc=com`, has a separate component called a replica. Each replica connects to the embedded replication server running within the Directory Server Java virtual machine (JVM) process.

When a client application updates an entry on the Directory Server, the replica sends an update message to its embedded replication server. The replication server applies the change to the `replicationChangeLog` backend repository and then sends an update message to the connected

replication server on another directory server. The replication server on other directory servers then passes the change to the appropriate replica, which in turn applies the change to its backend after performing conflict resolution.

The following figure shows the standard setup.

## Replicas and Replication Servers

1. The client or application sends a modification request to Identity Store A. The identity store applies the change.
2. The Replica backend in Identity Store A sends an update message to the Replication Server in Identity Store A.
3. The Replication Server in Identity Store A pushes the update to the Replication Server in Identity Store B.
4. The Replication Server in Identity Store B applies the update to the Replica backend in Identity Store B.

## Authentication and authorization

Directory Server uses a simple authentication model to authorize replication servers.

After it is authenticated, the remote Directory Server is fully authorized to exchange replication messages with the local Directory Server. There is no other access control in place.

Authentication in the replication protocol is based on public key cryptography using TLS client certificate authentication. The certificate used for authentication is stored in the `ads-truststore` backend of the Directory Server.

During replication setup, the command-line utility distributes public keys to all directory servers to establish trust between the Directory Servers and to enable TLS client authentication.

## Logging

The access log messages in the Directory Server indicate if the update was received by replication and includes the corresponding change number. This allows the administrator to track which Directory Server the update originated from.

## Replication deployment planning

Consider the following factors before deploying replication in a production environment:

### Minimizing Replication Conflicts

If two different clients attempt to create an entry with the same distinguished name (DN) at the same time against different servers, it's possible that both client requests will succeed. This will trigger the server to send a conflict alert. You can minimize these conflicts by understanding the client traffic

pattern beforehand. PingDirectory's Assured Replication feature and the PingDirectoryProxy Server can both assist in minimizing conflicts.

For more information, see [Configuring assured replication](#) on page 857 and [PingDirectoryProxy](#) on page 845.

### Replication Purge Delay

Adjust the default one-day replication purge delay to accommodate automatic catchup of changes when a server is offline for an extended period of time. The replication changes database, stored in `<server-root>/changelogDb`, grows larger with longer replication purge delays.

Define a minimum value for the replication purge delay. Make sure the value is consistent across all servers.

For more information, see [Modifying the replication purge delay](#) on page 869.

### Location

If your deployment incorporates multiple data regions, you should configure the directory servers with location information.

To set locations, use the `dsconfig create-location` and `dsconfig set-global-configuration-prop` commands.

The Directory Server cannot determine LAN boundaries automatically, so incorrect location settings can result in undesired WAN communication. By default, replication compresses all traffic between directory servers in different locations.

Set up the locations prior to enabling replication. The `dsreplication enable` command prompts for location information if you have forgotten to define the property.

### User-defined LDAP

Directory Servers participating in replication must have a uniform user-defined schema.

The `dsreplication` command-line utility sets up replication for the schema backend the first time replication is enabled to ensure that future schema changes are propagated to all directory servers.

### Disk space

Replication increases the disk space required for the Directory Server.

The Replication Changelog backend keeps changes from all directory servers for 24 hours by default. After this time period, also known as the purge delay, the backend is trimmed automatically.

In addition, within the `userRoot` and other local DN backends, attribute-level changes are recorded for a short period of time in the `ds-sync-hist` attribute of the entry targeted by an LDAP Modify operation. This attribute is used to resolve all conflicts resulting from LDAP Modify operations automatically.

The disk space impact of replication is dependent on the rate and size of changes in the replication topology and the Replication Changelog purge delay.

### Memory

Replicated directory server instances require slightly more memory than a standalone directory server.

All of the items discussed in [Disk space](#) have an impact on the amount of memory the Directory Server is using. The additional replication overhead is typically less than 5%.

### Time synchronization

Even though replication has a built-in mechanism to compensate for the potential clock skew between hosts, you should keep system clocks in sync within the deployment.

## Communication ports

The replication server component in each directory server listens on a TCP/IP port for replication communication.

This replication server port, typically 8989, must be accessible from all directory servers participating in replication. The server-to-server communication channel is kept alive using a heartbeat, which occurs every 10 seconds. This traffic prevents firewalls from closing connections prematurely.

The replication command-line utility (`dsreplication`) requires access to all directory servers participating in replication. This includes the LDAP or LDAPS port of the directory servers.

### Tip:

When configuring firewalls, keep these communication requirements in mind.

## Hardware load balancers

Replication allows write operations to be directed to any directory server in the topology. Distributing write operations in a round-robin fashion could introduce conflicts. In particular, distributing a series of LDAP `add`, `delete`, and `modify` DN operations targeting the same distinguished name (DN) in quick succession can cause conflicts that require manual intervention.

The Assured Replication feature can help prevent conflicts created by the same client application. For more information, see [Configuring assured replication](#) on page 857.

Consider using server affinity with the load balancer that either associates a client IP address or a client connection with a single directory server instance at a time.

For load balancing LDAP traffic, consider using the PingDirectoryProxy Server. The Server Affinity feature in PingDirectoryProxy Server enables replication-friendly load balancing. For more information, see [Configuring server affinity](#) on page 1272.

## PingDirectoryProxy

To facilitate replication-friendly load balancing, consider using PingDirectoryProxy Server in every replication deployment.

Directory Proxy Server can automatically adapt to conditions in backend directory servers using health checks and route traffic accordingly.

For example, Directory Proxy Server can re-route traffic from directory servers with a large backlog of replication updates.

## Displaying the server information for a replication deployment

### Steps

- To display the server information for a replication deployment, run the `dsreplication status` command with the `--displayServerTable` option.

```
$ bin/dsreplication status --displayServerTable
```

### Result:

```

--- Replication Status for dc=example,dc=com: ---
Server                                     : Location : Priority (1) : Status
-----
austin-01.example.com:8989                : US       : 1 (*)       : Available
austin-02.example.com:8989                : US       : 2           : Available
london-01.example.com:8989                : UK       : 5           : Available
london-02.example.com:8989                : UK       : 5 (*)       : Available
sydney-01.example.com:8989                : AU       : 5 (*)       : Available

```

```

sydney-02.example.com:8989      : AU      : 5      : Available

[1] WAN Gateway Priority. WAN gateways are marked with a *. To minimize
WAN utilization, the server with the WAN Gateway role is the only server
in a location that exchanges updates with remote locations.

--- Replication Status for dc=example,dc=com: Enabled ---
Server                          : Location : Entries : Conflict Entries :
Backlog : Recent Change Rate
-----:-----:-----:-----:-----:

30     : 332

```

## Displaying all status information for a replication deployment

### Steps

- To display the status information for a replication deployment, run the **dsreplication status** command with the **--showAll** option.

You can also use the **--showAll** option together with the **--displayServerTable** option to see the server table information for the replication topology.

## Enabling replication

Enabling replication between multiple directory servers ensures that changes within the replicated base distinguished name (DN) are automatically propagated to all other directory servers in the topology.

Configuration changes are not replicated by default but can be through the use of server groups. Each directory server should be configured according to the deployment design.

### Overview

To interface with the replication topology, Directory Server provides a command-line utility, **dsreplication**, that should be used to manage and monitor replication.

The cluster name for an instance should be set to a unique name during install. The cluster-name controls a handle of configuration settings that are used cluster-wide; any changes to the configuration will always get pushed out to other members of the topology. If the cluster-name is set to a unique name for each server, any change to the configuration via the **dsconfig** command or the console needs to be done on every server in the topology. In a devops model, it is recommended that the cluster name be unique so that everything can be managed with server profiles. If you are doing an on-premise install, you may want to use a common cluster-name across the topology.

#### Note:

You should set a cluster name for the topology if you want cluster-wide settings to propagate across the topology in a single action.

Replication setup involves the following basic steps:

- Set up the servers.

This is the basic installation step to set up a Directory Server instance.

- Import or restore data to one server.

After setting up the servers, at least one server should have the target data loaded through `import-ldif` or `restore`.

- Enable replication between the servers.

Using the `dsreplication` tool, enable replication for each server to be included in the replication topology. The `dsreplication enable` subcommand should be run N - 1 times for a topology of N servers. For more information, see [Command Line Interface](#).

- Initialize data from source server to all servers in the topology.

Run the `dsreplication initialize` subcommand for every target server that needs a copy of the data from the source server.

- Verify the replication topology.

Check the replication status after configuring the topology using the `dsreplication status` tool.

### Command-line interface

Replication topologies are configured and maintained using the `dsreplication` command-line utility, which supports interactive and non-interactive modes. If you are running the server for the first time, use the `dsreplication` tool in interactive mode.

The `dsreplication` tool uses the following format, including some important subcommands listed in the section [The dsreplication Command-Line Utility](#).

```
dsreplication {subcommand} {connection parameters}
```

The `dsreplication` tool keeps a history of invocations in the `logs/tools/dsreplication.history` file and keeps a log of up to 10 `dsreplication` sessions in the `logs/tools` directory.

### What happens when you enable replication

The `dsreplication enable` subcommand is used to set up replication. The `enable` subcommand carries out the following functions:

- If it does not already exist, the global administrator user is created. The global administrator user has all the rights and privileges to update replication-related configuration objects. Most `dsreplication` subcommands require the global administrator.
- The server instances are registered in the `cn=topology,cn=config` tree. The registration includes basic host name, port information, and the public key used during the replication authentication process.

If both servers are already participating in replication, the `cn=topology,cn=config` is merged to retain the server information from existing topologies.

- The embedded replication server is enabled. Servers already in replication see their replication server configuration updated with the information of the new replication server.
- A replication domain is created for the requested base distinguished names (DNs). If the first base DN is enabled, the replication domains for two additional base DN are also enabled: `cn=topology,cn=config` and `cn=schema`.
- Initialization for the `cn=schema` base DN is executed. This ensures that a uniform schema is present in the replication topology.
- Initialization must be performed for the enabled base DN.

**Important:**

The `dsreplication enable` subcommand removes all existing topology administrative users except for the default `uid=admin` that is provided to enable replication. Administrative users must be re-added after enabling replication.

## Initialization

Replica initialization transfers a copy of the backend containing the replication domain to a target server. You should perform this after replication is enabled with the `dsreplication initialize` subcommand. There is no impact on the source server during this process.

### Note:

When enabling or initializing servers, the `--topologyFilePath` option can be used with `dsreplication` to specify a file with a series of hosts and ports available in the topology that can be used as source servers.

This option is used in place of specifying `host 1, port 1`. When the `hosts` file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available for replication. This file is generated with the `manage-topology export` command.

## `dsreplication initialize`

The recommended approach for replica initialization. The `dsreplication initialize` subcommand performs the most efficient copy of data needed to initialize one or more replicas on a target server. Existing data on the target server replica is lost and the backend containing the base DN is taken offline on the target server during the initialization.

### Binary copy

The database copy method involves copying database backup files from the source directory server to one or more target servers. The Directory Server provides tools necessary for backing up and restoring backends. Using `server-root/bin/backup`, create a backup of the backend containing the replicated base DN. The backup files must then be transferred to the target servers and restored individually with `server-root/bin/restore`. There are additional considerations when using database copy as the means to initialize a target replica:

- If encryption is enabled on the servers, then a database `bin/encryption-settings export` followed by `bin/encryption-settings import` must be performed on the `encryption-settings` backend.
- When using database copy to initialize a server that has been offline longer than the replication purge delay, the database copy of the `replicationChanges`, `schema`, and `adminRoot` backends are required.

### Import/export LDIF

The import/export LDIF method is the most flexible approach, as it works well in environments where target replicas are configured differently than the backend containing the data (for example, the target replica has different indexes than the source server). The process involves exporting the backend data as LDIF from the source server and importing the LDIF into the target servers. Replicas can be initialized locally while the server is offline or online through remote access. For more information, see [Importing and exporting data](#) on page 571.

## Replica generation ID

Each replica has a generation ID, which is an integer that summarizes the replica. It provides replication with a quick and simple means of determining if two replicas contain the same data. Two replicas containing the same data have the same generation ID.

When replication is operating correctly, all of the replicas for each replicated base DN have the same generation ID. The generation ID is stored on each replica as the operational attribute `ds-sync-generation-id`, as in the following example.

```
ldapsearch -b 'dc=example,dc=com' -s base '(&)' ds-sync-generation-id
dn: dc=example,dc=com
ds-sync-generation-id: 2058329333
```

When the server starts, or when replication is enabled, the generation ID is computed for each affected replica that does not already have a generation ID stored as `ds-sync-generation-id`. The following is used to calculate the generation ID:

- The total number of entries in the replica. This is referred to as the count.
- The first 1000 entries in the replica are converted to normalized LDIF, referred to as the LDIF. Normalized LDIF only includes attributes `objectclass`, `sn`, `cn`, and `ds-entry-unique-id` and uses OIDs in place of attribute names.
- The Adler-32 checksum is calculated with the string produced by concatenating the count and the LDIF as input. This Adler-32 checksum is the generation ID.
- The generation ID is stored on the base DN as `ds-sync-generation-id`. This ensures that the ID does not need to be computed the next time the replica is loaded.

## Deploying a basic replication topology

Set up a two-server replication topology.

About this task

The example uses the LDAP and replication server ports 1389 and 8989, respectively.

### Replica Ports

Host Name	LDAP Port	Replication Port
server1.example.com	1389	8989
server2.example.com	1389	8989

### Steps

1. Install the first directory server with 2000 sample entries.

Example:

```
$ ./setup --cli --acceptLicense \  
--baseDN "dc=example,dc=com" --ldapPort 1389 \  
--rootUserPassword pass \  
--sampleData 10000 --no-prompt
```

2. Install the second directory server either on a separate host or the same host as the first, but with a different LDAP port.

Example:

```
$ ./setup --cli --acceptLicense --baseDN "dc=example,dc=com" \  
--ldapPort 1389 \ --rootUserPassword pass --no-prompt
```

3. To configure a replication topology, from the first server, run the `bin/dsreplication` command in interactive mode.

Example:

```
$ bin/dsreplication
```

4. From the Replication Main Menu, **select** Manage the topology.

Example:

```
>>>> Replication Main Menu

What do you want to do?

    1) Display replication status
    2) Manage the topology (add and remove servers)
    3) Initialize replica data over the network
    4) Initialize replica data manually
    5) Replace existing data on all servers

    q) quit

Enter choice: 2
```

5. From the Manage Replication Topology menu, **select** Enable Replication.

Example:

```
>>>> Manage Replication Topology

Select an operation for more information.

    1) Enable Replication -- add or re-attach a server to the topology
    2) Disable Replication -- permanently remove a running replica from
the topology
    3) Remove Defunct Server -- permanently remove an unavailable server
from the
        topology
    4) Cleanup Server -- remove replication artifacts from an offline,
local server
        (allowing it to be re-added to a topology)

    b) back
    q) quit

Enter choice [b]: 1
```

6. From the Enable Replication menu, read the setup introduction. To continue the enable process, enter `c`.

7. Enter the LDAP connection parameters for the first of the two server replicas that you are configuring.
  - a. Enter the host name or IP address of the server.
  - b. Enter the type of LDAP connection to the server.

Choose from:

- LDAP
  - LDAP with SSL
  - LDAP with StartTLS
- c. Enter the LDAP listener port for the server.

**Note:**

If you are a root user, you see port 389 as the default. Others see port 1389.

- d. Authenticate as a root distinguished name (DN), such as **cn=Directory Manager**.

**Note:**

Later in the process, you are prompted to set up a global administrator and password. The global administrator is the user ID that manages the replication topology group.

8. Repeat steps 7a-7d for the second server replica.
9. When the **dsreplication** tool checks for the base DN on both servers, press enter to select the default base DN.

**Note:**

To enable replication, data must be present on at least one of the servers.

Example:

```
Choose one or more available base DNs for which to enable replication:
```

```
1) dc=example,dc=com
```

```
c) cancel
```

```
Enter one or more choices separated by commas [1]:
```

**Note:**

If you see the following message, in most cases, a base DN was not set up on one of the directory servers, or the backend is disabled.

```
There are no base DNs available to enable replication between the two servers.
```

10. When you are prompted to set up entry balancing using the Directory Proxy Server, press enter to accept the default value.

**Note:**

For more information, see the PingDirectoryProxy Server Administration Guide.

**Example:**

```
Do you plan to configure entry balancing using the Directory Proxy
Server? (yes / no) [no]:
```

11. Enter the replication port for the first replica.

**Note:**

The default replication port is 8989.

The port you enter must be free.

12. If you are prompted to enter a location, press enter to accept the default and set up a location for the first server. Enter the name of the server's location.

**Note:**

You are prompted for the location if you did not pre-define a location setting for the server.

**Example:**

```
The first server has not been configured with a location.
Assigning a location to each server in the replication topology reduces
network traffic in multi-site deployments. Would you like to set the
location in the first server? (yes / no) [yes]
```

```
The location of the first server: Austin
```

13. Repeat steps 9-12 for the second directory server.

**Note:**

If you did not pre-define a location setting for the second server, you are prompted to enter location information for the server.

14. Set up the global administrator user ID and a password for this account.

**Note:**

The default global administrator user ID is `admin`.

The global administrator user ID manages the directory servers used in the replication topology.

**Example:**

```
Specify the user ID of the global administrator account
that will be used to manage the Ping Identity
Directory Server
instances to be replicated [admin]:
```

```
Password for the global administrator:
Confirm Password:
```

15. Return to the Replication Main Menu and enter the number corresponding to initializing data over the network.
16. To initialize data on a single server, from the Initialize Replica Data over the Network menu, select Initialize, and enter `c` to continue.
17. To specify a server in the replication topology, enter the following information for the first server:
  - Host name or IP address
  - LDAP connection type
  - LDAP port
  - Global admin user ID and password
18. Select the source server that is hosting the data to which the target server will be initialized. For this example, select the first server, since the sample dataset has been loaded onto this server.
19. Select the base DN to initialize.

**Note:**

In most cases, the base DN for the root suffix is replicated. In this example, `dc=example,dc=com`.

20. Select the second server to have its data initialized, and enter the global admin user ID and password for the target server.

**Note:**

Any data present on the target server is over-written.

21. To confirm that you want to initialize data on the target server, press enter.

Example:

```
Initializing the contents of a base DN removes all the existing contents
of
that base DN. Do you want to remove the contents of the selected base DN's
on server
server2.example.com:1389 and replace them with the contents of server
server1.example.com:1389? (yes / no) [yes]:
```

**Result:** The server displays a Base DN initialized successfully message.

22. On the Initialize Replica Data Over Network menu, enter `b` to back out one level to the main menu.
23. To view the replication status, on the Replication Main Menu, enter the host name or IP address.

Example:

```
--- Replication Servers: dc=example,dc=com ---
Server          : Location : Conflict Entries : Backlog : Recent
Change Rate
-----
ds1 (example.com:1389) : austin : 0                : 0       : 0
ds2 (example.com:1389) : austin : 0                : 0       : 0
```

## Example deployment with non-interactive dsreplication

The following example creates a 4-server topology spanning two data centers.

In the example, the four servers are already installed and have locations Austin and Budapest defined.

### Note:

When enabling or initializing servers, the `--topologyFilePath` option can be used with `dsreplication` to specify a file with a series of hosts and ports available in the topology that can be used as source servers. This option is used in place of specifying `host 1, port 1`.

When the hosts file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available for replication. This file is generated with the `manage-topology export` command.

## Deploying with non-interactive dsreplication

### Steps

1. To generate the sample data on the first server, use the `make-ldif` tool.

Example:

```
$ bin/make-ldif --templateFile config/MakeLDIF/example-10K.template \
  --ldifFile ldif/10K.ldif
```

2. To import the data, select a server from which to import data and to be the source for future initialization to other servers, and then follow the import steps.
  - a. Stop the server.
  - b. To import the sample LDIF to the server, run `import-ldif`.
  - c. Start the server.

Example:

```
$ bin/stop-server
$ bin/import-ldif --backendID userRoot --ldifFile ldif/10K.ldif
$ bin/start-server
```

3. To enable replication, select a specific server and run `dsreplication enable` three times.

### Note:

For the first invocation, create the replication topology administrator with the name `admin`.

Example:

```
$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 austin02.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt

$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 budapest01.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
```

```

--adminPassword password --no-prompt

$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
--bindDN1 "cn=Directory Manager" --bindPassword1 password \
--replicationPort1 8989 --host2 budapest02.example.com --port2 1389 \
--bindDN2 "cn=Directory Manager" --bindPassword2 password \
--replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
--adminPassword password --no-prompt

```

4. To initialize the other servers, the `dc=example,dc=com` replicas, from the server you imported the data into with `import-ldif`, run `dsreplication initialize`.

Example:

For this example, initialize `budapest02` from `budapest01` to minimize the WAN transfers.

```

$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
--hostDestination austin02.example.com --portDestination 1389 \
--adminUID admin --adminPassword password --baseDN dc=example,dc=com --
no-prompt

$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
--hostDestination budapest01.example.com --portDestination 1389 \
--adminUID admin --adminPassword password --baseDN dc=example,dc=com --
no-prompt

$ bin/dsreplication initialize --hostSource budapest01.example.com --
portSource 1389 \
--hostDestination budapest02.example.com --portDestination 1389 \
--adminUID admin --adminPassword password --baseDN dc=example,dc=com --
no-prompt

```

5. To view the replication state, run `dsreplication status`.

Example:

```

$ bin/dsreplication status --adminPassword password --no-prompt --
displayServerTable --showAll

```

## Using dsreplication with SASL GSSAPI (Kerberos)

Before you begin

This example procedure assumes that you have configured SASL GSSAPI on all servers in the replication topology and that they are working properly.

About this task

Directory Server's utilities all support SASL GSSAPI options for systems using Kerberos as its main authentication mechanism. The following procedure shows how to use `dsreplication` with SASL GSSAPI to set up a new `replication.admin` identity while enabling replication on a server.

### Note:

A separate Kerberos identity is required to manage replication. Existing Kerberos credentials can be used to interact with the server when enabling replication and creating the new identity.

The new identity, such as `replication.admin`, must not exist as the `cn` or `uid` value under any public base distinguished name (DN).

## Steps

1. To set the LDAP Connection Handler to explicitly listen on the server's host name address, run **dsconfig** with the `set-connection-handler-prop` option.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --remove listen-address:0.0.0.0 --add listen-address:host.example.com
```

2. To update the identity mapper to have `cn=topology,cn=config` included in the list of base DNs and to add the `cn` attribute to match attributes, run **dsconfig** with the `set-identity-mapper-prop` option.

### Note:

You must do this to map the admin account to the Kerberos realm.

Example:

```
$ bin/dsconfig set-identity-mapper-prop \
  --mapper-name "Regular Expression" \
  --add match-attribute:cn \
  --set "match-base-dn:cn=topology,cn=config" \
  --set match-base-dn:dc=example,dc=com
```

3. To invoke replication enable, authenticate as the existing Kerberos `authid`, and then run **dsreplication enable**.

### Note:

No bind DNs and passwords are required to authenticate because you are using SASL binding. However, the new replication admin user requires a password at creation time, and you should use a strong random password. After SASL is working, you no longer have to provide this random password.

You must use the ticket cache, so make sure you have properly authenticated as `ds.admin` from your local host and the ticket is not expired in the cache.

Example:

```
$ kinit -p ds.admin
$ bin/dsreplication enable \
  --host1 server1.example.com --port1 1389 --replicationPort1 1989 \
  --host2 server2.example.com --port2 2389 --replicationPort2 2989 \
  --baseDN dc=example,dc=com \
  --adminUID replication.admin --adminPassword strongPassword \
  --saslOption1 mech=gssapi --saslOption1 authid=ds.admin@EXAMPLE.COM \
  --saslOption1 useTicketCache=true --saslOption1 requireCache=true \
  --saslOption2 mech=gssapi --saslOption2 authid=ds.admin@EXAMPLE.COM \
  --saslOption2 useTicketCache=true --saslOption2 requireCache=true
```

4. To initialize data on the remote server, run **dsreplication initialize**.

Example:

```
$ kinit -p replication.admin
$ bin/dsreplication initialize \
  --hostSource server1.example.com --portSource 1389 \
  --hostDestination server2.example.com --portDestination 2389 \
  --baseDN dc=example,dc=com \
```

```
--saslOption mech=GSSAPI \  
--saslOption authID=replication.admin@EXAMPLE.COM \  
--no-prompt
```

5. To delete the temporary `userPassword` from the `replication.admin` entry, create an LDIF file.  
Example:

In this example, the file is named `remove-password.ldif` and contains the following.

```
dn: cn=replication.admin,cn=Administrators,cn=topology,cn=config  
changetype: modify  
delete: userPassword
```

6. To apply the modifications, use the `ldapmodify` tool.

Example:

```
$ ./ldapmodify --filename remove-password.ldif -o mech=GSSAPI  
-o authid=replication.admin@example.com \  
--saslOption useTicketCache=true \  
--hostname host.example.com --port 1389 \  
--noPropertiesFile
```

7. To check the topology's status, run `dsreplication status`.

#### Note:

After the admin account and mappers are created, you can use the `--saslOption useTicketCache=true` and `--saslOption requireCache=true` properties instead of a password for all `dsreplication` commands.

Example:

```
$ bin/dsreplication status \  
--saslOption mech=gssapi \  
--saslOption authid=replication.admin@EXAMPLE.COM \  
--saslOption useTicketCache=true --saslOption requireCache=true \  
--hostname host.example.com --port 1389 \  
--no-prompt
```

## Configuring assured replication

PingDirectory Server's replication mechanism is based on the eventual-consistency model, which is a loosely-connected topology that propagates updates to other servers without waiting for their corresponding replication response messages.

There is a small window of time where updates are not all present on the replicas while the changes are replicating through the system. However, there are deployments that require immediate access to replicated data. In such cases, administrators can configure assured replication, which ensures that replication has completed before the update response is returned to the client.

From the LDAP client's perspective, assured replication has no bearing on the result code of the operation, just on the time in which it takes to receive the response for those requests in which replication assurance is applied. Detailed information regarding assurance processing is available to an LDAP client with awareness of the assured replication control.

The assured replication mechanism uses server location to distinguish between local and remote servers to allow different policies to apply. For example, a common assurance approach is to respond to a client update after all servers in the same location have applied the update and one or more servers in remote locations have received the update. The level of assurance applied to each operation can be explicitly

requested by the client, specified by the server configuration using the Replication Assurance Policy, or both.

Assured replication is supported by client requests directly to PingDirectory Server, through a PingDirectoryProxy Server, or both.

### About the Replication Assurance Policy

Assured replication uses a Replication Assurance Policy to define the properties needed to ensure that replication has completed before the update response is returned to the client. Multiple policies can be defined, but only one policy is matched with a client update request. Each policy contains an evaluation order index that, together with an optional request and connection criteria, provides flexibility in matching a policy to request.

The Replication Assurance Policy defines local and remote assurance levels. A level defines how rigorous the policy should be when waiting for propagation of updates while local and remote distinguish servers in the same location versus servers in remote locations. Although optional, you should associate request or connection criteria with a policy to apply replication assurance appropriately.

Directory Server contains a default Replication Assurance Policy that is enabled with the local-level processed-all-servers assurance level. In addition to using the Default Replication Assurance Policy, any number of policies can be created and enabled. When a client request is received, the server iterates through the list of enabled policies according to each policy's `evaluation-order-index` property. A smaller `evaluation-order-index` value (such as 1) has precedence over policies with larger `evaluation-order-index` values (such as 2, 3, 4, and so forth). The `evaluation-order-index` values do not need to be contiguous. The first policy that matches a request is associated with the operation.

The Replication Assurance Policy, which is defined on the PingDirectory Server and not on the PingDirectoryProxy Server, has the following properties:

#### `evaluation-order-index`

Determines the evaluation order among multiple Replication Assurance Policies that match against an operation. The smaller value has precedence.

#### `local-level`

Specifies the assurance level used to replicate to local servers. A local server is defined as a server with the same `location` property value as set in the global configuration. The `local-level` property must be set to an assurance level as strict as the `remote-level` property. For example, if the `remote-level` is set to `processed-all-remote-locations`, then the `local-level` property must be `processed-all-servers`.

#### None

Replication to any local server is not assured.

#### `received-any-server`

At least one available local server must receive a replication update before a response is sent to the client.

#### `processed-all-servers`

All available local servers must complete replay of the replication update before the response is sent to the client. If a singular server is enabled, or only one server is available for a particular location, `processed-all-servers` returns a value of `false`.

#### `remote-level`

Specifies the assurance level used to replicate to remote servers. A remote server is defined as a server that has a different `location` property value as set in the global configuration.

None

Replication to any remote server is not assured.

received-any-remote-location

At least one server at any available remote location must receive a replication update before a response is sent to the client.

received-all-remote-locations

All available remote servers must receive a replication update before the response is sent to the client.

processed-all-remote-servers

All available servers at all locations must complete replay of the replication update before the response is sent to the client. If a single server is enabled, or only one server is available for a particular location, `processed-all-remote-servers` returns a value of `false`.

timeout

Specifies the maximum length of time to wait for the replication assurance requirements to be met before timeout and replying to the client.

connection-criteria

Specifies connection criteria used to indicate which operations from clients matching this criteria use this policy. If both connection criteria and request criteria are specified for a policy, then both must match an operation for the policy to be assigned.

request-criteria

Specifies request criteria used to indicate which operations from clients matching this criteria use this policy. If both connection criteria and a request criteria are specified for a policy, then both must match an operation for the policy to be assigned.

Servers in a replication topology are not required to share a homogeneous set of policies. You can configure the Replication Assurance Policies differently on the replicas in a topology. For example, if you configure server A to match add operations to a `processed-all-servers` assurance level, and server B to match add operations to a local `received-any-server` level, then add operations received on server A have the assurance level of `processed-all-servers` and add operations received on server B have the assurance level of `received-any-server`.

For more information, see the PingDirectory Server Configuration Reference Guide.

### About assured replication

When implementing assured replication, make note of the following.

Item	Description
Client Controls	<p>The client can include an assured replication request control with each operation. This control allows the client to specify bounds on assurance levels, override the timeout assigned by the matching replication assurance policy for the associated operation, or both. The server always honors these request controls.</p> <p>For more information, see <a href="#">About the Assured Replication Controls</a>.</p>

Item	Description
Directory Proxy Server	Replication assurance policies are not supported on PingDirectoryProxy Server. Replication client controls are passed through to the underlying Directory Server backend.
Schema backend Replication	The schema backend is not supported by assured replication. Replication assurance policies that include criteria to match this backend are rejected.
Backward Compatibility	Server versions that support assured replication are backwards-compatible with prior versions that do not support assured replication.
WAN-Friendly Replication	Assured replication functions independently from WAN-Friendly Replication and the notion of WAN Gateways.
Global Configuration Properties	<p>Directory Server provides two configurable global configuration properties that determine the timing of the assurance source and maximum number of replication backup updates recognized as an available source.</p> <p><code>replication-assurance-source-timeout-suspend-duration</code></p> <p>Specifies the amount of time a replication assurance source is suspended from assurance requirements if it experiences an assurance timeout. While suspended, the source is excluded from assurance requirements for all operations originating on this Directory Server. This avoids the situation of repeated timeouts caused by degraded or offline servers. The default time is 10 seconds.</p> <p><code>replication-assurance-source-backlog-fast-start-threshold</code></p> <p>Specifies the maximum number of replication backlog updates a replication assurance source can have and be immediately recognized as an available source. If a source connects to this server with more than the configured threshold backlog updates, it is excluded from assurance requirements for all operations originating from this Directory Server until it completes at least one assurance successfully, indicated by this Directory Server receiving an update acknowledgment message from it within the timeout window. The default maximum number of updates is 1000.</p>

## Configuring assured replication

### About this task

It is common for all servers to have the same policy. The following example, which demonstrates the configuration of various assured replication policies, assumes that three servers are configured on localhost, on ports 1389, 2389, and 3389.

#### Note:

In this example, each server has a default Replication Assurance Policy with no assurance levels set.

### Steps

1. To create request criteria for add operations on server 1, run **dsconfig** with the `create-request-criteria` option.

#### Note:

This request criteria is used to match any add operation with the Replication Assurance Policy that is configured in the following step.

#### Example:

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Adds \
  --type simple \
  --set operation-type:add
```

2. To make all add operations assured with a level of `processed-all-servers` on server 1, set up the Replication Assurance Policy using **dsconfig** and specify the `Adds` request criteria configured in the previous step.

#### Note:

The `processed-all-servers` level indicates that all local servers in the topology must complete replay of the replication update before the response is sent to the client.

#### Example:

```
$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Adds Processed All Locally" \
  --set evaluation-order-index:1 \
  --set local-level:processed-all-servers \
  --set "timeout:500ms" \
  --set request-criteria:Adds
```

- On server 1, repeat steps 1-2 for `modify` operations.

**Note:**

The Replication Assurance Policy `Mods Received Any Locally` ensures that at least one available local server must receive a replication modify update before a response is sent to the client.

**Example:**

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Mods \
  --type simple \
  --set operation-type:modify

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Mods Received Any Locally" \
  --set evaluation-order-index:2 \
  --set local-level:received-any-server \
  --set "timeout:500ms" \
  --set request-criteria:Mods
```

- To set up the `Adds` and `Mods` request criteria and a Replication Assurance Policy on server 2, repeat steps 1-3.

**Example:**

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Adds \
  --type simple \
  --set operation-type:add

$ bin/dsconfig create-request-criteria \
  --criteria-name Mods \
  --type simple \
  --set operation-type:modify

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Adds Received Any Locally" \
  --set evaluation-order-index:1 \
  --set local-level:received-any-server \
  --set "timeout:500ms" \
  --set request-criteria:Adds

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Mods Processed All Locally" \
  --set evaluation-order-index:2 \
  --set local-level:processed-all-servers \
  --set "timeout:500ms" \
  --set request-criteria:Mods
```

**Note:**

Leave server 3 with the default Replication Assurance Policy configured with no assurance levels or criteria. In practice, it is common for all servers to have the same assurance levels or criteria.

- To list the policies on server 1 to confirm that they exist, run `dsconfig` with the `list-replication-assurance-policies` option.

Example:

```
$ bin/dsconfig list-replication-assurance-policies
```

- Repeat step 5 for server 2 and server 3.

Server 3 should only show the Default Replication Assurance Policy.

- To check the Replication Assurance counters on all servers before any add or modify operation, use `ldapsearch`.

**Note:**

The counters should be set to zero. These counters are on the replica server where the policy is matched and assigned.

Example:

For this example, on server 1, run the following command.

```
$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-local-completed-normally: 0
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

- To check the Replication Summary table on all of the servers, use `ldapsearch`.

Example:

For this example, on server 1, run the following command.

```
$ bin/ldapsearch --baseDN "cn=Replication Summary
dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 0
replication-assurance-local-completed-normally: 0
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

- To add an entry to server 1 on Directory Server, use `ldapmodify`.

The counters should match the newly added entry to the `Adds Processed All Locally` policy and complete assured.

Example:

```
$ bin/ldapmodify --filename add-user.ldif --defaultAdd

$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 1
replication-assurance-local-completed-normally: 1
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
replication-assurance-policy-matches: Adds Processed All Locally: 1
replication-assurance-policy-matches: Default Replication Assurance
  Policy: 0
replication-assurance-policy-matches: Mods Received Any Locally: 0
replication-assurance-local-level-uses: processed-all-servers: 1
replication-assurance-remote-level-uses: none: 1

$ bin/ldapsearch --baseDN "cn=Replication Summary
  dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 1
replication-assurance-local-completed-normally: 1
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

- Perform a modify of an entry under `dc=example,dc=com` on server 1.

The counters should match the `modify` operation to the `Mods Processed All Locally` policy and the operations should complete assured.

Example:

```
$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 2
replication-assurance-local-completed-normally: 2
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
```

```

replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
replication-assurance-policy-matches: Adds Processed All Locally: 1
replication-assurance-policy-matches: Default Replication Assurance
  Policy: 0
replication-assurance-policy-matches: Mods Received Any Locally: 1
replication-assurance-local-level-uses: processed-all-servers: 1
replication-assurance-local-level-uses: received-any-server: 1
replication-assurance-remote-level-uses: none: 2

$ bin/ldapsearch --baseDN "cn=Replication Summary
  dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 2
replication-assurance-local-completed-normally: 2
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0

```

Result: You have successfully configured Assured Replication.

### About the assured replication controls

The LDAP SDK for Java provides an implementation of an LDAP control that can be included in `add`, `bind`, `modify`, `modifyDN`, and certain extended requests to indicate the optimal level of replication assurance for the associated operation. The OID for this control is 1.3.6.1.4.1.30221.2.5.28 and can have a criticality of either `TRUE` or `FALSE`.

For more information, see the LDAP SDK Javadoc for the `AssuredReplicationRequestControl` class.

## Managing the topology

The following sections describe common topology management operations.

When enabling or disabling replication within a topology that contains multiple product versions, you must run the `dsreplication` tool from the server root location of a member of the topology that has the oldest product version.

### Adding a server to the topology

Before you begin

You must:

- Have an existing directory server topology.
- Ensure that more than 50% of servers in the topology and the new server are online.

About this task

The commands are identical for initial enablement between two servers where one server contains data for the replication domain stored in the `userRoot` backend. If database encryption is being used on the servers in the topology, the server being initialized must have a copy of the `encryption-settings` backend from the source server.

## Steps

1. To enable replication for the base distinguished name (DN), or base DNs, run **dsreplication enable** using an existing server as **host1** and the new server as **host2**.

Example:

```
$ bin/dsreplication enable \
  --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 austin03.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt
```

2. Optional: To compare the configurations between the two hosts used in the **dsreplication enable** command, run **config-diff**.

### Note:

Ensure settings are consistent across the topology and are also consistent with the new system.

Example:

```
$ bin/config-diff --sourceLocal \
  --targetHost austin03.example.com \
  --targetBindDN "cn=directory manager" \
  --targetBindPassword pass --targetPort 1389
```

## Disabling replication and removing a server from the topology

Before you begin

More than 50% of the servers not being removed from the topology must be online during the process.

About this task

When removing a server from the topology, the remaining servers need to be made aware of the change. If additional servers are offline and cannot be online while removing the server, you must distinguish between offline servers that are offline permanently and those that are offline temporarily.

### Note:

If servers are offline permanently, use **remove-defunct-server** to remove them. If servers are offline temporarily, they update automatically after they are online.

## Steps

1. To remove a server from the topology:

Choose from:

- To remove a server that is online, run **dsreplication disable** from any server.

```
$ bin/dsreplication disable --hostname austin03.example.com --port
1389 \
  --baseDN dc=example,dc=com --adminUID admin --adminPassword password \
```

```
--no-prompt
```

 **Note:**

If the server to remove is online, only one invocation of **dsreplication disable** is necessary.

- To remove a server that is offline, run **remove-defunct-server** in the following locations:
  - a. From any server not being removed from the topology
  - b. On the offline server to be removed

```
$ bin/remove-defunct-server --serverInstanceName austin01 \
--bindDN "cn=Directory Manager" --bindPassword password
```

 **Tip:**

To speed up the process of removing multiple servers, change the default 10-minute timeout for each server you are taking out of rotation by setting the Java virtual machine (JVM) property `com.unboundid.connectionutils.LdapResponseTimeoutMillis` before you run **remove-defunct-server**.

2. To remove any topology references, run the **remove-defunct-server** tool on each server that is removed from the topology.

Example:

```
$ bin/remove-defunct-server --no-prompt
```

 **Note:**

The `--ignore-online` option removes an online server cleanly from the topology.

## Replacing the data for a replicating domain

About this task

In case the data for the entire replication domain, such as the backend, needs to be replaced, perform the following steps:

Steps

1. With all servers online, run **dsreplication pre-external-initialization** against any server in the topology.

Example:

```
$ bin/dsreplication pre-external-initialization --hostname
austin01.example.com \
--port 1389 --baseDN dc=example,dc=com --adminUID admin \
--adminPassword password --no-prompt
```

Result: Replication is stopped for the domain. No writes are made by clients to any of the servers.

2. To replace the data for `dc=example,dc=com`, use `import-ldif`.
  - a. Optional: To overwrite the existing data for the domain, use the `--overwriteExistingEntries` option.
  - b. Optional: To ensure that the input LDIF is free of any replication attributes, use the `--excludeReplication` option.

Example:

In this example, you perform the `import-ldif` with the server offline using the `--excludeReplication` and `--overwriteExistingEntries` options.

```
$ bin/import-ldif --ldifFile new-data.ldif --backendID userRoot --
excludeReplication --overwriteExistingEntries
```

3. To initialize the other servers in the topology, run `dsreplication initialize` using the server that has the new data as the source host.

Example:

```
$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
--hostDestination budapest01.example.com --portDestination 1389 \
--adminUID admin --adminPassword password --baseDN dc=example,dc=com \
--no-prompt
```

4. From any server in the topology, run `dsreplication post-external-initialization` once.

**Note:**

All servers in the topology must be online.

Example:

```
$ bin/dsreplication post-external-initialization --hostname
austin01.example.com \
--port 1389 --baseDN dc=example,dc=com --adminUID admin \
--adminPassword password --no-prompt
```

## Advanced configuration

The following sections cover advanced configuration procedures for your company's deployment needs.

### Changing the replicationChanges DB Location

About this task

If on-disk space issues arise, you can change the `replicationChanges` database (DB) location. The replication changelog database can live outside `<server-root>` and be placed in another location on the file system. To do this, specify the absolute path of the replication changelog directory.

## Steps

1. To change the database location for the replication changelog, use the `dsconfig` tool.

### Note:

By default, the database location is at `<server-root>/changelogDb`.

Example: The following command sets the replication Changelog Backend to `<server-root>/data/directory/changelogDB`.

### Note:

Remember to include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

```
$ bin/dsconfig set-replication-server-prop \
--provider-name "Multimaster Synchronization" \
--set "replication-db-directory:/data/directory/changelogDb" \
--bindDN "cn=Directory Manager" --bindPassword secret --no-prompt
```

2. Stop the server.

Example:

```
$ bin/stop-server
```

3. Move the DB files.

Example:

```
$ mv changelogDb /data/directory
```

4. Restart the server.

Example:

```
$ bin/start-server
```

## Modifying the replication purge delay

The replication purge delay specifies the period after which the directory server purges replication server database changes. Any change that is older than the purge delay is removed from the replication server database regardless of whether the change has been applied.

About this task

Currently, PingDirectory Server sets the default purge delay to one day. Administrators can change the default purge delay using the `dsconfig` tool.

### Note:

To ensure proper replication processing, you must have the same purge delay value set for all replication servers in the topology.

## Steps

- To change the purge delay, choose from one of the following options:  
Choose from:
  - Use the `dsconfig` tool.
  - Use the `dsconfig` tool in interactive mode:
    1. Open the **Advanced objects** menu.
    2. Select **Replication Server**.
    3. Select the replication synchronization provider.
    4. Select the option to change the replication purge delay.

The property accepts time units of seconds (s), minutes (m), hours (h), days (d), or weeks (w).

Example:

The following command changes the purge delay from the default of one day to two days.

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set "replication-purge-delay:2 d"
```

## Configuring a single listener-address for the replication server

Configure a single listener-address for the replication server to change the default setting of listening on all addresses.

### About this task

By default, the replication server binds the listening ports to all available interfaces of the machine. To bind the listener to a specific address, change the address to the host name provided when replication is enabled and set the `listen-on-all-addresses` property to `FALSE`.

The replication server's configuration entry stores a host name for itself so that it can resolve the address and specify it during the socket bind. If the server information is missing from the system, an error message generates with instructions on specific address binding. You can use the `dsconfig` tool to change the value of the `listen-on-all-addresses` property from `TRUE` (default) to `FALSE`.

To configure a replication server to listen on a single address:

## Steps

1. Create a new directory server instance and enable replication on port 8989.
2. To see the ports bound for listening on port 8989, run `netstat`.

### Note:

A port of `*.8989` means that it is listening on all addresses.

Example:

```
$ netstat -an | grep LISTEN | grep 8989
```

3. To disable listening on all addresses for the replication server, run the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set listen-on-all-addresses:false
```

- To see the ports bound for listening on port 8989, run `netstat` again.

**Note:**

A port of `<address>.8989`, such as `10.8.1.211.8989`, means that it is listening on the one address.

## Monitoring replication

This section covers how to use the PingDirectory Server to monitor replication.

The PingDirectory Server monitors replication in the following ways:

- Use the `dsreplication` tool with the `status` subcommand to display basic information about the replicated base distinguish names (DNs), the number of entries replicated, as well as the approximate size of replication backlogs at each Directory Server.
- Obtain more detailed information about the state of replication through the information exposed in its monitoring framework under `cn=monitor`.
- Use Periodic Stats Logger plugin, which allows collecting replication statistics for profiling server performance. For more information, see [Profiling Server Performance Using the Periodic Stats Logger](#).

Administrators can monitor their replication topologies using several tools and protocols:

- The PingDataMetrics Server
- SNMP
- LDAP
- JMX
- The Administrative Console. For more information, see [Managing Logging](#) and [Managing Monitoring](#).

### Monitoring replication using `cn=monitor`

The `cn=monitor` branch has a number of entries that store the replication state of a topology.

#### `cn=monitor` branch entries and their descriptions

<code>cn=monitor</code> entries	Description
Direct LDAP Server <code>&lt;baseDN&gt;&lt;host name:port&gt;&lt;serverID&gt;</code>	<p>Defines an LDAP server that directly connects to the replication server you are querying. The information in this entry applies to the replication server local to the <code>cn=monitor</code> entry.</p> <p>For more information, see <a href="#">Summary of the Direct LDAP Monitor Information</a>.</p>
Indirect LDAP Server <code>&lt;baseDN&gt;&lt;serverID&gt;</code>	<p>Defines an LDAP server that connects to another replication server in the topology. While this server connects to the same topology, it does not connect to the replication server you are querying.</p> <p>For more information, see <a href="#">Summary of the Indirect LDAP Server Monitor Information</a>.</p>
Remote Repl Server <code>&lt;baseDN&gt;&lt;host name:port&gt;&lt;serverID&gt;</code>	<p>Defines a remote replication server that connects to the local replication server. Information in this entry is in respect to the Replication Server local to the <code>cn=monitor</code> branch.</p> <p>For more information, see <a href="#">Summary of the Remote Replication Server Monitor Information</a>.</p>

cn=monitor entries	Description
Replica <baseDN>	<p>Stores information for an instance of the replicated naming context, also known as the replica, with respect to the Directory Server and its communication with a replication server. The replica information sends and receives changes from the replication servers.</p> <p>For more information, see <a href="#">Summary of the Replica Monitor Information</a>.</p>
Replication Server <replPort><serverID>	<p>Shows the information specific to the Replication Server running, such as on the replication port &lt;replPort&gt; with a server ID of &lt;serverID&gt;. This entry defines the replication server.</p> <p>For more information, see <a href="#">Summary of the Replication Server Monitor Information</a>.</p>
Replication Server Database <baseDN><serverID>	<p>Shows information for the changelog table of replica (suffix) in the replication server. As the Replication Server receives updates from the Directory Server, it records those changes in the changelog table.</p> <p>For more information, see <a href="#">Summary of the Replication Server Database Monitor Information</a>.</p>
Replication Server Database Environment <baseDN>	<p>Shows the information for the database environment for the replication server backend as well as the total number of records added to and deleted from the database.</p> <p>For more information, see <a href="#">Summary of the Replication Server Database Environment Monitor Information</a>.</p>
Replication Summary <baseDN>	<p>Shows summary information on the replication topology and the state for a particular base distinguish name (DN).</p> <p>For more information, see <a href="#">Summary of the Replication Summary Monitor Information</a>.</p>
Replication Changes Backend	<p>Shows the backend information for all replication changes.</p> <p>For more information, see <a href="#">Summary of the Replication Changes Backend Monitor Information</a>.</p>
Replication Protocol Buffer	<p>Shows the state of the buffer (initially 4k) for protocol operations, which is stored in thread local storage.</p> <p>For more information, see <a href="#">Summary of the Replication Protocol Buffer Monitor Information</a>.</p>

## Replication best practices

This section covers the best practices for replication based on our observations in production environments.

### About the `dsreplication` command-line utility

The following points involve some security practices that apply to replication. For specific questions, contact your authorized support provider.

#### Developing Scripts

The `dsreplication` utility maintains the history of executed `dsreplication` commands with the full command-line arguments in the `logs/tools/dsreplication.history` file. Use the recorded commands to develop scripts to set up and configure replication.

Scripts invoking the `dsreplication` utility in non-interactive mode check the return code from the `dsreplication` process. A non-zero return code indicates a failure.

To exclude output messages from the `dsreplication` utility, use the `--quiet` option to suppress them.

By default, the utility fails if one or more warnings are issued during the command execution. To suppress warnings, use the `--ignoreWarnings` option.

#### Note:

This option is required when using `dsreplication` with non-fully-qualified host names, such as `localhost`. Otherwise `dsreplication` fails. However, you should avoid using this flag in production environments.

#### Concurrent Use

With the exception of using the `dsreplication` utility with the `status` subcommand, the `dsreplication` subcommands cannot execute concurrently. The command-line utility locks the replication topology at one or more servers to prevent accidental configuration changes caused by multiple `dsreplication` subcommands running at the same time. For best practices, avoid making concurrent configuration changes.

#### Status

Using the `dsreplication` utility with the `status` subcommand requires the Replication Servers to provide monitoring information. This can lead to a delay before the output of `dsreplication status` displays. By default, `dsreplication` displays the status for all replicated domains with the exception of the special domains of the schema and the server registry.

Select a particular base distinguished name (DN) for `dsreplication status` if multiple base DNs are configured for replication.

Avoid invoking `dsreplication status` too often, such as more than once every 15 seconds or from multiple locations at the same time. Some of the information displayed by `dsreplication status` is based on monitor information that does not refresh every time the monitor is queried.

Do not use the `status` subcommand for collecting performance metrics. It is best to use the Periodic Stats Logger plugin for replication-related information.

#### Topology Tasks

The `dsreplication` tool allows specifying more than one server in a topology to act as the host for other servers for the enable and initialize actions. Use the `--topologyFilePath` option to specify a file with a series of hosts and ports in the topology.

For example, when the `hosts` file is used for an `enable` or `initialize` action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available. This file generates with the `manage-topology export` command.

### Replication conflicts

This section provides in-depth information about the mechanisms and possible scenarios behind replication conflicts.

Updates to the Directory Server entries in a replication topology can happen independently because replication guarantees only eventual consistency and not strong consistency. The eventual consistency model enables applying conflicting changes at different directory server instances. In most cases, the Directory Server can resolve these conflicts automatically and in a consistent manner: for example, all directory server instances in a replication topology resolving each and every conflict the same way. However, in some scenarios, manual administrative action is required. For any of these unresolved conflicts, the administrator receives notification through administrative alerts.

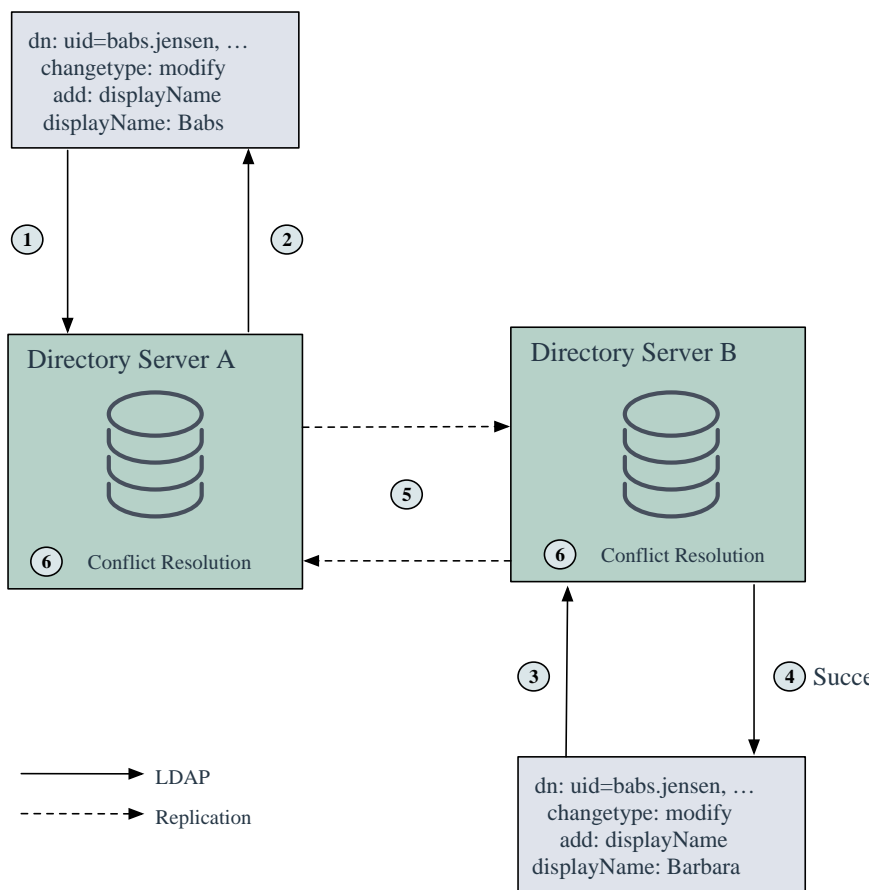

On a high level, the conflict resolution algorithm tries to resolve conflicts as if the operations causing the conflict in a distributed environment apply to a single directory server instance. For example, if the same entry is added to two different directory server instances at about the same time, after these operations are replicated, both directory servers keep only the first entry added.

The following image highlights the differences between standalone versus replicated environments.

#### Standalone

#### Replicated

**Conflicting Operations in Standalone versus Replicated Environments**

### Processing steps

1. Client sends LDAP modify request to Directory Server and succeeds.
2. Client sends another LDAP modify request that conflicts with the first.
3. In the standalone case, the request is rejected. In the replicated case, the request succeeds.
4. Replication propagates the updates (replicated only).
5. Conflict resolution (replicated only): A ignores the update from B. B sets the attribute value to the value on A.

### Types of replication conflicts

There are two types of replication conflicts:

#### Naming conflicts

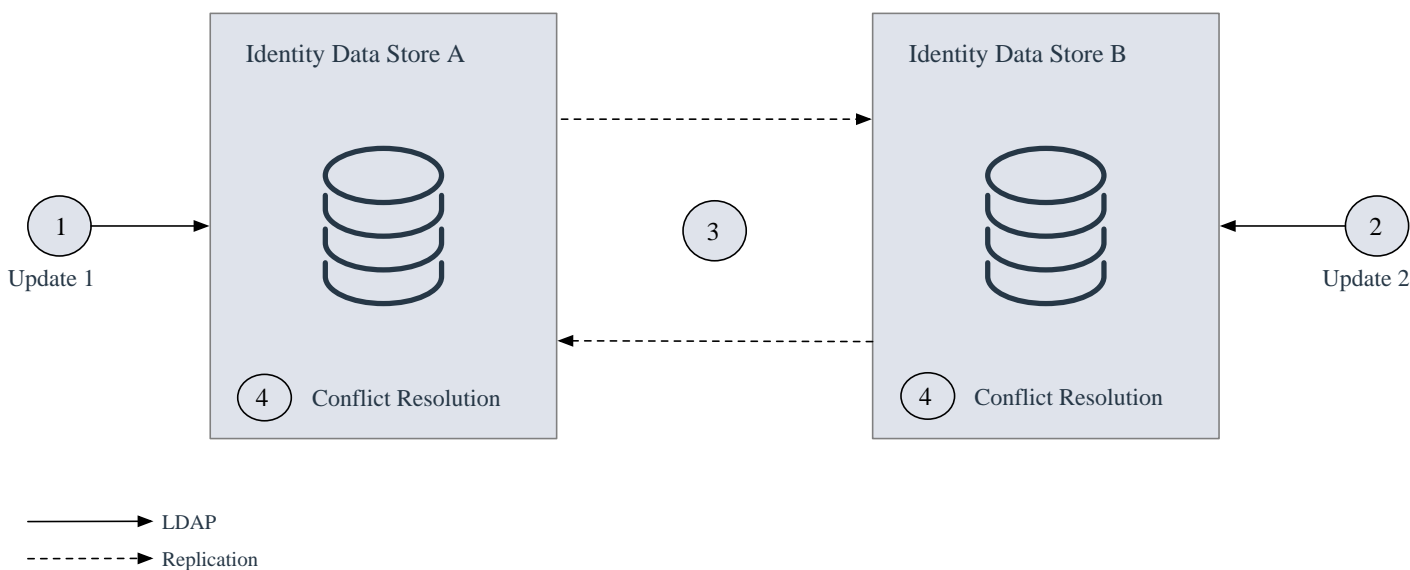

Naming conflicts include operations that cause conflicts with the naming of the distinguish name (DN) of the existing or new entries.

#### Modification conflicts

Modification conflicts include operations that result in conflicts in the modification of attributes.

### Naming conflict scenarios

The following illustration depicts the naming conflict scenario.

### Processing steps

1. The Client sends an update (Add, Delete, or Modify DN) request to server A.
2. The Client sends an update (Add, Delete, or Modify DN) request conflicting with the first request to server A.
3. Replication propagates the updates.
4. Conflict resolution takes place.

The following table shows the result of a modification conflict depending on the type of updates that occur. The code does not compare change sequence numbers (CSNs) but applies operations in the order they were received. This might lead to inconsistent replays.

For all of the naming conflict scenarios, assume the following:

- Update 1 was applied at Directory Server 1.

- Update 2 was applied at Directory Server 2.
- Update 1 occurred shortly before Update 2 so that Directory Server 2 received Update 1 after Update 2 was applied.

### Naming Conflict Scenarios

Update 1	Update 2	Automatic Resolution?	Result of Conflict Resolution at Directory Server 2 When Update 1 is received
Modify	Delete	Yes	Modify is discarded.
Modify	Modify DN	Yes	New entry is located based on the entryUUID and Modify is applied to the renamed entry.
Delete	Delete	Yes	Delete operation is ignored.
Delete	Modify DN	Yes	Delete operation is applied to the renamed entry.
Delete of A	Add of B under A	Yes	Entry B is renamed and Entry A is deleted.
Modify DN	Delete of the same entry targeted by the Modify DN	Yes	Modify DN operation is ignored.
Modify DN with a new parent	Delete of parent	No	The entry targeted in the Modify DN operation is marked as a conflict entry.
Modify DN with a new parent	Modify DN of the parent	Yes	The entry is moved under the new DN of the parent.
Modify DN of A with new DN B	Modify DN of C with new DN B	No	A and B will be conflict entries.
Add A	Modify DN of the parent of A	Yes	The entry is added under the new DN of the parent.
Add A	Delete of the parent of A	No	The added entry is marked as a conflict entry.
Add A	Add A with same set of attributes	Yes	The entryUUID of the incoming Add operation applied to the existing entry.
Add A	Add A with different set of attributes (or values)	No	The existing entry is marked as a conflicting entry and the incoming Add is executed.

### Modification conflict scenarios

Modification conflicts resolve automatically and no manual action is required. The LDAPModify operation allows the following modification types:

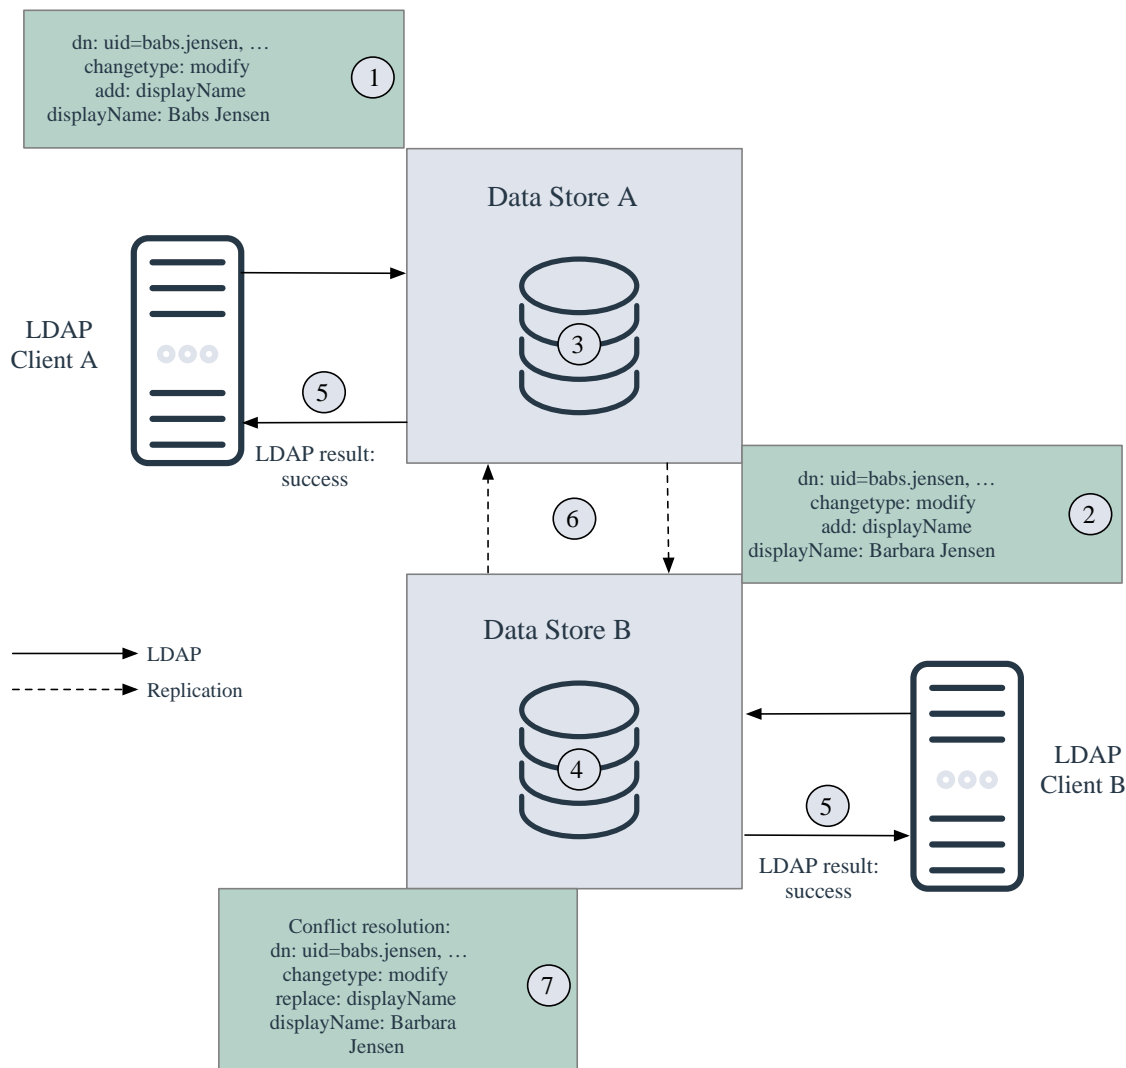

- Add of one or more values
- Delete of one or more values or the entire attribute
- Replacement of all values

**Note:**

Replication does not currently support the increment LDAP modification type.

The following illustration presents a modification conflict scenario.

**Processing steps**

1. LDAP client A sends a `modify` request to Directory Server A.
2. LDAP client B sends a conflicting `modify` request to Directory Server B.
3. Directory Server A applies the modification.
4. Directory Server B applies the modification.
5. The LDAP clients receive successful responses.
6. Replication propagates the updates.
7. Conflict resolution on Directory Server A updates the entry to reflect the value on Directory Server B.

Conflict resolution on Directory Server B ignores the update received from Directory Server A.

The following table shows the result of a modification conflict depending on the type of updates that occur. For all of the operations in the table, assume the following:

- LDAP Modify 1 was applied at Directory Server 1.
- LDAP Modify 2 was applied at Directory Server 2.
- LDAP Modify 1 occurred shortly before LDAP Modify 2, so that Directory Server 2 received LDAP Modify 1 after LDAP Modify 2 was applied.

### Modification Conflict Scenarios

Modify 1	Modify 2	Result of Conflict Resolution at Directory Server 2 When Modify 1 is received
Add of a single-value attribute	Add of the same attribute with a different value	Incoming <code>Modify</code> is ignored.
Delete of a single-valued attribute	Replacement of the value of the same attribute	Incoming <code>Delete</code> is ignored.
Replacement of a single-valued attribute	Delete of the same attribute	Incoming Replacement is ignored.
Delete some values from a multi-valued attribute	Delete some values from a multi-valued attribute	Incoming <code>Delete</code> is ignored.
Delete a multi-valued attribute	Delete of the same multi-valued attribute	Incoming <code>Delete</code> is ignored.
Delete a multi-valued attribute	Add the same multi-valued attribute	Incoming <code>Delete</code> is ignored.
Delete value X from a multi-valued attribute	Delete value X from the same multi-valued attribute	Incoming <code>Delete</code> is ignored.
Delete value X from a multi-valued attribute	Add value Y to the same multi-valued attribute	Delete of value X is applied.
Delete value X from a multi-valued attribute	Delete value Y from the same multi-valued attribute	Delete of value X is applied.
Delete value X from a multi-valued attribute	Replace all values of the same multi-valued attribute	Incoming <code>Delete</code> is ignored.
Add of values X and Y to a multi-valued attribute	Delete value X from the same multi-valued attribute	Only value Y is added.
Delete value X from a multi-valued attribute	Add of values X and Y to the same multi-valued attribute	Incoming <code>Delete</code> is ignored.

## Troubleshooting replication

This section covers information on troubleshooting your replication deployment.

### Recovering a replica with missed changes

If a server has been offline for a period of time longer than the replication purge delay, you must run the `dsreplication initialize` command to bring the replica into sync with the topology.

Any missed changes are detected at the time of server startup. A missed change is a change that the replica detects it needs, but the change is not found within any other replication server's replicationChanges backend stored in the `/changeLogDb` server root path.

If missed changes are detected, the server enters lockdown mode, where only privileged clients can make requests. Any other server that is not missing changes can be used as a source for `dsreplication initialize`.

If the server requires a manual backup and restore, perform the following steps, which are equivalent to `dsreplication initialize`.

### Performing a manual initialization

About this task

To manually initialize a server when an online initialization isn't possible:

#### Steps

1. From another server in the replication topology, back up the `userRoot`, `schema`, and `replicationChanges` backends to the `<server-root>/bak` directory.

#### Tip:

If data encryption is enabled, export the `encryption-settings` backend because you might need to import one or more encryption settings IDs into the new replica.

Example:

```
$ source-server-root>/bin/backup --backendID userRoot --backupDirectory \
  bak/userRoot
$ <source-server-root>/bin/backup --backendID schema --backupDirectory \
  bak/schema
$ <source-server-root>/bin/backup --backendID replicationChanges \
  --backupDirectory bak/replicationChanges
$ <source-server-root>/bin/encryption-settings export --id <id> \
  --output-file bak/exported-key
```

2. Copy the `bak` directory to the new replica.

Example:

```
$ scp -r <source-server-root>/bak/* \
  <user>@<destination-server>:<destination-server-root>/bak
```

3. Stop the server.

#### 4. Restore the `userRoot`, `schema`, `changelog`, and `replicationChanges` backends.

##### Important:

If the `encryption-settings` backend was exported, import it before restoring any of the backends.

##### Example:

```
$ <destination-server-root>bin/encryption-settings import --input-file \
  bak/exported-key --set-preferred
Enter the PIN used to encrypt the definition:
$ <destination-server-root>/bin/restore --backupDirectory bak/userRoot
$ <destination-server-root>/bin/restore --backupDirectory bak/schema
$ <destination-server-root>/bin/restore --backupDirectory \
  bak/replicationChanges
```

#### 5. Start the server using `bin/start-server`.

### Fixing replication conflicts

Replication conflicts occur when an incompatible change to an entry is made on two replicas at the same time. The change processes on one replica and then replicates to the other replica, which causes the conflict. While most conflicts resolve automatically, some require manual action.

To fix replication conflicts, initialize the replica containing the conflicts with the data from another replica that does not have conflicts. If the database is large and the number of conflicts is small, and the command includes the Replication Repair Control specified by OID value `1.3.6.1.4.1.30221.1.5.2`, run `ldapmodify` against the server with the conflict. The Replication Repair Control prevents the change from replicating and enables changing operational attribute values, which are not normally writable.

The following tasks use the Replication Repair Control to fix replication conflicts and apply change only to the server with the conflict. There are two examples provided to fix replication conflicts: one for fixing a modify conflict using the `ldap-diff` tool and the other for fixing a naming conflict.

### Fixing a modify conflict

#### Steps

1. To isolate conflicting entries between two replicas, use the `bin/ldap-diff` tool.

##### Note:

Replace the `sourceHost` value with the server that needs the adjustment.

##### Example:

The following example uses the tool to search across the entire base distinguish name (DN) for any difference in user attributes and reports the difference in `difference.ldif`.

```
$ bin/ldap-diff --sourceHost austin02.example.com --sourcePort 1389 \
  --sourceBindDN "cn=Directory Manager" --
sourceBindPassword pass \
  --targetHost austin01.example.com --targetPort
1389 \
  --targetBindDN "cn=Directory Manager" --
targetBindPassword
difference.ldif \
  --baseDN "dc=example,dc=com" --outputLDIF
  --searchFilter "(objectclass=*)" --numPasses 3
"*" pass \
```

```
    "^userPassword"
```

2. To apply changes to the server that contains conflicts, use the `difference.ldif` file in a format compatible with `ldapmodify`.

### Important:

Run `ldap-diff` command with the `sourceHost` value as the server with conflicts.

Example:

The following is an example of the contents of `difference.ldif` file.

```
dn: uid=user.1,ou=people,dc=example,dc=com
    changetype: modify
    add: mobile
    mobile: +1 568 232 6789
    -
    delete: mobile
    mobile: +1 568 591 7372
    -
```

3. To correct the entries on the sole server with conflicts, run `bin/ldapmodify`.

Example:

```
$ bin/ldapmodify --bindPassword password -J "1.3.6.1.4.1.30221.1.5.2" \
  --filename difference.ldif
```

## Fixing a naming conflict

About this task

In this example, a naming conflict was encountered when the replica attempted to replay an `ADD` of `uid=user.200,ou=people,dc=example,dc=com`. Because of this conflict, the server returns a replication conflict message. See the following example message.

```
[18/Feb/2010:14:53:12 -0600] category=EXTENSIONS severity=SEVERE ERROR
msgID=1880359005 msg="Administrative alert type=replication-unresolved-
conflict
id=bbd2cbaf-90a4-42af-94a8-c1a42df32fc6
class=com.unboundid.directory.server.replication.plugin.ReplicationDomain
msg='An unresolved conflict was detected for DN
uid=user.200,ou=People,dc=example,dc=com.
The conflicting entry has been renamed to
entryuid=69807e3d-ab27-43a3-8759-
ec0d8d6b3107+uid=user.200,ou=People,dc=example,dc=com'"
```

The Directory Server prepends the entryUUID to the DN of the conflicting attribute and adds a `ds-sync-conflict-entry` auxiliary object class to the entry to aid in search.

To resolve the conflict:

Steps

1. Search for any entry that has the `ds-sync-conflict-entry` objectclass and returns only the DNs that match the filter.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub \
```

```
"(objectclass=ds-sync-conflict-entry)" "1.1"
```

Result: The search results display the conflicting entry for uid=user.200.

```
dn: entryuuid=69807e3d-ab27-43a3-8759-ec0d8d6b3107+uid=user.200,ou=People,dc=example,dc=com
```

```
dn: entryuuid=523c430e-a870-4ebe-90f8-9cd811946420+uid=user.200,ou=People,dc=example,dc=com
```

 **Note:**

Conflict entries are not returned unless the `objectclass=ds-sync-conflict-entry` is present in the search filter.

2. Compare the conflict entry with the target entry.
3. Apply the difference in two ways:  
Choose from:
  - Use the `ldapmodify` tool with the Replication Repair Control.

 **Note:**

You can also delete the conflict entry using this command.

- Run `bin/ldapmodify` with the Replication Repair Control to make the fix.

 **Note:**

When making changes using the Replication Repair Control, the updates are not propagated through replication. Examine each replica individually, and apply the necessary modifications using the request control.

Example:

```
$ bin/ldapmodify -J "1.3.6.1.4.1.30221.1.5.2" \
  --filename difference.ldif
```

## Fixing mismatched generation IDs

About this task

If you receive a warning message that multiple generation IDs were detected for a specific suffix, you must re-initialize one or more replicas. If the warning is presented from a server after an initialization, it could be that the `post-external-initialization` command was not run as part of a global change in data.

Try the following fixes as needed.

Steps

- To re-initialize replicas as part of a global change in data, run the `post-external-initialization` command.
- To fix mismatched generation IDs, run the `dsreplication` command.
- To warn when any generation IDs are different across the topology, run the `dsreplication` tool with the `status` command.

## Replication reference

This section covers general reference information about replication.

### Summary of the `dsreplication` Subcommands

Use this topic as a reference for `dsreplication` subcommands and functions and their descriptions.

The following table presents a summary of the `dsreplication` subcommands and functions.

#### Tip:

To see the available options for each subcommand, run `bin/dsreplication <subcommand> --help`.

Subcommand	Description
<code>disable</code>	Disables replication on the specified server for the provided base distinguish name (DN) and removes references to this server in the other servers with which it is replicating data.
<code>enable</code>	Updates the configuration of the servers to replicate the data under the specified base DN.  If one of the servers is already replicating the data under the base DN with other servers, executing this subcommand updates the configuration of all the servers. It is sufficient to execute the command line one time for each server you add to the replication topology.
<code>initialize</code>	Initializes the data under the specified base DN on the destination server with the contents on the source server.
<code>initialize-all</code>	Initializes the data under the specified base DN on all servers in the replication topology with the contents on the specified server.
<code>post-external-initialization</code>	Used with <code>pre-external-initialization</code> , the command resets the generation ID based on the newly-loaded data.  Consider the following using this subcommand: <ul style="list-style-type: none"> <li>▪ You must call this subcommand after initializing the contents of all the replicated servers using the <code>import-ldif</code> tool or <code>dsreplication initialize</code>.</li> <li>▪ Specify the list of base DNs that have been initialized and provide the credentials of any of the servers that are being replicated. For more information, see the usage of the <code>pre-external-initialization</code> subcommand.</li> <li>▪ This subcommand only needs to be run one time on one of the replicas.</li> </ul>

Subcommand	Description
<b>pre-external-initialization</b>	<p>Clears the existing generation ID and removes all accumulated changes of the replicated suffix from the Replication Changelog Database on every replication server.</p> <p>Consider the following using this subcommand:</p> <ul style="list-style-type: none"> <li>Use this subcommand when globally restoring the replicas on all of the servers in a topology.</li> <li>You must specify the list of base DN's that will be initialized and provide the credentials of any of the servers that are being replicated.</li> <li>After calling this subcommand, initialize the contents of all the servers in the topology, then call the <b>post-external-initialization</b> subcommand.</li> <li>You only need to run this subcommand one time on one of the replicas.</li> </ul>
<b>remove-defunct-server</b>	Removes an offline defunct server from the replication on all servers in the topology.
<b>status</b>	<p>Displays the status of replication domains. If no base DN's are specified as parameters, the information for all base DN's displays.</p> <p>Available options with the status subcommand are:</p> <ul style="list-style-type: none"> <li>--showAll</li> <li>--displayServerTable</li> <li>--location</li> </ul>

### Summary of the Direct LDAP Monitor information

The following table provides a description of the attributes in the `cn=Direct LDAP Server` monitor entry.

The following is the distinguished name (DN) for the monitor entry.

```
dn: cn=Direct LDAP Server <baseDN> <host name:ldapPort>
    <serverID>,cn=monitor
```

### Direct LDAP Monitor Information

Monitor Attribute	Description
<code>replica-id:&lt;serverID&gt;</code>	Replica ID number.
<code>replication-backlog</code>	Number of changes that the replication server has not seen from the server.
<code>missing-changes</code>	Number of missing changes.
<code>approximate-delay</code>	Difference between the time of the last change that the replication server has seen from the LDAP server and the most current timestamp on the latest change on the server.
<code>base-dn</code>	Base DN
<code>ssl-encryption</code>	Flag to indicate if SSL encryption is in use.

Monitor Attribute	Description
protocol-version	Displays the replication protocol version.
generation-id	Generation ID for the base DN on the Directory Server.
restricted	Boolean that indicates whether the replication domain is restricted in an Entry Balancing Configuration with the Directory Proxy Server.
ack-sent	Number of acknowledgment messages sent to this replica not currently used.
ack-received	Number of acknowledgment messages received from this replica not currently used.
add-sent	Number of protocol messages with an LDAPAdd sent to this replica.
add-received	Number of protocol messages with an LDAPAdd received from this replica.
delete-sent	Number of protocol messages with an LDAPDelete sent to this replica.
delete-received	Number of protocol messages with an LDAPDelete received from this replica.
done-sent	Number of done messages sent to this replica. A done message indicates an end of an online initialization session.  If the value is non-zero, then this replica has been initialized over the replication protocol.
done-received	Number of done messages received from this replica. A done message indicates an end of online initialization session.  If the value is non-zero, then this replica has completed the initialization of other replicas over the replication protocol.
entry-sent	Number of entry messages sent to this replica. Entry messages carry replicated data to initialize replicas over the replication protocol.
entry-received	Number of entry messages received from this replica. Entry messages carry replicated data to initialize replicas over the replication protocol.
error-sent	Number of error messages sent to this replica.
error-received	Number of error messages received from this replica.
heartbeat-sent	Number of heartbeat messages sent to this replica.
heartbeat-received	Number of heartbeat messages received from this replica.   <b>Note:</b> The number of messages should always be 0 because the replica never sends a heartbeat message to the server.

Monitor Attribute	Description
initialize-request-sent	Number of initialize-request messages sent to this replica. This message is sent when another replica requested initialization of its data using the replication protocol.
initialize-request-received	Number of initialize-request messages received from this replica. This message is sent when this replica requested initialization of its data using the replication protocol from another replica.
initialize-target-sent	Number of initialize-target messages sent to this replica. This message is sent before another replica has started the initialization of this replica.
initialize-target-received	Number of initialize-target messages received from this replica. This message is sent before this replica starts the initialization of one or more replicas.
ldap-server: <hostname:ldapPort>	The host name and port of the local replication server.
modify-sent	Number of protocol messages with an LDAPModify sent to this replica.
modify-received	Number of protocol messages with an LDAPModify received from this replica.
modify-dn-sent	Number of protocol messages with an LDAPModify DN sent to this replica.
modify-dn-received	Number of protocol messages with an LDAPModify DN received from this replica.
repl-server-start-sent	Number of replication-server-start messages sent to this replica. The Replication Server responds with this message to the start message received from the replica.
	 <b>Note:</b> The number of messages should never be more than 1.
repl-server-start-received	Number of replication-server-start messages received from this replica.
	 <b>Note:</b> The number of messages should always be 0.
reset-generation-id-sent	Number of reset generation ID messages received from this replica.

Monitor Attribute	Description
reset-generation-id-received	<p>Number of reset generation ID messages sent to this replica.</p> <p> <b>Note:</b> The number of messages should always be 0.</p>
server-start-sent	<p>Number of server-start messages sent to this replica.</p> <p> <b>Note:</b> The number of messages should always be 0.</p>
server-start-received	<p>Number of server-start messages received from this replica. Server-start is the first message the replica sends after establishing a replication connection.</p> <p> <b>Note:</b> The number of messages should never be more than 1.</p>
window-sent	Number of window messages sent to this replica. Window messages are used for cumulative acknowledgment in the replication protocol.
window-received	Number of window messages received from this replica. Window messages are used for cumulative acknowledgment in the replication protocol.
window-probe-sent	<p>Number of window probe messages sent to this replica.</p> <p> <b>Note:</b> The number of messages should always be 0.</p>
window-probe-received	Number of window probe messages received from this replica. The replica sends a window probe message to the server if the send window in the replica is closed and the replica is unable to publish updates to the server.
update-sent	Number of changes sent to this server.
update-received	Number of changes received from this server.
internal-connection	Indicates if the replica is in the same process as the replication server.
server-state	Displays the state of the replica. Displays the latest change number that the replica has seen from all the other replicas including itself.
consumed-update-recent-rate	Rate that the connected Directory Server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last five seconds.

Monitor Attribute	Description
consumed-update-peak-rate	Highest rate that the connected Directory Server has consumed updates sent by this replication server, measured over a 5 second period from the start of the replication server.
produced-update-recent-rate	Rate that the connected Directory Server has sent updates to this replication server, expressed as the number of updates per second and measured over the last 5 seconds.
produced-update-peak-rate	Highest rate that the connected Directory Server has sent updates to this replication server, measured over a 5 second period from the start of the replication server.
max-send-window	Maximum number of changes that can send to the LDAP server before requiring an ACK.
current-send-window	Current number of changes remaining to be sent to the LDAP server before requiring an ACK.
max-rcv-window	Maximum number of changes that can be received by the LDAP server before sending an ACK.
current-rcv-window	Number of changes remaining to be received by the LDAP server before sending an ACK.
degraded	Indicates that the generation ID of the replica does not match the generation ID of the server. When loading data into the topology, this is a temporary state. If this is not a temporary state, the replica has not been initialized.   <b>Note:</b> The <code>degraded</code> value should be false.

### Summary of the Indirect LDAP Server Monitor information

Use this topic as a reference for Indirect LDAP Server Monitor attribute information.

These attributes provide information about a Directory Server that is connected to a different replication server in the topology.

The following is the distinguished name (DN) for the Indirect LDAP server monitor entry.

```
dn: cn=Indirect LDAP Server <baseDN> <serverID>,cn=monitor
```

The following table provides a description of the attributes in the `cn=Indirect LDAP Server` monitor entry.

Monitor Attribute	Description
<code>replica-id: &lt;serverID&gt;</code>	ID number identifying the replica
<code>base-dn: &lt;baseDN&gt;</code>	Base DN

Monitor Attribute	Description
connected-to: Remote Repl Server <baseDN> <host name:replPort> <replID>	Replication server to which the directory server is connected
replication-backlog	Number of changes that the replication server has not seen from the server
approximate-delay	Amount of time between the last change seen by this Directory Server and the most recent change seen by the remote replication server   <b>Note:</b> This value is the amount of time between the time stamps, not the amount of time required to synchronize the 2 servers.
generation-id	Generation ID for this suffix on this remote replication server
consumed-update-recent-rate	Rate that the connected Replication Server is consuming updates sent by this replication server  This value is expressed as the number of updates per second and measured over the last 5 seconds.
consumed-update-peak-rate	Highest rate that the connected Replication Server has consumed updates sent by this replication server  This value is measured over a 5 second period beginning at the start of the replication server.

### Summary of the Remote Replication Server Monitor information

Use this topic as a reference for Remote Replication Server Monitor attribute information.

The following is the distinguished name (DN) for the Remote Replication Server monitor entry.

```
dn: cn=Remote Repl Server <baseDN> <host name:replPort>
    <serverID>,cn=monitor
```

The following table provides a description of the attributes in the `cn=Remote Repl Server` monitor entry.

Monitor Attribute	Description
replication-server: <host name>:<repl port>	Host name and replication port number of the Replication Server.
replication-server-id:<serverID>	Server ID for the Replication Server.
available	Indicates if the remote replication server is available or not. Values: true or false.
sending-paused	Indicates if sending is paused. Values: true or false.

Monitor Attribute	Description
receiving-paused	Indicates if receiving is paused. Values: true or false.
wan-gateway-priority	Specifies the WAN Gateway priority of the remote replication server.
is-wan-gateway	Indicates if the remote replication server is a WAN Gateway. Values: true or false.
wan-gateway-desired	<p>Indicates if the remote replication server is a desired gateway. Values: true or false. This entry together with the <code>is-wan-gateway</code> property indicates the desired state.</p> <p><code>is-wan-gateway=false, wan-gateway-desire=false</code> Indicates another server with a higher gateway priority exists or the gateway priority is set to disabled.</p> <p><code>is-wan-gateway=false, wan-gateway-desire=true</code> Indicates that the remote replication server wants to be a WAN gateway.</p> <p><code>is-wan-gateway=true, wan-gateway-desire=false</code> Indicates that the remote replication server wants to give up its role as a WAN gateway.</p> <p><code>is-wan-gateway=false, wan-gateway-desire=true</code> Indicates the remote replication server wants to remain as a gateway server.</p>
base-dn	base DN
ssl-encryption	Flag to indicate if SSL encryption is in use.
protocol-version	Replication protocol version.
generation-id	Generation ID for this suffix on this remote replication server.
restricted	Indicates that remote replication server is in an entry-balancing deployment.
add-sent	Number of protocol messages with an <code>ldapadd</code> sent to the remote replication server.
add-received	Number of protocol messages with an <code>ldapadd</code> received from the remote replication server.
delete-sent	Number of protocol messages with an <code>ldapdelete</code> sent to the remote replication server.
delete-received	Number of protocol messages with an <code>ldapdelete</code> received from the remote replication server.
done-sent	Number of done messages sent to the remote replication server. A done message indicates an end of online initialization session.

Monitor Attribute	Description
done-received	Number of done messages received from the remote replication server. A done message indicates an end of online initialization session.
entry-sent	Number of entry messages sent to the remote replication server. Entry messages carry replicated data to initialize replicas over the replication protocol.
entry-received	Number of entry messages received from the remote replication server. Entry messages carry replicated data to initialize replicas over the replication protocol.
error-sent	Number of error messages sent to the remote replication server.
error-received	Number of error messages received from the remote replication server.
heartbeat-sent	Number of heartbeat messages sent to the remote replication server.
heartbeat-received	Number of heartbeat messages received from the remote replication server.
initialize-request-sent	Number of initialize-request messages sent to the remote replication server. This message is used during online initialization from one replica to another.
initialize-request-received	Number of initialize-request messages received from the remote replication server. This message is used during online initialization from one replica to another.
initialize-target-sent	Number of initialize-target messages sent to the remote replication server. This message is used before online initialization from one replica to another.
initialize-target-received	Number of initialize-target messages received from the remote replication server. This message is used before online initialization from one replica to another.
modify-sent	Number of protocol messages with an <code>ldapmodify</code> sent to the remote replication server.
modify-received	Number of protocol messages with an <code>ldapmodify</code> received from the remote replication server.
modify-dn-sent	Number of protocol messages with an <code>ldapmodify DN</code> sent to the remote replication server.
modify-dn-received	Number of protocol messages with an <code>ldapmodify DN</code> received from the remote replication server.

Monitor Attribute	Description
monitor-sent	Number of monitor messages sent to the remote replication server. This message is used when communicating with directory servers running an earlier release.
monitor-received	Number of monitor messages received from the remote replication server. This message is primarily used when communicating with directory servers running an earlier release.
monitor-request-sent	Number of monitor requests sent to the remote replication server. The receiving server responds with a monitor message that includes server's information about the state of the topology.
monitor-request-received	Number of monitor requests received from the remote replication server. This server responds with a monitor message that includes server's information about the state of the topology.
monitor-v2-sent	<p>Number of monitor messages sent to the remote server.</p> <p> <b>Note:</b> This monitor message is only used with Directory Server 3.5 or later.</p>
monitor-v2-received	<p>Number of monitor messages received from the remote server.</p> <p> <b>Note:</b> This monitor message is only used with Directory Server 3.5 or later.</p>
pause-sending-updates-sent	Number of pause-sending-updates messages sent to the remote server. The remote server must stop sending update messages to this server when receiving this message.
pause-sending-updates-received	Number of pause-sending-updates messages received from the remote server. This server stops sending update messages to the remote server when it receives this message.
repl-server-start-sent	<p>Number of replication-server-start messages sent to the remote replication server. The Replication Server responds with this message to the replication-server-start message received from remote replication servers.</p> <p> <b>Note:</b> The number of messages should never be more than 1.</p>

Monitor Attribute	Description
repl-server-start-received	<p>Number of <code>replication-server-start</code> messages received from the remote replication server.</p> <p> <b>Note:</b> The number of messages should never be more than 1.</p>
reset-generation-id-sent	Number of reset generation ID messages received from the remote replication server. This message is sent before and after the data is initialized in the topology.
reset-generation-id-received	Number of reset generation ID messages sent to the remote replication server. This message is sent before and after the data is initialized in the topology.
server-info-sent	Number of replication server information messages sent to the remote replication server. This message tells other replication servers about the replicas directly connected to the sending server. This message is also used to distribute information about the location of replicas.
server-info-received	Number of replication server information messages received from the remote replication server. This message tells other replication servers about the replicas directly connected to the sending server. This message is also used to distribute information about the location of replicas.
set-source-location-sent	Number of <code>set-source-locations</code> messages sent to the remote replication server. This message is used by WAN gateway servers to request update messages from additional locations.
set-source-location-received	Number of <code>set-source-locations</code> messages sent to the remote replication server. This message is used by WAN gateway servers to request update messages from additional locations.
start-sending-updates-sent	Number of <code>start-sending-updates</code> messages sent to the remote replication server. The remote server can only start sending updates to this server after receiving this message.
start-sending-updates-received	Number of <code>start-sending-updates</code> messages received from the remote server. Sending update messages to the remote server may only start after receiving this message.
window-sent	Number of window messages sent to the remote replication server. Window messages are used for cumulative acknowledgment in the replication protocol.
window-received	Number of window messages received from the remote replication server. Window messages are used for cumulative acknowledgment in the replication protocol.

Monitor Attribute	Description
messages-sent	Total number of messages sent.
messages-received	Total number of messages received.
update-sent	Total number of updates sent.
update-received	Total number of updates received.
server-state	Displays the server state of the remote replication server. It displays the last change seen on the remote replication server.
consumed-update-recent-rate	Rate that the connected Directory Server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last 5 seconds.
consumed-update-peak-rate	Highest rate that the connected Directory Server has consumed updates sent by this replication server, measured over a 5 second period from the time the replication server was started.
produced-update-recent-rate	Rate that the connected Directory Server has sent updates to this replication server, expressed as the number of updates per second and measured over the last 5 seconds.
produced-update-peak-rate	Highest rate that the connected Directory Server has sent updates to this replication server, measured over a 5 second period since the replication server was started.
max-send-window	Maximum number of changes that can be sent to the remote replication server before requiring an ACK.
current-send-window	Number of changes remaining to be sent to the remote replication server before requiring an ACK.
max-rcv-window	Maximum number of changes that can be received from the remote replication server before sending an ACK.
current-rcv-window	Number of changes remaining to be received from the remote replication server before sending an ACK.
degraded	<p>Indicates that the generation ID of the replica does not match the generation ID of the remote replication server. This is a temporary state when loading data into the topology or the replica has not been initialized.</p> <p> <b>Note:</b> Normally, the <code>degraded</code> value should be <code>false</code>.</p>

### Summary of the Replica Monitor information

The following table provides a description of the attributes in the `cn=Replica` monitor entry for a specific base DN.

The following is the distinguished name (DN) for the Replica Monitor server monitor entry.

```
dn: cn=Replica <baseDN>,cn=monitor
```

Monitor Attribute	Description
<code>base-DN: &lt;baseDN&gt;</code>	Specified base DN The monitor entries track your company's base DN or <code>base-DN: &lt;baseDN&gt;,dc=example,dc=com, cn=schema base-DN: and cn=topology,cn=config.</code>
<code>connected-to: Replication Server &lt;replPort&gt; &lt;serverID&gt;</code>	Replication port number and server ID of the replication server to which this LDAP Server is connected The first number is the replication server port number and the second number is the <code>server-id</code> of the replication server.
<code>lost-connections</code>	Number of times the Directory Server has lost connection to a replication server
<code>received-updates</code>	Number of updates that the Directory Server Replica has received from the connected replication server
<code>sent-updates</code>	Number of updates sent to the replication server.
<code>pending-updates</code>	Number of updates pending to send to the replication server.
<code>replayed-updates</code>	Total number of updates from the replication server that have been replayed for this replica.
<code>replayed-updates-ok</code>	Number of updates for this replica that have been successfully replayed with no conflicts.
<code>replayed-update-failed</code>	Number of updates for this replica that were successfully replayed after automatically resolving a modify conflict.
<code>resolved-modify-conflicts</code>	Number of updates for this replica that were successfully resolved after a modify conflict.
<code>resolved-naming-conflicts</code>	Number of updates for this replica that were successfully resolved after a naming conflict.
<code>unresolved-naming-conflicts</code>	Number of updates for this replica that could not be replayed due to an unresolvable naming conflict.
<code>replica-id</code>	Server ID for this replica.
<code>max-rcv-window</code>	Maximum number of changes that the Directory Server Replica can receive at a time before sending an acknowledgment back to the replication server.

Monitor Attribute	Description
current-rcv-window	Current received window size for this replica.
max-send-window	Maximum number of changes that the Directory Server Replica can send at a time to the replication server before requiring an ACK.
current-rcv-window	Number of changes remaining to be received from the replication server before it must send an ACK.
max-send-window	Maximum number of changes that the Directory Server Replica can send at a time to the replication server before requiring an ACK.
current-send-window	Number of changes remaining to be sent to the replication server before requiring an ACK.
ssl-encryption	Flag to indicate if SSL encryption is in use.
generation-id	Generation ID for this suffix on the Directory Server.
replication-backlog	Number of changes that are from this replica.

### Summary of the Replication Server Monitor information

Use this topic as a reference for the Replication Server Monitor attributes and information.

The following is the distinguish name (DN) for the replication server monitor entry.

```
dn: cn=Replication Server <baseDN> <replServerID>,cn=monitor
```

The following table provides a description of the attributes in the `cn=Replication Server` monitor entry.

Attribute	Description
replication-server-id	Server ID for the Replication server ID
replication-server-port	Port number on which the replication server listens for communication from other servers
base-dn:<baseDN>	Indicates the suffix to which this replication server database applies
Generation IDs by Base DN	List of generation IDs for each base DN on the server
num-outgoing-replication-server-connections	Number of outgoing connections from the replication server
num-incoming-replication-server-connections	Number of incoming connections into the replication server
num-incoming-replica-connections	Number of incoming connections to the replica

### Summary of the Replication Server Database Monitor information

The following table provides a description of the attributes in the `cn=Replication Server database monitor` entry.

The following is the distinguished name (DN) for the Replica Server Database Monitor entry.

```
dn: cn=Replication Server database <baseDN> <replServerID>,cn=monitor
```

### Replication Server Database Monitor Information

Monitor Attribute	Description
<code>database-replica-id:</code> <code>&lt;replicaID&gt;</code>	Specifies the replication server ID.
<code>base-dn:</code> <code>&lt;baseDN&gt;</code>	Indicates the suffix to which this replication server database applies.
<code>first-change</code>	<p>First change number that is in this replication database table for this suffix from this <code>server-id</code>.</p> <p>The following is an example entry.</p> <pre>0000012209EA622C390D00000002 Mon Jun 22 16:41:11 CDT 2011</pre>
<code>last-change</code>	<p>Last change number that is in this replication database table for this suffix from this <code>server-id</code>.</p> <p>The following is an example entry.</p> <pre>0000012209EA622C390D00000002 Mon Jun 22 16:41:11 CDT 2011</pre>
<code>queue-size</code>	Number of changes in the replication server queue waiting to be sent to this remote replication server database.
<code>queue-size-bytes</code>	Size in bytes of all the messages waiting in the queue.
<code>records-added</code>	Displays the number of records changed or added to the directory information tree (DIT).
<code>records-removed</code>	Displays the number of records removed from the DIT.

### Summary of the Replication Server Database Environment Monitor information

The following table provides a description of the attributes in the `cn=Replication Server Database Environment monitor` entry, which includes the environment variables associated with the Oracle Berkeley Database Java Edition backend.

The following is the distinguished name (DN) for the Replica Server Database Monitor entry.

```
dn: cn=Replication Server Database Environment,cn=monitor
```

Monitor Attribute	Description
<code>je-version</code>	Current version of the Oracle Berkeley Java Edition.

Monitor Attribute	Description
current-db-cache-size	Current database (DB) cache size.
max-db-cache-size	Maximum DB cache size.
db-cache-percent-full	Percentage of the cache used by the Directory Server.
db-directory	Directory that holds the changelogDb file.
db-on-disk-size	Size of the DB on disk.
cleaner-backlog	Number of log files that must be cleaned for the cleaner to meet its target utilization.
random-read-count	Number of disk reads which required repositioning the disk head more than 1MB from the previous file position.
random-write-count	Number of disk writes which required repositioning the disk head by more than 1MB from the previous file position.
sequential-read-count	Number of disk reads which did not require repositioning the disk head more than 1MB from the previous file position.
sequential-write-count	Number of disk writes which did not require repositioning the disk head by more than 1MB from the previous file position.
nodes-evicted	Accumulated number of nodes evicted.
active-transaction-count	Number of currently active transactions.
num-checkpoints	Number of checkpoints. A checkpoint is a process that writes to your log files all the internal BTree nodes and structures modified as a part of write operations to your log files to facilitate a quick recovery.
checkpoint-in-progress: false	Indicates if a checkpoint is in progress.
total-checkpoint- duration-millis	Total time in milliseconds for all checkpoints.
average-checkpoint- duration-millis	Average time in milliseconds for all checkpoints.
last-checkpoint-duration- millis	Duration in milliseconds of the last checkpoint run.
last-checkpoint-start- time	Start time of the last checkpoint.
last-checkpoint-stop-time	Stop time of the last checkpoint.
millis-since-last- checkpoint	Time in milliseconds since the last checkpoint.

Monitor Attribute	Description
read-locks-held	Total read locks currently held.
write-locks-held	Total write locks currently held.
transactions-waiting-on-locks	Total transactions waiting for locks.
je-env-stat-AdminBytes	Number of bytes of JE cache used for log cleaning metadata and other administrative structure.
je-env-stat-BufferBytes	Total memory currently consumed by log buffers, in bytes.
je-env-stat-CacheDataBytes	Total memory of cache used for data.
je-env-stat-CacheTotalBytes	Total amount of JE cache in use, in bytes.
je-env-stat-CleanerBacklog	Number of files to be cleaned to reach the target utilization.
je-env-stat-CursorsBins	Number of bottom internal nodes (BINS) encountered by the INCompressor that had cursors referring to them when the compressor ran. The compressor thread cleans up the internal BTree as records are deleted to ensure unused nodes are not present.
je-env-stat-DataBytes	Amount of JE cache used for holding data, keys and internal Btree nodes, in bytes.
je-env-stat-DbClosedBins	Number of bins encountered by the INCompressor that had their database closed between the time they were put on the compressor queue and when the compressor ran.
je-env-stat-EndOfLog	Location of the next entry to be written to the log.
je-env-stat-InCompQueueSize	Number of entries in the INCompressor queue when the <code>getStats()</code> call was made.
je-env-stat-LastCheckpointEnd	Location in the log of the last checkpoint end.
je-env-stat-LastCheckpointId	ID of the last checkpoint.
je-env-stat-lastCheckpointStart	Location in the log of the last checkpoint start.
je-env-stat-lockBytes	Number of bytes of Java Edition (JE) cache used for holding locks and transactions.
je-env-stat-NBINSStripped	Number of BINS stripped by the evictor.

Monitor Attribute	Description
je-env-stat-NCacheMiss	Total number of requests for database objects that were not in memory.
je-env-stat-NCheckpoints	Total number of checkpoints run so far.
je-env-stat-NCleanerDeletions	Number of cleaner file deletions this session.
je-env-stat-NCleanerEntriesRead	Accumulated number of log entries read by the cleaner.
je-env-stat-NCleanerRuns	Number of cleaner runs this session.
je-env-stat-NClusterLNProcessed	Accumulated number of leaf nodes (LNs) processed because they qualify for clustering.
je-env-stat-NDeltaINFlush	Accumulated number of delta internal nodes (INs) flushed to the log.
je-env-stat-NEvictPasses	Number of passes made to the evictor.
je-env-stat-NFSyncRequests	Number of fsyncs requested through the group commit manager. <code>fsync()</code> synchronizes the file system after a write or a transaction.
je-env-stat-NFSyncTimeouts	Number of fsync requests submitted to the group commit manager which timed out.
je-env-stat-NFSyncs	Number of fsyncs issued through the group commit manager.
je-env-stat-NFileOpens	Number of times a log file has been opened.
je-env-stat-NFullBINFlush	Accumulated number of full BINs flushed to the log.
je-env-stat-NFullINFlush	Accumulated number of full INs flushed to the log.
je-env-stat-NINsCleaned	Accumulated number of INs cleaned.
je-env-stat-NINsDead	Accumulated number of INs that were not found in the tree anymore (deleted).
je-env-stat-NINsMigrated	Accumulated number of INs migrated.
je-env-stat-NINsObsolete	Accumulated number of INs obsolete.
je-env-stat-NLNQueueHits	Accumulated number of LNs processed without a tree lookup.
je-env-stat-NLNsCleaned	Accumulated number of LNs cleaned.
je-env-stat-NLNsDead	Accumulated number of LNs that were not found in the tree anymore (deleted).
je-env-stat-NLNsLocked	Accumulated number of LNs encountered that were locked.

Monitor Attribute	Description
je-env-stat-NLNsMarked	Accumulated number of LNs that were marked for migration during cleaning.
je-env-stat-NLNsMigrated	Accumulated number of LNs migrated.
je-env-stat-NLNsObsolete	Accumulated number of LNs obsolete.
je-env-stat-NLogBuffers	Number of log buffers currently instantiated.
je-env-stat-NMarkedLNProcessed	Accumulated number of LNs processed because they were previously marked for migration.
je-env-stat-NNodesExplicitlyEvicted	Accumulated number of nodes evicted.
je-env-stat-NNodesScanned	Accumulated number of nodes scanned to select the eviction set.
je-env-stat-NNodesSelected	Accumulated number of nodes selected to evict.
je-env-stat-NNotResident	Number of requests for database objects not contained within the in memory data structures.
je-env-stat-NOpenFiles	Number of files currently open in the file cache.
je-env-stat-NPendingLNLocked	Accumulated number of pending LNs that could not be locked for migration because of a long duration application lock.
je-env-stat-NPendingLNProcessed	Accumulated number of LNs processed because they were previously locked.
je-env-stat-NRandomReadBytes	Number of bytes read which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomReads	Number of disk reads which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomWriteBytes	Number of bytes written which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomWrites	Number of disk writes which required repositioning the disk head by more than 1MB from the previous file position.
je-env-stat-NRepeatFaultReads	Number of reads that had to be repeated when faulting in an object from disk because the read chunk size controlled by <code>je.log.faultReadSize</code> is too small.
je-env-stat-NRepeatIteratorReads	Number of times we try to read a log entry larger than the read buffer size and can't grow the log buffer to accommodate the large object.
je-env-stat-NRootNodesEvicted	Accumulated number of database root nodes evicted.

Monitor Attribute	Description
je-env-stat-NSequentialReadBytes	Number of bytes read which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialReads	Number of disk reads which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialWriteBytes	Number of bytes written which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialWrites	Number of disk writes which did not require repositioning the disk head by more than 1MB from the previous file position.
je-env-stat-NSharedCacheEnvironments	Number of environments using the shared cache.
je-env-stat-NTempBufferWrites	Number of writes which had to be completed using the temporary marshalling buffer because the fixed size log buffers specified by <code>je.log.totalBufferBytes</code> and <code>je.log.numBuffers</code> were not large enough.
je-env-stat-NToBeCleanedLNsWithinProcess	Accumulated number of LNs processed because they are soon to be cleaned.
je-env-stat-NonEmptyBins	Number of non-empty bins.
je-env-stat-ProcessedBins	Number of bins that were successfully processed by the INCompressor.
je-env-stat-RequiredEvictBytes	Number of bytes that must be evicted to get within the memory budget.
je-env-stat-SharedCacheTotalBytes	Total amount of the shared JE cache in use in bytes.
je-env-stat-SplitBins	Number of bins encountered by the INCompressor that were split between the time they were put on the compressor queue and when the compressor ran.
je-env-stat-TotalLogSize	Approximation of the current total log size in bytes.
je-env-stat-NOwners	Total lock owners in the lock table.
je-env-stat-NReadLocks	Total read locks currently held.
je-env-stat-NRequests	Total number of lock requests to date.
je-env-stat-NTotalLocks	Total locks currently in the lock table.
je-env-stat-NWaiters	Total transactions waiting for locks.
je-env-stat-NWaits	Total number of lock waits to date.

Monitor Attribute	Description
je-env-stat-NWriteLocks	Total write locks currently held.
je-env-stat-LastCheckpointTime	Time of the last checkpoint.
je-env-stat-LastTxnId	Last transaction ID allocated.
je-env-stat-NAborts	Number of transactions that have aborted.
je-env-stat-NActive	Number of transactions that are currently active.
je-env-stat-NBegins	Number of transactions that have begun.
je-env-stat-NCommits	Number of transactions that have committed.
je-env-stat-NXAAborts	Number of XA transactions that have aborted.
je-env-stat-NXACommits	Number of XA transactions that have committed.
je-env-stat-NXAPrepares	Number of XA transactions that have been prepared.

#### Summary of the Replication Summary Monitor information

The following table provides a description of the attributes in the `cn=Replication Summary` monitor entry, `dn: cn=Replication Summary <baseDN>,cn=monitor`.

Monitor Attribute	Description
base-dn: <baseDN>	Base DN summary.
replica: replica-id, ldap-server connected-to, generation-id, replication-backlog, recent-update-rate, peak-update-rate, age-of-oldest-backlog-change	Summary information for each replica in the topology. This entry appears for each replica in the topology with its own respective properties.
replication-server: server-id, server, generation-id, status, last-connected, last-failed, failed-attempts, attributes.	Summary information for each remote replication server only in the topology. This entry appears for each Replication Server in the topology with its own respective <code>serverID</code> and <code>server</code> properties.

Monitor Attribute	Description
<p>update-queue: id, max-count, current-count, max-size, current-size, polling-source, polling-source-changed</p>	<p>Summary information for each update queue on a server:</p> <p><b>id</b></p> <p>The ID of the receiving replica or replication server.</p> <p><b>max-count</b></p> <p>The maximum number of update messages that the sending replication server will keep in memory for the receiving replica or replication server. If the receiver cannot accept messages fast enough for any reason, such as high load and network latency, then this queue fills up.</p> <p>When that happens, the sending replication server reads update messages from the changelog backend and slows down the update processing considerably.</p> <p><b>current-count</b></p> <p>The number of update messages currently on the queue that have not been sent to the receiving replica or replication server. Every time the sending replication server sends an update to the receiving replica or replication server, this counter is decremented.</p> <p><b>max-size</b></p> <p>The maximum total size in bytes of update messages that can be in the queue.</p> <p>This queue is capped by both the <code>max-count</code> and the <code>max-size</code> setting, whichever is reached first.</p> <p><b>current-size</b></p> <p>The total size of update messages currently on the queue that have not been sent to the receiving replica or replication server. Every time the sending replication server sends an update to the receiving replica or replication server, this value is decremented by the size of the published update message.</p> <p><b>polling-source</b></p> <p>Set to either <code>memory</code> or <code>db</code>. If set to <code>memory</code>, the sending replication server relies only on the in-memory queue to push update messages to the receiving replica or replication server. If set to <code>db</code>, update messages are read and sorted from the changelog database, which is significantly slower than publishing updates from the in-memory queue.</p> <p><b>polling-source-changed</b></p> <p>The total number of times the <code>polling-source</code> attribute has changed value either from <code>db</code> to <code>memory</code> or from <code>memory</code> to <code>db</code>.</p> <div data-bbox="678 1717 1466 1896" style="border: 1px solid black; padding: 5px;"> <p> <b>Tip:</b></p> <p>If this value changes frequently, the queue size setting is too low.</p> </div>

### Summary of the replicationChanges Backend Monitor information

The following table provides a description of the attributes in the `cn=replicationChanges Backend Monitor` entry.

The following is the distinguished name (DN) for the replicationChanges Backend Monitor entry.

```
dn: cn=replicationChanges Backend,cn=monitor
```

Monitor Attribute	Description
<code>ds-backend-id</code>	ID descriptor for the backend.   <b>Note:</b> Typically, this is <code>replicationChanges</code> .
<code>ds-backend-base-dn</code>	Base DN for the backend.   <b>Note:</b> Typically, this is <code>replicationChanges</code> .
<code>ds-backend-is-private</code>	Flag to indicate if the backend is private.
<code>ds-backend-entry-count</code>	Entry count for the backend.
<code>ds-base-dn-entry-count</code>	Entry count for the base DN and the specified base DN.
<code>ds-backend-writability-mode</code>	Flag to indicate if the backend is writable or not.

### Summary of the Replication Protocol Buffer Monitor information

The following table provides a description of the attributes in the `cn=Replication Protocol Buffer monitor` entry.

The following is the distinguished name (DN) for the Replication Protocol Buffer Monitor entry. The monitors provide information on the state of the buffer for protocol operations, which is kept in the local storage.

```
dn: cn=Replication Protocol Buffer,cn=monitor
```

### Replication Protocol Buffer Monitor Information

Monitor Attribute	Description
<code>saved-buffers</code>	Number of protocol buffers.   <b>Note:</b> Initial buffer size is 4k.

Monitor Attribute	Description
reallocations	Number of times the buffers had to be reallocated due to insufficient size.
large-buffer-creates	Number of times a buffer larger than 512k was requested.
large-buffer-evictions	Number of times a buffer was removed from the thread local storage because it has grown above 512k.

## Advanced topics reference

This section provides background reference information for advanced replication topics.

Topics in this section include:

- [Performing disaster recovery](#) on page 913

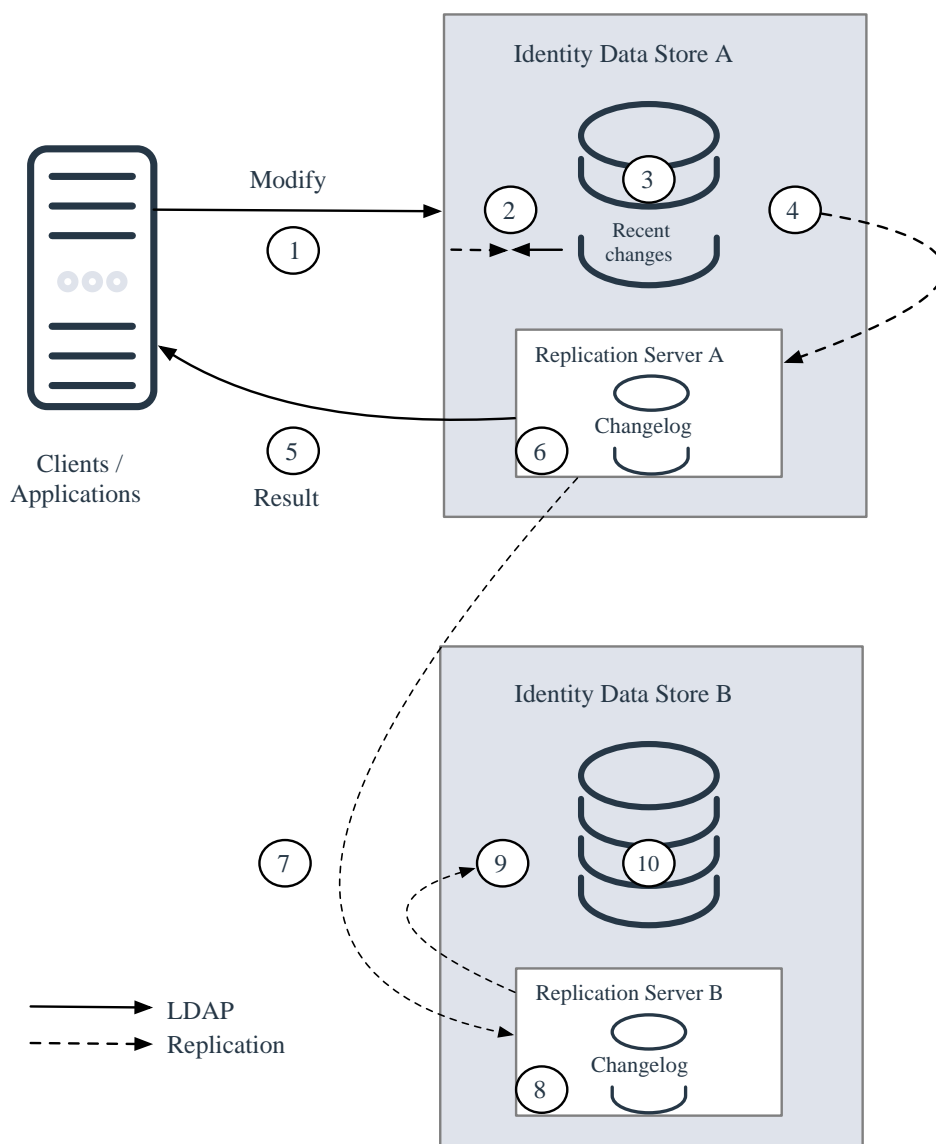

### About the replication protocol

The topic covers the replication, topology, protocol process, and background information.

Replication communication uses a proprietary binary protocol that implements on top of the TCP/IP protocol using SSL encryption. Some protocol messages are used for administrative purposes, such as WAN Gateway server negotiation or flow control, some carry updates to replicated data, and others are directed to all servers for monitoring requests.

In a replicated topology, each participating Directory Server connects to every other server through the replication server port to monitor health. Servers that share the same location setting are connected to rapidly replicate changes, and the WAN Gateway servers are all interconnected to replicate changes across locations.

The Directory Servers keep connections open as long as possible to reduce the communication latency when exchanging messages. Heartbeat messages transmit on a regular basis to detect a network failure or an unresponsive directory server as early as possible. Heartbeat messages also prevent idle connections from being closed by firewalls.

1. The client sends a `MODIFY` request to Directory Server A.
2. Directory Server A assigns a unique change number to the operation. Conflict resolution is executed to see if the `MODIFY` request is in conflict with the existing attribute types or values in the existing entry. The change number is assigned before the Directory Server backend is updated to preserve the arrival order of client requests. Historical data in the target entry is updated to reflect the change.

**Note:**

Historical data is only updated for `ADD` and `MODIFY` operations.

3. Directory Server applies the modifications in the corresponding backend.
4. If the `MODIFY` operation successfully completes, then the Directory Server submits the update to its embedded Replication Server. The Replication Server is a component within the Directory Server process responsible for propagating updates to and from the replication topology. The Directory Server itself only communicates with a single replication server, whereas the replication server component is connected to all other replication servers. If the Directory Server process exits unexpectedly and some updates haven't been passed to the Replication Server, the backend has the ability to recover the last 50,000 recent changes that were processed at this server, guaranteeing that these changes can be

- replicated when the server starts up. The figure above also shows that replication protocol is used not just between replication servers but also between the Directory Server and the Replication Server.
5. The response is sent to the client. In this example, a successful response is assumed.
  6. The Replication Server records the update in its own Changelog backend, such as backend ID of `replicationChanges` and on disk with the path to `changelogDb` under the server root. The Replication Changelog backend keeps track of updates at each and every Directory Server in the replication topology. When a Directory Server joins the replication topology after being disconnected for some reason, updates from the Replication Changelog backend are re-sent to this Directory Server. Old records from the Replication Changelog backend are purged, which, by default, removes records older than 24 hours. If the backend doesn't contain all of the records that another Directory Server needed when rejoining the replication topology, then the replicated data set in the Directory Server must be re-initialized. In this case, the Directory Server enters lockdown mode and sends an administrative alert.
  7. The Replication Server submits the update to the replication server component in Directory Server B. If there were more Directory Servers in this example, the Replication Server would submit the update to all the other replication servers in the same location.
  8. Just like in Step 6, the Replication Server component receiving an update inserts the change into its Replication Changelog backend.
  9. The update forwards to the Replica in Directory Server B. Conflict resolution executes to see if the `MODIFY` request is in conflict with the existing attribute types or values in the existing entry.
  10. The Directory Server applies the modification in the corresponding backend. The Recent Changes database doesn't update because only updates that originate at this Directory Server record in the Recent Changes database.

### Change number

This topic provides the change number purpose, functions, and components.

As detailed in [About the replication protocol](#) on page 906, the Directory Server assigns a unique change number to each update operation, specifically `ADD`, `DELETE`, `MODIFY`, or `MODIFY DN` operations, to track each request received from a client. The change number is attached to each update propagated through replication and allows each Directory Server to order updates exactly the same way.

The change number is composed of the following fields:

#### Timestamp

Identifies when the update was made. The timestamp is time-zone-independent and recorded with millisecond resolution.

#### Server ID

Uniquely identifies the Directory Server where the update was made.

#### Sequence number

Defines the order of the updates received from external clients at a particular directory server.

#### Tip:

The replication protocol sets a virtual clock that eliminates the need for synchronized time on servers. For troubleshooting purposes, you should keep the system clocks synchronized.

### Conflict resolution

This topic covers background information, the conflict resolution process flow, and explanation of conflict resolution.

Replication employs an eventual-consistency model which can introduce a window where conflicting updates targeting the same entry might be applied at two different Directory Servers. In general, if the update that arrived later fails, two updates to the same Directory Server are in conflict. Conflict resolution,

when possible, corrects conflicts introduced by clients automatically. There are some exceptions, however, when manual administrative action is required. For example, adding an entry in one replica and simultaneously deleting the parent of this entry on another replica introduces a conflict that requires manual action. In a carefully implemented deployment, the risk of introducing conflicts that require manual action can be significantly reduced or even eliminated.

The conflict resolution algorithm in PingDirectory Server uses a mechanism that orders all updates in the replication topology. The Directory Server assigns a unique change number to each update. The change number is attached to each update propagated through replication and allows each Directory Server to order updates exactly the same way. See the following diagram for an example.

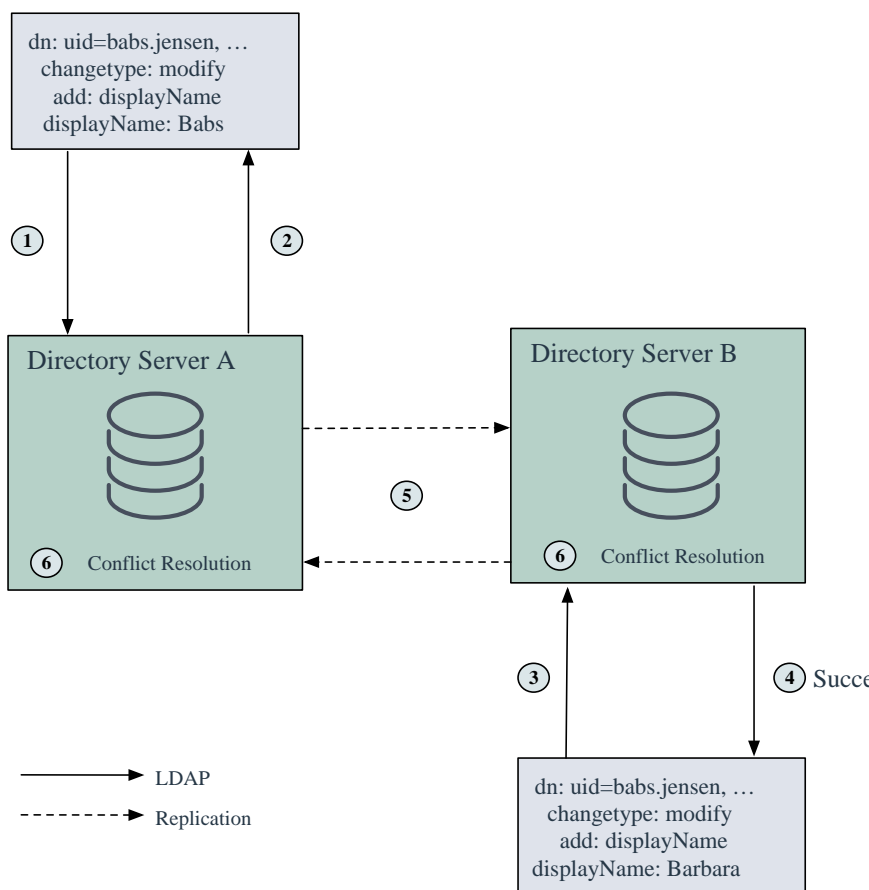

### Conflict resolution process flow

The following diagram depicts adding a single-valued attribute with different values to an entry concurrently at two Directory Servers resulting in a conflict as well as the conflict resolution in the standalone environment versus the replicated environment.

## Standalone

## Replicated

### Processing steps

1. The client sends a modify request to the Identity Data Store and succeeds.
2. The client sends another modify request that conflicts with the first.
3. In the standalone environment, the request is rejected. In the replicated environment, the request succeeds.
4. In the replicated environment only: Replication propagates the updates.

5. In the replicated environment only: Conflict resolution concludes with A ignores the update from B, B sets the attribute value to the value on A.

From the diagram example, you can make the following observations:

- The second operation fails if a client attempted to add the same attribute to the same entry at the same Directory Server.
- In a replicated environment, the conflict is not immediately seen if these updates are applied concurrently at two different Directory Servers.
- The conflict is handled only after replication propagates the updates.
- The Directory Servers resolve the conflict independently of the other server. On one Directory Server, the entry updates to reflect the correct value. On the other Directory Server, the value stays the same. As a result, each Directory Server independently resolves the conflict the same way based on the ordering of the updates.

### **WAN-friendly replication**

Minimize latency with Directory Server if you are using a WAN for your client applications.

Many multinational corporations that have data centers in different countries must minimize latency over WAN to ensure acceptable performance for their client applications.

To minimize WAN latency, the Directory Server assigns one of following two roles to the replication servers:

- The role of standard replication transmitting updates to the other co-located replication servers.
- The role of a WAN-dedicated replication server designed to send updates to other WAN-designated replication servers in other locations.

This two-role system minimizes WAN traffic by pushing all replication updates onto the connected replication servers that are designated as WAN Gateway Servers. Only the designated WAN Gateway Servers can transmit the update messages to other connected WAN Gateway servers at other locations.

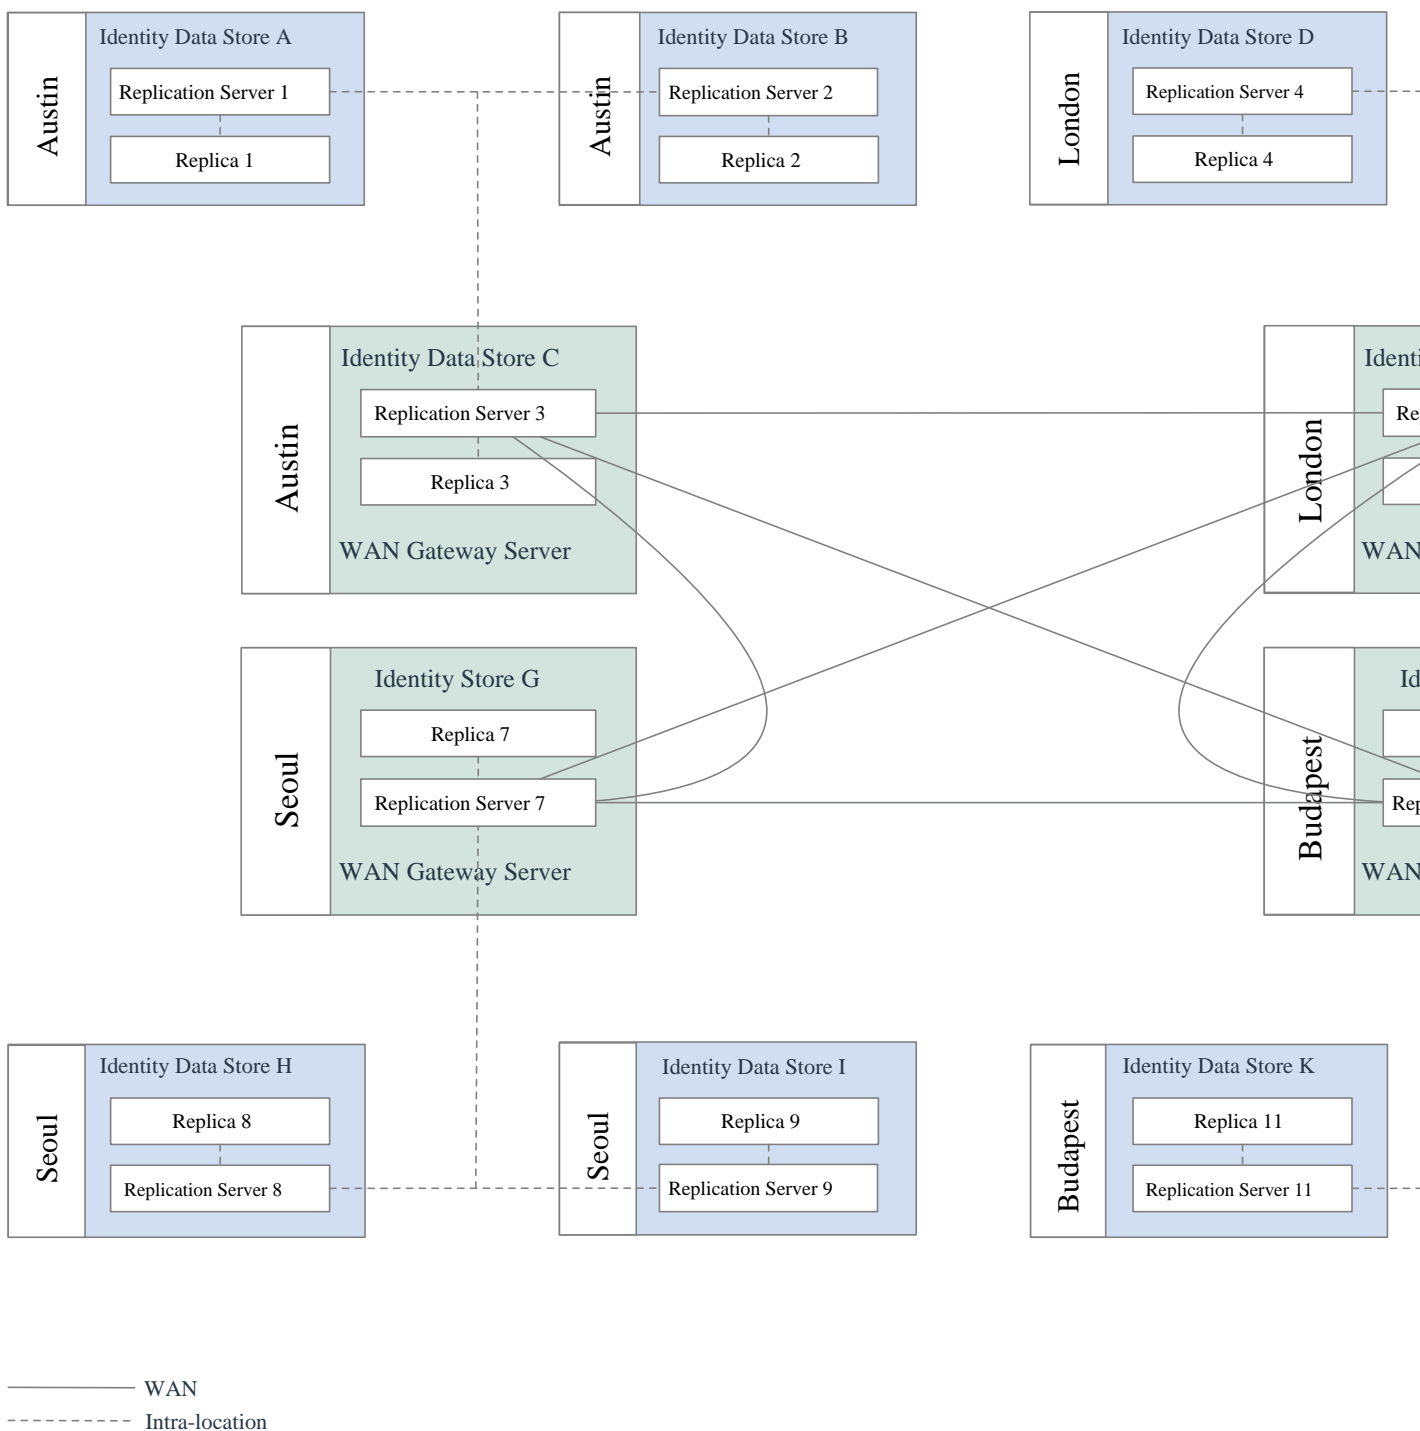

### **WAN Gateway Server**

The Directory Server's replication mechanism relies on the server's location information to reduce protocol traffic on WAN links.

During protocol negotiation, the replication server with the highest WAN Gateway priority (priority 1 indicates the highest priority) automatically assumes the role as the WAN Gateway Server for that particular location. The Gateway Server's main function is to route update messages from other non-gateway servers at the same location to remote WAN Gateway servers at other locations. At the destination point, the replication server with the WAN Gateway role receives update messages from other WAN gateway servers at other locations and pushes them out to all replication servers at the current location.

This setup ensures that all WAN communication flows through the WAN Gateway Servers.

The following diagram shows a basic connection configuration for updates. All of the replication servers are fully connected to each other for monitoring or server negotiation purposes.

If the WAN Gateway Server is temporarily unavailable due to planned or unplanned downtime, the system dynamically re-routes updates to a newly-designated WAN Gateway Server in the same location. The replication server with the next highest WAN Gateway priority number automatically assumes the WAN Gateway role. For deployments with entry-balancing Directory Proxy Servers, there is one WAN Gateway Server per data set.

 **Note:**

By default, all servers are enabled to serve as WAN Gateways and all are set to priority 5, which makes them all equal. After replication has been enabled, you can change the WAN Gateway priority using `dsconfig`.

### WAN message routing

Non-gateway replication servers forward update messages from replicas to co-located replication servers only. It is the responsibility of the WAN gateway server to forward these messages to WAN gateway servers at other locations.

The following figure illustrates how an update message is routed from a non-gateway server to a remote location.

### Processing steps

1. Update received at Identity Data Store 1 at the north location is sent to the embedded Replication Server.
2. Replication Server 1 routes message to the WAN Gateway only.
3. The WAN Gateway at the North location (Identity Data Store 2) routes message to Replica 2 and to the WAN Gateway at the south location.
4. Replication Server 3, which is the WAN Gateway at the south location, routes the message to Replica 3.

### WAN Gateway Server selection

The WAN Gateway role is dynamically assigned to the most suitable server in a particular location.

In most cases, the replication server with the higher WAN Gateway priority (priority 1 is the highest priority) assumes this role.

A replication server does not attempt to become a WAN Gateway if any of the following conditions exists:

- The WAN Gateway priority is set to 0.

- The replication server is backlogged at server startup.
- The current WAN Gateway has higher priority.
- The WAN Gateway has not been elected yet, but higher priority replication servers are present in the location.

The currently active WAN Gateway server gives up the gateway role in the following cases:

- The server has started the shutdown process.
- The server is preparing for a scheduled maintenance cycle.
- The server learns about a higher priority replication server in its location.

Replication servers send WAN Gateway information to other servers at regular intervals using the replication protocol. This allows the replication servers to take the appropriate action, such as to become a WAN Gateway, if necessary, without any manual administrative action.

### WAN replication in mixed-version environments

This topic covers the WAN Gateway role, replication actions, and updates in PingDirectory Servers mixed version environments.

Consider the following when using the WAN Gateway role in mixed-version environments:

- WAN Gateway Role assignment is only available on PingDirectory Servers version 3.5 and later.
- Legacy servers earlier than 3.5, are never selected as WAN Gateways.
- Updates from legacy replication servers forward to all replication servers and do not funnel to a single WAN Gateway, which increases WAN during replication.
- Updates from remote WAN Gateways forward to the legacy replication servers, which increases WAN traffic during replication.

### Recovering a replication changelog

If the replication changelog, `<server-root>/changelogDb`, is compromised because of a disk or NAS failure, you can recover a replication changelog.

About this task

To recover a replication changelog:

#### Steps

1. Stop the server.
2. Backup **replicationChanges** from a remote server using the following command.

```
$ bin/backup --backupDirectory /app/backups/replicationChanges \
--backendID replicationChanges
```

3. Copy the **replicationChanges** backup from the remote server and restore it on the local host using the following command.

```
$ bin/restore --backupDirectory /app/tmp/replicationChanges
```

4. Start the server.

### Performing disaster recovery

If data is compromised across all systems and a restore is necessary, you can perform disaster recovery.

About this task

**Note:**

Consider the following for disaster recovery:

- With the default configuration, the server automatically exports all data nightly using the **Export All Non-Administrative Backends** recurring task. Up to 7 days of exports are maintained.

**Note:**

You should archive these exports on another system.

- The Data Recovery Log logs all changes in a reversible format to `logs/data-recovery/data-recovery`.
- The `bin/extract-data-recovery-log-changes` tool provides the ability to redo or undo any changes from the `logs/data-recovery/data-recovery` logs.

The combination of these allows you to either rebuild the data set to any point in time or to revert specific changes on a live data set, such as if an errant application mistakenly wipes out some data.

For more information about LDIF exports, see [LDIF export as a recurring task](#) on page 405.

**Note:**

These steps assume that no server performs read or write operations during this process.

To complete a restore of your systems and perform a disaster recovery:

### Steps

1. Stop all servers.
2. Go to one of the servers and remove it from the topology:  
Example: `bin/remove-defunct-server`  
This also cleans replication artifacts on this server instance as long as bind credentials are not provided. For this reason, don't provide `--bindDN` or `--bindPassword` with this.
3. The server might ask you to reconnect for each offline server, enter `no`.
4. Locate the backup or exported LDIF file that represents the last working copy of the database.
5. Restore the backup or import the LDIF file on a single server. If importing an LDIF file, use the `--excludeReplication` option with the `bin/import-ldif` command.
6. Start the restored server. The server can now receive client requests.
7. The server might ask you to reconnect for each offline server, enter `no`.
8. Clean up replication artifacts from the next server before starting it up:  
Example: `bin/remove-defunct-server`
9. Start the server in lockdown mode with the following command:  
Example: `bin/start-server --skipPrime --lockdownMode`
10. Enable replication from the first server to the second server.  
Example: `bin/dsreplication enable`
11. Initialize the second server from the first with the following command:  
Example: `bin/dsreplication initialize`
12. Restart the second server or use the `bin/leave-lockdown-mode` command to exit lockdown mode.  
The second server can now receive client requests.
13. Repeat steps 6 through 10 for any other servers.

## Managing Logging

The PingDirectory Server supports a rich set of log publishers to monitor access, debug, and error messages that occur during normal server processing.

Administrators can view the standard set of default log files and configure custom log publishers with pre-defined filtering with its own log rotation and retention policies.

### Default Directory Server logs

The Directory Server provides a standard set of default log files to monitor the server activity.

#### Directory Server Logs

View this set of logs in the `PingDirectory/logs` directory. The following default log files are available on the Directory Server and are defined in the following table.

Log File	Description
<code>access</code>	File-based Access Log that records operations processed by the Directory Server. Access log records can be used to provide information about problems during operation processing, such as unindexed searches, failed requests, and so forth, and provide information about the time required to process each operation.
<code>change-notifications.log</code>	Records changes to data anywhere in the server, which match one or more configured change subscriptions.
<code>config-audit.log</code>	Records information about changes made to the Directory Server configuration in a format that can be replayed using the <code>dsconfig</code> tool.
<code>errors</code>	File-based Error Log. Provides information about warnings, errors, and significant events that occur during server processing.
<code>expensive-ops</code>	Expensive Operations Log. Disabled by default. Provides only those operations that took longer than 1000 milliseconds to complete.
<code>failed-ops</code>	Failed Operations Log. Provides information on all operations that failed in single-line log format.
<code>replication</code>	Records any replication errors and publishes them to the file system.
<code>searches-returning-no-entries</code>	Searches Returning No Entries Log. Disabled by default. Provides information only on operations that did not return any entries.
<code>server.out</code>	Records anything written to standard output or standard error, which includes startup messages. If garbage collection debugging is enabled, then the information is written to <code>server.out</code> .
<code>server.pid</code>	Stores the server's process ID.
<code>server.status</code>	Stores the timestamp, a status code, and an optional message providing additional information on the server status.

Log File	Description
setup.log	Records messages that occur during the initial configuration of a Directory Server with the <code>setup</code> tool.
tools	Directory that holds logs for long running utilities <code>import-ldif</code> , <code>export-ldif</code> , <code>backup</code> , <code>restore</code> , and <code>verify-index</code> . Current and previous copies of the log are present in the Directory Server.
update.log	Records messages that occur during a Directory Server update.

## Types of log publishers

PingDirectory Server provides several classes of log publishers for parsing, aggregating, and filtering information events that occur during normal processing in the server.

There are three primary types of log publishers:

- Access log publishers
- Debug log publishers
- Error log publishers

Each type has multiple subtypes of log files based on the log server type.

### Access log publishers

Access log publishers provide the requests received and the responses returned by the Directory Server. This information can be used to understand the operations performed by clients and to debug problems with the client applications. It can also be used for collecting usage information for performance and capacity planning purposes.

For information on tools that can analyze the access log to provide summaries of LDAP activity and performance, see [Monitoring PingDirectory metrics with Splunk](#) on page 970 and the `summarize-access-log` tool description in [Available command-line tools](#) on page 1086.

Access log type	Description
File-based audit log	<p>Special type of access logger that provides detailed information about changes processed within the server.</p> <p>Disabled by default.</p> <p><b>Data Recovery Log</b></p> <p>Publishes information about each write operation processed in the server in a manner that allows those changes to be reverted or replayed (in conjunction with the <code>extract-data-recovery-log-changes</code> tool) if data recovery is needed.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/data-recovery/data-recovery</code> directory.</p>
JDBC-based access log	<p>Stores access log information using a Java Database Connectivity (JDBC) database connection.</p> <p>Disabled by default.</p>

Access log type	Description
File-based access logs	<p>Provides a character-based stream used by TextWriter publishers as a target for outputting log records. There are several types of file-based access loggers:</p> <p><b>Admin Alert Access Log</b></p> <p>Generates administrative alerts for any operations that match the criteria for this access logger. Disabled by default.</p> <p><b>File-based Access Log</b></p> <p>Publishes access log messages to the file system. Enabled by default.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/access</code> directory.</p> <p><b>Syslog-based Access Log</b></p> <p>Publishes access log messages to a syslogd port. Disabled by default.</p> <p><b>Expensive-Operations Access Log</b></p> <p>Publishes only those access log messages of operations that take longer than 1000 milliseconds. Disabled by default.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/expensive-ops</code> directory.</p> <p><b>Failed-Operations Access Log</b></p> <p>Publishes only those access log messages of operations that failed for any reason. Enabled by default.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/failed-ops</code> directory.</p> <p><b>Successful Searches with No Entries Returned Log</b></p> <p>Publishes only those access log messages of search operations that failed to return any entries. Disabled by default.</p> <p><b>JSON Access Logger</b></p> <p>Publishes JSON-formatted access log messages to the file system.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/access.json</code> directory.</p> <p><b>Console JSON Access Logger</b></p> <p>Publishes JSON-formatted access log messages to the Java virtual machine (JVM)'s standard output or standard error stream.</p> <div data-bbox="581 1608 1461 1812" style="border: 1px solid black; padding: 10px; margin: 10px 0;"> <p> <b>Note:</b></p> <p>This log publisher is only recommended when the server is run in no-detach mode and is best suited for use in Docker or other containers that can capture log content written to standard output or standard error.</p> </div> <p><b>Third-Party Access Log Publisher</b></p> <p>Publishes access log messages using a custom log publisher created using the Server SDK.</p> <p><b>Third-Party File-Based Access Log Publisher</b></p> <p>Publishes access log messages to a file using a custom log publisher created using the Server SDK, including enhanced support for log file rotation and retention.</p>

Access log type	Description
HTTP operation log publishers	<p>Common Log File HTTP Operation Log Publisher</p> <p>Publishes information about HTTP requests in the W3C common log format.</p> <p>HTTP Detailed Access</p> <p>Publishes detailed information about HTTP requests processed by the server.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/http-detailed-access</code> directory.</p>

### Debug log publishers

Debug log publishers provide information about warnings, errors, or significant events that occur within the server.

Debug log type	Description
Debug Loggers	<p>Debug ACI Logger</p> <p>Stores debug information on access control instruction (ACI) evaluation for any request operations against the server.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/debug-aci</code> directory.</p> <p>Server SDK Extension Debug Logger</p> <p>Provides simplified access to debug messages generated by Server SDK extension.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/server-sdk-extension-debug</code> directory.</p>

### Error log publishers

The Error log reports errors, warnings, and informational messages about events that occur during the course of the server's operation.

Error log type	
File-based error logs	<p>There are several types of File-based error logs:</p> <p><b>Error log</b></p> <p>Publishes error messages to the file system. Enabled by default.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/errors</code> directory.</p> <p><b>Replication log</b></p> <p>Publishes replication error messages to the file system. Enabled by default.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/replication</code> directory.</p> <p><b>JSON Error Logger</b></p> <p>Publishes JSON-formatted error log messages to the file system.</p> <p>You can find this log publisher in the <code>&lt;pd_install&gt;/logs/errors.json</code> directory.</p> <p><b>Console JSON Access Logger</b></p> <p>Publishes JSON-formatted access log messages to the JVM's standard output or standard error stream.</p> <div data-bbox="581 978 1464 1184" style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;"> <p> <b>Note:</b></p> <p>This log publisher is only recommended when the server is run in no-detach mode and is best suited for use in Docker or other containers that can capture log content written to standard output or standard error.</p> </div> <p><b>Third-Party Error Log Publisher</b></p> <p>Publishes error log messages using a custom log publisher created using the Server SDK.</p> <p><b>Third-Party File-Based Error Log Publisher</b></p> <p>Publishes error log messages to a file using a custom log publisher created using the Server SDK, including enhanced support for log file rotation and retention.</p>
JDBC-based error logs	Stores error log information using a Java Database Connectivity (JDBC) database connection. Disabled by default.
Syslog-based error logs	Publishes error messages to a syslog port.

### Viewing the list of log publishers

View the list of log publishers on the Directory Server using the `dsconfig` tool.

About this task

 **Note:**

You must specifically configure the Java Database Connectivity (JDBC), syslog, and admin alert log publishers using `dsconfig` before they appear in the list of log publishers. Procedures to configure these types of log publishers appear later in this section.

### Steps

- To view the log publishers, run `dsconfig` with the `list-log-publishers` subcommand.

Example:

```
$ bin/dsconfig list-log-publishers
```

Result:

Log Publisher	Type	Enabled
enabled		
Debug ACI Logger	debug-access	false
Expensive Operations Access Logger	file-based-access	false
Failed Operations Access Logger	file-based-access	true
File-Based Access Logger	file-based-access	true
File-Based Audit Logger	file-based-audit	false
File-Based Debug Logger	file-based-debug	false
File-Based Error Logger	file-based-error	true
Replication Repair Logger	file-based-error	true
Successful Searches with No Entries Returned	file-based-access	false

### Enabling or disabling a default log publisher

You can enable or disable any log publisher available on the Directory Server using the `dsconfig` tool.

#### About this task

By default, the following loggers are disabled and should only be enabled when troubleshooting an issue on the server:

- Expensive Operations Access Logger
- File-Based Audit Logger
- File-Based Debug Logger
- Successful Searches with No Entries Returned

### Steps

- To enable an access log publisher, run `dsconfig` with the `set-log-publisher-prop` subcommand.

Example:

In this example, the Expensive-Ops log is enabled, which records only those access log messages that take 1000 milliseconds or longer.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Expensive Operations Access Logger" --set
  enabled:true
```

## Managing access and error log publishers

The access log records every request received and response returned by the Directory Server.

The access log stores the IDs for the client connection, operation, the LDAP message involved with each client request, and the server response. The information can be used to debug any problems with a client application by correlating the numeric operation identifier to the client request or response.

The Directory Server supports multiple classes of access log publishers depending on your logging requirements. The following types of access log publishers are available on the system:

### File-Based Access Log Publishers

Provides a character-based TextWriter stream for outputting log records. There are three subclasses of TextWriter access logs:

#### File-Based Access Logs

Enabled by default. The File-based Access Log publishes access messages to the file system as `<server-root>/logs/access`. The Failed-Operations Log, Expensive-Operations Log, and the Searches with No Entries Returned Log are specialized types of the File-Based Access Log and shows only specific information necessary for troubleshooting purposes.

#### Admin-Alert Access Logs

Disabled by default. The Admin-Alert Access Log is a specialized type of logger that automatically generates administrative alerts for any operations that match a criteria for this access log publisher.

#### Syslog-Based Access Logs

Disabled by default. The Syslog Access Log publishes access messages to a syslogd port.

### File-Based Audit Logs

Disabled by default. The Audit Log provides detailed information about modifications (writes) processed within the Directory Server. The File-based Audit Log publishes access messages to the file system as `<server-root>/logs/audit`.

### JDBC-Based Access Logs

Disabled by default. The Java Database Connectivity (JDBC)-based Access Log provides information using a JDBC database connection.

### JDBC-Based Error Logs

Disabled by default. The JDBC-based Error Log provides information using a JDBC database connection.

## Managing file-based access log publishers

The PingDirectory Server supports a flexible and configurable access logging system that provides a full set of customized components to meet your system's logging requirements.

The default access log can be configured to write information to a log file with two records per operation, one for the request received and one for the response returned. It can also be configured to write one message per operation or configured to record information about a subset of operations processed by the server. In addition to modifying existing default log files, you can create custom log publishers to monitor specific properties or connection criteria. For more information, see [Creating New Log Publishers](#).

The Directory Server can be configured to use multiple access log publishers writing logs to different files using different configurations. This approach makes it possible to have fine-grained logging for various purposes, such as a log that contains only failed operations, a log that contains only operations requested by root users or a log that contains only operations that took longer than 20ms to complete.

The Directory Server provides an additional mechanism to filter access logs to record only a subset of messages of one or more types. The access log filtering mechanism uses the operation criteria (connection, request, result, search-entry, search-reference) to determine whether a given message should be logged based on information associated with the client connection as well as information in the operation request and response messages. For more information, see [Configuring Filtered Logging](#).

### Access log format

The access log has a standard format that lists various elements identifying the connection and operation occurring within the Directory Server.

By default, each operation generates one access log message.

The access log displays the following common properties.

Property	Description
Timestamp	Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>
Connection Type	Displays the connection type requested by the client and the response by the server. Examples include the following: <ul style="list-style-type: none"> <li>▪ CONNECT</li> <li>▪ BIND REQUEST/RESULT</li> <li>▪ UNBIND REQUEST</li> <li>▪ DISCONNECT</li> <li>▪ SEARCH REQUEST/RESULT</li> <li>▪ MODIFY REQUEST/RESPONSE</li> <li>▪ ABANDON</li> <li>▪ ADD</li> <li>▪ COMPARE</li> <li>▪ DELETE</li> <li>▪ EXTENDED OPERATION</li> <li>▪ MODIFY</li> <li>▪ MODIFY DN</li> </ul>
Connection ID	Numeric identifier, starting incrementally with 0, that identifies the client connection that is requesting the operation. The connection ID is unique for a span of time on a single server. Values of the connection ID are re-used when the server restarts or when it has had enough connections to cause the identifier to wrap back to zero.
Operation ID	Numeric identifier, starting incrementally with 0, that identifies the operation. The operation ID is unique for a span of time on a single server. Values of the operation ID are re-used when the server restarts or when it has serviced enough operations to cause the identifier to wrap back to zero.

Property	Description
Result Code	<p>LDAP result code that determines the success or failure of the operation result. Result messages include a result element that indicates whether the operation succeeded or failed, the general category for the failure, and an etime element that indicates the length of time in milliseconds that the server spent processing the operation.</p> <p>The Directory Server provides a useful tool <code>&lt;server-root&gt;/bin/ldap-result-code</code> (UNIX, Linux) or <code>&lt;server-root&gt;\bat\ldap-result-code</code> (Windows), that displays all of the result codes used in the system. You can use the utility if you are not sure what a result code means. For example, use the following:</p> <ul style="list-style-type: none"> <li>▪ <code>ldap-result-code --list</code> displays all of the defined result codes in the Directory Server.</li> <li>▪ <code>ldap-result-code --int-value 16654</code> displays the name of the result code with a numeric value of 16654.</li> <li>▪ <code>ldap-result-code --search operation</code> displays a list of all result codes whose name includes the substring "operation".</li> </ul>
Elapsed Time	Displays the elapsed time (milliseconds) during which the operation completed its processing.
Message ID	Numeric identifier, starting incrementally with 1, that identifies the LDAP message used to request the operation.

### Access log example

The following example shows output from the access log in `<server-root>/logs/access`.

```
[01/Jun/2011:14:48:17 -0500] CONNECT conn=0 from="10.8.1.243"
to="10.8.1.243" protocol="LDAP"
[01/Jun/2011:14:48:17 -0500] BIND REQUEST conn=0 op=0 msgID=1 version="3"
dn="cn=Directory Manager"
authType="SIMPLE"
[01/Jun/2011:14:48:17 -0500] BIND RESULT conn=0 op=0 msgID=1 resultCode=0
etime=26.357
authDN="cn=Directory Manager,cn=Root DNs,cn=config"
[01/Jun/2011:14:48:17 -0500] UNBIND REQUEST conn=0 op=1 msgID=2
[01/Jun/2011:14:48:17 -0500] DISCONNECT conn=0 reason="Client Unbind"
... (more output) ...
```

### Modifying the access log using dsconfig interactive mode

The File-Based Access Log can be modified to include or exclude all log messages of a given type using the `dsconfig` tool in interactive or non-interactive mode.

About this task

## Steps

1. Use `dsconfig` in interactive mode to modify the access log properties.

Example:

```
$ bin/dsconfig
```

2. Follow the prompts to specify the LDAP connection parameters for host name or IP address, connection type (LDAP, SSL, or StartTLS), port number, bind DN and password.
3. On the Directory Server main menu, type the number corresponding to the Log Publisher.
4. On the **Log Publisher Management** menu, enter the option to view and edit an existing log publisher.
5. On the **Log Publisher** menu, type the number corresponding to File-based Access Logger.
6. On the **File-Based Access Log Publisher** menu, enter the number corresponding to the property that you want to change, and then follow the prompts.
7. Type `f` to apply the changes.

## Modifying the access log using dsconfig non-interactive mode

Use the `dsconfig` tool in non-interactive mode to modify a log publisher property on the command line or in a script.

### About this task

For information on each property, see the Directory Server [Configuration Reference Guide](#), which is an HTML document listing the various properties for each Directory Server component.

## Steps

- Use `dsconfig` with the `--no-prompt` option with the properties you want to modify or set for your access log.

Example:

In this example, enable the properties to include the instance name and startup ID.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Access
Logger" \
  --set include-instance-name:true --set include-startup-id:true
```

## Modifying the maximum length of log message strings

Change the maximum length of log message strings by setting the `max-string-length` configuration property.

### About this task

By default, the Directory Server sets the maximum length of log message strings to 2000 characters. This value is configurable for any access log publisher, except the syslog publisher, which is set to 500 characters. If any string has more than the configured number of characters, then that string is truncated and a placeholder is appended to indicate the number of remaining characters in the original string.

## Steps

- To set the `max-string-length` property for an access log, run `dsconfig`.

Example:

The following command configures the File-based Access Logger to include the instance name and the maximum length of the log message strings to 5000 characters.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
```

```
--set include-instance-name:true \
--set max-string-length:5000
```

## Disabling logging of inter-server periodic search requests

Disable logging of inter-server periodic search requests.

### Steps

1. Create a request criteria that matches all search requests with the inter-server request control.

Example:

```
dsconfig create-request-criteria --criteria-name "Inter-server Searches" \
--type simple --set operation-type:search \
--set any-included-request-control:1.3.6.1.4.1.30221.2.5.42
```

2. Create a request criteria that matches all requests that are not searches with the inter-server request control.

Example:

```
dsconfig create-request-criteria --criteria-name "Exclude Inter-server Searches" \
--type aggregate --set "none-included-request-criteria:Inter-server Searches"
```

3. Configure the access logger to use the request criteria you created.

This disables the logging of internal search requests and their corresponding results to the access log.

Example:

```
dsconfig set-log-publisher-prop --publisher-name "File-Based Access Logger" \
--set "request-criteria:Exclude Inter-server Searches"
```

## Generating access logs summaries

The Directory Server provides a convenience tool, `summarize-access-log`, that generates a summary of one or more file-based access logs.

### About this task

The summary provides analytical metric information that could be useful for administrators. The following metrics are provided in each summary:

- Total time span covered by the log files
- Number of connections established and the average rate of new connections per second
- IP addresses of up to the top 20 of the clients that most frequently connect to the server, the number of connections by each address, and the percentage of connections of each
- Total number of operations processed, the number of operations of each type, the percentage of each type out of the total number, and the average rate per second for each type of operation
- Average processing time for all operations and for each type of operation
- Histogram of the processing times for each type of operation
- Up to the 20 most common result codes for each type of operation, the number of operations of that type with that result code, and the percentage of operations of that type with that result code
- Number of unindexed searches processed by the server
- Breakdown of the scopes used for search operations with the number of percentage of searches with each scope

- Breakdown of the most common entry counts for search operations with the number and percentage of searches that returned that number of entries
- Breakdown of the most commonly used filter types for searches with a scope other than base (that is, those searches for which the server uses when processing the filter)

These filters are represented in a generic manner so that any distinct assertion values or substring assertion elements are replaced with question marks and attribute names in all lowercase characters such as `(givenName=John)` would be represented as `(givenName=?)`.

## Steps

- Use the `bin/summarize-access-log` with the path to one or more access log files.

Example:

```
$ bin/summarize-access-log /path/to/logs/access
```

Result:

The system displays the following information.

```
Examining access log /path/to/logs/access Examined 500 lines in 1 file
  covering a total duration of 1 day, 22 hours, 57 minutes, 31 seconds

Total connections established: 69 (0.000/second)
Total disconnects: 69 (0.000/second)

Most common client addresses:
127.0.0.1: 61 (88.406)
10.8.1.209: 8 (11.594)

Total operations examined: 181 ...
(metric for each operation examined) ...

Average operation processing duration: 22.727ms
Average add operation processing duration: 226.600ms
Average bind operation processing duration: 5.721ms
Average delete operation processing duration: 77.692ms
Average modify operation processing duration: 35.530ms
Average search operation processing duration: 4.017ms

Count of add operations by processing time:
... (histogram for add operations) ...

Count of bind operations by processing time:
... (histogram for bind operations) ...

Count of delete operations by processing time:
... (histogram for delete operations) ...

Count of modify operations by processing time:
... (histogram for modify operations) ...

Count of search operations by processing time:
... (histogram for search operations) ...

Most common add operation result codes:
success: 11 (84.615%)
entry already exists: 2 (15.385%)

Most common bind operation result codes:
success: 4 (50.000%)
invalid credentials: 4 (50.000%)
```

```

Most common delete operation result codes:
success: 1 (100.000%)

Most common modify operation result codes:
success: 9 (69.231%)
no such object: 4 (30.769%)

Most common search operation result codes:
success: 133 (91.724%)
no such object: 12 (8.276%)

Number of unindexed searches: 0

Most common search scopes:
BASE: 114 (78.621%)
SUB: 16 (11.034%)
ONE: 15 (10.345%)

Most common search entry counts:
1: 119 (82.069%)
0: 17 (11.724%)
2: 5 (3.448%)
10: 4 (2.759%)

Most common generic filters for searches with a non-base scope:
(objectclass=?): 19 (61.290%)
(ds-backend-id=?): 12 (38.710%)

```

## About log compression

The Directory Server supports the ability to compress log files as they are written.

This feature can significantly increase the amount of data that can be stored in a given amount of space so that log information can be kept for a longer period of time.

Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled at the time the logger is created. Compression cannot be turned on or off when the logger is configured. Because of problems in trying to append to an existing compressed file, if the server encounters an existing log file at startup, it rotates that file and begin a new one rather than attempting to append to the previous file.

Compression is performed using the standard gzip algorithm, so compressed log files can be accessed using readily available tools. The `summarize-access-log` tool can also work directly on compressed log files rather than requiring them to be uncompressed first.

However, because it can be useful to have a small amount of uncompressed log data available for troubleshooting purposes, administrators using compressed logging might want to have a second logger defined that does not use compression and has rotation and retention policies that minimizes the amount of space consumed by those logs while still making them useful for diagnostic purposes without the need to uncompress the files before examining them.

Configure compression by setting the `compression-mechanism` property to have the value of `gzip` when creating a new logger.

## About log signing

The Directory Server supports the ability to cryptographically sign a log to ensure that it has not been modified in any way.

For example, financial institutions require audit logs for all transactions to check for correctness. Tamper-proof files are needed to ensure that these transactions can be properly validated and ensure that they have not been modified by any third-party entity or internally by unscrupulous employees.

Use the **dsconfig** tool to enable the `sign-log` property on a log publisher to turn on cryptographic signing.

When enabling signing for a logger that already exists and was enabled without signing, the first log file is not completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled are considered completely valid. For the same reason, if a log file is still open for writing, then signature validation does not indicate that the log is completely valid because the log doesn't include the necessary end signed content indicator at the end of the file.

To validate log file signatures, use the **validate-file-signature** tool provided in the `bin` directory of the server or the `bat` directory for Windows systems.

After you have enabled this property, you must disable and then re-enable the log publisher for the changes to take effect.

## About encrypting log files

The Directory Server lets you encrypt log files as they are written.

The **encrypt-log** configuration property controls whether encryption is enabled for the logger. Enabling encryption causes the log file to have an `.encrypted` extension. If both encryption and compression are enabled, the extension is `.gz.encrypted`. Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption cannot be turned on or off after the logger is configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This reduces the overall size of the log file. The **encrypt-file** tool or custom code, using the LDAP SDK's `com.unboundid.util.PassphraseEncryptedInputStream`, is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the **encryption-settings create** command. By default, the encryption is performed with the server's preferred encryption settings definition.

To explicitly specify which definition should be used for the encryption, set the **encryption-settings-definition-id** property with the ID of that definition. You should set the encryption settings definition to be created from a passphrase so that the file can be decrypted by providing that passphrase even if the original encryption settings definition is no longer available. You can also create a randomly generated encryption settings definition, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data might remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it cannot write an incomplete block of data until the file is closed. This is not an issue for any log file that is not being actively written.

To examine the contents of a log file that is being actively written, use the **rotate-log** tool to force the file to be rotated before attempting to examine it.

## Configuring log signing

Configure log signing.

### Steps

1. To enable log signing for a log publisher, use **dsconfig**.

Example:

In this example, the `sign-log` property is set on the File-based Audit Log Publisher.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
  Logger" \
  --set sign-log:true
```

2. Disable and then re-enable the log publisher for the change to take effect.

Example:

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
  --set enabled:false
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
  --set enabled:true
```

### Validating a signed file

The Directory Server provides a tool, **validate-file-signature**, that checks if a file has not been tampered with in any way.

#### Steps

- Run the **validate-file-signature** tool to check if a signed file has been tampered with.

Example:

For this example, assume that the `sign-log` property was enabled for the File-Based Audit Log Publisher.

```
$ bin/validate-file-signature --file logs/audit
```

Result:

```
All signature information in file 'logs/audit' is valid
```

#### Note:

If any validation errors occur, you will see a message similar to the one as follows.

```
One or more signature validation errors were encountered
while validating the contents of file 'logs/audit':
* The end of the input stream was encountered without
  encountering the end of an active signature block.
  The contents of this signed block cannot be trusted
  because the signature cannot be verified
```

### Configuring log file encryption

Configure log file encryption.

#### Steps

1. To enable encryption for a log publisher, use **dsconfig**.

Example:

In this example, the File-based Access Log Publisher "Encrypted Access" is created, compression is set, and rotation and retention policies are set.

```
$ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted
Access" \
  --type file-based-access \
  --set enabled:true \
  --set compression-mechanism:gzip \
  --set encryption-settings-definition-
id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
```

```
--set encrypt-log:true \
--set log-file:logs/encrypted-access \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy" \
--set "retention-policy:Size Limit Retention Policy"
```

## 2. Decrypt and decompress the file.

Example:

```
$ bin/encrypt-file --decrypt \
--decompress-input \
--input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
--output-file decrypted-access
Initializing the server's encryption framework...Done
Writing decrypted data to file '/ds/Data-Sync/decrypted-access' using a
key generated from encryption settings definition
'332c846ef0dcd1d5187c1592e4c74cad33fc1e5fc20b726cd301cdd2b3ffbc2b'
Successfully wrote 123,456,789 bytes of decrypted data
```

## Creating new log publishers

The PingDirectory Server provides customization options to help you create your own log publishers with the `dsconfig` command.

When you create a new log publisher, you must also configure the log retention and rotation policies for each new publisher.

For more information, see [Configuring Log Rotation](#) and [Configuring Log Retention](#).

### Creating a new log publisher

#### Steps

1. Use the `dsconfig` command in non-interactive mode to create and configure the new log publisher.

Example:

This example shows how to create a logger that only logs disconnect operations.

```
$ bin/dsconfig create-log-publisher \
--type file-based-access --publisher-name "Disconnect Logger" \
--set enabled:true \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set log-connects:false \
--set log-requests:false --set log-results:false \
--set log-file:logs/disconnect.log
```

#### Note:

To configure compression on the logger, add the `--set compression-mechanism: gzip` option to the previous command.

Because compression cannot be disabled or turned off after configured for the logger, plan carefully to determine your logging requirements, including log rotation and retention with regards to compressed logs.

2. View log publishers with the following command.

```
$ bin/dsconfig list-log-publishers
```

## Creating a log publisher using dsconfig interactive command-line mode

### Steps

1. In the command line, enter `bin/dsconfig`.
2. Authenticate to the server by following the prompts.
3. In the main menu, select the option to configure the log publisher.
4. In the `Log Publisher` menu, select the option to create a new log publisher.
5. Select the Log Publisher type.  
For this example, select **File-Based Access Log Publisher**.
6. Enter a name for the log publisher.
7. Enable it.
8. Enter the path to the log file, relative to the Directory Server root.  
For this example, `logs/disconnect.log`.
9. Select the rotation policy to use for this log publisher.
10. Select the retention policy to use for this log publisher.
11. In the `Log Publisher Properties` menu, select the option for `log-connects:false`, `log-disconnects:true`, `log-requests:false`, and `log-results:false`.
12. Enter `f` to apply the changes.

## Configuring log rotation

The Directory Server allows you to configure the log rotation policy for the server.

### About this task

When any rotation limit is reached, the Directory Server rotates the current log and starts a new log.

If you create a new log publisher, you must configure at least one log rotation policy.

You can select the following properties:

#### Time Limit Rotation Policy

Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every 7 days.

#### Fixed Time Rotation Policy

Rotates the logs every day at a specified time (based on 24-hour time). The default time is 2359.

#### Size Limit Rotation Policy

Rotates the logs when the file reaches the maximum size for each log. The default size limit is 100 MB.

#### Never Rotate Policy

Used in a rare event that does not require log rotation.

## Steps

- Use `dsconfig` to modify the log rotation policy for the access logger.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

## Configuring log rotation listeners

The Directory Server provides two log file rotation listener, the copy log file rotation listener and the summarize log file rotation listener, which you can enable with a log publisher.

### About this task

Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file is subject to deletion by a log file retention policy, but the copy is not automatically removed.

The summarize log file rotation listener invokes the `summarize-access-log` tool on a recently-rotated log file and writes its output to a file in a specified location. This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the `summarize-access-log` tool, including the `file-based-access` and `operation-timing-access` logger types.

## Steps

- Use the following command to create a new copy log file rotation listener.

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Copy on Rotate" \
  --type copy \
  --set enabled:true \
  --set copy-to-directory:/path/to/archive/directory \
  --set compress-on-copy:true
```

### Note:

The path specified by the `copy-to-directory` property must exist, and the file system containing that directory must have enough space to hold all of the log files that are written there. The server automatically monitors free disk space on the target file system and generates administrative alerts if the amount of free space gets too low.

- Use the following command to create a new summarize log file rotation listener.

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Summarize on Rotate" \
  --type summarize \
  --set enabled:true \
```

```
--set output-directory:/path/to/summary/directory
```

#### Note:

The summary output files have the same name as the rotated log file, with an extension of `.summary`. If the `output-directory` property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.

As with the copy log file rotation listener, summary files are not automatically deleted. Although files are generally small in comparison to the log files themselves, make sure that enough space is available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

## Configuring log retention

The Directory Server allows you to configure the log retention policy for each log on the server.

### About this task

When a retention limit is reached, the Directory Server removes the oldest archived log before creating a new log. Log retention is only effective if you have a log rotation policy in place.

If you create a new log publisher, you must configure at least one log retention policy.

#### File Count Retention Policy

Sets the number of log files you want the Directory Server to retain. The default file count is 10 logs. If the file count is set to 1, then the log continues to grow indefinitely without being rotated.

#### Free Disk Space Retention Policy

Sets the minimum amount of free disk space. The default free disk space is 500 MBytes.

#### Size Limit Retention Policy

Sets the maximum size of the combined archived logs. The default size limit is 500 MBytes.

#### Time Limit Retention Policy

Sets the maximum length of time that rotated log files should be retained.

#### Custom Retention Policy

Create a new retention policy that meets your Directory Server's requirements. This requires developing custom code to implement the desired log retention policy

#### Never Delete Retention Policy

Used in a rare event that does not require log deletion.

### Steps

- Use `dsconfig` to modify the log retention policy for the access logger.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

## Configuring filtered logging

The PingDirectory Server provides a mechanism to filter access log messages based on specific criteria.

### About this task

You can use the filtered log with a custom log publisher to create and generate your own custom logs. Adding new filtered logs and associate publishers doesn't change the behavior of any existing logs. For example, adding a new log that only contains operations that were unsuccessful doesn't result in those operations being removed from the default access log.

The following example shows how to create a set of criteria that matches any operation that didn't complete successfully. It then explains how to create a custom access log publisher that logs only operations matching that criteria.

#### Note:

This log does not include messages for connects or disconnects, and only a single message is logged per operation. This message contains both the request and result details.

To run log filtering based on any operation result, such as result code, processing time, and response controls, turn off request logging and set the `include-request-details-in-result-messages` property to `TRUE`.

Because filtering based on the results of an operation can't be done until the operation completes, the server has no idea whether to log the request. Therefore, it might log request messages but not log any result messages. If you can only log result messages and include request details in the result messages, then only messages for operations that match the result criteria are logged. All pertinent information about the corresponding requests are included.

### Steps

1. Use the `dsconfig` command in non-interactive mode to create a result criteria object set to `failure-result-codes`, a predefined set of result codes that indicate when an operation didn't complete successfully.

Example:

```
$ bin/dsconfig create-result-criteria --type simple \
  --criteria-name "Failed Operations" --set result-code-criteria:failure-
  result-codes
```

2. Use `dsconfig` to create the corresponding log publisher that uses the result criteria.

#### Note:

The log rotation and retention policies are also set with this command.

Example:

```
$ bin/dsconfig create-log-publisher \
  --type file-based-access \
  --publisher-name "Filtered Failed Operations" \
  --set enabled:true \
  --set log-connects:false \
  --set log-disconnects:false \
  --set log-requests:false \
  --set "result-criteria:Failed Operations" \
  --set log-file:logs/failed-ops.log \
  --set include-request-details-in-result-messages:true \
```

```
--set "rotation-policy:7 Days Time Limit Rotation Policy" \  
--set "retention-policy:Free Disk Space Retention Policy"
```

3. View the `failed-ops.log` in the `logs` directory and verify that only information about failed operations was written to it.

## Managing Admin Alert Access Logs

Admin Alert Access Logs are a specialized form of filtered log that automatically generates an administrative alert when criteria configured for the log publisher matches those messages in the access log.

### About access log criteria

Configuring an Admin Alert Access Log requires you to configure the criteria for the access log messages.

Each criteria can be either a Simple or an Aggregate type. The Simple type uses the set of properties for the client connection, operation request, and the contents of any operation-specific requests or results. The Aggregate type provides criteria that contains Boolean combination of other operation-specific criteria objects.

For more information, see the Ping Identity Directory Server [Configuration Reference](#).

The criteria can be one or more of the following:

#### Connection Criteria

Defines sets of criteria for grouping and describing client connections based on a number of properties, including:

- Protocol
- Client address
- Connection security
- Authentication state

#### Request Criteria

Defines sets of criteria for grouping and describing operation requests based on a number of properties, including:

- Properties for the associated client connection
- The type of operation
- Targeted entry
- Request controls
- Target attributes
- Other operation-specific terms

#### Result Criteria

Defines sets of criteria for grouping and describing operation results based on a number of properties, including:

- The associated client connection and operation request
- The result code
- Response controls
- Privileges missing or used
- Other operation-specific terms

#### Search Entry Criteria

Defines sets of criteria for grouping and describing search result entries based on a number of properties, including:

- The associated client connection and operation request
- The entry location and contents
- Included controls

#### Search Reference Criteria

Defines sets of criteria for grouping and describing search result references based on a number of properties, including:

- The associated client connection and operation request
- Reference contents
- Included controls

### Configuring an Admin Alert Access Log publisher

Before configuring an Admin Alert Access Log, you must establish an administrative alert handler in your system.

#### About this task

For more information, see [Working with Administrative Alert Handlers](#).

#### Steps

1. To create a criteria object for the Admin Alert Access Log, use **dsconfig**.

If you are using the **dsconfig** tool in interactive mode, the menu items for the criteria operations are located in the `Standard objects` menu.

Example:

For this example, we want to log only write operations that target user entries. The following command matches any of the specified operations whose target entry matches the filter (`objectClass=person`).

```
$ bin/dsconfig create-request-criteria --type simple \
  --criteria-name "User Updates" \
  --set operation-type:add \
  --set operation-type:delete \
  --set operation-type:modify \
  --set operation-type:modify-dn \
  --set "any-included-target-entry-filter:(objectClass=person)"
```

2. To create a log publisher of type `admin-alert-access`, use **dsconfig**.

Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "User Updates Admin Alert Access Log" \
  --type admin-alert-access \
  --set "request-criteria:User Updates" \
  --set include-request-details-in-result-messages:true \
  --set enabled:true
```

### Managing the Syslog-Based Access Log Publishers

The Directory Server supports access logging using the syslog protocol that is part of the Berkeley Software Distribution (BSD) operating systems.

Syslog provides a flexible, simple means to generate, store, and transfer log messages that's supported on most UNIX and Linux operating systems.

The quasi-standard syslog message format cannot exceed 1 KB and has three important parts:

## PRI

Specifies the message priority based on its facility and severity. The message facility is a numeric identifier that specifies the type of log messages, such as kernel messages and mail system messages. The severity is a numeric identifier that specifies the severity level of the operation that is being reported. Together, the facility and the severity determine the priority of the log message indicated by angled brackets and 1-3 digit priority number. For example, <0>, <13>, and <103> are valid representations of the PRI.

## Timestamp and host name

The timestamp displays the current date and time of the log. The host name or IP address displays the source of the log.

## Message

Displays the actual log message.

You can configure syslog to handle log messages using log priorities that are based on the message's facility and severity. This feature allows users to configure the logging system so that messages with high severities are sent to a centralized repository while lower severity messages are stored locally on a server.

### Note:

Because the numeric values of the severity and facility are operating system-dependent, the central repository must only include syslog messages from compatible OS types. Otherwise, the meaning of the PRI field is ambiguous.

## Before you begin

You must identify the host name and port to which you want to connect.

Because the Syslog Protocol uses user datagram protocol (UDP) packets, you should use `localhost` and use some additional logging tools, such as `syslog-ng`. UDP is an unreliable and unsecure means to transfer data packets between hosts.

## Logging with syslog

The PingDirectory Server can write log messages using the syslog protocol for both access and error logs.

This allows messages to be aggregated at the system level and potentially forwarded to a centralized system. The messages are written to syslog as they are generated, so attackers do not have a chance to alter these log messages.

If you want to use syslog-based logging, configure the server to log to a syslog server running on the local server over the loopback interface. The local syslog server can then forward the messages to a remote server over a secure connection.

Logging over TCP for improved reliability is supported.

UDP-based communication is in the clear, so a network observer can see all of the log messages. You should only use syslog to log to a local syslog server and have it forward messages to a remote server in a secure manner. TLS encryption for TCP-based communication is optionally supported, so you can safely configure the server to log directly to a remote syslog server.

UDP does not provide any feedback about whether messages are successfully delivered, but TCP does provide this feedback. When using TCP-based logging, you can optionally specify information about multiple syslog servers. If the primary syslog server becomes unavailable, the logger can fail over to an alternative syslog server.

Logging access and error log messages can be logged as JSON objects or in legacy space-delimited text format.

In addition to access and error logging over syslog, loggers that can write JSON-formatted audit and HTTP operation log messages are also provided.

### Default access log severity level

All messages are logged at the syslog severity level of 6, which are `Informational: informational` messages.

#### Note:

This value is not standard across different types of UNIX or Linux systems. For more information, consult your operating system.

## syslog-facility properties

### Syslog Facility Properties

When using syslog, specify a facility for the access log messages. As an advanced property, you can select a number that corresponds to the facility you want to use. The default value for the `syslog-facility` property is 1 for user-level messages.

#### Note:

These values are not standard across different types of UNIX or Linux systems. Consult your particular operating system documentation for properties specific to that system.

Facility	Description
0	kernel messages
1	user-level messages (default)
2	mail system
3	system daemons
4	security/authorization messages
5	messages generated internally by syslogd
6	line printer subsystem
7	network news subsystem
8	UUCP subsystem
9	clock daemon
10	security/authorization messages
11	FTP daemon
12	NTP subsystem
13	log audit

Facility	Description
14	log alert
15	clock daemon
16	local use 0
17	local use 1
18	local use 2
19	local use 3
20	local use 4
21	local use 5
22	local use 6
23	local use 7

### queue-size property

The `queue-size` property determines the maximum number of log records that can be stored in the asynchronous queue.

The default queue size set is 10000, which means that the server continuously flushes messages from the queue to the log. The server does not wait for the queue to fill up before flushing to the log. Lowering this value impacts performance.

### Configuring a Syslog-Based Access Log Publisher

About this task

You can configure a Syslog-based Access Log Publisher using the `dsconfig` tool. We recommend that you use syslog locally on localhost and use `syslog-ng` to send the syslog messages to remote syslog servers.

Because syslog implementations differ by vendor, please review your particular vendor's syslog configuration.

#### Steps

- Use `dsconfig` to create a log publisher of type `syslog-based-access`.

If you are using the `dsconfig` tool in interactive mode, the menu item for Syslog Facility is an advanced property, which can be exposed by typing `a` (for "show advanced properties") on the Syslog-Based Access Log Publisher menu.

Example:

```
$ bin/dsconfig create-log-publisher \
--publisher-name "syslog-access" \
--type syslog-based-access \
--set syslog-facility:4 \
--set enabled:true
```

## Managing the File-Based Audit Log Publishers

The Directory Server provides an audit log, a specialized version of the access log, for troubleshooting problems that might occur during processing.

The log records all changes to the data in LDIF format so that administrators can quickly diagnose the changes an application made to the data or replay the changes to another server for testing purposes.

The audit log does not record authentication attempts but can be used in conjunction with the access log to troubleshoot security-related issues. Because the audit log adversely impacts the server's write performance, it is disabled by default.

### Audit log format

The audit log uses standard LDIF format so that administrators can analyze what changes occurred to the data. The audit log begins logging when enabled and should be used to debug any issues that might have occurred.

Common properties include:

#### Timestamp

Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>.

#### Connection ID

Numeric identifier, starting incrementally with 0, that identifies the client connection that is requesting the operation.

#### Operation ID

Numeric identifier, starting incrementally with 0, that identifies the operation.

#### Modifiers Name

Displays the distinguished name (DN) of the user who made the change.

#### Update Time

Records the `modifyTimestamp` operational attribute.

### Audit log example

The following example shows output from the audit log in the `<server-root>/logs/audit`. The first entry shows when the audit log was enabled. The second entry show changes made to a user entry.

```
# 05/Jun/2011:10:29:04 -0500; conn=0; op=55
dn: cn=File-Based Audit Logger,cn=Loggers,cn=config
changetype: modify
replace: ds-cfg-enabled
ds-cfg-enabled: true
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z

# 05/Jun/2011:10:31:20 -0500; conn=2; op=1
dn: uid=user.996,ou=People,dc=example,dc=com
changetype: modify
replace: pager
pager: +1 115 426 4748
-
replace: homePhone
```

```
homePhone: +1 407 383 4949
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z
```

## Enabling the File-Based Audit Log Publisher

### About this task

Enable the File-Based Audit Log Publisher using the `dsconfig` tool. The audit log impacts the Directory Server's write performance. Enable it only when troubleshooting.

### Steps

- To enable the File-Based Audit Log Publisher, run `dsconfig`.

Example:

In this example, the instance name and startup ID are also enabled in the audit log.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
  --set include-instance-name:true \
  --set include-startup-id:true
```

## Obscuring values in the audit log

### About this task

Each value of an obscured attribute is replaced in the audit log with `***** OBSCURED VALUE *****`.

### Steps

- To obscure the values of specific attributes in the audit log, use the `obscure-attribute` property.

By default, attributes are not obscured because the values of password attributes appear in hashed form rather than in cleartext.

## Managing the JDBC Access Log Publishers

You can configure the Directory Server to implement a centralized logging system with different databases by connecting to a database.

The Directory Server supports the Java Database Connectivity (JDBC) API, which allows access to SQL datastores by means of its JDBC drivers. The JDBC 4.0 API, part of the Java SDK, provides a seamless method to interface with various database types in heterogeneous environments.

Centralized logging simplifies log correlation and analysis tasks and provides security by storing data in a single repository. However, data flow asymmetries might complicate synchronization or network provisioning and could unduly burden the central repository with heavy loads.

### Before you begin

Before configuring the Java Database Connectivity (JDBC) Access Log Publisher, you must carry out two essential steps to set up the database.

To set up the database:

- Install the database drivers in the Directory Server `lib` directory.

- Define the log mapping tables needed to map access log elements to the database column data.

**Note:**

Only those elements in the log mapping table get logged by the JDBC log publisher.

## Configuring the JDBC drivers

### About this task

The Directory Server supports a number of JDBC drivers available in the market. You should use the JDBC 4 drivers supported in the Java platform. For example, for Oracle databases, you must use the `ojdbc.jar` driver for Java and any associated JAR files (National Language Support `.jars` and others) required to connect with the particular database. The following databases are supported:

- DB2
- MySQL
- Oracle Call Interface (OCI)
- Oracle Thin
- PostgreSQL
- SQL Server

### Steps

- Obtain the `.jar` file or files for your particular database and copy them into the `<server-root>/lib` directory.

## Configuring the log field mapping tables

### About this task

The log field mapping table associates access log fields with the database column names. Configure the log field mapping table using the `dsconfig` tool, which generates a DDL file that you can import into your database. The DDL file is generated when you create the JDBC Log Publisher.

To uniquely identify a log record, you should map the following fields:

- `timestamp`
- `startupid`
- `message-type`
- `connection-id`
- `operation-type`
- `instance-name`

**Note:**

The table name is not part of this mapping.

The Directory Server also provides these options that you can select for creating a log field mapping table:

#### Complete JDBC Access Log Field Mappings

Maps all 52 object properties.

#### Complete JDBC Error Log Field Mappings

Maps all 8 object properties.

### Simple JDBC Access Log Field Mappings

Maps a common set of object properties.

### Custom JDBC Access Log Field Mappings

Create a custom set of JDBC log field mappings.

### Custom JDBC Error Log Field Mappings

Create a custom set of JDBC error log field mappings.

## Steps

1. Use `dsconfig` to create a log field mapping table.
2. In the main menu, enter `o` to change to the `Standard Object` menu, and enter the number corresponding to `Log Field Mapping`.
3. In the `Log Field Mapping management` menu, enter the option to create a new `Log Field Mapping`.
4. In the `Log Field Mapping template` menu, enter the option to select a complete `JDBC Access Log Field mapping` to use as a template for your new field mapping.
5. Enter a name for the new field mapping.  
For this example, enter `my-jdbc-test`.
6. In the `Access Log Field Mapping Properties` menu, select a property for which you want to change the value.  
Any property that is undefined is not logged by the `JDBC Access Log Publisher`.
7. Enter `f` to save and apply the changes.
8. In the `Log Field Mapping Management` menu, enter `q` to exit the menu.
9. View the existing `Log Mappings` on the system.

Example:

```
$ bin/dsconfig list-log-field-mappings
```

Result:

```
Log Field Mapping                : Type
-----:-----
Complete JDBC Access Log Field Mappings : access
Complete JDBC Error Log Field Mappings  : error
my-jdbc-test                       : access
Simple JDBC Access Log Field Mappings   : access
```

## Configuring the JDBC Access Log Publisher using dsconfig interactive mode

### About this task

After setting up the drivers and the log mapping table, use the `dsconfig` tool to configure the `JDBC Access Log Publisher` on the Directory Server. The following example uses `dsconfig` interactive mode to illustrate the steps required to configure the log publisher and the external database server.

## Steps

1. Copy the database `.JAR` files to the `<server-root>/lib` directory, and then restart the Directory Server.

2. Launch the `dsconfig` tool in interactive command-line mode.

Example:

```
$ bin/dsconfig
```

3. Enter the connection parameters to bind to the Directory Server.

Enter the host name or IP address, type of LDAP connection (LDAP, SSL, or StartTLS) that you are using on the Directory Server, the LDAP listener port number, the user bind DN, and the bind DN password.

4. In the main menu, enter the number corresponding to `Log Publisher`.
5. In the `Log Publisher` management menu, enter the option to create a new log publisher.
6. In the `Log Publisher` template menu, enter `n` to create a new Log Publisher.
7. In the `Log Publisher Type` menu, enter the option to create a new JDBC-Based Access Log Publisher.
8. Enter a name for the JDBC Access Log Publisher.
9. In the `Enabled Property` menu, enter the option to enable the log publisher.
10. In the `Server Property` menu, enter the option to create a new JDBC External Server.
11. Enter the name for the JDBC External Server.

This is a symbolic name used to represent the database management system (DBMS).

12. In the `JDBC Driver Type Property` menu, enter the number corresponding to the type of JDBC database driver type.
13. Enter a name for the `database-name` property.

This is the DBMS database name. The database name must contain the table referred to in the generated DDL.

14. Enter the host name or IP address (`server-host-name`) of the external server.
15. Enter the server listener port.

For this example, enter `1541`.

16. Review the properties for the external server, and then enter `f` to apply the changes.
17. If you need to supply your own JDBC URL, enter `a` for advanced properties to open the `jdbc-driver-url` property and supply the appropriate URL.

Example:

The example below shows how to access an Oracle Thin Client connection using a SID instead of a Service.

```
>>>> Configure the properties of the JDBC External Server

Property Value(s)
-----
1) description -
2) jdbc-driver-type oraclethin
3) jdbc-driver-url jdbc:oracle:thin@myhost:1541:my_SID
4) database-name jdbc-test
5) server-host-name localhost
6) server-port 1541
7) user-name -
8) password -

?) help
f) finish - create the new JDBC External Server
a) hide advanced properties of the JDBC External Server
d) display the equivalent dsconfig arguments to create this object
b) back
```

```
q) quit
Enter choice [b]: f
```

**Result:**

When the JDBC Log Publisher is created, the Directory Server automatically generates a DDL file of the Log Field Mappings in the `<server-root>/logs/ddls/<name-of-logger>.sql` file, and you receive the following message.

```
JDBC External Server was created successfully
```

18. Import the DDL file to your database.

**Configuring the JDBC Access Log Publisher using dsconfig non-interactive mode**

## About this task

The following example uses `dsconfig` non-interactive mode to illustrate the steps to configure the log publisher and the external database server presented in the previous section.

## Steps

1. Use `dsconfig` with the `--no-prompt` option to create the JDBC external server.

## Example:

```
$ bin/dsconfig --no-prompt create-external-server \
  --server-name jdbc-external \ --type jdbc \
  --set jdbc-driver-type:oraclethin \
  --set database-name:ubid_access_log \
  --set server-host-name:localhost --set server-port:1541
```

2. Use `dsconfig` to create the log publisher.

## Example:

```
$ bin/dsconfig --no-prompt create-log-publisher \
  --publisher-name jdbc-test \
  --type jdbc-based-access \
  --set enabled:true \
  --set server:jdbc-external \
  --set "log-field-mapping:Simple JDBC Access Log Field Mappings"
```

**Result:**

When the JDBC Log Publisher is created, the Directory Server automatically generates a DDL file of the Log Field Mappings in the `<server-root>/logs/ddls/<name-of-logger>.sql` file.

3. Import the DDL file to your database.

The procedure to configure the JDBC-Based Error Log Publisher is similar to creating a JDBC-Based Access Log Publisher. You can run the previous `dsconfig` command with the `--type jdbc-based-error` as follows.

```
$ bin/dsconfig --no-prompt create-log-publisher \
  --publisher-name jdbc-error-test \
  --type jdbc-based-error \
  --set enabled:true \
  --set server:jdbc-external \
  --set "log-field-mapping:Simple JDBC Access Log Field Mappings"
```

## Managing the File-Based Error Log Publisher

The Error Log reports errors, warnings, and informational messages about events that occur during the course of the Directory Server's operation.

Each entry in the error log records the following properties (some are disabled by default and must be enabled):

### Timestamp

Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>

### Category

Specifies the message category that is loosely based on the server components.

### Severity

Specifies the message severity of the event, which defines the importance of the message in terms of major errors that need to be quickly addressed. The default severity levels are:

- fatal-error
- notice
- severe-error
- severe-warning

### Message ID

Specifies the numeric identifier of the message.

### Message

Stores the error, warning, or informational message.

## Error log example

The following example displays the error log for the PingDataMetrics Server. The log is enabled by default and is accessible in the `<server-root>/logs/errors` file.

```
[21/Oct/2012:05:15:23.048 -0500] category=RUNTIME_INFORMATION

## Modifying the File-Based Error Logs

### Steps

- To modify the default File-Based Error Log, use `dsconfig`.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Error Logger" \
  --set include-product-name:true --set include-instance-name:true \
  --set include-startup-id:true
```

## Managing the Syslog-Based Error Log Publisher

The Directory Server supports a Syslog-Based Error Log Publisher using the same mechanism as the Syslog-Based Access Log Publisher.

Configure the error logger using the `dsconfig` tool.

### Syslog error mapping

The Directory Server automatically maps error log severities to the syslog severities. The following mappings are used.

Error Log Severities	Syslog Severity
FATAL_ERROR,0	Syslog Emergency
SEVERE_ERROR,1	Syslog Alert
SEVERE_WARNING,2	Syslog Critical
MILD_ERROR,3	Syslog Error
MILD_WARNING,4	Syslog Warn
NOTICE,5	Syslog Notice
INFORMATION,6	Syslog Info
DEBUG,7	Syslog Debug

## Configuring a Syslog-Based Error Log Publisher

About this task

Configure a Syslog-based Error Log Publisher using the `dsconfig` tool. You should use syslog locally on `localhost` and use `syslog-ng` to send the data packets over the UDP protocol.

Because syslog implementations differ by vendor, review your particular vendor's syslog configuration.

## Steps

- Use **dsconfig** to create a log publisher of type `syslog-based-error`.

Example:

In this example, set the syslog facility to 4 for security/authorization messages.

```
$ bin/dsconfig create-log-publisher --publisher-name "syslog-error" \
  --type syslog-based-error --set syslog-facility:4 --set enabled:true
```

## Creating File-Based Debug Log Publishers

The Directory Server provides a File-Based Debug Log Publisher that can be configured when troubleshooting a problem that could occur during server processing.

Because the debug data might be too large to maintain during normal operations, the Debug Log Publisher must be specifically configured and enabled. The Debug Log reports the following types of information:

- Exception data thrown by the server.
- Data read or written to network clients.
- Data read or written to the database.
- Access control or password policy data made within the server.

Use the **dsconfig** tool to create a debug log publisher.

### Note:

You should only create a debug logger when troubleshooting a problem because of the voluminous output the Directory Server generates.

## Creating a File-Based Debug Log Publisher

### Steps

- To create the debug log publisher, use **dsconfig**.

The `log-file` property (required) sets the debug log path. You must also specify the rotation and retention policy for the debug log.

Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "File-Based Debug Logger" \
  --type file-based-debug \
  --set enabled:true \
  --set log-file:/logs/debug \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy"
```

## Deleting a File-Based Debug Log Publisher

### Steps

- To create the debug log publisher, use **dsconfig**.

Example:

```
$ bin/dsconfig delete-log-publisher \
  --publisher-name "File-Based Debug Logger"
```

## Managing Monitoring

PingDirectory Server provides a flexible monitoring framework so you can track server performance.

This framework exposes its monitoring information under the `cn=monitor` entry and provides interfaces through the PingDataMetrics Server, the Administrative Console, SNMP, Java Management Extensions (JMX), and over LDAP. The Directory Server also provides a tool, the Periodic Stats Logger, to profile server performance.

### The monitor backend

Directory Server exposes its monitoring information under the `cn=monitor` entry.

Administrators can use various means to monitor the servers, including the PingDataMetrics Server, through SNMP, the Administrative Console, JConsole, LDAP command-line tools, and the Periodic Stats Logger.

#### Note:

To display server component activity and state, use the `bin/status` tool.

To see the list of all monitor entries, use `ldapsearch` as in the following example.

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
--bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
--baseDN "cn=monitor" "(objectclass=*)" cn
```

The following table describes a subset of the monitor entries.

### Directory Server Monitoring Components

Component	Description
Active Operations	Provides information about the operations currently being processed by the Directory Server. Shows the number of operations, information on each operation, and the number of active persistent searches.
Backends	Provides general information about the state of a Directory Server backend, including the entry count. If the backend is a local database, there is a corresponding database environment monitor entry with information on cache usage and on-disk size.
Client Connections	Provides information about all client connections to the Directory Server. The client connection information contains a name followed by an equal sign and a quoted value, such as <code>connID="15"</code> , <code>connectTime="20100308223038Z"</code> and so forth.
Connection Handlers	Provides information about the available connection handlers on the Directory Server, which includes the LDAP and LDIF connection handlers. These handlers are used to accept client connections and to read requests and send responses to those clients.
Disk Space Usage	Provides information about the disk space available to various components of the Directory Server.

Component	Description
General	Provides general information about the state of the Directory Server, including product name, vendor name, server version, etc.
Index	The monitor captures the number of keys preloaded, and counters for read/write/remove/open-cursor/read-for-search. These counters provide insight into how useful an index is for a given workload.
HTTP/HTTPS Connection Handler Statistics	Provides statistics about the interaction that the associated HTTP connection handler has had with its clients, including the number of connections accepted, average requests per connection, average connection duration, total bytes returned, and average processing time by status code.
JVM Stack Trace	Provides a stack trace of all threads processing within the Java virtual machine (JVM).
LDAP Connection Handler Statistics	Provides statistics about the interaction that the associated LDAP connection handler has had with its clients, including the number of connections established and closed, bytes read and written, LDAP messages read and written, operations initiated, completed, and abandoned, etc.
Processing Time Histogram	Categorizes operation processing times into a number of user-defined buckets of information, including the total number of operations processed, overall average response time in milliseconds (ms), number of processing times between 0ms and 1ms, and so forth.
System Information	Provides general information about the system and the JVM on which the Directory Server is running, including system host name, operation system, JVM architecture, Java home, Java version, and so forth.
Version	Provides information about the Directory Server version, including build ID, version, revision number, etc.
Work Queue	<p>Provides information about the state of the Directory Server work queue, which holds requests until they can be processed by a worker thread, including the requests rejected, current work queue size, number of worker threads, and number of busy worker threads. The work queue configuration has a <code>monitor-queue-time</code> property set to <code>true</code> by default. This logs messages for new operations with a <code>qtime</code> attribute included in the log messages. Its value is expressed in milliseconds and represents the length of time that operations are held in the work queue.</p> <p>A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the <code>ldapsearch</code> command for example, use the <code>--useAdministrativeSession</code> option. The requester must have the <code>use-admin-session</code> privilege, which is included for root users. By default, eight threads are available for this purpose. This can be changed with the <code>num-administrative-session-worker-threads</code> property in the work queue configuration.</p>

## Monitoring disk space usage

The disk space usage monitor provides information about the amount of usable disk space available for Directory Server components.

The disk space usage monitor evaluates the free space at locations registered through the `DiskSpaceConsumer` interface by various components of the server. Disk space monitoring excludes disk locations that do not have server components registered. However, other disk locations might still impact server performance, such as the operating system disk, if it becomes full. When relevant to the server, these locations include the server root, the location of the `/config` directory, the location of every log file, all Java Runtime Environment (JRE) backend directories, the location of the changelog, the location of the replication environment database, and the location of any server extension that registers itself with the `DiskSpaceConsumer` interface.

The disk space usage monitor provides the ability to generate administrative alerts and take additional action if the amount of usable space drops below the defined thresholds.

You can configure three thresholds for this monitor:

### Low space warning threshold

This threshold is defined as either a percentage or absolute amount of usable space. If the amount of usable space drops below this threshold, then the Directory Server generates an administrative alert but remains fully functional. It generates alerts at regular intervals that you configure (such as once a day) unless action is taken to increase the amount of usable space. The Directory Server generates additional alerts as the amount of usable space is further reduced, such as each time the amount of usable space drops below a value 10% closer to the low space error threshold. If an administrator frees up disk space or adds additional capacity, then the server should automatically recognize this and stop generating alerts.

### Low space error threshold

This threshold is also defined as either a percentage or absolute size. If the amount of usable space drops below this threshold, the server generates an alert notification and begins rejecting all operations requested by non-root users with `UNAVAILABLE` results. The server should continue to generate alerts during this time. When the server enters this mode, an administrator has to take some kind of action, such as, running a command to invoke a task or removing a signal file, before the server resumes normal operation. This threshold must be less than or equal to the low space warning threshold. If they are equal, the server begins rejecting requests from non-root users immediately upon detecting low usable disk space.

### Out of space error threshold

This threshold can also be defined as a percentage or absolute size. If the amount of usable space drops below this threshold, the PingDirectory Server generates a final administrative alert and shuts itself down. This threshold must be less than or equal to the low space error threshold. If they are equal, the server shuts itself down rather than rejecting requests from non-root users.

The server monitors disk space consumption during processing for the `export-ldif`, `rebuild-index`, and `backup` tools. Space is monitored every 10 seconds if usable space for all monitored paths is greater than 15 percent of the capacity of those volumes. If usable space for any path drops below 15 percent, or below 10GB free, the space check frequency is increased to every second. Warning messages are generated if available space falls below 10 percent, or below 5GB free. If usable space for any path drops below two percent, or 1GB free, the tool processing is aborted and files can be removed to free up space.

The default configuration uses the same values for the low space error threshold and out of space error threshold. This is to prevent having the server online but rejecting requests, which causes problems with applications trying to interact with the server. The low space warning threshold generates an alert before the problem becomes serious, well in advance of available disk space dropping to a point that it is critical.

The default values might not be suitable for all disk sizes, and should be adjusted to fit the deployment. Determining the best values should factor in the size of the disk, how big the database might become, how much space log files might consume, and how many backups are stored.

The threshold values can be specified either as absolute sizes or as percentages of the total available disk space. You must specify all values as absolute values or as percentages. A mix of absolute values and percentages cannot be used. The low space warning threshold must be greater than or equal to the low space error threshold, the low space error threshold must be greater than or equal to the out of space error threshold, and the out of space error threshold must be greater than or equal to zero.

If the out of space error threshold is set to zero, then the server does not attempt to automatically shut itself down if it detects that usable disk space has become critically low. If the amount of usable space reaches zero, then the database preserves its integrity but might enter a state in which it rejects all operations with an error and requires the server, or at least the affected backends, to be restarted. If the low space error threshold is also set to zero, then the server generates periodic warnings about low available disk space but remains fully functional for as long as possible. If all three threshold values are set to zero, then the server does not attempt to warn about or otherwise react to a lack of usable disk space.

## Monitoring with the PingDataMetrics Server

The PingDataMetrics Server is an invaluable tool for collecting, aggregating and exposing historical and instantaneous data from the various Ping Identity servers in a deployment.

The PingDataMetrics Server relies on a captive PostgreSQL datastore for the metrics that it collects from internal instrumentation across the instances, replicas, and data centers in your environment. The data is available through a Monitoring API that can be used to build custom dashboards and monitoring applications to monitor the overall health of your PingData Platform system. For more information, see the PingDataMetrics Server Administration Guide.

## About the collection of system monitoring data

All PingDirectory Servers have the capability to monitor the health of the server and host system they run on for diagnostic review and troubleshooting.

Initially, the servers do not collect any performance data until they are prepared for monitoring by a Metrics Server using the `monitored-servers add-servers` tool or an administrator enables system health data collection for real-time inspection and querying. At a high level, all of the important server and machine metrics that can be monitored are available in the `cn=monitor` backend.

The Stats Collector plugin relies exclusively on entries in the `cn=monitor` backend to sample data using LDAP queries. The Stats Collector plugin is the primary driver of performance data collection for LDAP, server response, replication, local Java Runtime Environment (JRE) databases, and host system machine metrics. Stats Collector configuration determines the sample and collection intervals, granularity of data (basic, extended, verbose), types of host system collection (CPU, disk, network) and the type of data aggregation that occurs for LDAP application statistics. The Stats Collector plugin is configured with the `dsconfig` tool and collects data using LDAP queries.

For example, the `--server-info:extended` option includes collection for the following:

- CPU
- Java virtual machine (JVM) memory
- Memory
- Disk information
- Network information

Utilization metrics are gathered through externally invoked OS commands, such as `iostat` and `netstat`, using platform-specific arguments and version-specific output parsing.

Enabling the Host System monitor provider automatically gathers CPU and memory utilization but only optionally gathers disk and network information. Disk and network interfaces are enumerated in the

configuration by device names, such as `eth0` or `lo`, and by disk device names, such as `sd1`, `sdab`, `sda2`, `scsi0`.

## Monitoring key performance indicators by application

PingDirectory Server can be configured to track many key performance metrics, such as throughput and response-time, by the client applications requesting them.

This feature is invaluable for measuring whether the Ping Identity identify infrastructure meets all of your service-level agreements (SLA) that have been defined for client applications.

When enabled, the per-application monitoring data:

- Can be accessed in the `cn=monitor` backend
- Can be accessed in the Periodic Stats Logger
- Can be made available for collection by the Metrics Server

For more information on using the Stats Logger, see [Profiling server performance using the Stats Logger](#) on page 963.

For details on configuring the server to expose metrics that interest you, see the Directory Server [Configuration section of the PingDataMetrics Server Administration Guide](#).

Tracked application information is exposed in the PingDataMetrics Server by metrics having the `application-name` dimension. For information on which metrics are available with the `application-name` dimension, see the documentation under `docs/metrics` of the PingDataMetrics Server.

## Configuring the external Servers

Before you install the PingDataMetrics Server, you must configure the servers you want to monitor:

- PingDirectory Server
- PingDirectoryProxy Server
- PingDataSync Server

The PingDataMetrics Server requires all servers to be 3.5.0 or later. See the administration guides for each product for installation instructions.

After you have installed Directory Server, use the `dsconfig` tool to make configuration changes for the PingDataMetrics Server. When using the `dsconfig` tool interactively, set the complexity level to `Advanced` so that you can make all the necessary configuration changes.

## Preparing the servers monitored by the PingDataMetrics Server

The Metrics Backend manages the storage of metrics and provides access to the stored blocks of metrics via LDAP. The Metrics Backend is configured to keep a maximum amount of metric history based on log retention policies.

The default retention policy uses the Default Size Limit Retention Policy, Free Disk Space Retention Policy, and the File Growth Limit Policy, limiting the total disk space used to 500 MB. This amount of disk typically contains more than 24 hours of metric history, which is ample. Directory Server keeps a metric history so that the PingDataMetrics Server can be down for a period and then catch up when it comes back online.

The following two commands create a Retention Policy that limits the number of files to 2000 and sets the Metrics Backend to flush data to a new file every 30 seconds.

```
$ bin/dsconfig create-log-retention-policy \
  --policy-name StatsCollectorRetentionPolicy \
  --type file-count --set number-of-files:2000

$ bin/dsconfig set-backend-prop \
  --backend-name metrics --set sample-flush-interval:30s \
  --set retention-policy:StatsCollectorRetentionPolicy
```

These commands configure the Metrics Backend to keep 16 hours of metric history, which consumes about 250 MB of disk, ensuring that captured metrics are available to the PingDataMetrics Server within 30 seconds of when the metric was captured. The value of the `sample-flush-interval` attribute determines the maximum delay between when a metric is captured and when it can be picked up by the PingDataMetrics Server.

You can set the flush interval between 15 seconds and 60 seconds, with longer values resulting in less processing load on the PingDataMetrics Server. However, this flush interval increases the latency between when the metric was captured and when it becomes visible in the Dashboard Application. If you change the `sample-flush-interval` attribute to 60 seconds in the example above, then the Directory Server keeps 2000 minutes of history. Because the number of metrics produced per unit of time can vary depending on the configuration, no exact formula can be used to compute how much storage is required for each hour of history. However, 20 MB per hour is a reasonable estimate.

## Configuring the Processing Time Histogram plugin

The Processing Time Histogram plugin is configured on each Directory Server and Directory Proxy Server as a set of histogram bucket ranges.

When the bucket ranges for a histogram change, the PingDataMetrics Server notices the change and marks samples differently. This process allows for histograms with the same set of bucket definitions to be properly aggregated and understood when returned in a query. If different servers have different bucket definitions, then a single metric query cannot return histogram data from the servers.

You should try to keep the Processing Time Histogram bucket definitions the same on all servers. Having different definitions restricts the ability of the PingDataMetrics Server API to aggregate histogram data across servers and makes the results of a query asking "What percentage of the search requests took less than 12 milliseconds?" harder to understand.

For each server in your topology, you must set the `separate-monitor-entry-per-tracked-application` property of the Processing Time Histogram plugin to true. This property must be set to expose per-application monitoring information under `cn=monitor`. When the `separate-monitor-entry-per-tracked-application` property is set to true, then the `per-application-ldap-stats` property must be set to `per-application-only` on the Stats Collector plugin and vice versa.

The following `dsconfig` command line sets the required properties of the Processing Time Histogram plugin.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Processing Time Histogram" \
  --set separate-monitor-entry-per-tracked-application:true
```

The following `dsconfig` command-line sets the `per-application-ldap-stats` property of the Stats Collector plugin to `per-application-only`.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Stats Collector" \
  --set per-application-ldap-stats:per-application-only
```

## Setting the connection criteria to collect SLA statistics by application

To collect data about your service level agreements (SLAs), configure connection criteria for each SLA that you want to track.

The connection criteria are used in many areas within the server. They are used by the client connection policies, and are used when the server needs to perform matching based on connection-level properties, such as filtered logging. For assistance using connection criteria, contact a Ping Identity support representative.

For example, if you are interested in collecting statistics on data that is accessed by clients authenticating as the Directory Manager, you should create connection criteria on the Directory Server that identifies any user authenticating as the Directory Manager. The connection criteria name corresponds to the `application-name` dimension value that clients specify when accessing the data through the API.

When you define the connection criteria, change the `included-user-base-dn` property to include the Directory Manager's full LDIF entry.

The following `dsconfig` command line creates connection criteria for the Directory Manager.

```
$ bin/dsconfig create-connection-criteria \  
  --criteria-name "Directory Manager" \  
  --type simple \  
  --set "included-user-base-dn:cn=Directory Manager,cn=Root DNs,cn=config"
```

## Proxy considerations for tracked applications

In a proxy environment, the criteria should be defined in the Directory Proxy Server because Directory Proxy Server passes the application name through to the Directory Server in the intermediate client control.

If a client of Directory Proxy Server or Directory Server happens to use the intermediate client control, then the client name specified in the control is used as the application name regardless of the criteria listed in the `tracked-application` property.

## Monitoring using SNMP

PingDirectory Server supports real-time monitoring using SNMP. Directory Server provides an embedded SNMPv3 subagent plugin that, when enabled, sets up the server as a managed device and exchanges monitoring information with a master agent based on the AgentX protocol.

## SNMP implementation

In a typical SNMP deployment, many production environments use a network management system (NMS) for a unified monitoring and administrative view of all SNMP-enabled devices.

The NMS communicates with a master agent, whose main responsibility is to translate the SNMP protocol messages and multiplex any request messages to the subagent on each managed device, such as a Directory Server instance, Directory Proxy Server, Data Sync Server, or OS Subagent. The master agent also processes responses or traps from the agents. Many vendors provide commercial NMS systems. Consult with your NMS system for specific information.

PingDirectory Server contains an SNMP subagent plugin that connects to a Net-SNMP master agent over TCP. The main configuration properties of the plugin are the address and port of the master agent, which default to localhost and port 705, respectively. When the plugin is initialized, it creates an AgentX subagent and a managed object server and then registers as a management information base (MIB) server with the Directory Server instance. After the plugin's startup method is called, it starts a session thread with the master agent. Whenever the connection is lost, the subagent automatically attempts to reconnect with the master agent. Directory Server's SNMP subagent plugin transmits only read-only values for polling or trap purposes. Set and inform operations are not supported. SNMP management applications cannot perform actions on the server on their own or through an NMS system.

### Example SNMP Deployment

#### Note:

PingDirectory Server was designed to interface with a Net-SNMP (5.3.2.2 or later) master agent implementation with AgentX over TCP. Many operating systems provide their own Net-SNMP module. However, Service Management Automation (SMA) disables some features present in the Net-SNMP package and only enables AgentX over UNIX Domain Sockets, which cannot be supported by Java. If your operating system has a native Net-SNMP master agent that only enables UNIX Domain Sockets, you should download and install a separate Net-SNMP binary from its website.

## Configuring SNMP

Because all server instances provide information for a common set of management information bases (MIBs), each server instance provides its information under a unique SNMPv3 context name equal to the server instance name.

About this task

The server instance name is defined in the Global Configuration and is constructed from the host name and the server LDAP port by default. Information must be requested using SNMPv3, specifying the context name that pertains to the desired server instance.

#### Note:

Directory Server supports SNMPv3, and only SNMPv3 can access the MIBs. For systems that implement SNMP v1 and v2c, Net-SNMP provides a proxy function to route requests in one version of SNMP to an agent using a different SNMP version.

## Steps

1. To enable Directory Server's SNMP plugin, use the `dsconfig` tool.

### Note:

The SNMPv3 context name is limited to 30 bytes maximum. Any context name longer than 30 characters returns an error message when you attempt to enable the plugin.

The default context server name is the server instance name and the LDAP port number, so take note of the length of the fully-qualified DNS host name.

- a. Specify the address and port of the SNMP master agent.
- b. On each Directory Server instance, enable the SNMP subagent.
- c. Enable the SNMP Subagent Alert Handler so that the sub-agent sends traps for administrative alerts generated by the server.

Example:

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" --set enabled:true
```

2. View the error log.

Result:

A message displays that the master agent is not connected because it is not yet online.

```
The SNMP sub-agent was unable to connect to the master
agent at localhost/705: Timeout
```

3. Edit the SNMP agent `snmpd.conf` configuration file and add the directive to run the agent as an AgentX master agent.

The file is often located in `/etc/snmp/snmpd.conf`.

Example:

```
master agentx agentXSocket tcp:localhost:705
```

### Note:

Using `localhost` means that only sub-agents running on the same host can connect to the master agent. This is necessary because there are no security mechanisms in the AgentX protocol.

4. Add the trap directive to send SNMPv2 traps to `localhost` with the community name, `public` (or whatever SNMP community has been configured for your environment) and the port.

Example:

```
trap2sink localhost public 162
```

5. To create a SNMPv3 user, add the following lines to the `/etc/snmp/snmpd.conf` file.

Example:

```
rwuser initial
createUser initial MD5 setup_passphrase DES
```

6. To create the SNMPv3 user, run **snmpusm**.

Example:

```
snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
localhost create snmpuser initial
```

7. Start the **snmpd** daemon.

Result:

A message displays in the Directory Server error log.

```
The SNMP subagent connected successfully to the master agent
at localhost:705. The SNMP context name is host.example.com:389
```

8. To see the alerts that are generated by Directory Server, set up a trap client.

- a. Create a config file in `/tmp/snmptrapd.conf`.
- b. Add the `authcommunity log`, execute `public` directive to the file.

 **Note:**

The directive specifies that the trap client can process traps using the public community string and can log and trigger executable actions.

9. Install the MIB definitions for the Net-SNMP client tools in the `/usr/share/snmp/mibs` directory.

Example:

```
$ cp resource/mib/* /usr/share/snmp/mibs
```

10. To run the trap client, run the **snmptrapd** command.

Example:

This example specifies that the command should not create a new process using `fork()` from the calling shell (`-f`), should not read any configuration files (`-C`) except the one specified with the `-c` option, should print to standard output (`-Lo`), and then specifies that debugging output should be turned on for the User-based Security Module (`-Dusm`). The path after the `-M` option is a directory that contains the MIBs shipped with our product (`server-root/resource/mib`).

```
$ snmptrapd -f -C -c /tmp/snmptrapd.conf -Lf /root/trap.log -Dusm \
-m all -M +/usr/share/snmp/mibs
```

11. To test the feature, run the Net-SNMP client tools.

You must use the following options:

- `-v <SNMP version>`
- `-u <user name>`
- `-l <security level>`
- `-n <context name (instance name)>`
- `-A <user password>`

Example:

In this example, the `-m all` option loads all MIBs in the default MIB directory in `/usr/share/snmp/mibs` so that MIB names can be used in place of numeric OIDs.

```
$ snmpget -v 3 -u snmpuser -A password -l authNoPriv -n
host.example.com:389 \
-m all localhost localDBBackendCount.0
```

```
$ snmpwalk -v 3 -u snmpuser -A password -l authNoPriv -n
  host.example.com:389 \
-m all localhost systemStatus
```

## MIBS

Directory Server provides SMIPv2-compliant management information base (MIB) definitions (RFC 2578, 2579, 2580) for distinct monitoring statistics. These MIB definition text files are in the server's `/resource/mib` directory.

Each MIB provides managed object tables for each specific SNMP management information as follows:

### LDAP Remote Server MIB

Provides information related to the health and status of the LDAP servers that the Directory Proxy Server connects to and statistics about the operations invoked by the Directory Proxy Server on those LDAP servers.

### LDAP Statistics MIB

Provides a collection of connection-oriented performance data that is based on a connection handler in the Directory Server.

A server typically contain only one connection handler and therefore supplies only one table entry.

### Local DB Backend MIB

Provides key metrics related to the state of the local database backends contained in the server.

### Processing Time MIB

Provides a collection of key performance data related to the processing time of operations broken down by several criteria but reported as a single aggregated data set.

### Replication MIB

Provides key metrics related to the current state of replication that can help diagnose how much outstanding work replication might have to do.

### System Status MIB

Provides a set of critical metrics for determining the status and health of the system in relation to its work load.

For information on the available monitoring statistics for each MIB available on Directory Server and the Directory Proxy Server, see the text files located in the server's `/resource/mib` directory.

Directory Server generates an extensive set of SNMP traps for event monitoring. The traps display the severity, description, name, OID, and summary. For information about the available alert types for event monitoring, see the `resource/mib/UNBOUNDDID-ALERT-MIB.txt` file.

## Monitoring with the Administrative Console

Before you begin  
Ensure that the Directory Server is running.

### About this task

Ping Identity has an Administrative Console for administrators to configure directory server. The console also provides a status option that accesses the server's monitor content.

To view the **Monitor Dashboard**:

### Steps

1. In your browser, enter `http://<server-name>:8443/console`.
2. Enter the root user distinguished name (DN) and password. Click **Login**.
3. In the top level navigation menu, select **Status**.
4. On the **Status** page, click the **Monitors** tab.

### Result

The **Monitors** page opens, and you can monitor your server using the Administrative Console.

## Accessing the Processing Time Histogram

PingDirectory Server provides a processing time histogram that classifies operation response time into user-defined buckets.

### About this task

The histogram tracks the processing on a per-operation basis and as a percentage of the overall processing time for all operations. It also provides statistics for each operation type:

- add
- bind
- compare
- delete
- modify
- modifyDN
- search

### Steps

1. From the Administrative Console, go to **Configuration # Status # Monitors**.
2. Select **Processing Time Histogram**.

#### Note:

You can access other monitor entries in similar ways.

## Monitoring with JMX

PingDirectory Server supports monitoring the Java virtual machine (JVM) through a Java Management Extensions (JMX) management agent, which can be accessed using JConsole or any other kind of JMX client.

The JMX interface provides JVM performance and resource utilization information for applications running Java. In addition to the monitor information that Directory Server provides, you can monitor generic metrics exposed by the JVM, including:

- Memory pools
- Threads
- Loaded classes
- MBeans

You can also subscribe to receive JMX notifications for any administrative alerts that are generated within the server.

## Running JConsole

Run `jconsole` to monitor the memory usage and thread activity of a Java virtual machine.

Before you begin

Before you can run `jconsole`, you must:

- Configure and enable the [MISSING glossAcronymn or glossSurfaceform for gJMX] Connection Handler for the server using the `dsconfig` tool.

### Note:

For more information, see [Configuring the JMX connection handler and alert handler](#) on page 977.

- Invoke the `jconsole` executable by entering `jconsole` in your command-line interface or terminal.

### Note:

If `<JDK_HOME>` is not set in your path, you can access `jconsole` in the `bin` directory of the `<JDK_HOME>` path.

## Steps

1. To open the **Java Monitoring & Management Console**, run `jconsole`:

If SSL is configured on the JMX Connection Handler, you must specify the `PingDirectory.jar` file in the class path when running `jconsole` over SSL, as in the following example:

```
$ jconsole \  
-J-Djavax.net.ssl.trustStore=/path/to/certStores/truststore \  
-J-Djavax.net.ssl.trustStorePassword=secret \  
-J-Djava.class.path=$SERVER_ROOT/lib/PingDirectory.jar:/Library/Java/  
JavaVirtualMachines/jdk-version_jdk/Contents/Home/lib/jconsole.jar
```

You need to set the following properties in the above command:

- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePath` property with the full trust store path.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStoreType` property if the default type, [MISSING glossAcronymn or glossSurfaceform for gJKS], is not used.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePin` property with the trust store file password, if there is one.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePinFile` property with the file path containing the trust store password in plain text.

Do not use this property if the

`com.unboundid.directory.server.protocol.jmx.trustStorePin` property is used.

### Note:

When establishing a connection to `jconsole`, a window opens asking if you want to retry connecting insecurely. Click **Insecure connection**.

Although `jconsole` considers anything other than `SslRmiClientSocketFactory` to be insecure, choosing to retry insecurely will enable PingDirectory's secure client socket factory.

2. In the **Java Monitoring & Administrative Console** window, click **Local Process**, and then click the **PID** corresponding to the server.

3. Review the resource monitoring information.

## Monitoring the Directory Server using JConsole

Set up JConsole to monitor the Directory Server using a remote process.

### Steps

1. Start the Directory Server.

Example:

```
$ bin/start-server
```

2. Enable the Java Management Extensions (JMX) Connection handler using `dsconfig` with the `set-connection-handler-prop` option.

#### Note:

The handler is disabled by default.

Include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "JMX Connection Handler" --set enabled:true
```

3. Assign privileges to a regular user account with the `ldapmodify` tool.

#### Warning:

Do not use a root user account, as using a root user account would be a security risk.

Example:

This example grants `jmx-read`, `jmx-write`, and `jmx-notify` privileges to the user.

```
$ bin/ldapmodify --hostname server1.example.com --port 1389 \
  --bindDN "cn=Directory Manager" --bindPassword secret
dn: uid=admin,dc=example,dc=com
changetype: modify
replace: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: jmx-write
ds-privilege-name: jmx-notify
```

4. In the **Java Monitoring & Administrative Console**, click **Remote Process**, and enter the following JMX URL using the host and port of your Directory Server.

```
service:jmx:rmi:///jndi/rmi://<host>:<port>/
com.unboundid.directory.server.protocols.jmx.client-unknown
```

5. In the **Username** and **Password** fields, enter the bind distinguished name (DN) and password for a user that has at least the `jmx-read` privilege.
6. Click **Connect**.
7. Click **com.unboundid.directory.server**, and expand the `rootDSE` node and the `cn-monitor` subnode.
8. Select a monitoring entry.

## Monitoring using the LDAP SDK

To retrieve monitor entries from the Directory Proxy Server and retrieve specific types of monitor entries, you can use the monitoring API.

For example, you can retrieve all monitor entries published by the Directory Server and print the information contained in each using the generic API for accessing monitor entry data as follows.

```
for (MonitorEntry e : MonitorManager.getMonitorEntries(connection))
{
    System.out.println("Monitor Name: " + e.getMonitorName());
    System.out.println("Monitor Type: " + e.getMonitorDisplayName());
    System.out.println("Monitor Data:");
    for (MonitorAttribute a : e.getMonitorAttributes().values())
    {
        for (Object value : a.getValues())
        {
            System.out.println(" " + a.getDisplayName() + ": " +
String.valueOf(value));
        }
    }
    System.out.println();
}
```

For more information about the LDAP SDK and the methods in this example, see the [LDAP SDK repository on GitHub](#).

## Monitoring over LDAP

PingDirectory Server exposes a majority of its information under the `cn=monitor` entry.

### Steps

- To access these entries over LDAP, use the `ldapsearch` tool.

Example:

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
--bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
--baseDN "cn=monitor" "(objectclass=*)" "
```

## Profiling server performance using the Stats Logger

Directory Server includes a built-in Stats Logger that is useful for profiling server performance for a given configuration.

At a specified interval, the Stats Logger can write server statistics to a JSON file or to a log file in a `.csv` file, which can be read by spreadsheet applications. The logger has a negligible impact on server performance unless the `log-interval` property is set to a value of less than 1 second. You can customize the statistics logged and their verbosity.

The Stats Logger can also be used to view historical information about server statistics, including:

- Replication
- LDAP operations
- Host information
- Gauges

To update the configuration of the existing Stats Logger Plugin, you can either:

- Set the advanced `gauge-info` property to `basic/extended` to include this information.
- Create a dedicated Periodic Stats Logger for information about statistics of interest.

For information about how to enable this logging and where to find the log file, see [Enabling the Stats Logger](#) on page 964.

## Enabling the Stats Logger

About this task

By default, Directory Server's built-in Stats Logger is disabled. To enable the Stats Logger:

Steps

1. Run `dsconfig` in interactive mode.

When you are prompted, enter the LDAP or LDAPS connection parameters.

Example:

```
$ bin/dsconfig
```

2. To change to the `Advanced Objects` menu, enter `o`.
3. On the main menu, enter the selection for `Plugins`.
4. On the `Plugin` menu, enter the selection for `View and edit an existing plugin`.
5. From the `Plugin` selection list, enter the selection for `Stats Logger`.
6. On the `Stats Logger Plugin` menu, enter the selection to set the `enabled` property to `TRUE`. To save and apply the configuration, enter `f`.

Result: The default logger logs information about the server every second to `<server-root>/logs/dsstats.csv`. If the server is idle, nothing is logged.

### Note:

To change the idle logging behavior, set the `suppress-if-idle` property to `FALSE`.

7. Run the Directory Server.

Example:

For example, if you are running in a test environment, you can run the `search-and-mod-rate` tool to apply some searches and modifications to the server.

### Tip:

To see an example command, run `search-and-mod-rate --help`.

8. View the Stats Logger output at `<server-root>/logs/dsstats.csv`.

You can open the file in a spreadsheet.

## Configuring multiple Periodic Stats Loggers

About this task

You can create multiple Periodic Stats Loggers to:

- Log different statistics
- View historical information about gauges
- To create a log at different intervals, such as logging cumulative operations statistics every hour

To create a new log, use the existing Stats Logger as a template to get reasonable settings, including rotation and retention policy.

## Steps

1. Run `dsconfig` in interactive mode.

When prompted, enter the LDAP or LDAPS connection parameters.

Example:

```
$ bin/dsconfig
```

2. To change to the `Advanced Objects` menu, enter `o`.
3. In the main menu, enter the selection for `Plugins`.
4. In the `Plugin management` menu, enter the selection for `Create a new plugin`.
5. To use an existing plugin as a template, in the `Create a New Periodic Stats Logger Plugin` menu, enter `t`.
6. Enter the number corresponding to the existing stats logger as a template.
7. Enter a descriptive name for the new stats logger.

For this example, enter `Stats Logger-10s`.

8. Enter the log file path to the file.

For this example, enter `logs/dsstats2.csv`.

9. In the menu, make any other changes to the logger. To save and apply the configuration, enter `f`.

Example:

For this example, change the `log-interval` to `10s`, and the `suppress-if-idle` to `FALSE`.

## Result

You should see two loggers, `dsstats.csv` and `dsstats2.csv`, in the `logs` directory.

## Enabling and configuring the StatsD monitoring endpoint

The Monitoring Endpoint configuration type provides the StatsD endpoint type that you can use to transfer metrics data in the StatsD format.

### About this task

You can configure the Monitoring Endpoint using the `dsconfig` command or the Administrative Console.

## Steps

- To create the StatsD monitoring Endpoint, use either of the following:  
Choose from:

- To use the command-line, run `dsconfig` with the `create-monitoring-endpoint` option.

This example configures a new StatsD Monitoring Endpoint to send UDP data to localhost port 8125 using `dsconfig`.

```
dsconfig create-monitoring-endpoint \
  --type statsd \
  --endpoint-name StatsDEndpoint \
  --set enabled:true \
  --set hostname:localhost \
  --set server-port:8125 \
```

```
--set connection-type:unencrypted-udp
```

- To use the Administrative Console:
  1. From the Administrative Console, click **Show Advanced Configuration**.
  2. In the **Logging, Monitoring, and Notifications** section, click **Monitoring Endpoints**.
  3. Click **New Monitoring Endpoint**.

When you configure Monitoring Endpoint include:

- The endpoint's host name
- The endpoint's port
- A toggle to use TCP or UDP
- A toggle to use SSL if you use TCP

You can configure a StatsD Monitoring Endpoint with custom tags using the `additional-tags` property. This adds the defined tags to each metric message sent to the endpoint. Each tag should be created in a "key=value" format. Additional tags are appended to the end of the StatsD message. Here is a sample StatsD message with custom tags:

```
example.metric:123|g|#tag1:value1,tag2:value2
```

**Note:**

You can send data to any number of monitoring endpoints.

### Enabling and configuring the Stats Collector Plugin

The Stats Collector Plugin controls the metrics used by the StatsD monitoring endpoint.

About this task

To send metrics with the StatsD monitoring endpoint, enable the Stats Collector Plugin and configure the plugin to indicate which metrics to send.

Examples of metrics you can send are:

- Busy worker thread count
- Garbage collection statistics
- Host system metrics such as CPU and memory

**Tip:**

For a list of available metrics, use the interactive `dsconfig` menu for the Stats Collector Plugin or in the Administrative Console, edit the Stats Collector plugin, as explained in the second example.

Steps

- To enable and configure the Stats Collector Plugin, use either of the following:

Choose from:

- To use the command-line, run `dsconfig` with the `set-plugin-prop` option.

This example enables the Stats Collector Plugin to send host CPU metric, memory metrics, and server status metrics using `dsconfig`.

```
dsconfig set-plugin-prop \
  --plugin-name "Stats Collector" \
  --set enabled:true \
```

```
--set host-info:cpu \
--set host-info:disk \
--set status-summary-info:basic
```

 **Note:**

If you are not using Data Metrics Server to monitor your server, you can disable the generation of some metrics files that are not necessary for the StatsD Monitoring Endpoint. To do this, set the `generate-collector-files` property on the Stats Collector Plugin to `false`.

- To use the Administrative Console:
  1. From the Administrative Console, click **Show Advanced Configuration**.
  2. In the **LDAP (Administration and Monitoring)** section, click **Plugin Root**.
  3. Edit the **Stats Collector** plugin and select the configuration options to indicate which metrics to send.

### Next steps

After you enable the Stats Collector and create the StatsD monitoring endpoint, you can:

- Use the data with Splunk, as explained in [Sending Metrics to Splunk with StatsD](#) on page 1439.
- Configure other tools that support StatsD, such as CloudWatch or a Prometheus StatsD exporter, to use the data. For more information about this configuration, see your tool's StatsD documentation.

## Adding custom logged statistics to a Periodic Stats Logger

Add custom statistics based on any attribute in any entry under `cn=monitor` with the Custom Logged Stats object.

This configuration object provides powerful controls for how monitor attributes are written to the log. For example, you can extract a value from a monitor attribute using a regular expression. New Custom Logged Stats are automatically included in the Periodic Stats Logger output.

In addition to allowing a straight pass-through of the values using the `raw` statistic-type, you can configure attributes to be treated as any of the following:

- A counter, where the interval includes the difference in the value since the last interval
- An average value held by the attribute during the specified interval
- A minimum value held by the attribute during the specified interval
- A maximum value held by the attribute during the specified interval

The value of an attribute can also be scaled by a fixed value or by the value of another monitor attribute.

 **Note:**

Custom third-party server extensions written using the Server SDK can also expose interval statistics using a Periodic Stats Logger. The extension must first implement the SDK's `MonitorProvider` interface and register with the server. The monitor attributes produced by this custom `MonitorProvider` are then available to be referenced by a Custom Logged Stats object.

To illustrate how to configure a Custom Logged Statistics Logger, the following section reproduces the built-in `Consumer Total GB` column that displays in the output when the `included-resource-stat` property is set to `memory-utilization` on the Periodic Stats Logger.

The column is derived from the `total-bytes-used-by-memory-consumers` attribute of the `cn=JVM Memory Usage,cn=monitor` entry as follows.

```
dn: cn=JVM Memory Usage,cn=monitor
```

```
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-memory-usage-monitor-entry
objectClass: extensibleObject
cn: JVM Memory Usage
...
total-bytes-used-by-memory-consumers: 3250017037
```

## Configuring a custom logged statistic using dsconfig interactive

### Steps

1. Run `dsconfig` and, when prompted, enter the LDAP or LDAPS connection parameters.

Example:

```
$ bin/dsconfig
```

2. In the Directory Server Advanced Objects menu, enter the selection for Custom Logged Stats.
3. In the Custom Logged Stats menu, enter the selection for Create a new Custom Logged Stats.
4. Select the Stats Logger Plugin from the list if more than one is present on the system. If you only have one stats logger, press Enter to confirm that you want to use the existing plugin.
5. Enter a descriptive name for the Custom Logged Stats.

For this example, enter `Memory Usage`.

6. From the `monitor-objectclass` property menu, enter the `objectclass` attribute to monitor.

For this example, enter `ds-memory-usage-monitor-entry`.

#### Note:

To view the entry, run `ldapsearch` using the base distinguished name (DN) `cn=JVM Memory Usage,cn=monitor` entry.

7. Enter the attributes of the monitor entry that you want to log in the stats logger, and then press Enter again to continue.  
For this example, enter `total-bytes-used-by-memory-consumers`.
8. Specify the type of statistics for the monitored attribute to appear in the log file.  
For this example, enter the option for `raw statistics` as recorded by the logger.
9. In the Custom Logged Stats menu, review the configuration.
10. To set up a column name that lists the memory usage, enter the option to change the `column-name` property.
11. To add a specific label for the column name, enter the option to add a value, and then enter `Memory Consumer Total (GB)`. To continue, press Enter.
12. Confirm that you want to use the `column-name` value that you entered in the previous step. To use the value, press Enter.
13. To scale the `Memory Consumer Totals (GB)` by 1 gigabyte (GB), in the Custom Logged Stats menu, enter the option to change the `divide-value-by` property.
14. In the `divide-value-by` property menu, enter the option to change the value, and then enter `1073741824`.

`1073741824` bytes is equivalent to 1 gigabyte.

15. In the Custom Logged Stats menu, review your configuration. To save and apply the settings, enter `f`.

Example:

```
>>>> Configure the properties of the Custom Logged Stats
>>>> via creating 'Memory Usage' Custom Logged Stats

Property                                     Value(s)
-----
1) description                               -
2) enabled                                   true
3) monitor-objectclass                       ds-memory-usage-monitor-entry
4) include-filter                            -
5) attribute-to-log                          total-bytes-used-by-memory-consumers
6) column-name                               Memory Consumer Total (GB)
7) statistic-type                            raw
8) header-prefix                             -
9) header-prefix-attribute                   -
10) regex-pattern                            -
11) regex-replacement                        -
12) divide-value-by                          1073741824
13) divide-value-by-attribute                 -
14) decimal-format                           #.##
15) non-zero-implies-not-idle                false

?) help
f) finish - create the new Custom Logged Stats
a) hide advanced properties of the Custom Logged Stats
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit

Enter choice [b]:
```

**Result:** A message of The Custom Logged Stats was created successfully is returned.

After the Custom Logged Stats configuration change is completed, the new stats value should immediately show up in the Stats Logger output file.

### Configuring a custom stats logger using `dsconfig` non-interactive

About this task

The following task replicates the previous procedure using `dsconfig` in non-interactive mode.

To create a custom stats logger:

Steps

- Run the `dsconfig` non-interactive command with the `create-custom-logged-stats` option.

Example:

In this example, the command produces a column named `Memory Consumer Total (GB)` that contains the value of the `total-bytes-used-by-memory-consumers` attribute pulled from the entry with the `ds-memory-usage-monitor-entry` objectclass. This value is scaled by `1073741824` to get to a value represented in GBs.

```
$ bin/dsconfig create-custom-logged-stats --plugin-name "Stats Logger" \
--stats-name "Memory Usage" --type custom \
--set monitor-objectclass:ds-memory-usage-monitor-entry \
--set attribute-to-log:total-bytes-used-by-memory-consumers \
```

```
--set "column-name:Memory Consumer Total (GB)" --set statistic-type:raw \
--set divide-value-by:1073741824
```

## Updating the Global Configuration

You must create Global Configuration tracked applications for each application (connection criteria) you intend to track.

About this task

The `tracked-application` property allows individual applications to be identified in the server by connection criteria.

### Note:

The name of the tracked application is the same as the name you defined for the connection criteria.

### Steps

- To add connection criteria to the list of tracked applications, run `dsconfig` with the `set-global-configuration-prop` option.

Example:

This example adds the connection criteria you created in the example in [Setting the connection criteria to collect SLA statistics by application](#) on page 954 to the list of tracked applications.

```
$ bin/dsconfig set-global-configuration-prop \
--set "tracked-application:Directory Manager"
```

### Note:

The value of the `tracked-application` field corresponds to the value of the `application-name` dimension value that clients specify when accessing the data through the API.

## Monitoring PingDirectory metrics with Splunk

Metrics from PingDirectory can be sent to Splunk through either StatsD or a Periodic Stats Logger

Ping provides a free Splunk (<https://splunkbase.splunk.com/app/5523/>) application for PingDirectory that customers can use to create dashboards.

Metrics from PingDirectory can be sent to Splunk either through StatsD pushed directly to Splunk, or through a Periodic Stats Logger that is monitored by a Splunk Universal Forwarder.

### Sending PingDirectory metrics with StatsD

Monitoring Directory Server using StatsD and Splunk.

In order to send metrics from PingDirectory to Splunk with StatsD, you will need to create a StatsD Monitoring Endpoint. On the Splunk side you will need to open the corresponding port to receive the metrics.

## Configuring a StatsD monitoring endpoint

The Stats Collector is used to create a StatsD monitoring endpoint.

### Steps

1. To enable the Stats Collector plugin, run the following command.

```
dsconfig set-plugin-prop \
  --plugin-name "Stats Collector" \
  --set enabled:true
```

2. To create a StatsD monitoring endpoint, run the following command. After running the command, Directory Server will send StatsD messages to your Splunk server over UDP at port 8125.

```
dsconfig create-monitoring-endpoint \
  --endpoint-name StatsDEndpoint \
  --type statsd \
  --set enabled:true \
  --set hostname:your-splunk.example.com \
  --set server-port:8125 \
  --set connection-type:unencrypted-udp
```

## Configuring Splunk to receive StatsD metrics

Splunk can be used to receive StatsD metrics.

### About this task

Run the following commands to configure Splunk to receive StatsD metrics.

### Steps

1. Log in to your Splunk dashboard at `http://your-splunk.example.com:8000`.
2. Go to **Settings > Data Inputs**.
3. Under Local inputs, click **UDP**.
4. Click **New Local UDP**.
5. Enter the following information:
  - Port:** 8125
6. Click **Next**.
7. Set **Source type** to **Metrics > statsd**.
8. Create a new **metrics** index for the input. Make a note of the index name you choose.
9. Set the **App Context** to `PingDirectory App for Splunk`.
10. Click **Review**.
11. Click **Submit**.

#### Note:

StatsD metrics are typically sent over UDP. Using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost. To more securely send metrics to Splunk, you can first send your StatsD metrics to a Splunk Universal Forwarder, and have the forwarder communicate with Splunk over SSL

## Sending Metrics with the Periodic Stats Logger and the Splunk Universal Forwarder

A Splunk Universal Forwarder can be used to forward Directory Server events to Splunk.

The Periodic Stats Logger plugin writes Directory Server metrics to a file in the server root. A Splunk Universal Forwarder can be configured to watch this file and forward the metrics to Splunk.

### Configuring the Periodic Stats Logger

Directory Server can log various metrics, including LDAP operation counts and GC activity, to a JSON-formatted log.

#### About this task

To configure Directory Server to log to a JSON-formatted log file with various metrics, including LDAP operation counts and GC activity, run the following command. The metrics will be written to `logs/dsstats.json` in the server root.

```
dsconfig set-plugin-prop \
  --plugin-name "Stats Logger" \
  --set enabled:true \
  --set log-file:logs/dsstats.json \
  --set log-file-format:json \
  --set local-db-backend-info:extended \
  --set header-prefix-per-column:true \
  --set empty-instead-of-zero:false \
  --set per-application-ldap-stats:per-application-and-aggregate
```

### Configuring the Splunk Universal Forwarder

You can use the Splunk Universal Forwarder to monitor the `logs/dsstats.json` file and forward the metrics to Splunk.

#### About this task

The Splunk Universal Forwarder can be configured to monitor the `logs/dsstats.json` file and forward the metrics to Splunk. Under the Splunk Forwarder application files, update the `etc/apps/search/local/inputs.conf` file with the following configuration for `dsstats.json`:

```
[monitor:///path/to/PingDirectory/logs/dsstats.json]
sourcetype=log2metrics_json
index=pdmetrics
disabled=false
host=pd1
```

The index name can be customized, and the host value can be configured to label where the metrics are being forwarded from.

## Using the Directory Server app for Splunk

You can access several dashboards for monitoring Directory Server.

When you have installed the Directory Server application for Splunk, you will have access to several dashboards for monitoring metrics. To use these dashboards, you will need to select the index name and metrics source you configured. If you are sending metrics with StatsD, use the metrics index you defined when creating the UDP input in Splunk, and select the StatsD radio button at the top of each dashboard. If you are sending metrics with the Periodic Stats Logger, use the index you defined in the Splunk Universal Forwarder configuration and select the **dsstats.json** radio button at the top of each dashboard.

## Managing Notifications and Alerts

---

PingDirectory Server provides delivery mechanisms for account status notifications and administrative alerts using SMTP, Java Management Extensions (JMX), or SNMP in addition to standard error logging.

Alerts and events reflect state changes within the server that might be of interest to a user or monitoring service.

Notifications are typically the delivery of an alert or event to a user or monitoring service.

**Note:**

Account status notifications are only delivered to the account owner, notifying a change in state in the account.

## Account status notifications

PingDirectory Server supports notification handlers that can notify users, administrators, or both of significant changes related to password policy state for user entries.

The following notification handlers are available:

### Error Log Account Status Notification Handler

Sends alerts to the error log when an account event occurs. Enabled by default.

### SMTP Account Status Notification Handler

Sends notifications to designated email address. Disabled by default, but you can enable it using the `dsconfig` command.

## Account status notification types

Notification handlers send alerts when one of the following account status events occurs during password policy processing.

### Account Status Notification Types

Account Status Notification Types	Description
<code>account-disabled</code>	Generates a notification when a user account is disabled by an administrator.
<code>account-enabled</code>	Generates a notification when a user account is enabled by an administrator.
<code>account-expired</code>	Generates a notification when a user authentication attempt fails because the account has expired.
<code>account-idle-locked</code>	Generates a notification when a user authentication attempt fails because the account has been locked after idling for too long.
<code>account-permanently-locked</code>	Generates a notification when a user account is permanently locked, requiring administrative action to unlock the account after too many failed authentication attempts.
<code>account-reset-locked</code>	Generates a notification when an authentication attempt fails because the user account is locked after the user failed to change a password that was reset by an administrator within the required interval.
<code>account-temporarily-locked</code>	Generates a notification when a user account is temporarily locked after too many failed attempts.
<code>account-unlocked</code>	Generates a notification when a user account is unlocked by an administrator.

Account Status Notification Types	Description
password-changed	Generates a notification when a user changes his or her own password.
password-expired	Generates a notification when a user authentication fails because the password has expired.
password-expiring	Generates a notification the first time a password expiration warning is encountered for a user password.
password-reset	Generates a notification when a user's password is reset by an administrator.

### Working with the Error Log Account Status Notification Handler

The Error Log Account Status Notification Handler is enabled by default and sends alerts when one of the account status events occur.

You can view the log at `logs/error`.

### Disabling the Error Log Account Status Notification Handler

#### Steps

- To disable the Error Log Handler, use the `dsconfig` tool.

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  ---handler-name "Error Log Handler" --set enabled:false
```

### Removing a notification type from the Error Log Handler

Although you can remove an account status notification type from the Error Log Handler, it's not recommended.

#### About this task

For a list of notification types, see [Account status notification types](#) on page 973.

#### Steps

- To remove an account status notification type, use the `dsconfig` tool with the `--remove` option.

Example:

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  --handler-name "Error Log Handler" \
  --remove account-status-notification-type: password-reset
```

### Working with the SMTP Account Status Notification Handler

You can enable account status notifications to be sent to designated email addresses of end users, administrators, or both through an outgoing SMTP server. The email message is automatically generated from template files that contain the text to use in the message body. For example, the message subject for the account-disabled event is:

```
account-disabled: Your directory account has been disabled.
```

The message templates are located in the `config/messages` directory. The typical message body template is as follows:

Your directory account has been disabled.

For further assistance, please contact a server administrator.

By default, the sender address is `notifications@example.com`, but you can configure your own address.

Before you enable the SMTP Account Status Notification Handler, you must configure the Directory Server to use at least one mail server as shown below. You can configure an SMTP server using `dsconfig` and the `set-global-configuration-prop` option.

### Configuring the SMTP server

#### Steps

1. To configure a simple mail server, use the `dsconfig` command.

Example:

```
$ bin/dsconfig create-external-server --server-name smtp1 \
  --type smtp --set server-host-name:smtp.example.com
```

2. To configure an SMTP server, use the `dsconfig` command.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set smtp-server:smtp1
```

This command adds the server to the global list of mail servers that Directory Server can use.

### Configuring a StartTLS connection to the SMTP server

#### Steps

1. To configure a StartTLS connection to the server, use the `dsconfig` command.

Example:

```
$ bin/dsconfig create-external-server \
  --server-name myTLSServer --type smtp \
  --set server-host-name:tls.smtp.example.com \
  --set server-port:587 \
  --set smtp-security:starttls \
  --set user-name:MyAccountName \
  --set password:AAD5yZ+DjvwiYkBSMer6GQ6B3szQ6gSSBjA=
```

2. To configure a newly-created SMTP server, use the `dsconfig` command.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  -set smtp-server:myTLSServer
```

This command adds the server to the global list of mail servers that Directory Server can use.

### Configuring an SSL connection to the SMTP server

#### Steps

1. To create an external SMTP server using SSL, run the `dsconfig` command.

Example:

```
$ bin/dsconfig create-external-server \
  --server-name ssl.smtp.example.com \
  --type smtp --set server-host-name:smtp.gmail.com \
```

```
--set server-port:465 \
--set smtp-security:ssl \
--set "user-name:my.name@example.com" \
--set password:xxxxxx --set "smtp-timeout:10s"
```

2. To configure an SMTP server, run the **dsconfig** command.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
--set smtp-server:ssl.smtp.example.com
```

This command adds the server to the global list of mail servers that Directory Server can use.

### Enabling the SMTP account status notification handler

#### Steps

- To enable the SMTP account status notification handler, use the **dsconfig** command.

Example:

```
$ bin/dsconfig set-account-status-notification-handler-prop \
--handler-name "SMTP Handler" --set enabled:true \
--set "recipient-address:admin@example.com" \
--set "sender-address:acct-status-notifications@example.com"
```

### Viewing the account status notification handlers

After you enable the SMTP server, you can view the list of account status notification handlers.

#### Steps

- To view the list of account status notification handlers, run the **dsconfig** command.

Example:

```
$ bin/dsconfig list-account-status-notification-handlers
```

Result:

```
Account Status Notification Handler : Type      : enabled
-----:-----:-----
Error Log Handler                   : error-log : true
SMTP Handler                         : smtp      : true
```

### Associating account status notification handlers with password policies

To generate notifications when password policy state changes occur in the server, you must configure the password policy that governs the entry being updated to use one or more account status notification handlers.

#### About this task

By default, password policies are not configured with such handlers, so no account status notifications are generated.

The `account-status-notification-handler` property controls the set of account status notification handlers for a password policy. You can be configure that property using **dsconfig** or the Administrative Console.

## Steps

- To configure the `account-status-notification-handler` notification handler property, run `dsconfig`.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "account-status-notification-handler:Error Log Handler"
```

This command updates the default password policy to trigger the error log account status notification handler for any appropriate password policy state changes.

## Administrative alert handlers

The PingDirectory Server provides mechanisms to send alert notifications to administrators when significant problems or events occur during processing, such as problems during server startup or shutdown. The Directory Server provides a number of alert handler implementations, including:

- **Error Log Alert Handler.** Sends administrative alerts to the configured server error logger(s).
- **Exec Alert Handler.** Executes a specified command on the local system if an administrative alert matching the criteria for this alert handler is generated by the Directory Server. Information about the administrative alert will be made available to the executed application as arguments provided by the command.
- **Groovy Scripted Alert Handler.** Provides alert handler implementations defined in a dynamically-loaded Groovy script that implements the `ScriptedAlertHandler` class defined in the Server SDK.
- **JMX Alert Handler.** Sends administrative alerts to clients using the Java Management Extensions (JMX) protocol. Ping Identity uses JMX for monitoring entries and requires that the JMX connection handler be enabled.
- **SMTP Alert Handler.** Sends administrative alerts to clients via email using the Simple Mail Transfer Protocol (SMTP). The server requires that one or more SMTP servers be defined in the global configuration.
- **SNMP Alert Handler.** Sends administrative alerts to clients using the Simple Network Monitoring Protocol (SNMP). The server must have an SNMP agent capable of communicating via SNMP 2c.
- **SNMP Subagent Alert Handler.** Sends SNMP traps to a master agent in response to administrative alerts generated within the server.
- **Third Party Alert Handler.** Provides alert handler implementations created in third-party code using the Server SDK.

### Administrative alert types

Directory Server can generate administrative alerts when the events occur.

A full listing of system alerts and their severity is available at `<server-root>/docs/admin-alerts-list.csv`.

## Configuring the JMX connection handler and alert handler

You can configure the Java Management Extensions (JMX) connection handler and the alert handler using the `dsconfig` tool.

To allow users to receive JMX notifications, enable the `jmx-read` and `jmx-notify` privileges. By default, these privileges aren't granted to any users, including root users or global administrators.

For security reasons, you should create a separate user account that has only these privileges.

You can also configure the JMX connection handler and the alert handler using `dsconfig` in interactive command-line mode, which is visible in the `Standard object` menu.

## Configuring the JMX connection handler

About this task

To enable the JMX connection handler:

Steps

1. Run **dsconfig**.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "JMX Connection Handler" \
  --set enabled:true \
  --set listen-port:1689
```

2. Add a new non-root user account with the `jmx-read` and `jmx-notify` privileges using the **ldapmodify** tool using an LDIF representation.

Example:

```
dn: cn=JMX User,cn=Root DNs,cn=config
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-cfg-root-dn-user
givenName: JMX
sn: User
cn: JMX User
userPassword: password
ds-cfg-inherit-default-root-privileges: false
ds-cfg-alternate-bind-dn: cn=JMX User
ds-privilege-name: jmx-read
ds-privilege-name: jmx-notify
```

## Configuring the JMX alert handler

About this task

To configure the Java Management Extensions (JMX) alert handler:

Steps

- Run **dsconfig**.

Example:

```
$ bin/dsconfig set-alert-handler-prop --handler-name "JMX Alert Handler" \
  --set enabled:true
```

## Configuring the SMTP alert handler

To create a new instance of an SMTP alert handler, use the **dsconfig** tool.

About this task

By default, there is no configuration entry for an SMTP alert handler.

## Steps

- Use the **dsconfig** tool to configure the SMTP Alert Handler.

Example:

```
$ bin/dsconfig create-alert-handler \
  --handler-name "SMTP Alert Handler" \
  --type smtp \
  --set enabled:true \
  --set "sender-address:alerts@example.com" \
  --set "recipient-address:administrators@example.com" \
  --set "message-subject:Directory Admin Alert \%%alert-type\%%" \
  --set "message-body:Administrative alert:\n\%%alert-message\%%"
```

## Configuring the SNMP subagent alert handler

You can configure the SNMP subagent alert handler using the **dsconfig** tool, which is visible in the Standard object menu.

### About this task

Before you begin, you need an SNMP subagent capable of communicating using SNMP2c. For more information about SNMP, see [Monitoring using SNMP](#) on page 955.

Directory Server also supports an SNMP alert handler, which is used in deployments that do not enable an SNMP subagent.

To configure the SNMP subagent alert handler:

## Steps

- Run **dsconfig**.

Example:

In this example:

- The **server-host-name** is the address of the system running the SNMP subagent.
- The **server-port** is the port number on which the subagent is running.
- The **community-name** is the name of the SNMP community that is used for the traps.

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" \
  --set enabled:true \
  --set server-host-name:host2 \
  --set server-port:162 \
  --set community-name:public
```

## Email account status notification handler

The e-mail account status notification handler enables the server to send messages that can contain either a plain-text body, an HTML-formatted body, or both.

If you configure the server to send both plain-text and HTML-formatted bodies, the recipient's email client determines which version to display. Messages can optionally include a set of attachments.

The `config/account-status-notification-email-templates` directory contains a set of template files that the server can use to generate multi-part email messages to send to end users and server administrators when certain events occur.

A separate template is used for each type of event so that the message contents, recipients, and other details can be customized for specific events.

## Account status notification types

The following account status notification types are available.

- **account-temporarily-locked** -- A user's account has been temporarily locked due to too many failed authentication attempts. The account will remain locked until a configured length of time elapses, or until the password is reset by an administrator.
- **account-permanently-locked** -- A user's account has been permanently locked due to too many failed authentication attempts. The account will remain locked until the password is reset by an administrator.
- **account-idle-locked** -- An authentication attempt failed because it has been too long (longer than the `idle-lockout-interval` configured in the associated password policy) since the user last successfully authenticated to the server. The account will remain locked until the password is reset by an administrator.
- **account-reset-locked** -- An authentication attempt failed because the user's account was in a "must change password" state following an administrative password reset, but the user did not choose a new password in a timely manner (within the `max-password-reset-age` duration configured in the associated password policy). The account will remain locked until the password is reset again by an administrator.
- **account-unlocked** -- A locked user account has been unlocked (for example, by an administrative password reset).
- **account-disabled** -- A user's account has been administratively disabled (by setting the `ds-pwp-account-disabled` operational attribute to `true` in the user entry). The user will not be allowed to authenticate until this attribute is removed or its value is set to `false`.
- **account-enabled** -- A user's account has been administratively enabled (by setting the `ds-pwp-account-disabled` operational attribute to `false` in the user entry, or by removing this attribute from the entry).
- **account-not-yet-active** -- An authentication attempt failed because the user account is configured with an activation time (via the `ds-pwp-account-activation-time` operational attribute in the user's entry) that is in the future. The user will not be allowed to authenticate until this time arrives, until the activation time is removed, or until the activation time is set to a time in the past.
- **account-expired** -- An authentication attempt failed because the user account is configured with an expiration time (via the `ds-pwp-account-expiration-time` operational attribute in the user's entry) that is in the past. The user will not be allowed to authenticate until the expiration time is removed or set to a time in the future.
- **password-expired** -- An authentication attempt failed because the user's password has expired. The user will not be allowed to authenticate until their password is reset by an administrator (or until they change their own password if `allow-expired-password-changes` is set to `true` in the associated password policy).
- **password-expiring** -- The user successfully authenticated, but their password will expire in the near future (as determined by the `password-expiration-warning-interval` setting in the associated password policy). This notification type will only be generated the first time that a user authenticated within a given warning interval.
- **password-reset** -- A user's password has been reset by an administrator.
- **password-changed** -- A user changed their own password.
- **account-created** -- A new account was created in an add request that matches the criteria specified in the `account-creation-notification-request-criteria` property of the account status notification handler configuration.
- **account-updated** -- An existing account was updated in a modify or modify DN request that matches the criteria specified in the `account-update-notification-request-criteria` property of the account status notification handler configuration.

## Message template file format

An email message for the email account status notification handler contains the following structure:

- A required header section describing the sender, recipients, subject, and other header elements  
This section must appear exactly once, and it must be the first section of the template file.
- An optional section providing a plain-text version of the message body  
This section may appear at most once, and at least one of the plain-text and HTML-formatted body sections must be present.
- An optional section providing an HTML-formatted version of the message body  
This section may appear at most once, and at least one of the plain-text and HTML-formatted body sections must be present.
- An optional section providing information about an attachment to include in the message  
This section can be included zero, one, or multiple times, and all attachment sections must appear after all other sections.

### Header section

A message template file must start with a header section that specifies the recipient and sender addresses, the message subject, and the values of any custom headers that should appear in the message. It also indicates whether the template should be enabled and used to send email messages.

The header section must begin with the line `----- BEGIN HEADERS -----` and can contain a number of name-value pairs that provide information about the message. Each name-value pair should appear on a separate line, and the name and value must be separated by a colon and optional spaces. The header section can include the following:

#### **ENABLED**

Specifies whether this template is enabled and should be used to generate an email message.

This element must be present and must have a value of either `true` or `false`. This is primarily intended for cases in which a message should only be generated under certain circumstances.

#### **Tip:**

If you don't want a message sent for a particular notification type, don't specify a template file for that notification type in the configuration for the multi-part email account status notification handler.

#### **TO**

Specifies a primary recipient for the email message. This recipient is visible to all recipients.

The value can be either an email address, such as `jdoe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdoe@example.com>`.

To specify multiple **TO** recipients, specify this element multiple times.

It can be omitted if the message should have only **CC** or **BCC** recipients, but the message must have at least one **TO**, **CC**, or **BCC** recipient.

#### **CC**

Specifies a carbon-copied recipient for the email message. This recipient is visible to all recipients.

The value can be either an email address, such as `jdoe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdoe@example.com>`.

To specify multiple **CC** recipients, specify this element multiple times.

It can be omitted if the message should have only **TO** or **BCC** recipients, but the message must have at least one **TO**, **CC**, or **BCC** recipient.

**BCC**

Specifies a blind carbon-copied recipient for the email message. This recipient is not visible to other recipients.

The value can be either an email address, such as `jdooe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdooe@example.com>`.

To specify multiple **BCC** recipients, specify this element multiple times.

It can be omitted if the message should have only **TO** or **CC** recipients, but the message must have at least one **TO**, **CC**, or **BCC** recipient.

**FROM**

Specifies the address from which the email message should appear to be sent.

This value can be either an email address, such as `jdooe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdooe@example.com>`.

This element must be specified exactly once.

**REPLY-TO**

Specifies the default address to which users should send replies.

The value can be either an email address, such as `jdooe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdooe@example.com>`.

This element is optional and can only be specified once.

**SUBJECT**

Specifies the subject for the email message.

This element must be specified exactly once.

**HEADER**

Defines a custom header for the email message.

The header value itself should be a name-value pair with the name and value separated by a colon and optional spaces, such as `X-Custom-Header-Name: Custom Header Value`.

This is an optional element and can be specified multiple times to specify multiple headers with the same or different names.

## Body sections

The header section must be followed by plain-text body sections, HTML-formatted body sections, or both. Each of these sections consists of free-form text that can span multiple lines and continues until the beginning of the next section or the end of the template file is reached.

If a plain-text body is included, it must begin with the line `----- BEGIN PLAIN-TEXT BODY -----`. If an HTML-formatted body is included, it must begin with the line `----- BEGIN HTML BODY -----`. At least one of these sections must be included. If an HTML-formatted body section is included, you should add a plain-text body for the benefit of clients that prefer plain text or cannot handle HTML content. Any blank lines at the beginning or end of the body text are removed, but blank lines in the middle of the body are preserved.

## Attachment sections

The template can contain any number of optional attachment sections that describe any attachments that should be included in the message. Specify each attachment in its own section at the end of the template,

after the header, plain-text, and HTML-formatted body sections. Each attachment section must begin with the line `----- BEGIN ATTACHMENT -----` and can include the following elements, using the same colon-delimited syntax used in the header section:

#### FILENAME

The name (without any path information) of the file to be attached. This must be specified, and the file must exist in the same directory as the template file.

#### CONTENT-TYPE

The `MIME` type for the attachment. This is an optional element. If it is not specified, a default content-type of `application/octet-stream` is used.

#### INLINE

If present, this value must be either `true` or `false`. If it is omitted, a default value of `false` is assumed.

If `true`, indicates that the attachment should be an inline attachment. For example, if you include an image that should be referenced within the HTML body, the image source path should be `cid:` followed by the filename, such as `cid:company-logo.png`.

### Customizing the message content

Before the server parses the template file to generate a message, it pre-processes the file with the Apache Velocity templating engine. This enables you to customize the message content with information from the account status notification, details from the associated user entry, and other information. For more information about Apache Velocity, see <https://velocity.apache.org/>.

The following variables are defined for use with custom directives.

Variable	Description
<code>\$account_entry</code>	The entry for the user associated with the account status notification.
<code>\$notification_type</code>	The name of the notification type for the account status notification.
<code>\$notification_message</code>	A human-readable message that provides a basic description of the account status notification.
<code>\$before_entry</code>	<p>A version of the associated entry as it appeared before the operation was processed.</p> <p> <b>Note:</b> This is only available for notifications generated as a result of modify or modify distinguished name (DN) operations.</p>

Variable	Description
<code>\$after_entry</code>	<p>A version of the associated entry as it appeared after the operation was processed.</p> <p> <b>Note:</b> This is only available for notifications generated as a result of modify or modify DN operations.</p>

In addition to the built-in directives provided by Velocity, the following custom directives are also available.

Directive	Syntax	Description
<code>#getEntryDN</code>	<i>entry, variableName</i>	Retrieves a string representation of the provided entry's DN and stores it in the specified Velocity context variable.
<code>#getHasAttribute</code>	<i>entry, attributeName, variableName</i>	Determines if the provided entry includes the specified attribute.  If it contains the specified attribute, a value of <code>true</code> is stored in the specified Velocity context variable. If not, a value of <code>false</code> is stored.
<code>#getUserAttributeNames</code>	<i>entry, variableName</i>	Retrieves a list of the names of the user attributes contained in the provided entry and stores this list in the specified Velocity context variable.
<code>#getOperationalAttributeNames</code>	<i>entry, variableName</i>	Retrieves a list of the names of the operational attributes contained in the provided entry and stores this list in the specified Velocity context variable.
<code>#getAttributeValue</code>	<i>entry, attributeName, variableName</i>	Retrieves the first value for the indicated attribute from the provided entry and stores it in the specified Velocity context variable.  If the attribute is not present in the entry, the variable is removed from the context.

Directive	Syntax	Description
<b>#getAttributeValues</b>	<i>entry, attributeName, variableName</i>	Retrieves the list of values for the indicated attribute from the provided entry and stores this list in the specified Velocity context variable.  If the attribute is not present in the entry, an empty list is stored.
<b>#getEntryMatchesLDAPFilter</b>	<i>entry, filterString, variableName</i>	Determines if the provided entry matches the LDAP filter with the given string representation.  If the entry matches, a value of <code>true</code> is stored in the Velocity context variable. Otherwise, a value of <code>false</code> is stored.
<b>#getJSONObjectValue</b>	<i>entry, attributeName, variableName</i>	Retrieves the first value that can be parsed as a JSON object for the indicated attribute and stores this object in the specified variable in the Velocity context.  If the attribute does not exist in the provided entry, or if none of its values can be parsed as a JSON object, the variable is removed from the context.
<b>#getJSONObjectValues</b>	<i>entry, attributeName, variableName</i>	Retrieves a list of all values that can be parsed as JSON objects for the indicated attribute and stores this list in the specified variable in the Velocity context.  If the attribute does not exist in the provided entry, or if none of its values can be parsed as JSON objects, an empty list is stored.

Directive	Syntax	Description
<b>#getJSONFieldValue</b>	<i>jsonObject, fieldName, variableName</i>	<p>Retrieves the first value for the indicated field from the provided JSON object and stores its string representation in the specified Velocity context variable.</p> <p>Nested fields can be targeted by using the period as a delimiter between field names.</p> <p>For example, <code>name.first</code> targets the <code>first</code> field inside a JSON object that is a value for the outer <code>name</code> field.</p> <p>If the field does not exist in the provided object, the variable is removed from the context.</p>
<b>#getJSONFieldValues</b>	<i>jsonObject, fieldName, variableName</i>	<p>Retrieves all values for the indicated field from the provided JSON object and stores a list of their string representations in the specified Velocity context variable.</p> <p>Nested fields can be targeted by using the period as a delimiter between field names.</p> <p>For example, <code>name.first</code> targets the <code>first</code> field inside a JSON object that is a value for the outer <code>name</code> field.</p> <p>If the field does not exist in the provided object, or if its value is an empty array, an empty list is stored.</p>
<b>#getJSONObjectMatchesFilter</b>	<i>jsonObject, jsonObjectFilterString, variableName</i>	<p>Determines if the provided JSON object matches the JSON object filter with the given string representation.</p> <p>If the JSON object matches, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.</p>

Directive	Syntax	Description
<b>#getEntry</b>	<i>entryDN, variableName</i>	Retrieves the entry with the provided DN from the server and stores it in the specified Velocity context variable.  If the entry does not exist, the variable is removed from the context.
<b>#searchForEntries</b>	<i>baseDN, scopeString, filterString, variableName</i>	Performs an internal search with the provided base DN; scope, which must be one of <i>base</i> , <i>one</i> , <i>sub</i> , or <i>subordinates</i> ; and filter; and stores the list of matching entries in the specified variable in the context.  If the search does not match any entries, if it matches more than 20 entries, or if the search criteria is not indexed, then an empty list is stored.
<b>#getParentDN</b>	<i>entryDN, variableName</i>	Determines the parent DN for the provided entry DN and stores it in the specified Velocity context variable.  If the provided DN contains only a single component, an empty string is stored.  If the provided DN is the null DN, and therefore does not have a parent, the variable is removed from the context.
<b>#getIsAttributeModified</b>	<i>beforeEntry, afterEntry, attributeName, variableName</i>	Determines if the indicated attribute has been modified between the provided before and after representations of the entry.  If the attribute has been modified, a value of <i>true</i> is stored in the specified Velocity context variable. Otherwise, a value of <i>false</i> is stored.

Directive	Syntax	Description
#getIsAnyAttributeModified	<i>beforeEntry, afterEntry, attributeName1, attributeName2, ..., variableName</i>	<p>Determines if at least one of the listed attributes has been modified between the provided before and after representations of the entry.</p> <p>If at least one of the listed attributes has been modified, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.</p> <p>The first two arguments to this directive must be the before and after representations of the target entry, and the last argument must be the name of the variable in which to store the result. All arguments in between these are treated as the names or OIDs of the attributes for which to make the determination. At least one attribute name or OID must be provided.</p>
#getModifiedAttributeNames	<i>beforeEntry, afterEntry, variableName</i>	<p>Determines which attributes have been modified between the provided before and after representations of the entry, and stores a list of their names in the specified Velocity context variable.</p> <p>If the provided entries are identical, an empty list is stored.</p>
#getModifiedAttributeAddedValues	<i>beforeEntry, afterEntry, attributeName, variableName</i>	<p>Retrieves a list of the values that have been added between the provided before and after representations of an entry for the indicated attribute, and stores this list in the specified Velocity context variable.</p> <p>If the attribute was not altered, or if values were only removed from the attribute, an empty list is stored.</p>

Directive	Syntax	Description
<code>#getModifiedAttributeRemovedValues</code>	<code>beforeEntry, afterEntry, attributeName, variableName</code>	Retrieves a list of the values that have been removed between the provided before and after representations of an entry for the indicated attribute, and stores this list in the specified Velocity context variable.  If the attribute was not altered, or if values were only added to the attribute, an empty list is stored.
<code>#getOperationMatchesConnectionCriteria</code>	<code>DN, variableName</code>	Determines if the operation that triggered the notification matches the connection criteria defined in the entry with the specified DN.  If it matches, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.
<code>#getOperationMatchesRequestCriteria</code>	<code>DN, variableName</code>	Determines if the operation that triggered the notification matches the request criteria defined in the entry with the specified DN.  If it matches, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.
<code>#getNotificationPropertyName</code>	<code>variableName</code>	Retrieves a list of the names of the account status notification properties that are defined for the notification and stores this list in the specified Velocity context variable.
<code>#getNotificationPropertyValue</code>	<code>propertyName, variableName</code>	Retrieves the first value for the given account status notification property and stores it in the specified Velocity context variable. If the property is not defined, the variable is removed from the context.  Refer to the following table for <i>propertyName</i> values.

Directive	Syntax	Description
<b>#getNotificationPropertyValue</b>	<i>propertyName, variableName</i>	Retrieves the list of values for the given account status notification property and stores this list in the specified Velocity context variable.  If the property is not defined, an empty list is stored.  Refer to the following table for <i>propertyName</i> values.
<b>#getFormattedTimestamp</b>	<i>timestamp, formatString, variableName</i>	Retrieves a representation of the provided timestamp, which must be in generalized time form, formatted with the provided format string, which must be compatible with the <code>java.text.SimpleDateFormat</code> class, and stores it in the specified Velocity context variable.  The default time zone of the JVM is used.
<b>#getFormattedTimestamp</b>	<i>timestamp, formatString, timeZone, variableName</i>	Retrieves a representation of the provided timestamp, which must be in generalized time form, formatted with the given format string, which must be compatible with the <code>java.text.SimpleDateFormat</code> class, in the indicated time zone, which must be compatible with the <code>java.time.ZoneId</code> class, and stores it in the specified Velocity context variable.
<b>#getFileExistsInTemplateDirectory</b>	<i>fileName, variableName</i>	Determines if a file with the provided name, which must not contain path information, exists in the same directory as the template.  If the file exists, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.

The following account status notification properties are available for use in conjunction with the `#getNotificationPropertyValue` and `#getNotificationPropertyValues` directives.

Property	Description
<code>notification-type</code>	The name of the account status notification type.
<code>notification-time</code>	A generalized time representation of the time that the notification was generated.
<code>account-dn</code>	The DN of the entry for the associated user account.
<code>password-policy-dn</code>	The DN of the password policy that governs the associated user account.
<code>password-changed-time</code>	A generalized time representation of the time the user's password was last changed.
<code>seconds-since-password-change</code>	The number of seconds since the account's password was last changed.
<code>time-since-password-change</code>	A human-readable duration indicating the length of time since the user's password was last changed.
<code>account-is-usable</code>	<p>The value is <code>true</code> if the account is considered usable, or <code>false</code> if it is not usable.</p> <p>The account is considered unusable if, for example, the account is locked, expired, or not yet active; if the password is expired; if the user must choose a new password; and so on.</p>
<code>account-usability-errors</code>	A list of human-readable strings providing information about any errors that currently affect the account's usability.
<code>account-usability-warnings</code>	A list of human-readable strings providing information about any warning conditions that have the potential to affect the account's usability in the near future.
<code>account-usability-notices</code>	A list of human-readable strings providing information about any notable account state conditions that are not expected to affect the account's usability in the near future.
<code>account-is-disabled</code>	The value is <code>true</code> if the account has been administratively disabled, or <code>false</code> if it has not been administratively disabled.
<code>account-is-not-yet-active</code>	The value is <code>true</code> if the account has an activation time in the future, or <code>false</code> if not.
<code>account-activation-time</code>	A generalized time representation of the account activation time, if defined.

Property	Description
<code>seconds-until-account-activation</code>	The number of seconds until the account becomes active if it has an activation time in the future.
<code>time-until-account-activation</code>	A human-readable duration indicating the length of time until the account becomes active if it has an activation time in the future.
<code>seconds-since-account-activation</code>	The number of seconds since the account became active if it has an activation time in the past.
<code>time-since-account-activation</code>	A human-readable duration indicating the length of time since the account became active if it has an activation time in the past.
<code>account-is-expired</code>	The value is <code>true</code> if the account has an expiration time in the past, or <code>false</code> if not.
<code>account-expiration-time</code>	A generalized time representation of the account expiration time, if defined.
<code>seconds-until-account-expiration</code>	The number of seconds until the account expires if it has an expiration time in the future.
<code>time-until-account-expiration</code>	A human-readable duration indicating the length of time until the account expires if it has an expiration time in the future.
<code>seconds-since-account-expiration</code>	The number of seconds since the account expired if it has an expiration time in the past.
<code>time-since-account-expiration</code>	A human-readable duration indicating the length of time since the account expired if it has an expiration time in the past.
<code>account-is-failure-locked</code>	The value is <code>true</code> if the account has been temporarily or permanently locked due to too many failed authentication attempts, or <code>false</code> if not.
<code>failure-locked-time</code>	A generalized time representation of the time that the account became failure-locked, if applicable.
<code>account-unlock-time</code>	A generalized time representation of the time that the account will be automatically unlocked, if it is temporarily locked due to too many failed authentication attempts.
<code>seconds-until-unlock</code>	The number of seconds until the account unlock time, if applicable.
<code>time-until-unlock</code>	A human-readable duration indicating the length of time until the account unlock time, if applicable.

Property	Description
<code>failure-lockout-count</code>	The number of failed authentication attempts required to lock an account, if configured.
<code>failure-lockout-duration-seconds</code>	The number of seconds that a failure-locked account will be prevented from authenticating, if defined.
<code>failure-lockout-duration</code>	A human-readable duration that indicates how long a failure-locked account will be prevented from authenticating, if defined.
<code>account-is-idle-locked</code>	The value is <code>true</code> if the account is locked because it has been too long since the user last authenticated, or <code>false</code> if not.
<code>idle-lockout-interval-seconds</code>	The maximum number of seconds that can pass between successful authentications before an account becomes idle-locked, if configured.
<code>idle-lockout-interval</code>	A human-readable duration that indicates how much time can pass between successful authentications before an account becomes idle-locked, if configured.
<code>last-login-time</code>	A generalized time representation of the time that the user last successfully authenticated, if available.
<code>seconds-since-last-login</code>	The number of seconds that have passed since the user last successfully authenticated, if available.
<code>time-since-last-login</code>	A human-readable duration indicating the length of time that has passed since the user last successfully authenticated, if available.
<code>last-login-ip-address</code>	The IP address of the client from which the user last authenticated, if available.
<code>account-is-reset-locked</code>	The value is <code>true</code> if the account is locked because the user failed to choose a new password in a timely manner after an administrative password reset, or <code>false</code> if not.
<code>maximum-password-reset-age-seconds</code>	The maximum number of seconds that a user has to choose a new password after an administrative password reset before the account becomes reset-locked, if defined.
<code>maximum-password-reset-age</code>	A human-readable duration indicating the maximum length of time that a user has to choose a new password after an administrative password reset before the account becomes reset-locked, if defined.

Property	Description
<code>must-change-password</code>	The value is <code>true</code> if the user will be required to choose a new password before they are allowed to perform any other operations on the server, or <code>false</code> if not.
<code>account-was-unlocked</code>	The value is <code>true</code> if the account had been locked but was just unlocked by the associated operation, or <code>false</code> if not.
<code>password-is-expired</code>	The value is <code>true</code> if the account has an expired password, or <code>false</code> if not.
<code>password-is-expiring</code>	The value is <code>true</code> if the account has a password that will expire in the near future, as determined by the <code>password-expiration-warning-interval</code> property in the associated password policy, or <code>false</code> if not.
<code>maximum-password-age-seconds</code>	The maximum number of seconds that an account is permitted to keep the same password before it expires, if defined.
<code>maximum-password-age</code>	A human-readable duration indicating the maximum length of time that an account is permitted to keep the same password before it expires, if defined.
<code>maximum-password-age</code>	A human-readable duration indicating the maximum length of time that an account is permitted to keep the same password before it expires, if defined.
<code>password-expiration-time</code>	A generalized time representation of the time that the account's password did or will expire, if applicable.
<code>seconds-until-password-expiration</code>	The number of seconds until the account's password will expire, if it has an expiration time in the future.
<code>time-until-password-expiration</code>	A human-readable duration indicating the length of time until the account's password will expire, if it has an expiration time in the future.
<code>seconds-since-password-expiration</code>	The number of seconds since the account's password expired, if it has an expiration time that is in the past.
<code>time-since-password-expiration</code>	A human-readable duration indicating the length of time since the account's password expired, if it has an expiration time in the past.
<code>old-password</code>	The clear-text password that the account had before the associated operation was processed, if available.

Property	Description
<code>new-password</code>	The clear-text password that the account has after the associated operation was processed, if available.
<code>new-generated-password</code>	The clear-text password that was generated for the account by the associated operation, if applicable.
<code>requester-ip-address</code>	The IP address of the client that requested the associated operation, if available.
<code>requester-dn</code>	The DN of the account that requested the associated operation.
<code>operation-type</code>	The name of the operation type for the associated operation.
<code>operation-id</code>	A string representation of the operation ID for the associated operation.
<code>connection-id</code>	A string representation of the connection ID for the associated operation.
<code>server-uuid</code>	A string representation of the unique identifier generated for the server instance that processed the associated operation.
<code>instance-name</code>	The instance name for the server instance that processed the associated operation.

## Working with the Alerts Backend

Directory Server stores recently-generated admin alerts in an Alerts Backend under the `cn=alerts` branch.

The backend makes it possible to obtain admin alert information over LDAP. The backend's primary job is to process search operations for alerts. It does not support `add`, `modify`, or `modify DN` operations of entries in the `cn=alerts` backend.

The alerts persist on the server in the `config/alerts.ldif` file so they can survive server restarts. By default, the alerts remain in the system for seven days before being removed. Administrators can configure the number of days alerts are retained by using the `dsconfig` tool.

The administrative alerts of `Warning` level or worse that have occurred in the last 48 hours are viewable from the output of the status command-line tool and in the Administrative Console.

### Viewing information in the Alerts Backend

About this task

To view admin alerts:

## Steps

- Run **ldapsearch**.

Example:

```
$ bin/ldapsearch --port 1389 --bindDN "cn=Directory Manager" \
  --bindPassword secret --baseDN cn=alerts "(objectclass=ds-admin-alert)"
```

Result:

```
dn: ds-alert-id=3d1857a2-e8cf-4e80-ac0e-ba933be59eca,cn=alerts
objectClass: top
objectClass: ds-admin-alert
ds-alert-id: 3d1857a2-e8cf-4e80-ac0e-ba933be59eca
ds-alert-type: server-started
ds-alert-severity: info
ds-alert-type-oid: 1.3.6.1.4.1.32473.2.11.33
ds-alert-time: 20110126041442.622Z
ds-alert-generator: com.unboundid.directory.server.core.directory.server
ds-alert-message: The Directory Server has started successfully
```

## Modifying the alert retention time

### Steps

- To change the retention time of admin alerts, run **dsconfig**.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name "alerts" \
  --set "alert-retention-time: 2 weeks"
```

After this time, the information is purged from the Directory Server. The minimum retention time is 0 milliseconds, which immediately purges the alert information.

- To view the `alert-retention-time` property, use **dsconfig**.

Example:

```
$ bin/dsconfig get-backend-prop --backend-name "alerts" \
  --property alert-retention-time
```

Result:

```
Property : Value(s)
-----:-----
alert-retention-time : 2 w
```

## Configuring duplicate alert suppression

### About this task

The `duplicate-alert-time-limit` property specifies the length of time that must pass before duplicate messages are sent over the administrative alert framework.

The `duplicate-alert-limit` property specifies the maximum number of duplicate alert messages that can be sent over the administrative alert framework in the time limit specified in the `duplicate-alert-time-limit` property.

To configure the maximum number of times an alert is generated within a particular timeframe for the same condition:

## Steps

- Run **dsconfig**.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set duplicate-alert-limit:2 \
  --set "duplicate-alert-time-limit:3 minutes"
```

## Working with alarms, alerts, and gauges

Alarms, alerts, and gauges alert administrators to changes in server conditions that might require attention.

### Alarms

An alarm represents a stateful condition of the server or a resource that might indicate a problem, such as low disk space or external server unavailability.

Alarms have severity, name, and message. Alarms will always have a Condition property, and can have a Specific Problem or Resource property. If surfaced through SNMP, a Probable Cause property and Alarm Type property are also listed. You can configure alarms to generate alerts when the alarm's severity changes.

You can configure the Alarm Manager, which governs the actions performed when an alarm state is entered, through the **dsconfig** tool and Administrative Console. A complete list of system alerts, alarms, and their severity is available in `<server-root>/docs/admin-alerts-list.csv`.

Directory Server complies with the International Telecommunication Union CCITT Recommendation X.733 (1992) standard for generating and clearing alarms. If configured, entering or exiting an alarm state might result in one or more alerts.

An alarm state is exited when the condition no longer applies. An `alarm_cleared` alert type is generated by the system when an alarm's severity changes from a non-normal severity to any other severity. An `alarm_cleared` alert will correlate to a previous alarm when the Condition and Resource properties are the same. The Condition corresponds to the Summary column in the `admin-alerts-list.csv` file.

Like the Alerts Backend, which stores information in `cn=alerts`, the Alarm Backend stores information within the `cn=alarms` backend. Unlike alerts, alarm thresholds have a state over time that can change in severity and be cleared when a monitored value returns to normal. You can view alarms with the **status** tool. As with other alert types, you can configure alert handlers can to manage the alerts generated by alarms.

### Alerts

There are two alert types supported by the server: standard and alarm-specific.

The server constantly monitors for conditions that might need administrator attention, such as low disk space. For this condition, the standard alert is `low-disk-space-warning`, and the alarm-specific alert is `alarm-warning`.

You can configure the server to generate alarm-specific alerts as well as standard alerts. By default, standard alerts are generated for conditions internally monitored by the server. However, gauges can only generate alarm-alerts.

### Gauges

A gauge defines a set of threshold values with a specified severity that, when crossed, cause the server to enter or exit an alarm state.

Numeric gauges monitor continuous values like CPU load or free disk space. Indicator gauges monitor enumerated set of values such as 'server unavailable' or 'server unavailable'. Gauges generate alarms when the gauge's severity changes due to changes in the monitored value.

Directory Server installs a set of gauges that are specific to the product and that can be cloned or configured through the `dsconfig` tool. You can tailor existing gauges to fit each environment by adjusting the update interval and threshold values. Configuration of system gauges determines the criteria by which alarms are triggered.

Use the Stats Logger to view historical information about the value and severity of all system gauges. For more information, see [Profiling server performance using the Stats Logger](#) on page 963.

## Viewing information in the Alarms Backend

About this task

Use `ldapsearch` to view alarms.

### Steps

- To display the listing for the CPU usage alarm, run the following command.

```
$ bin/ldapsearch --port 1389 --bindDN "cn=Directory Manager" \
  --bindPassword secret --baseDN cn=alarms "(objectclass=ds-admin-alarm) "
```

Result:

```
dn: ds-alarm-id=CPU Usage (Percent)-Host System,cn=alarms
dn: ds-alarm-id=CPU Usage (Percent)-Host System,cn=alarms
objectClass: top
objectClass: ds-admin-alarm
ds-alarm-id: CPU Usage (Percent)-Host System
ds-alarm-condition: CPU Usage (Percent)
ds-alarm-specific-resource: Host System
ds-alarm-severity: CRITICAL
ds-alarm-previous-severity: CRITICAL
ds-alarm-details: Gauge CPU Usage (Percent) for Host System
                   has value 99, having had a value of 83.13 in the
                   previous interval. The severity is critical, having
                   assumed this severity Thu Sep 25 10:24:20 CDT 2014
                   when the value crossed threshold 80
ds-alarm-additional-text: If CPU use is high, check the server's current
                          workload
                          and other processes on this system and make any needed
                          adjustments. Reducing
                          the load on the system will lead to better response times
ds-alarm-start-time: 20140925152420.004Z
ds-alarm-critical-last-time: 20140925152420.004Z
ds-alarm-critical-total-duration-millis: 0
```

## Testing alerts and alarms

After alarms and alert handlers are configured, you can manually increase the severity of a gauge to verify that the server takes the appropriate action when an alarm state change.

You can then use the `status` tool to verify alarms and alerts.

## Testing alarms and alerts

### Steps

1. Use `dsconfig` to configure a gauge and set the `override-severity` property to critical.

The following example configures the CPU Usage (Percent) gauge.

Example:

```
$ dsconfig set-gauge-prop \
  --gauge-name "CPU Usage (Percent)" \
  --set override-severity:critical
```

2. Run the `status` tool to verify that an alarm was generated with corresponding alerts.

The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts and alarms.

Example:

The sample output has been shortened to show just the alarms and alerts information.

```
$ bin/status

```

### Indeterminate alarms

Directory Server raises indeterminate alarms for a server condition for which a severity cannot be determined.

In most cases these alarms are benign and do not issue alerts, nor do they appear in the output of the `status` tool or Administrative Console by default.

These alarms are usually caused by an enabled gauge that is intended to measure an aspect of the server that is not currently enabled. For example, gauges intended to monitor metrics related to replication might produce indeterminate alarms if a directory server is not currently replicating data. The gauge can be disabled if needed.

For more information about indeterminate alarms, view the gauge's associated monitor entry. There might be messages that can help determine the issue.

The following is sample output from the `status` tool run with the `-alarmSeverity=indeterminate` option.

```

--- Alarms ---
Severity      : Severity Start : Condition      : Resource      : Details
: Time       :                :                :                :
-----
Normal       : 26/Aug/2014   : Startup Begun : cn=config     : The Directory
Server
: 14:16:29 -0500 :                :                :                : is starting.
:                :                :                :                :
Indeterminate: 26/Aug/2014   : Replication   : not           : The value of

## Managing SCIM Servlet Extensions

The PingDirectory Server provides two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure, fast, and simple way. The SCIM 1.1 implementation is provided by the servlet extension named SCIM. The SCIM 2 implementation is provided by the servlet extension named SIMC2.

### SCIM 1.1 and 2.0 servlet extensions management

The PingDirectory Server provides two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure, fast, and simple way. SCIM is an alternative to LDAP, allowing identity data provisioning between cloud-based applications over HTTPS. One servlet implements SCIM 1.1 and the other servlet implements SCIM 2.

This section describes fundamental SCIM concepts and provides information on configuring SCIM on your server.

#### Overview of SCIM 1.1 fundamentals

Understanding the basic concepts of SCIM can help you use the SCIM extension to meet your deployment needs. SCIM allows you to:

- **Provision identities.** Through the API, you have access to the basic create, read, update, and delete functions, as well as other special functions.
- **Provision groups.** SCIM also allows you to manage groups.
- **Interoperate using a common schema.** SCIM provides a well-defined, platform-neutral user and group schema, as well as a simple mechanism to extend it.

The SCIM extension implements the 1.1 version of the SCIM specification. Familiarize yourself with this specification to help you understand and make efficient use of the SCIM extension and the SCIM SDK. The SCIM specifications are located on the Simplecloud website.

#### Note:

SCIM 1.1 will be deprecated in a future release.

#### Summary of SCIM 1.1 protocol support

PingDirectory Server supports all required features of the SCIM 1.1 protocol and most optional features. The following table describes SCIM features and whether they are supported.

#### SCIM Protocol Support

SCIM Feature	Supported
Etags	Yes

SCIM Feature	Supported
JSON	Yes
XML*	Yes
Authentication/Authorization	Yes, via HTTP basic authentication or OAuth 2.0 bearer tokens
Service Provider Configuration	Yes
Schema	Yes
User resources	Yes
Group resources	Yes
User-defined resources	Yes
Resource retrieval via GET	Yes
List/query resources	Yes
Query filtering*	Yes
Query result sorting*	Yes
Query result pagination*	Yes (Directory Server, not Directory Proxy Server)
Resource updates via PUT	Yes
Partial resource updates via PATCH*	Yes
Resource deletes via DELETE	Yes
Resource versioning*	Yes (requires configuration for updated servers)
Bulk*	Yes
HTTP method overloading	Yes
Raw LDAP Endpoints**	Yes

\* denotes an optional feature of the SCIM protocol.

\*\* denotes a PingDirectory Server extension to the basic SCIM functionality.

### About the Identity Access API

The PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server support an extension to the SCIM 1.1 standard called the Identity Access API. The Identity Access API provides an alternative to LDAP by supporting CRUD (create, read, update, and delete) operations to access directory server data over an HTTP connection.

SCIM 1.1 and the Identity Access API are provided as a unified service through the SCIM HTTP Servlet Extension. The SCIM HTTP Servlet Extension can be configured to only enable core SCIM resources (e.g., 'Users' and 'Groups'), only LDAP object classes (e.g., `top`, `domain`, `inetOrgPerson`, or `groupOfUniqueNames`), or both. Because SCIM and the Identity Access API have different schemas, if both are enabled, there may be two representations with different schemas for any resources defined in the `scim-resources.xml` file: the SCIM representation and the raw LDAP representation. Likewise, because resources are exposed by an LDAP object class, and because these are hierarchical (e.g., `top` --> `person` --> `organizationalPerson` --> `inetOrgPerson`, etc.), a client application can access an entry in multiple ways due to the different paths/URIs to a given resource.

This chapter provides information on configuring the SCIM and the Identity Access API services on the PingDirectory Server.

## Configuring SCIM 1.1

This section discusses details about the PingDirectory Server implementation of the SCIM protocol. Before reading this chapter, familiarize yourself with the SCIM Protocol specification, available on the Simplecloud website.

### *Creating your own SCIM 1.1 application*

To create your own System for Cross-domain Identity Management (SCIM) 1.1 application, you must download the SCIM 1.1 SDK.

SCIM is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 1.1 SDK is available for download at <https://github.com/pingidentity/scim>.

#### Note:

The value of a read-only SCIM attribute can be set by a POST operation if the SCIM attribute is a custom attribute in the `scim-resource.xml` config file, but not if the SCIM attribute is a core SCIM attribute.

### *Configuring the SCIM 1.1 servlet extension*

The Directory Server provides a default SCIM HTTP Servlet Extension that can be enabled and configured using a `dsconfig` batch script located in the `config` directory. The script runs a series of commands that enables an HTTPS Connection Handler, increases the level of detail logged by the HTTP Detailed Access log publisher, and adds access controls to allow access to LDAP controls used by the SCIM Servlet Extension. There are additional optional configurations (e.g., changing the log format, enable `entryDN` virtual attribute and using VLV indexes) that you can make by altering the `dsconfig` batch script.

The SCIM resource mappings are defined by the `scim-resources.xml` file located in the `config` directory. This file defines the SCIM schema and maps it to the LDAP schema. This file can be customized to define and expose deployment specific resources. See [Managing the SCIM Schema](#) for more information.

The following procedures show how to configure SCIM on the server. The first example procedure shows the steps to manually configure SCIM without using the script. The second example procedure uses the `dsconfig` batch script to configure SCIM.

## Configuring SCIM manually

### About this task

The following example procedure assumes that you have configured the Directory Server using the default settings, which means that SSL and the HTTPS Connection Handler have not been configured. The example also shows the `dsconfig` non-interactive commands. You can easily use the `dsconfig` interactive commands, which uses a menu-driven interface. If you use the `dsconfig` interactive, you must change to the Standard or Advanced object menu to access many of these configuration settings.

### Steps

1. Set up your certificates. Follow the examples shown in the section [Managing Certificates](#). You should have a keystore and truststore set up in the `config` directory. Make sure that the `keystore.pin` and `truststore.pin` are set.
2. Enable the key manager provider. The key manager provider accesses the certificate during the SSL handshaking process. If running `dsconfig` interactive, open the main menu, select "Key Manager

Provider" -> "View and edit an existing Key Manager Provider" -> "JKS" (or the type of certificate you are working with) -> "enabled" and then set the value to "true". Click "finish" to save the setting.

Example:

```
$ bin/dsconfig create-key-manager-provider \
  --provider-name JKS \
  --type file-based --set enabled:true
  --set key-store-file:config/keystore \
  --set key-store-type:JKS
  --set key-store-pin-file:config/keystore.pin
```

3. Enable the trust manager provider. The trust manager provider determines if a presented certificate can be trusted. If running **dsconfig** interactive, open the main menu, select "Trust Manager Provider" -> "View and edit an existing Trust Manager Provider" -> "JKS" (or the type of certificate you are working with) -> "enabled" and then set the value to "true". Click "finish" to save the setting.

Example:

```
$ bin/dsconfig create-trust-manager-provider
  --provider-name JKS \
  --type file-based --set enabled:true \
  --set trust-store-file:config/truststore \
  --set trust-store-type:JKS \
  --set trust-store-pin-file:config/truststore.pin
```

4. Configure the HTTPS Connection Handler. If not already created, this command creates and enables the connection handler, specifies the SCIM HTTP servlet extension and sets the listen port to a port of your choice, in this example, use 8443. The command also specifies the type of key manager and trust manager providers and sets the log publisher to "HTTP Detailed Access." If running **dsconfig** interactive, open the main menu, select "Connection Handler" -> "View and edit an existing Connection Handler" -> "HTTPS Connection Handler". Change the parameters to match your setup, and then, click "finish" to save the setting.

Example:

```
$ bin/dsconfig create-connection-handler \
  --handler-name "HTTPS Connection Handler" \
  --type http --set enabled:true \
  --set listen-port:8443 \
  --set use-ssl:true \
  --set http-servlet-extension:SCIM \
  --set "http-operation-log-publisher:HTTP Detailed Access" \
  --set key-manager-provider:JKS --set trust-manager-provider:JKS
```

If the HTTPS Connection Handler already exists, use the following:

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:SCIM
```

5. Turn on the connection handler.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:SCIM
```

6. Add access controls to allow access to LDAP controls used by the SCIM Servlet Extension. These controls are the Post-Read Request Control (1.3.6.1.1.13.2), Server-Side Sort Request Control (1.2.840.113556.1.4.473), Simple Paged Results Control (1.2.840.113556.1.4.319), and Virtual List

View Request Control (2.16.840.1.113730.3.4.9). We recommend using the following command to add access control instructions, rather than its **dsconfig** interactive equivalent.

Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetcontrol="1.3.6.1.1.13.2 ||
  1.2.840.113556.1.4.473 || 1.2.840.113556.1.4.319 ||
  2.16.840.1.113730.3.4.9")
  (version 3.0;acl "Authenticated access to controls used by the SCIM
  servlet
  extension"; allow (all) userdn="ldap:///all");'
```

7. Add access controls to allow read access to operational attributes used by the SCIM Servlet Extension. We recommend using the following non-interactive command to add access control instructions, rather than its **dsconfig** interactive equivalent.

Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id
  ||
  createTimestamp || modifyTimestamp")
  (version 3.0;acl "Authenticated read access to operational attributes \
  used by the SCIM servlet extension"; allow (read,search,compare)
  userdn="ldap:///all");'
```

8. Optional. The SCIM HTTP Connection Handler automatically uses a detailed HTTP log publisher, which is implemented in a proprietary format. If you need a standard W3C common log format publisher, enter the following command. If running **dsconfig** interactive, open the main menu, select "Log Publisher" -> "Create a new Log Publisher" -> "new Log Publisher created from scratch" -> "File Based Access Log Publisher", enter the parameters to match your setup, and then, click "finish" to save the setting. Go back to the main menu, select "Connection Handler" -> "HTTPS Connection Handler", and then add "HTTP Common Access" to the `http-operation-log-publisher` property. Click "finish" to save the setting.

Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access" \
  --type common-log-file-http-operation --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add "http-operation-log-publisher:HTTP Common Access"
```

9. Optional. To support searching or filtering by DN using the Identity Access API, you can enable the `entryDN` virtual attribute. If running **dsconfig** interactive, open the main menu, select "Virtual Attribute" -> "View and edit an existing Virtual Attribute" -> "Entry DN", and then change the enabled property to "true". Click "finish" to save the setting.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name entryDN --set enabled:true
```

10. Optional. To support pagination, create some Virtual List View indexes. If running **dsconfig** interactive, open the main menu, select "Local DB VLV Index" -> "Create a new Local DB VLV Index" and then enter the properties needed for your setup. Click "finish" to save the setting. Repeat again

for the "ascending-sn" index. Then, run the **rebuild-index** command to let the VLV Indexes take effect.

Example:

```
$ bin/dsconfig create-local-db-ylv-index --backend-name userRoot \
  --index-name ascending-uid --set base-dn:dc=example,dc=com \
  --set scope:whole-subtree \
  --set "filter:(objectclass=inetorgperson)" \
  --set "sort-order:+uid"

$ bin/dsconfig create-local-db-ylv-index --backend-name userRoot \
  --index-name ascending-sn \
  --set base-dn:dc=example,dc=com \
  --set scope:whole-subtree \
  --set "filter:(objectclass=inetorgperson)" \
  --set "sort-order:+sn"

$ bin/rebuild-index --baseDN dc=example,dc=com \
  --index vlv.ascending-uid \
  --index vlv.ascending-sn
```

## Enabling resource versioning

### About this task

Resource versioning is enabled by default in new installations. Upgraded servers that had SCIM enabled need additional configuration to enable resource versioning.

### Steps

1. Enable the **ds-entry-checksum** virtual attribute.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop \
  --name ds-entry-checksum \
  --set enabled:true
```

2. Remove any existing access controls required by SCIM for read access to operational attributes:

Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --remove 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimeStamp || ds-create-time || modifyTimeStamp || ds-update-time")(version 3.0;acl "Authenticated read access to operational attributes used by the SCIM servlet extension"; allow (read,search,compare) userdn="ldap:///all"'
```

3. Add new access controls required by SCIM for read access to operational attributes with the addition of the **ds-entry-checksum**:

Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimeStamp || ds-create-time || modifyTimeStamp || ds-update-time || ds-entry-checksum")(version 3.0;acl "Authenticated read access to operational attributes used by the SCIM servlet extension"; allow (read,search,compare) userdn="ldap:///all"'
```

4. Enable SCIM resource versioning using the entry checksum virtual attribute:

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
```

```
--extension-name SCIM \  
--set entity-tag-ldap-attribute:ds-entry-checksum
```

Result: If enabled, the value of the **ds-entry-checksum** attribute is returned as the **ETag** header value when accessing the resource through SCIM, and is checked against the **If-Match** header when updating the resource. When accessing the resource through LDAP, use the **ds-entry-checksum** attribute instead.

## Configuring the SCIM servlet extension using the batch script

### About this task

The following example procedure assumes that you have set up your certificates, keystore, and truststore

### Steps

1. Open the `<server-root>/config/scim-config-ds.dsconfig` script in a text editor.
2. For the optional elements (W3C common log, filtering by DN, and VLV Indexes, remove the comment (#) symbol on the **dsconfig** commands. Save the file when finished editing.
3. To enable the SCIM servlet extension, run the **dsconfig** batch file. Remember to include the bind parameters.

Example:

```
$ bin/dsconfig --batch-file config/scim-config-ds.dsconfig
```

Result:

### *SCIM 1.1 servlet extension authentication*

The SCIM 1.1 servlet supports authentication using either the HTTP Basic authentication scheme, or OAuth 2.0 bearer tokens. When authenticating using HTTP Basic authentication, the SCIM 1.1 servlet attempts to correlate the user name component of the Authorization header to a DN in the Directory Server. If the user name value cannot be parsed directly as a DN, it is correlated to a DN using an Identity Mapper. The DN is then used in a simple bind request to verify the password.

In deployments that use an OAuth authorization server, the SCIM 1.1 extension can be configured to authenticate requests using OAuth bearer tokens. The SCIM 1.1 extension supports authentication with OAuth 2.0 bearer tokens (per RFC 6750) using an OAuth Token Handler Server SDK Extension. Because the OAuth 2.0 specification does not specify how contents of a bearer token are formatted, PingDirectory Server provides the token handler API to decode incoming bearer tokens and extract or correlate associated authorization DNs.

Neither HTTP Basic authentication nor OAuth 2.0 bearer token authentication are secure unless SSL is used to encrypt the HTTP traffic.

## Configuring basic authentication using an identity mapper

### About this task

By default, the SCIM servlet is configured to use the Exact Match Identity Mapper, which matches against the **uid** attribute. In this example, an alternate Identity Mapper is created so that clients can authenticate using **cn** values.

### Steps

1. Create a new Identity Mapper that uses a match attribute of **cn**.

Example:

```
$ bin/dsconfig create-identity-mapper \  
--mapper-name "CN Identity Mapper" \  
--type exact-match \  
--match-attribute cn
```

```
--set enabled:true \
--set match-attribute:cn
```

2. Configure the SCIM servlet to use the new Identity Mapper.

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
--extension-name SCIM \
--set "identity-mapper:CN Identity Mapper"
```

## Enabling OAuth authentication

### About this task

To enable OAuth authentication, you need to create an implementation of the `OAuthTokenHandler` using the API provided in the Server SDK. For details on creating an `OAuthTokenHandler` extension, see the Server SDK documentation.

### Steps

1. Install your OAuth token handler on the server using `dsconfig`.

Example:

```
$ bin/dsconfig create-oauth-token-handler \
--handler-name ExampleOAuthTokenHandler \
--type third-party \
--set extension-
class:com.unboundid.directory.sdk.examples.ExampleOAuthTokenHandler
```

2. Configure the SCIM servlet extension to use it as follows:

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
--extension-name SCIM \
--set oauth-token-handler:ExampleOAuthTokenHandler
```

### Verifying the SCIM 1.1 servlet extension configuration

### About this task

You can verify the configuration of the SCIM 1.1 extension by navigating to a SCIM resource URL via the command line or through a browser window.

To verify the SCIM servlet extension configuration:

### Steps

- Run `curl` to verify that the SCIM extension is running. The `-k` (or `--insecure`) option is used to turn off curl's verification of the server certificate, since the example Directory Server is using a self-signed certificate.

Example:

```
$ curl -u "cn=Directory Manager:password" \
-k "https://localhost:8443/scim/ServiceProviderConfigs"

{"schemas":["urn:scim:schemas:core:1.0"],"id":"urn:scim:schemas:core:1.0",
"patch":{"supported":true},"bulk":{"supported":true,"maxOperations":10000,
"maxPayloadSize":10485760},"filter":{"supported":true,"maxResults":100},
"changePassword":{"supported":true},"sort":{"supported":true},
"etag":{"supported":false},"authenticationSchemes":[{"name":"HttpBasic",
"description":"The HTTP Basic Access Authentication scheme. This scheme is
```

```
not considered to be a secure method of user authentication (unless used
in
conjunction with some external secure system such as SSL), as the user
name and password are passed over the network as cleartext.", "specUrl":
"http://www.ietf.org/rfc/rfc2617", "documentationUrl":
"http://en.wikipedia.org/wiki/Basic_access_authentication"]}]}
```

- If the user ID is a valid DN (such as `cn=Directory Manager`), the SCIM extension authenticates by binding to the Directory Server as that user. If the user ID is not a valid DN, the SCIM extension searches for an entry with that `uid` value, and binds to the server as that user. To verify authentication to the server as the user with the `uid` of `user.0`, run the following command:

Example:

```
$ curl -u "user.0:password" \
-k "https://localhost:8443/scim/ServiceProviderConfigs"
```

## Configuring the Identity Access API

Once you have run the `<server-root>/config/scim-config-ds.dsconfig` script, the resources defined in the `scim-resources.xml` will be available as well as the Identity Access API. However, to allow SCIM access to the raw LDAP data, you must set a combination of configuration properties on the SCIM Servlet Extension using the `dsconfig` tool.

- **include-ldap-objectclass.** Specifies a multi-valued property that lists the object classes for entries that will be exposed. The object class used here will be the one that clients need to use when referencing Identity Access API resources. This property allows the special value "\*" to allow all object classes. If "\*" is used, then the SCIM servlet uses the same case used in the Directory Server LDAP Schema.
- **exclude-ldap-objectclass.** Specifies a multi-valued property that lists the object classes for entries that will not be exposed. When this property is specified, all object classes will be exposed except those in this list.
- **include-ldap-base-dn.** Specifies a multi-valued property that lists the base DN's that will be exposed. If specified, only entries under these base DN's will be accessible. No parent-child relationships in the DN's are allowed here.
- **exclude-ldap-base-dn.** Specifies a multi-valued property that lists the base DN's that will not be exposed. If specified, entries under these base DN's will not be accessible. No parent-child relationships in the DN's are allowed here.

Using a combination of these properties, SCIM endpoints will be available for all included object classes, just as if they were SCIM Resources defined in the `scim-resources.xml` file.

### Configuring the Identity Access API

#### Steps

1. Ensure that you have run the `scim-config-ds.dsconfig` script to configure the SCIM interface. Be sure to enable the `entryDN` virtual attribute. See the [Configure SCIM](#) section for more information.
2. Set a combination of properties to allow the SCIM clients access to the raw LDAP data: `include-ldap-objectclass`, `exclude-ldap-objectclass`, `include-ldap-base-dn`, or `exclude-ldap-base-dn`.

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
--extension-name SCIM --set 'include-ldap-objectclass:*' \
--set include-ldap-base-dn:ou=People,dc=example,dc=com
```

Result: The SCIM clients now have access to the raw LDAP data via LDAP object class-based resources as well as core SCIM resources as defined in the `scim.resource.xml` file.

## Disabling core SCIM resources

### Steps

1. Open the `config/scim-resources.xml` file, and comment out or remove the `<resource>` elements that you would like to disable.
2. Disable and re-enable the HTTP Connection Handler, or restart the server to make the changes take effect. In general, changing the `scim-resources.xml` file requires a HTTP Connection Handler restart or server restart.

**Note:**

When making other changes to the SCIM configuration by modifying the SCIM HTTP Servlet Extension using `dsconfig`, the changes take effect immediately without any restart required.

## Verifying the Identity Access API configuration

### Steps

- Perform a curl request to verify the Identity Access API configuration.

**Result:**

```
$ curl -k -u "cn=directory manager:password" \
-H "Accept: application/json" \
"https://example.com/top/56c9fd6b-f870-35ef-9959-691c783b7318?
  attributes=entryDN,uid,givenName,sn,entryUUID"
  {"schemas":
["urn:scim:schemas:core:1.0", "urn:unboundid:schemas:scim:ldap:1.0"],
  "id": "56c9fd6b-f870-35ef-9959-691c783b7318",
  "meta": {"lastModified": "2013-01-11T23:38:26.489Z",
  "location": "https://example.com:443/v1/top/56c9fd6b-
f870-35ef-9959-691c783b7318"},
  "urn:unboundid:schemas:scim:ldap:1.0": {"givenName": ["Rufus"], "uid":
["user.1"],
  "sn": ["Firefly"], "entryUUID": ["56c9fd6b-
f870-35ef-9959-691c783b7318"],
  "entrydn": "uid=user.1,ou=people,dc=example,dc=com"}}
```

## Monitoring the SCIM servlet extension

The SCIM SDK provides a command-line tool, `scim-query-rate`, that measures the SCIM query performance for your extension. The SCIM extension also exposes monitoring information for each SCIM resource, such as the number of successful operations per request, the number of failed operations per request, the number of operations with XML or JSON to and from the client. Finally, the Directory Server automatically logs SCIM-initiated LDAP operations to the default File-based Access Logger. These operations will have an `origin='scim'` attribute to distinguish them from operations initiated by LDAP clients. You can also create custom logger or request criteria objects that can track incoming HTTP requests, which the SCIM extension rewrites as internal LDAP operations.

### Testing SCIM query performance

You can use the `scim-query-rate` tool, provided in the SCIM SDK, to test query performance, by performing repeated resource queries against the SCIM server.

The `scim-query-rate` tool performs searches using a query filter or can request resources by ID. For example, you can test performance by using a filter to query randomly across a set of one million users with eight concurrent threads. The user resources returned to the client in this example is in XML format and includes the `userName` and `name` attributes.

```
scim-query-rate --hostname server.example.com --port 80 \
--authID admin --authPassword password --xml \
```

```
--filter 'userName eq "user.[1-1000000]"' --attribute userName \
--attribute name --numThreads 8
```

You can request resources by specifying a resource ID pattern using the `--resourceID` argument as follows:

```
scim-query-rate --hostname server.example.com --port 443 \
--authID admin --authPassword password --useSSL --trustAll \
--resourceName User \
--resourceID 'uid=user.[1-150000],ou=people,dc=example,dc=com'
```

The `scim-query-rate` tool reports the error `"java.net.SocketException: Too many open files"` if the open file limit is too low. You can increase the open file limit to increase the number of file descriptors.

### *Monitoring resources using the SCIM extension*

The monitor provider exposes the following information for each resource:

- Number of successful operations per request type (such as GET, PUT, and POST).
- Number of failed operations and their error codes per request type.
- Number of operations with XML or JSON from client.
- Number of operations that sent XML or JSON to client.

In addition to the information about the user-defined resources, monitoring information is also generated for the schema, service provider configuration, and monitor resources. The attributes of the monitor entry are formatted as follows:

```
{resource name}-resource-{request type}-{successful or error status code}
```

You can search for one of these monitor providers using an `ldapsearch` such as the following:

```
$ bin/ldapsearch --port 1389 bindDN uid=admin,dc=example,dc=com \
--bindPassword password --baseDN cn=monitor \
--searchScope sub "(objectclass=scim-servlet-monitor-entry)"
```

For example, the following monitor output was produced by a test environment with three distinct SCIM servlet instances, Aleph, Beth, and Gimel. Note that the first instance has a custom resource type called `host`.

```
$ bin/ldapsearch --baseDN cn=monitor \
'(objectClass=scim-servlet-monitor-entry)'
dn: cn=SCIM Servlet (SCIM HTTP Connection Handler),cn=monitor

### *About the HTTP log publishers*

HTTP operations may be logged using either a Common Log File HTTP Operation Log Publisher or a Detailed HTTP Operation Log Publisher. The Common Log File HTTP Operation Log Publisher is a built-in log publisher that records HTTP operation information to a file using the W3C common log format. Because the W3C common log format is used, logs produced by this log publisher can be parsed by many existing web analysis tools.

Log messages are formatted as follows:

- IP address of the client.
- RFC 1413 identification protocol. The Ident Protocol is used to format information about the client.
- The user ID provided by the client in an Authorization header, which is typically available server-side in the REMOTE\_USER environment variable. A dash appears in this field if this information is not available.
- A timestamp, formatted as "[dd/MM/yyyy:HH:mm:ss Z]"
- Request information, with the HTTP method followed by the request path and HTTP protocol version.
- The HTTP status code value.
- The content size of the response body in bytes. This number does not include the size of the response headers.

The HTTP Detailed Access Log Publisher provides more information than the common log format in a format that is familiar to administrators who use the File-Based Access Log Publisher.

The HTTP Detailed Access Log Publisher generates log messages such as the following. The lines have been wrapped for readability.

```

[15/Feb/2012:21:17:04 -0600] RESULT requestID=10834128
from="10.2.1.114:57555" method="PUT"
url="https://10.2.1.129:443/Aleph/Users/6272c691-
38c6-012f-d227-0dfae261c79e" authorizationType="Basic"
requestContentType="application/json" statusCode=200
etime=3.544 responseContentLength=1063
redirectURI="https://server1.example.com:443/Aleph/Users/6272c691-38c6-012f-
d227-0dfae261c79e"
responseContentType="application/json"

```

In this example, only default log publisher properties are used. Though this message is for a RESULT, it contains information about the request, such as the client address, the request method, the request URL, the authentication method used, and the Content-Type requested. For the response, it includes the response length, the redirect URI, the Content-Type, and the HTTP status code.

You can modify the information logged, including adding request parameters, cookies, and specific request and response headers. For more information, refer to the `dsconfig` command-line tool help.

### **Configuring advanced SCIM 1.1 extension features**

The following sections show how to configure advanced SCIM 1.1 servlet extension features, such as bulk operation implementation, mapping SCIM resource IDs, and transformations.

## Managing the SCIM 1.1 schema

This section describes the SCIM schema and provides information on how to map LDAP schema to the SCIM resource schema.

### *About the SCIM schema*

SCIM provides a common user schema and extension model, making it easier to interoperate with multiple Service Providers. The core SCIM schema defines a concrete schema for user and group resources that encompasses common attributes found in many existing schemas.

Each attribute is defined as either a single attribute, allowing only one instance per resource, or a multi-valued attribute, in which case several instances may be present for each resource. Attributes may be defined as simple, name-value pairs or as complex structures that define sub-attributes.

While the SCIM schema follows an object extension model similar to object classes in LDAP, it does not have an inheritance model. Instead, all extensions are additive, similar to LDAP Auxiliary Object Classes.

### *Mapping the LDAP schema to the SCIM resource schema*

The resources configuration file is an XML file that is used to define the SCIM resource schema and its mapping to LDAP schema. The default configuration of the `scim-resources.xml` file provides definitions for the standard SCIM Users and Groups resources, and mappings to the standard LDAP `inetOrgPerson` and `groupOfUniqueNames` object classes.

The default configuration may be customized by adding extension attributes to the Users and Groups resources, or by adding new extension resources. The resources file is composed of a single `<resources>` element, containing one or more `<resource>` elements.

For any given SCIM resource endpoint, only one `<LDAPAdd>` template can be defined, and only one `<LDAPSearch>` element can be referenced. If entries of the same object class can be located under different subtrees or base DN's of the Directory Server, then a distinct SCIM resource must be defined for each unique entry location in the Directory Information Tree. This can be implemented in many ways. For example:

- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, and each running under a unique HTTP connection handler.
- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, each running under a single, shared HTTP connection handler, but each with a unique context path.

Note that LDAP attributes are allowed to contain characters that are invalid in XML (because not all valid UTF-8 characters are valid XML characters). The easiest and most-correct way to handle this is to make sure that any attributes that may contain binary data are declared using `"dataType=binary"` in the `scim-resources.xml` file. Likewise, when using the Identity Access API make sure that the underlying LDAP schema uses the Binary or Octet String attribute syntax for attributes which may contain binary data. This will cause the server to automatically base64-encode the data before returning it to clients and will also make it predictable for clients because they can assume the data will always be base64-encoded.

However, it is still possible that attributes that are not declared as binary in the schema may contain binary data (or just data that is invalid in XML), and the server will always check for this before returning them to the client. If the client has set the content-type to XML, then the server may choose to base64-encode any values which are found to include invalid XML characters. When this is done, a special attribute is added to the XML element to alert the client that the value is base64-encoded. For example:

```
<scim:value base64Encoded="true">AAABPB0EBZc=</scim:value>
```

The remainder of this section describes the mapping elements available in the `scim-resources.xml` file.

### About the `resource` element

A `resource` element has the following XML attributes:

- **schema**: a required attribute specifying the SCIM schema URN for the resource. Standard SCIM resources already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom resources using any of the standard URN assignment methods.
- **name**: a required attribute specifying the name of the resource used to access it through the SCIM REST API.
- **mapping**: a custom Java class that provides the logic for the resource mapper. This class must extend the `com.unboundid.scim.ldap.ResourceMapper` class.

A resource element contains the following XML elements in sequence:

- **description**: a required element describing the resource.
- **endpoint**: a required element specifying the endpoint to access the resource using the SCIM REST API.
- **LDAPSearchRef**: a mandatory element that points to an `LDAPSearch` element. The `LDAPSearch` element allows a SCIM query for the resource to be handled by an LDAP service and also specifies how the SCIM resource ID is mapped to the LDAP server.
- **LDAPAdd**: an optional element specifying information to allow a new SCIM resource to be added through an LDAP service. If the element is not provided then new resources cannot be created through the SCIM service.
- **attribute**: one or more elements specifying the SCIM attributes for the resource.

#### About the `attribute` element

An `attribute` element has the following XML attributes:

- **schema**: a required attribute specifying the schema URN for the SCIM attribute. If omitted, the schema URN is assumed to be the same as that of the enclosing resource, so this only needs to be provided for SCIM extension attributes. Standard SCIM attributes already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom SCIM attributes using any of the standard URN assignment methods.
- **name**: a required attribute specifying the name of the SCIM attribute.
- **readOnly**: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- **required**: an optional attribute indicating whether the SCIM attribute is required to be present in the resource. The default value is `false`.

An attribute element contains the following XML elements in sequence:

- **description**: a required element describing the attribute. Then just one of the following elements:
  - **simple**: specifies a simple, singular SCIM attribute.
  - **complex**: specifies a complex, singular SCIM attribute.
  - **simpleMultiValued**: specifies a simple, multi-valued SCIM attribute.
  - **complexMultiValued**: specifies a complex, multi-valued SCIM attribute.

#### About the `simple` element

A `simple` element has the following XML attributes:

- **dataType**: a required attribute specifying the simple data type for the SCIM attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `decimal`, `integer`, `string`.
- **caseExact**: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A simple element contains the following XML element:

- **mapping**: an optional element specifying a mapping between the SCIM attribute and an LDAP attribute. If this element is omitted, then the SCIM attribute has no mapping and the SCIM service ignores any values provided for the SCIM attribute.

### About the `complex` element

The `complex` element does not have any XML attributes. It contains the following XML element:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute, and an optional mapping to LDAP. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

### About the `simpleMultiValued` element

A `simpleMultiValued` element has the following XML attributes:

- `childName`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard emails SCIM attribute is `email`.
- `dataType`: a required attribute specifying the simple data type for the plural SCIM attribute (i.e. the data type for the value sub-attribute). The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `simpleMultiValued` element contains the following XML elements in sequence:

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.
- `mapping`: an optional element specifying a default mapping between the SCIM attribute and an LDAP attribute.

### About the `complexMultiValued` element

A `complexMultiValued` element has the following XML attribute:

- `tag`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard addresses SCIM attribute is `address`.

A `complexMultiValued` element contains the following XML elements in sequence:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.
- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.

### About the `subAttribute` element

A `subAttribute` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- `required`: an optional attribute indicating whether the SCIM sub-attribute is required to be present in the SCIM attribute. The default value is `false`.
- `dataType`: a required attribute specifying the simple data type for the SCIM sub-attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `subAttribute` element contains the following XML elements in sequence:

- `description`: a required element describing the sub-attribute.

- `mapping`: an optional element specifying a mapping between the SCIM sub-attribute and an LDAP attribute. This element is not applicable within the `complexMultiValued` element.

#### About the `canonicalValue` element

A `canonicalValue` element has the following XML attribute:

- `name`: specifies the value of the type sub-attribute. For example, `work` is the value for emails, phone numbers and addresses intended for business purposes.

A `canonicalValue` element contains the following XML element:

- `subMapping`: an optional element specifying mappings for one or more of the sub-attributes. Any sub-attributes that have no mappings will be ignored by the mapping service.

#### About the `mapping` element

A `mapping` element has the following XML attributes:

- `ldapAttribute`: A required element specifying the name of the LDAP attribute to which the SCIM attribute or sub-attribute map.
- `transform`: An optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described in the [Mapping LDAP Entries to SCIM Using the SCIM-LDAP API](#) section.

#### About the `subMapping` element

A `subMapping` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute that is mapped.
- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM sub-attribute maps.
- `transform`: an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described later. The available transformations are described in [Mapping LDAP Entries to SCIM Using the SCIM-LDAP API](#).

#### About the `LDAPSearch` element

An `LDAPSearch` element contains the following XML elements in sequence:

- `baseDN`: a required element specifying one or more LDAP search base DN's to be used when querying for the SCIM resource.
- `filter`: a required element specifying an LDAP filter that matches entries representing the SCIM resource. This filter is typically an equality filter on the LDAP object class.
- `resourceIDMapping`: an optional element specifying a mapping from the SCIM resource ID to an LDAP attribute. When the element is omitted, the resource ID maps to the LDAP entry DN. Note The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them via an `ID` attribute.

#### Note:

The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them via an `ID` attribute.

#### About the `resourceIDMapping` element

The `resourceIDMapping` element has the following XML attributes:

- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM resource ID maps.
- `createdBy`: a required element specifying the source of the resource ID value when a new resource is created by the SCIM consumer using a POST operation. Allowable values for this element include `scim-consumer`, meaning that a value must be present in the initial resource content provided by the

SCIM consumer, or Directory Server, meaning that a value is automatically provided by the Directory Server (as would be the case if the mapped LDAP attribute is `entryUUID`).

The following example illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

```
<LDAPSearch id="userSearchParams">
  <baseDN>ou=people,dc=example,dc=com</baseDN>
  <filter>(objectClass=inetOrgPerson)</filter>
  <resourceIDMapping ldapAttribute="entryUUID" createdBy="directory"/>
</LDAPSearch>
```

#### About the `LDAPAdd` element

An `LDAPAdd` element contains the following XML elements in sequence:

- `DNTemplate`: a required element specifying a template that is used to construct the DN of an entry representing a SCIM resource when it is created. The template may reference values of the entry after it has been mapped using `{ldapAttr}`, where `ldapAttr` is the name of an LDAP attribute.
- `fixedAttribute`: zero or more elements specifying fixed LDAP values to be inserted into the entry after it has been mapped from the SCIM resource.

#### About the `fixedAttribute` element

A `fixedAttribute` element has the following XML attributes:

- `ldapAttribute`: a required attribute specifying the name of the LDAP attribute for the fixed values.
- `onConflict`: an optional attribute specifying the behavior when the LDAP entry already contains the specified LDAP attribute. The value `merge` indicates that the fixed values should be merged with the existing values. The value `overwrite` indicates that the existing values are to be overwritten by the fixed values. The value `preserve` indicates that no changes should be made. The default value is `merge`.

A `fixedAttribute` element contains one or more `fixedValue` XML element, which specify the fixed LDAP values.

#### *Validating the updated SCIM schema*

The PingDirectory Server SCIM extension is bundled with an XML Schema document, `resources.xsd`, which describes the structure of a `scim-resources.xml` resource configuration file. After updating the resource configuration file, you should confirm that its contents are well-formed and valid using a tool such as `xmllint`.

For example, you could validate your updated file as follows:

```
$ xmllint --noout --schema resources.xsd scim-resources.xml
scim-resources.xml validates
```

### Mapping SCIM resource IDs

The default `scim-resources.xml` configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. The `entryUUID` attribute, whose read-only value is assigned by the Directory Server, meets the requirements of the SCIM specification regarding resource ID immutability. However, configuring a mapping to the attribute may result in inefficient group processing, since LDAP groups use the entry DN as the basis of group membership. The resource configuration allows the SCIM resource ID to be mapped to the LDAP entry DN. However, the entry DN does not meet the requirements of the SCIM specification regarding resource ID immutability. LDAP permits entries to be renamed or moved, thus modifying the DN. Likewise, you can use the Identity Access API to change the value of an entry's RDN attribute, thereby triggering a `MODDN` operation.

A resource may also be configured such that its SCIM resource ID is provided by an arbitrary attribute in the request body during `POST` operations. This SCIM attribute must be mapped to an LDAP attribute so that the SCIM resource ID may be stored in the Directory Server. By default, it is the responsibility of the SCIM client to guarantee ID uniqueness. However, the `UID Unique Attribute Plugin` may be used by the Directory Server to enforce attribute value uniqueness. For information about the `UID Unique Attribute`

Plugin, see "Working with the UID Unique Attribute plugin" in the *PingDirectory Server Administration Guide*.

**Note:**

Resource IDs may not be mapped to virtual attributes. For more information about configuring SCIM Resource IDs, see "About the <resourceIDMapping> Element".

### Using pre-defined transformations

Transformations are required to change SCIM data types to LDAP syntax values. The following pre-defined transformations may be referenced by the transform XML attribute:

- `com.unboundid.scim.ldap.BooleanTransformation`. Transforms SCIM boolean data type values to LDAP Boolean syntax values and vice-versa.
- `com.unboundid.scim.ldap.GeneralizedTimeTransformation`. Transforms SCIM dateTime data type values to LDAP Generalized Time syntax values and vice-versa.
- `com.unboundid.scim.ldap.PostalAddressTransformation`. Transforms SCIM formatted address values to LDAP Postal Address syntax values and vice-versa. SCIM formatted physical mailing addresses are represented as strings with embedded new lines, whereas LDAP uses the \$ character to separate address lines. This transformation interprets new lines in SCIM values as address line separators.
- `com.unboundid.scim.ldap.TelephoneNumberTransformation`. Transforms LDAP Telephone Number syntax (E.123) to RFC3966 format and vice-versa.

You can also write your own transformations using the SCIM API described in the following section.

### Mapping LDAP entries to SCIM using the SCIM-LDAP API

In addition to the SCIM SDK, PingDirectory Server provides a library called SCIM-LDAP, which provides facilities for writing custom transformations and more advanced mapping.

You can add the SCIM-LDAP library to your project using the following dependency:

```
<dependency>
  <groupId>com.unboundid.product.scim</groupId>
  <artifactId>scim-ldap</artifactId>
  <version>1.5.0</version>
</dependency>
```

Create your custom transformation by extending the `com.unboundid.scim.ldap.Transformation` class. Place your custom transformation class in a jar file in the server's `lib` directory.

**Note:**

The Identity Access API automatically maps LDAP attribute syntaxes to the appropriate SCIM attribute types. For example, an LDAP DirectoryString is automatically mapped to a SCIM string.

### SCIM authentication

SCIM requests to the LDAP endpoints will support HTTP Basic Authentication and OAuth2 Authentication using a bearer token. There is existing support for this feature in the Directory Server and the Directory Proxy Server using the OAuthTokenHandler API (i.e., via a Server SDK extension, which requires some technical work to implement).

Note that our implementation only supports the HTTP Authorization header for this purpose; we do not support the form-encoded body parameter or URI query parameter mechanisms for specifying the credentials or bearer token.

### SCIM logging

The Directory Server already provides a detailed HTTP log publisher to capture the SCIM and HTTP request details. To be able to correlate this data to the internal LDAP operations that are invoked behind

the scenes, the Access Log Publisher will use "origin=scim" in access log messages that are generated by the SCIM servlet.

For example, you will see a message for operations invoked by replication:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="replication" dn="uid=user.3,ou=people,dc=example,dc=com"
```

Likewise for SCIM messages, you will see a message like this:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="scim" dn="uid=user.3,ou=people,dc=example,dc=com"
```

### SCIM monitoring

There are two facilities that can be used to monitor the SCIM activity in the server.

- **HTTPConnectionHandlerStatisticsMonitorProvider** -- Provides statistics straight about total and average active connections, requests per connection, connection duration, processing time, invocation count, etc.
- **SCIMServletMonitorProvider** -- Provides high level statistics about request methods (POST, PUT, GET, etc.), content types (JSON, XML), and response codes, for example, "user-patch-404:26".

The LDAP object class endpoints are treated as their own resource types, so that for requests using the Identity Access API, there will be statistics, such as `person-get-200` and `inetorgperson-post-401`.

### Managing the SCIM 2.0 servlet extension

The PingDirectory Server provides a servlet extension that implements version 2.0 of the System for Cross-domain Identity Management (SCIM) specification. The SCIM 2.0 extension does not replace the existing SCIM 1.1 extension, and there are significant differences in how they are configured..

### Supported SCIM 2.0 endpoints

PingDirectory Server supports the following SCIM 2.0 endpoints:

Endpoint	Description	Supported HTTP methods
/ServiceProviderConfig	Provides metadata that indicates the PingDirectory Server's authentication scheme (which is always OAuth 2.0) and its support for features that are optional in the SCIM standard.  This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
/Schemas	Lists the SCIM schemas that are configured for use on PingDirectory Server, and defines the various attributes available to resource types.  This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET

Endpoint	Description	Supported HTTP methods
/Schemas/<schema>	Retrieves a specific SCIM schema, as specified by the schema ID.  This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
/ResourceTypes	Lists all of the SCIM resource types that are configured for use on PingDirectory Server. Clients can use this information to determine the endpoint, core schema, and extension schemas of any resource types that the server supports.  This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
/ResourceTypes/<resourceType>	Retrieves a specific SCIM resource type, as specified by its ID.  This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
/<resourceType>	Creates a new resource (POST), or lists and filters resources (GET).	GET, POST
/<resourceType>/search	Lists and filters resources. This is used if passing query parameters in the URL is undesirable.	POST
/<resourceType>/<resourceId>	Retrieves a single resource (GET), modifies a single resource (PUT, PATCH), or deletes a single resource (DELETE).	GET, PUT, PATCH, DELETE

### *Creating Your Own SCIM 2 application*

The System for Cross-domain Identity Management (SCIM) is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 2 SDK is available for download at <https://github.com/pingidentity/scim2>.

### *Authentication requirements for SCIM 2.0 requests*

All SCIM requests on a PingDirectory Server must use OAuth 2.0 bearer token authentication. Bearer tokens are evaluated using the SCIM 2 servlet extension's configured Access Token Validators. Basic authentication is not supported.

In addition to requiring bearer tokens, the server will not process any SCIM requests unless it has at least one encryption-settings definition in its encryption-settings database. You can create the necessary definition(s) with the encryption-settings command-line tool. See [Encrypting Sensitive Data](#) on page 685 for more information.

#### **Note:**

Encryption settings need to be defined on the Proxy and all backend PD servers, and the encryption settings should match.

### *Defining permissions for SCIM 2.0 requests*

Whether or not a SCIM request is executed on a server depends primarily on both the configured Access Control Instructions (ACIs) in the server and the scopes which are present in the provided OAuth bearer token used to authenticate the request.

Internally, all SCIM 2.0 requests are processed using the `cn=SCIM2 Servlet, cn=Root DNs, cn=config` service account. Whether a requested operation is allowed depends on the ACIs that apply to the operation. The `oauthscope` bind rule is particularly useful for this, since it allows the administrator to use the supplied OAuth scopes in ACI logic.

Due to implementation details, access to the `objectclass` operational LDAP attribute is necessary for SCIM requests to properly execute. However, it is not advisable to give the service account access to `objectclass` on a global level. Instead, add the ACI granting `objectclass` access to the LDAP subtree you wish to expose to clients. See [Configuring permissions for SCIM 2.0 operations](#) on page 1030 for an example of this.

#### **Note:**

ACIs that do not use the `oauthscope` bind rule can still apply to requested operations. For example, an ACI that grants unconditional read access to any authenticated LDAP user will also grant unconditional read access to SCIM requests regardless of the provided OAuth scopes, since the requests are processed through the service account.

### *SCIM 2.0 components*

Unlike the SCIM 1.1 servlet extension, the SCIM 2.0 system is configured through the Administrative Console or with the `dsconfig` command-line tool. The SCIM 2.0 system consists of the following components:

- SCIM resource types

- SCIM schemas
  - SCIM attributes
  - SCIM sub-attributes
- SCIM attribute mappings (mapping resource types only)
- Correlated LDAP Data Views

A SCIM resource type defines a class of resources, such as users or devices. Every SCIM resource type features at least one SCIM schema, which defines the attributes that are available to each resource. If enabled for use, a SCIM resource type must also have a designated LDAP structural objectclass as well as an associated base DN.

The two types of SCIM resource types, mapping and pass-through, differ based on the definitions of the SCIM schema the resource types use.

- An LDAP mapping SCIM resource type requires an explicitly defined SCIM schema with explicitly defined mappings of SCIM attributes to LDAP attributes. Use a mapping SCIM resource type to exercise detailed control over the SCIM schema and its attributes and mappings.
- An LDAP pass-through SCIM resource type, by contrast, does not use an explicitly defined SCIM schema. Instead, an implicit schema is generated dynamically, based on the underlying LDAP schema. Use a pass-through SCIM resource type when you need to get started quickly.

A SCIM schema defines a collection of SCIM attributes, grouped under an identifier called a schema URN. Each SCIM resource type possesses a single core schema and can feature schema extensions, which act as secondary attribute groupings that the schema URN namespaces. SCIM Schemas are defined independently of SCIM resource types, and multiple SCIM resource types can use a single SCIM schema as a core schema or schema extension.

A SCIM attribute defines an attribute that is available under a SCIM schema. The configuration for a SCIM attribute defines its data type, regardless of whether it is required, single-valued, or multi-valued. When a SCIM attribute consists of SCIM sub-attributes, it is defined as a complex attribute.

A SCIM attribute mapping defines the manner in which a SCIM resource type maps the attributes in its SCIM schemas to native LDAP attributes of the PingDirectory Server.

A Correlated LDAP Data View allows a single SCIM resource that consists of attributes that are retrieved from multiple LDAP entries (see [Correlated LDAP data views](#) on page 1024).

#### *Correlated LDAP data views*

Correlated LDAP data views can be attached to a SCIM resource type to allow that resource type to use attributes from other LDAP entries. A SCIM resource type can have multiple data views configured.

Correlated LDAP data views share many configuration settings with SCIM resource types. The following exceptions are below:

- **primary-correlation-attribute**: The LDAP attribute from the SCIM Resource Type whose value will be used to match entries in the data view. This property must be defined.
- **secondary-correlation-attribute**: The LDAP attribute from the data view whose value will be matched with the primary-correlation-attribute. This property must be defined.
- **ldap-correlation-attribute-pair**: Optional correlation attribute pairs. If these are configured, entries between the SCIM resource type and the correlated LDAP data view must also have matching values for the specified attributes for them to be returned together.

#### **Note:**

A correlated LDAP Data View cannot provide attributes from more than one LDAP entry at a time. If there are multiple LDAP entries with secondary-correlation-attribute values that match the primary-correlation-attribute from the SCIM resource type's entry, an error will be thrown.

If the correlated LDAP data view is attached to a pass-through SCIM resource type, its attributes will appear as schema extensions, similar to the following:

```
{
  ...
  "uid": [
    "user.8"
  ],
  "entryDN": "uid=user.8,ou=people,dc=example,dc=com",
  "urn:pingidentity:schemas:correlated:Document": {
    "documentIdentifier": [
      "user.8"
    ],
    "description": [
      "This is the description for the document user.8 under
ou=Documents,dc=example,dc=com."
    ],
    ...
  },
  ...
  "schemas": [
    "urn:pingidentity:schemas:correlated:Document",
    "urn:pingidentity:schemas:passthrough:PassthroughUsers"
  ]
}
```

If the correlated LDAP data view is attached to a Mapping SCIM resource type, its attributes must be mapped to a schema used by the SCIM resource type. This is done through the `correlated-ldap-data-view` property in a SCIM attribute mapping.

### *Configuring an LDAP Mapping SCIM 2.0 resource type*

#### About this task

This example shows how to add a simple mapping SCIM 2.0 resource type to a PingDirectory Server, backed by the `inetOrgPerson` LDAP objectclass. This example assumes that the PingDirectory Server has been configured using the default settings, meaning that sample data has been imported into the server and that data encryption has been set up.

#### Steps

1. Create the SCIM schema that the resource type will use:

```
dsconfig create-scim-schema \
--schema-name urn:pingidentity:schemas:User:1.0 \
--set display-name:User
```

2. Under this schema, add the following SCIM attributes.

```
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name displayName
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--set type:complex
dsconfig create-scim-subattribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--subattribute-name familyName
dsconfig create-scim-subattribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
```

```
--attribute-name name \
--subattribute-name formatted
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name userName
```

3. Create the LDAP mapping SCIM resource type on the PingDirectory Server.

```
dsconfig create-scim-resource-type \
--type-name Users \
--type ldap-mapping \
--set enabled:true \
--set endpoint:Users \
--set structural-ldap-objectclass:inetOrgPerson \
--set include-base-dn:ou=People,dc=example,dc=com \
--set lookthrough-limit:500 \
--set core-schema:urn:pingidentity:schemas:User:1.0
```

4. Run the following commands to create the SCIM attribute mappings.

```
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name displayName \
--set scim-resource-type-attribute:displayName \
--set ldap-attribute:displayName
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.formatted \
--set scim-resource-type-attribute:name.formatted \
--set ldap-attribute:cn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.familyName \
--set scim-resource-type-attribute:name.familyName \
--set ldap-attribute:sn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name userName \
--set scim-resource-type-attribute:userName \
--set ldap-attribute:uid \
--set searchable:true
```

5. Configure the SCIM2 HTTP Servlet Extension to use a Mock Access Token Validator. Note that Mock Access Token Validators should never be used in production environments or with sensitive data.

```
dsconfig create-access-token-validator \
--validator-name "SCIM2 Mock Validator" \
--type mock \
--set enabled:true
dsconfig set-http-servlet-extension-prop \
--extension-name SCIM2 \
--set "access-token-validator:SCIM2 Mock Validator"
```

6. Send the following request to the SCIM /ResourceTypes endpoint to confirm that the new resource type has been added.

```
curl -k -X GET \
https://localhost:8443/scim/v2/ResourceTypes \
-H 'Authorization: Bearer {"active":true}'
```

7. The following JSON object should appear in the response in the “Resources” array:

```
{
  ...
  "Resources": [{
    "schemas": ["urn:ietf:params:scim:schemas:core:2.0:ResourceType"],
    "id": "Users",
    "name": "Users",
    "endpoint": "Users",
    "schema": "urn:pingidentity:schemas:Users:1.0",
    "meta": {
      "resourceType": "ResourceType",
      "location": "https://localhost:8443/scim/v2/ResourceTypes/Users"
    }
  }]
  ...
}
```

### Configuring a correlated LDAP data view

#### About this task

The following example shows how to add a correlated LDAP data view to a LDAP mapping SCIM resource type on a PingDirectory server. The SCIM resource type will be a user, and the correlated LDAP data view will allow access to a document that matches their user ID.

In this example, a new PingDirectory server is set up using custom sample data. When configuring the correlation, administrators should use attributes that are inherently either immutable or non-volatile, such as `uid` or `entryUUID`. This prevents errors produced by a conflict between the values of primary and secondary correlation attributes.

#### Note:

Administrators can make the correlation SCIM attributes immutable by setting the `--set mutability:read-only` property when defining an attribute in the SCIM schema configuration. That way, SCIM requests cannot modify the values of those attributes.

#### Steps

1. Copy the following text into the server root directory and save it as `entries.ldif.template`:

```
define suffix=dc=example,dc=com
define maildomain=example.com
define numusers=101

branch: [suffix]
subordinateTemplate: admin:1
aci: (targetattr="*")(version 3.0; acl "Grant full access for the
  scim2allaccess OAuth 2 scope"; allow (all) oauthscope="scim2allaccess");

branch: ou=People,[suffix]
subordinateTemplate: person:[numusers]

branch: ou=Documents,[suffix]
subordinateTemplate: document:[numusers]

template: admin
rdnAttr: uid
objectClass: top
objectClass: person
```

```

objectClass: organizationalPerson
objectClass: inetOrgPerson
uid: admin
givenName: Admin
sn: User
cn: Admin User
userPassword: password

template: person
rdnAttr: uid
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
employeeNumber: <sequential:0>
uid: user.{employeeNumber}
sn: {uid}
cn: {uid}
userPassword: password

template: document
rdnAttr: documentIdentifier
objectClass: top
objectClass: document
documentIdentifier: user.<sequential:0>
description: This is the description for the document
{documentIdentifier} under ou=Documents,dc=example,dc=com.

```

2. Run the following command:

```
$ bin/make-ldif --templateFile entries.ldif.template --ldifFile
entries.ldif
```

3. Run setup for the PingDirectory server.

Make sure to import the created `entries.ldif` file and set up encryption settings. After this is done, set up the SCIM resource type and the Correlated LDAP Data View.

4. Run the following command to define the SCIM schema:

```
"dsconfig create-scim-schema --schema-name urn:example:Users \
  --set "description:Users schema" --set display-name:Users
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name email --set required:true --set multi-valued:true
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name uid --set required:true --set mutability:read-only
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name documentId
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name documentDescription"
```

5. Run the following command to create the SCIM resource type:

```
dsconfig create-scim-resource-type \
  --type-name Users \
  --type ldap-mapping \
  --set core-schema:urn:example:Users \
  --set enabled:true \
  --set endpoint:Users \
  --set structural-ldap-objectclass:inetOrgPerson \
  --set include-base-dn:ou=people,dc=example,dc=com \
  --set create-dn-pattern:entryUUID=generated,ou=people,dc=example,dc=com
```

6. Run the following command to create the Correlated LDAP Data View:

```
dsconfig create-correlated-ldap-data-view \
  --type-name Users \
  --view-name Document \
  --set structural-ldap-objectclass:document \
  --set include-base-dn:ou=documents,dc=example,dc=com \
  --set create-dn-
pattern:entryUUID=generated,ou=documents,dc=example,dc=com \
  --set primary-correlation-attribute:uid \
  --set secondary-correlation-attribute:documentIdentifier
```

7. Run the following command to create the attribute mappings for the SCIM resource type attributes.

Note that the **correlated-ldap-data-view** property is not set.

```
# The uid attribute, provided by the base SCIM Resource Type
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name uid \
  --set scim-resource-type-attribute:uid --set ldap-attribute:uid \
  --set writable:false --set searchable:true

# The email attribute, provided by the base SCIM Resource Type
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name email \
  --set scim-resource-type-attribute:email --set ldap-attribute:mail \
  --set searchable:true
```

8. Run the following command to create the **DocumentId** attribute mapping for the correlated LDAP data view attributes.

**Note:**

The only meaningful difference between mappings for SCIM resource type attributes and correlated LDAP data view attributes is the value of the **correlated-ldap-data-view** property.

```
# The documentId attribute
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name document.id \
  --set correlated-ldap-data-view:Document \
  --set scim-resource-type-attribute:documentId --set ldap-
attribute:documentIdentifier

# The documentDescription attribute
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name description \
  --set correlated-ldap-data-view:Document \
  --set scim-resource-type-attribute:documentDescription \
  --set ldap-attribute:description
```

9. Run the following command to send a SCIM request:

```
curl -k -X GET \
  https://localhost:8443/scim/v2/Users \
  -H 'Authorization: Bearer {"active":true, "scope":"scim2allaccess}"'
```

The response should look similar to the following. Notice that 'uid' and 'documentId' have the same value, as they are in a correlation attribute pair.

```
{
  "schemas": [
```

```

    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 101,
  "Resources": [
    {
      "uid": "user.8",
      "id": "3715c022-1f34-36d9-bebc-7e74912106ec",
      "documentDescription": "This is the description \
for the document user.8 under
ou=Documents,dc=example,dc=com.",
      "documentId": "user.8",
      "meta": {
        "resourceType": "Users",
        "location": "https://localhost:8443/scim/v2/
Users/3715c022-1f34-36d9-bebc-7e74912106ec"
      },
      "schemas": [
        "urn:example:Users"
      ]
    },
    ...
  ]
}

```

### Configuring permissions for SCIM 2.0 operations

#### About this task

This example shows how to correctly configure permissions so POST requests with the "userAdd" scope will succeed. This example assumes that you have set up an LDAP mapping SCIM 2.0 Resource Type for the `inetOrgPerson` objectclass (see [Configuring an LDAP Mapping SCIM 2.0 resource type](#) on page 1025).

#### Steps

1. If the SCIM Resource Type being targeted already has a value for the `create-dn-pattern` property, skip to step 2. Otherwise, the following `dsconfig` command can be used:

```

dsconfig set-scim-resource-type-prop \
  --type-name Users \
  --set create-dn-pattern:entryUUID=generated,ou=People,dc=example,dc=com

```

2. Send the following request to the SCIM /Users endpoint:

```

curl -k -X POST \
  https://localhost:8443/scim/v2/Users/ \
  -H 'Authorization: Bearer {"active":true}' \
  -H 'Content-type: application/json' \
  --data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'

```

The response from the server should have a status of 403 and contain a correlation ID, similar to the following:

```

{
  "schemas":["urn:ietf:params:scim:api:messages:2.0:Error"],
  "status":"403",
  "detail":"Request failed:
correlationID='faa707b3-5d48-42e6-9e78-2c8dbb1e2cac'"
}

```

```
}

```

This is the expected response since this SCIM request does not have the permission needed to write to an entry. See [Troubleshoot the SCIM 2.0 servlet extension](#) on page 1035 for instructions on viewing the full server error message.

3. An ACI should now be added to the `ou=People,dc=example,dc=com` subtree. This will grant permission to add entries to the said subtree as long as the SCIM request includes the `'userAdd'` scope. This can be done by running the following `ldapmodify` command. Note that this ACI does not grant write access to attributes, which means modify operations will fail. See [Overview of access control](#) for more information on configuring ACIs.

```
$ ldapmodify
dn:ou=People,dc=example,dc=com
changetype:modify
add:aci
aci:(version 3.0; acl "ACI for userAdd scope"; allow (add)
oauthscope="userAdd");)

```

4. Send the POST request to the SCIM / Users endpoint again, this time including the `userAdd` scope in the bearer token:

```
curl -k -X POST \
https://localhost:8443/scim/v2/Users \
-H 'Authorization: Bearer {"active":true, "scope":"userAdd"}' \
-H 'Content-type: application/json' \
--data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'

```

The response from the server should now contain the created SCIM resource, which should also contain values for the name and username attributes, similar to the following:

```
{
  "name":{
    "familyName":"User",
    "formatted":"Test"
  },
  "username":"user.test",
  "id":"6f9a89b8-e766-478c-9667-def049daf6bc",
  "meta":{
    "resourceType":"Users",
    "location":"https://localhost:8443/scim/v2/Users/6f9a89b8-e766-478c-9667-def049daf6bc"
  },
  "schemas":["urn:pingidentity:schemas:User:1.0"]
}

```

### SCIM 2.0 searches

To prevent exhausting server resources, we recommend capping the total number of resources that are matched by a search. The configuration for each SCIM 2.0 resource type contains a `lookthrough-limit` property that defines this limit (the default `lookthrough-limit` value is 500).

If a search request exceeds the lookthrough limit, the client receives a 400 response with an error message similar to the following:

```
{
  "detail": "The search request matched too many results",
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:Error"],
  "scimType": "tooMany",
  "status": "400"
}

```

}

To prevent this error, you have these options:

- The client must refine its search filter to return fewer matches.
- Configure paged searches as explained in [Using paged SCIM searches](#) on page 1032.

### Using paged SCIM searches

When searching large data sets, the results can be numerous and produce errors about a request matching too many results relative to the lookthrough limit. Paged searches avoid these errors and also reduce memory utilization.

### About this task

PingDirectory does SCIM searches using LDAP requests. After you complete the steps below, PingDirectory creates LDAP requests that include request controls to sort and page the search results before returning the results.

If your SCIM searches result in an error because the request matched too many results, as discussed in [SCIM 2.0 searches](#) on page 1031, you can avoid the error by using paged searches.

Complete the following steps for each search.

### Steps

1. Decide your SCIM search.

#### Note:

To get paged results, your search must include at least one of these parameters: `startIndex`, `count`, or `sortBy`.

For example, your search might look like the following search.

```
https://<directory-hostname>:<directory-port>/scim/v2/Users/?filter=st eq
"TX"&sortBy=sn&sortOrder=ascending
```

Here is the corresponding encoded version.

```
https://<directory-hostname>:<directory-port>/scim/v2/Users/?filter=st
%20eq%20%22TX%22&sortBy=sn&sortOrder=ascending
```

On your PingDirectory Server, collect some information to use later. Find the SCIM resource type, `structural-ldap-objectclass`, `include-base-dn`, and `include-filter` values by running this command.

```
$ dsconfig get-scim-resource-type-prop --type-name <SCIM-resource-type-
name> \
--property structural-ldap-objectclass \
--property include-base-dn \
--property include-filter
```

2. On the PingDirectory server, complete the following steps.
  - a. Create a Virtual List View (VLV) index for your search.

Each SCIM search that you want to produce paged results must have its own VLV index.

Create this index using `dsconfig create-local-db-vlv-index` with the following options.

Option	Description
<code>--index-name</code>	Names the index.
<code>--backend-name</code>	Specifies the name of the local database backend in which to place the index.  The default database backend for PingDirectory is <code>userRoot</code> .
<code>--set base-dn</code>	Specifies the desired base dn. This value must match the value of the <code>include-base-dn</code> property that you found in the previous step.
<code>--set scope</code>	Is always <code>whole-subtree</code> .
<code>--set filter</code>	<p>Specifies the filter.</p> <p>Specify</p> <pre>"(objectclass=&lt;name-of-SCIM-resource-type-objectclass&gt;)"</pre> <p>where <code>&lt;name-of-SCIM-resource-type-objectclass&gt;</code> is the name of the objectclass used by the SCIM resource type, which you found in the previous step.</p> <p>If the SCIM resource type has the <code>include-filter</code> property set, also specify that property value in the filter. For example, if the filter for the objectclass is <code>(objectclass=inetorgperson)</code> and the <code>include-filter</code> value is <code>(st=CA)</code>, specify the <code>--set filter</code> argument as <code>"(&amp;(objectclass=inetorgperson)(st=CA))"</code>.</p> <p>Specify the LDAP attributes for all the components of your SCIM search filter.</p> <p>For example, if a mapping SCIM resource type maps the LDAP attribute <code>st</code> to the SCIM attribute <code>address.region</code> and the SCIM search filter requires that <code>address.region eq TX</code>, then this filter must include <code>(st = TX)</code> instead of <code>(address.region = TX)</code>.</p>

Option	Description
<code>--set sort-order</code>	Specifies whether to sort ascending (+) or descending (-) and the LDAP attribute to sort by.  If the SCIM search does not specify the <code>sortBy</code> parameter, specify the sort order as <code>+entryUUID</code> .

Recall the original, decoded SCIM search, shown here.

```
https://<directory-hostname>:<directory-port>/scim/v2/Users/?filter=st
eq "TX"&sortBy=sn&sortOrder=ascending
```

For example, to create a VLV index for that search, run the following command.

```
$ dsconfig create-local-db-ylv-index --index-name sn \
--backend-name userRoot --set base-dn:ou=people,dc=example,dc=com \
--set scope:whole-subtree \
--set filter:"(&(objectclass=inetorgperson)(st=TX))" --set sort-order:
+sn
```

- b. Stop the server. Rebuild the index. Start the server. Run the `rebuild-index` command specifying the baseDN and the name of the index.

```
$ rebuild-index --baseDN <baseDN-value> --index <name-of-index>
```

For example, run these commands.

```
$ stop-server
$ rebuild-index --baseDN dc=example,dc=com --index vlv.sn
$ start-server
```

3. Run your SCIM search filter.

**Note:**

The search can include only the filter you specified with `--set filter` in the earlier step without the `"(objectclass=<name-of-SCIM-resource-type-objectclass>)"` portion.

In addition to the Virtual List View request control, PingDirectory adds a Server Side request control to the LDAP request. These request controls require certain parameters be set. To satisfy this requirement, PingDirectory uses the following parameters. If the client does not provide values for one of the parameters, the search uses the corresponding default value shown in the following table.

Parameter	Default
<code>startIndex</code>	1
<code>count</code>	The value of the <code>lookthrough-limit</code> property of the SCIM resource type being searched. That default is 500.
<code>sortBy</code>	<code>entryUUID</code>  With this default, the results appear unsorted.
<code>sortOrder</code>	<code>ascending</code>

### SCIM 2.0 PATCH operations

When using a `PATCH` request to modify a SCIM 2.0 resource that has one or more required SCIM 2.0 attributes, the requester must have permissions to read the values of these required attributes in addition to write permissions for the attributes being modified, even if the `PATCH` request does not alter said requirements.

For example, assume we want to modify an LDAP Mapping SCIM 2.0 resource type using the following schema definition, where `uid` and `cn` are mapped to their LDAP equivalents:

```
{
  "schemas": ["urn:ietf:params:scim:schemas:core:2.0:Schema"],
  "id": "urn:test:schema:person",
  "attributes": [
    {
      "name": "uid",
      "type": "string",
      "multiValued": false,
      "required": true,
      "caseExact": false,
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none"
    },
    {
      "name": "cn",
      "type": "string",
      "multiValued": false,
      "required": false,
      "caseExact": false,
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none"
    }
  ],
  ...
}
```

The following `PATCH` operation will fail if the SCIM 2 service account does not have access to both `uid` and `cn`:

```
{
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:PatchOp"],
  "Operations": [{
    "op": "add",
    "path": "cn",
    "value": "new cn value"
  }]
}
```

### Troubleshoot the SCIM 2.0 servlet extension

For security reasons, error messages specifically regarding LDAP systems are suppressed and do not appear in the HTTP responses from the server. Instead, you will see something similar to the following:

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": "400",
  "detail": "Request failed:
correlationID='073eb1a8-8c51-48b3-83a0-380e1d4b4ab9'"
}
```

```
}

```

To view these messages, the Debug Trace Logger needs to be enabled. You can do this through the Administrative Console or with the following `dsconfig` command:

```
dsconfig set-log-publisher-prop --publisher-name "Debug Trace Logger" \
  --set enabled:true --add scim-message-type:error
```

After the Debug Trace Logger is enabled, the server will begin logging information related to SCIM operations to the file `/logs/debug-trace`, which will look somewhat like the following:

```
[09/Jun/2020:05:23:10.992 -0500] HTTP REQUEST requestID=3
correlationID="073eb1a8-8c51-48b3-83a0-380e1d4b4ab9" product="Ping Identity
Directory Server" instanceName="example" startupID="Xt9fJg==" threadID=173
from=[0:0:0:0:0:0:0:1]:53978 method=POST
url="https://0:0:0:0:0:0:0:1:9443/scim/v2/Users"
```

Note the presence of `correlationID` in these messages. By matching the id in the HTTP responses to the messages in the `debug-trace` log, the appropriate LDAP error message can be determined.

#### *Disabling the SCIM 2.0 servlet extension*

If you do not need to expose data through the SCIM 2 servlet, you can disable the SCIM 2.0 servlet extension by removing the SCIM2 HTTP servlet extension from the HTTPS connection handler, or from any other HTTP connection handler, and restart the handler:

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --remove http-servlet-extension:SCIM2 \
  --set enabled:false

dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true
```

#### *Troubleshooting a multiple correlation entry error*

When using secondary store adapters in PingAuthorize or correlated [MISSING glossAcronymn or glossSurfaceform for gLDAP] data views with the [MISSING glossAcronymn or glossSurfaceform for gSCIM] 2 implementation in PingDirectory or PingDirectoryProxy, an error is displayed in the SCIM 2 response to the user request if multiple entries have a secondary correlation attribute value that matches the primary correlation attribute value. The error is applicable to each product.

There are three options for resolving this error:

- Configure one or more correlation attribute pairs on the secondary store adapter or correlated LDAP data view so that for each primary entry, there is only one other entry with matching secondary correlation attribute values. This is the recommended option.
- Modify the server data so that for each primary entry, there is only one other entry with a matching secondary correlation attribute value.

#### **Note:**

Because this option requires making changes to individual entries, it is not efficient for larger servers.

- Remove the secondary store adapter or correlated LDAP data view.

**Important:**

Because this option involves complete removal of the feature, only do it if the other options do not resolve the error.

## Managing Server SDK Extensions

---

The PingDirectory Server provides support for any custom extensions that you create using the Server SDK. This chapter summarizes the various features and extensions that can be developed using the Server SDK.

### About the Server SDK

You can create extensions that use the Server SDK to extend the functionality of your Directory Server. Extension bundles are installed from a .zip archive or a file system directory. You can use the **manage-extension** tool to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

**Note:**

The **manage-extension** tool may only be used with Java extensions packaged using the extension bundle format. Groovy extensions do not use the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation, which describes the extension bundle format and how to build an extension.

### Available types of extensions

The Server SDK provides support for creating a number of different types of extensions for Ping Identity Server Products, including the PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server. Some of those extensions include:

#### Cross-Product Extensions

- Access Loggers
- Alert Handlers
- Error Loggers
- Key Manager Providers
- Monitor Providers
- Trust Manager Providers
- OAuth Token Handlers
- Manage Extension Plugins

#### PingDirectory Server Extensions

- Certificate Mappers
- Change Subscription Handlers
- Extended Operation Handlers
- Identity Mappers
- Password Generators
- Password Storage Schemes
- Password Validators
- Plugins

- Tasks
- Virtual Attribute Providers

### **PingDirectoryProxy Server Extensions**

- LDAP Health Checks
- Placement Algorithms
- Proxy Transformations

### **PingDataSync Server Extensions**

- JDBC Sync Sources
- JDBC Sync Destinations
- LDAP Sync Source Plugins
- LDAP Sync Destination Plugins
- Sync SourcesSync Destinations
- Sync Pipe Plugins

For more information on the Server SDK, see the documentation available in the SDK build.

## **DevOps and infrastructure-as-code**

---

### **Limitations when automating PingDirectory Server deployments**

PingDirectory Server is a stateful application. User data is associated with it, and servers in a topology must be able to communicate bidirectionally with each other. The deployment of stateful applications is generally more challenging to automate than the deployment of stateless applications. However, by following certain industry-wide best practices, the deployment of stateful applications becomes easier to manage.

For stateful applications, we recommend maintaining a well-known network identifier for a server that does not change over its lifetime. Without this guarantee, the deployment automation workflows for the PingDirectory Server software does not work as expected. On infrastructure platforms like AWS, servers are generally assigned cattle-like internal host names. This strategy is acceptable if a well-defined external name is registered in a service discovery or lookup service, such as DNS.

Another important recommendation for stateful applications is the use of external, redundant persistent storage that is always available, and that functions independently of the server itself. Servers might come and go, but they are always guaranteed to be attached to the same persistent storage when they are resurrected. Although the PingDirectory Server software does not require this guarantee, we recommend it for simpler, less error-prone deployment automation and for easier disaster recovery. For more information, see [Deployment automation](#) on page 1045.

### **Server profiles**

Regardless of the service model that your company follows, *server profiles* help you achieve your goals. At a basic level, a server profile defines a format for the configuration of a server by combining the following files into a single concrete structure:

- `dsconfig`
- Initial DIT
- Setup arguments
- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDirectory Server and related products by using deployment automation frameworks. When products support this capability, the amount

of scripting that is required across automation frameworks – like Docker, Kubernetes, and Ansible – is reduced considerably.

The following image shows the role that a server profile plays in building a fully functional running server.

As a declarative form of a full server configuration, a server profile provides the following advantages:

- Provides a more complete and easily comparable way to define an individual server's configuration. Changes between different servers are easier to understand, and incremental changes to a server's configuration are easier to track.
- Ensures that each server instance is configured identically to its peers.
- Can be applied directly to new as well as previously installed instances.
- Shares a common configuration across a deployment pipeline of development, test, and production environments without unnecessary duplication. For information about substituting variables that differ by environment, see [Variable substitution](#) on page 1040.
- Facilitates deployment automation by representing configuration as code.
- Reduces the number of additional configuration steps that are required to place a server into production.
- Makes the execution of various configuration changes more consistent and repeatable. The strategy of using a server profile to represent the final state of a server is less error-prone than recording a step-by-step process to attain that state.
- Can be managed easily in a version-control system.
- Simplifies the management of servers outside deployment automation frameworks.

A continuous deployment workflow can work with server profiles to make certain that changes to a server profile are moved automatically into production. In a stateful environment, the `manage-profile replace-profile` subcommand can be used to update existing servers. In a stateless environment, in which servers are considered immutable, `manage-profile setup` can be used to deploy new servers whenever a profile changes. With multiple environments, this deployment can be performed in a test environment before moving to production.

When working with zipped server SDK extensions and other files that might not be stored in a version-control system, the server profile can be modified to include these files prior to its use. For example, if the code for an extension is stored in a separate repository, it can be built and dropped into the server profile

immediately before the `manage-profile` tool is run. This process is part of the deployment automation logic that uses the server profile, and it can be followed for any files that are needed by the server profile but whose versions are not controlled.

For more information about the `manage-profile` tool, see [About the manage-profile tool](#) on page 1042.

### Variable substitution

You can use the `manage-profile` tool to substitute different variables in server profiles.

The `manage-profile` tool uses the format `${VARIABLE}` to support the substitution of variables in profiles. This format can be escaped by using another `$`. For example, after substitution, `$$${VARIABLE}` becomes `${VARIABLE}`.

Variable values can be read from a profile variables file or from environment variable values. If both options are used, the values that are specified in the file overwrite any environment variables.

The following code provides an example of how you can set user-defined variables by using a variables file in the server profile.

```
HOSTNAME=testserver.example.com
PORT=389
```

The following table describes built-in variables that can also be referenced in the server profile. Use these variables in the format previously described.

Built-in variable	Description
PING_SERVER_ROOT	Evaluates to the absolute path of the server's root directory
PING_PROFILE_ROOT	Evaluates to the individual profile's root directory   <b>Note:</b> Use <code>PING_PROFILE_ROOT</code> only with files that are not needed after initial setup, such as password files in <code>setup-arguments.txt</code> . Do not use the <code>PING_PROFILE_ROOT</code> variable for files needed while the server is running. The <code>manage-profile</code> tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under <code>PING_PROFILE_ROOT</code> when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's <code>server-root/pre-setup</code> directory, and then refer to the files using with the <code>PING_SERVER_ROOT</code> variable.

For more information about the tool's usage, run the command `bin/manage-profile --help`.

### Profile structure

Use either of the following methods to create a server profile:

- Use the template named `server-profile-template.zip`, which is located in the `resource/` directory.
- Run the `manage-profile generate-profile` subcommand. The `manage-profile` tool references a file system directory structure rather than a ZIP file.

Files can be added to each directory as needed.

The following hierarchy represents the file structure of a basic server profile:

```
-server-profile/
  |-- dsconfig/
  |-- ldif/
  |   |-- userRoot/
  |-- misc-files/
  |-- server-root/
  |   |-- post-setup/
  |   |-- pre-setup/
  |-- server-sdk-extensions/
  |-- setup-arguments.txt
  |-- variables-ignore.txt
```

### setup-arguments.txt

When creating a [profile](#), the first step is to add arguments to the `setup-arguments.txt` file, located in the `resources/server-profile-template.zip` archive.

When you run the `manage-profile setup` command, these arguments are passed to the server's setup tool. To view the arguments available in this file, run the server's `setup --help` command.

To provide the equivalent, non-interactive command-line interface (CLI) arguments after any prompts have been completed, run `setup` interactively. The `setup-arguments.txt` file in the server profile template contains an example set of arguments that can be changed.

`setup-arguments.txt` is the only required file in the profile.

### dsconfig/

`dsconfig` batch files can be added to the `dsconfig` directory. These files, each of which must include a `.dsconfig` extension, contain `dsconfig` commands to apply to server.

Because the `dsconfig` batch files are ordered lexicographically, `00-base.dsconfig` runs before `01-second.dsconfig`, and so on.

To produce a `dsconfig` batch file that reproduces the current configuration, run `bin/config-diff`.

### server-root/

Any server root files can be added to the `server-root` directory, including schema files, email template files, custom password dictionaries, and other files that must be present on the final server root. Add these files to the `server-root/pre-setup` or `server-root/post-setup` directory, depending on when they need to be copied to the server root. Most server root files are added to the `server-root/pre-setup` directory.

### ldif/

Use LDIF files in the server profile to supply a base DIT, but not to import user data. Add LDIF files under the `ldif` directory. Place each LDIF file in a subdirectory that indicates the backend to which it is imported, such as `ldif/userRoot/` for the `userRoot` backend.

LDIF files require an `.ldif` extension and are ordered lexicographically.

### server-sdk-extensions/

Add server SDK extension `.zip` files to the `server-sdk-extensions` directory. Include any configuration that is necessary for the extensions in the profile's `dsconfig` batch files.

### variables-ignore.txt

The `variables-ignore.txt` file is an optional component of the server profile. It is useful when adding bash scripts to the server root because such files often contain expressions that the `manage-profile` tool normally interprets as variables.

Add `variables-ignore.txt` to a profile's root directory to indicate the relative paths of any files that are not to have their variables substituted.

The following example shows the contents of a typical `variables-ignore.txt` file:

```
server-root/pre-setup/script-to-ignore.sh
server-root/post-setup/another-file-to-ignore.txt
```

### server-root/permissions.properties

The `permissions.properties` file, located in the `server-root` directory, is an optional file that specifies the permissions to apply to files that are copied to the server root. These permissions are represented in octal notation. By default, server root files maintain their permissions when copied.

The following example shows the contents of a typical `permissions.properties` file:

```
default=700
file-with-special-permissions.txt=600
new-subdirectory/file-with-special-permissions.txt=644
bin/example-script.sh=760
```

### misc-files/

Additional documentation and other files can be added to the `misc-files` directory, which the `manage-profile` tool does not use. Use the variable `PING_PROFILE_ROOT` to refer to files in this directory from other locations, such as `setup-arguments.txt`.

#### Note:

Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using with the `PING_SERVER_ROOT` variable.

For example, a password file named `password.txt` in the `misc-files` directory could be referenced with `${PING_PROFILE_ROOT}/misc-files/password.txt` in `setup-arguments.txt`. Use a reference like this example to supply the file for the `--rootUserPasswordFile` argument in `setup-arguments.txt`.

### About the manage-profile tool

The `manage-profile` tool is provided with the server to work with server profiles. It includes subcommands for creating, applying, and replacing server profiles, all of which significantly reduce the effort required by an administrator to configure a server appropriately.

The following sections describe these subcommands in more detail. For more information about the `manage-profile` tool, run `manage-profile --help`. For more information about each individual subcommand and its options, run `manage-profile <subcommand> --help`.

### manage-profile generate-profile

To create a server profile from a configured server, use the **generate-profile** subcommand. The generated profile contains the following information, which provides a base for completing a profile:

- Command-line arguments that were used to set up the server
- **dsconfig** commands necessary to configure the server
- Installed server SDK extensions
- Files that are added to the server root

To produce a complete profile, some parts of the generated profile might require modifications, such as adding password files that `setup-arguments.txt` uses. The **--instanceName** and **--localHostName** arguments in `setup-arguments.txt` are made variables by **generate-profile**, and must be provided values when other **manage-profile** subcommands use the generated profile.

LDIF files must also be added manually to the generated profile.

### manage-profile setup

To apply a server profile to a fresh, unconfigured server, use the **setup** subcommand, which replaces the normal setup tool when using a server profile. Run **manage-profile setup** to complete the following tasks:

- Copies the pre-setup files to the server root
- Runs the setup tool
- Copies the post-setup files to the server root
- Installs any server SDK extensions
- Runs any dsconfig batch files
- Imports any LDIF files
- Starts the server

While **manage-profile setup** is running, a copy of the profile is created in a temporary directory that can be specified by using the **--tempProfileDirectory** argument. The command leaves the server in a complete and running state when finished, unless the **--doNotStart** argument is specified.

### manage-profile replace-profile

Run the **replace-profile** subcommand on a server that was originally set up with a server profile to replace its configuration with a new profile. The tool applies a specified server profile to an existing server while preserving its data, topology configuration, and replication configuration. New LDIF files from the replacement server profile are not imported.

While **manage-profile replace-profile** is running, the existing server is stopped and moved to a temporary directory that the **--tempServerDirectory** argument can specify. A fresh, new server is subsequently installed and set up with the new profile. The final server is left running if it was running before the command was started, and remains stopped if it was stopped.

Run **manage-profile replace-profile** from a second unzipped server install package on the same host as the existing server, similar to the **update** tool. Use the **--serverRoot** argument to specify the root of the existing server that will have its profile replaced.

If files have been added or modified in the server root since the most recent **manage-profile setup** or **manage-profile replace-profile** was run, they are included in the final server with the replaced profile. Otherwise, files specifically added from the `server-root` directory of the previous server profile are absent from the final server with the replaced profile. If errors occur during the subcommand, such as the new profile having an invalid `setup-arguments.txt` file, the existing server returns to its original state from before **manage-profile replace-profile** was run.

#### Note:

The **manage-profile replace-profile** tool can update the server version when needed.

**Note:**

The `manage-profile replace-profile` tool can directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to `dsconfig`.

**Server Profiles in a Pets Service Model**

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server. Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new pet server has been set up with a server profile, `manage-profile replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see [About the manage-profile tool](#) on page 1042.

**Topology-management tools**

Because PingDirectory Server topology-management tools like `dsreplication` and `remove-defunct-server` feature internal retries, external deployment automation scripts are not required to incorporate retries. This approach mitigates transient failures and makes servers more robust in automated environments.

To support this approach, `dsreplication` and `remove-defunct-server` include a `--retryTimeoutSeconds` option, which specifies a timeout value for the entire command. If the command fails, it is retried until the timeout value is reached. The command is not aborted if the timeout expires mid-execution, so it is guaranteed to be executed at least once. The default value of zero indicates the command does not have a timeout and is not retried upon initial failure.

The `remove-defunct-server` tool can also be used to complete the following tasks:

- Remove an online server.

Because a server runs as a container's main process, and because shutting down a server re-spins the container, this task was impossible to complete in deployment automation environments that use containers. Automation scripts often resorted to hacks like impersonating an offline server by taking down the LDAP connection handler. In environments where security concerns prevented the use of LDAP, removing an online server was never an option.

- Remove servers without forcing a topology master when you do not have a quorum majority of online servers.

The topology registry uses a master-slave architecture in which all write requests are chained through a single write-master. When a master could not be nominated, the topology becomes read-only. To work around this issue, a single server had to be forced as a master to apply changes.

- Remove servers concurrently.

The `--ignoreOnline` option can be used to remove an online server, and the `--retryTimeoutSeconds` option can be used to increase robustness in concurrent environments.

Finally, `dsreplication enable` provides internal support for a seed server before the replication topology exists. To prevent the creation of separate islands of replicating servers when simultaneously enabling replication on multiple hosts with a topology JSON file, the server that appears first in lexicographical order in the topology JSON file is designated as the seed server. When enabling replication on the seed server itself with the topology JSON file, it stops and returns a `ERROR_SEED_AND_TARGET_SERVER_ARE_THE_SAME` code. This precaution avoids deadlocking a `dsreplication` process when replication is invoked concurrently. On the seed server itself, deployment automation scripts can treat this code as being successful.

## Deployment automation

Automated workflows help shift the deployment process from a pets service model to a cattle service model. The primary tools that are required to manage the replication topology are `dsreplication` and `remove-defunct-server`.

Another key to every topology-management workflow is the `topology.json` file, which represents the intended state of the topology at any time. An administrator should create this file manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.

The following code shows an example `topology.json` file:

```
{
  "serverInstances" : [
    {
      "instanceName" : "ds-0",
      "hostname" : "ds-0.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-1",
      "hostname" : "ds-1.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-2",
      "hostname" : "ds-2.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-3",
```

```

    "hostname" : "ds-3.ds-topology.production.svc.cluster.local",
    "location" : "Austin",
    "ldapPort" : 389,
    "ldapsPort" : 636,
    "replicationPort" : 989,
    "startTLSEnabled" : true,
    "preferredSecurity" : "SSL",
    "product" : "DIRECTORY"
  },
  ...
]
}

```

The remaining sections in this chapter describe the deployment automation that is necessary to satisfy the following workflows:

- Setting up the initial topology
- Initializing data on all servers
- Replacing crashed instances and scaling up
- Scaling down
- Rolling updates

Consistent network identifiers are required for each server instance. Additionally, we strongly recommend persistent storage for all server bits. The required level of automation changes slightly when this recommendation is not followed, as noted in each section.

## Setting up the initial topology

About this task

The `server.uid` file in the server's `config` directory indicates whether the server is being set up initially or being updated.

### Note:

If you're not using persistent storage, set up a new server and skip step 3. If you are using persistent storage, start on step 3.

For more information about server profiles, see [Server profiles](#) on page 1038.

## Steps

1. Create or obtain the `topology.json` file either manually or by using external automation.

When promoting from a `dev/test` environment to a `stage/prod` environment, you can obtain a `topology.json` file using `manage-topology export`.

2. To install and configure a server instance, run the `manage-profile` command with the `setup` option.

Example:

```

manage-profile setup \
  --profile /path/to/server-profile \
  --profileVariablesFile /path/to/instance-specific-variables.properties

```

3. If you're using persistent storage, replace the current server profile. Otherwise, proceed to step 4. To replace the current profile, run the `manage-profile replace-profile` command from a second, extracted server install package on the same host as the existing server.

Example:

```
manage-profile replace-profile \
  --profile /path/to/server-profile \
  --profileVariablesFile /path/to/instance-specific-variables.properties
  --serverRoot /path/to/existing/server
```

4. To enable replication within the topology, run `dsreplication` with the `enable` option.

Example:

```
dsreplication enable \
  --topologyFilePath /path/to/topology.json \
  --retryTimeoutSeconds 120
```

5. To initialize the replication data, run `dsreplication` with the `initialize` option.

Example:

```
dsreplication initialize \
  --topologyFilePath /path/to/topology.json
```

### Prefer topology administrator accounts over root users

In PingDirectory Server, administrative accounts can be placed in any of three places.

- They can be created as root users. These accounts exist in the configuration (after `cn=Root DNs,cn=config`) and are not synchronized across server instances. If you want to use root accounts across multiple servers, then you must create the account in each server and keep it up to date across all of them. Root user accounts can optionally automatically inherit a default set of privileges, and you can also explicitly grant and revoke privileges as needed.
- They can be created as topology administrators. These accounts also exist in the configuration (after `cn=Topology Admin Users,cn=topology,cn=config`), and these accounts are automatically synchronized between server instances within the same topology. Topology administrators can also automatically inherit a default set of privileges, and you can also explicitly grant or revoke privileges.
- They can be created in the user data. These accounts will be replicated across all Directory Servers and they can be used to authenticate to PingDirectory and PingDirectoryProxy Servers, but they cannot be used to authenticate to PingDataSync or PingDataMetrics Servers. They cannot automatically inherit a default set of privileges, but you can explicitly grant privileges to them as needed. Accounts created in the user data can also be unavailable if the backend containing that data is offline, such as when performing an online restore, replica initialization, or LDIF import.

We recommend using topology administrator accounts over root users or accounts created in the user data. Topology administrators have all of the same capabilities as root users, and their accounts are also automatically synchronized across all servers in the topology so there is no need to apply the same change across multiple servers.

See the `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file for more information about creating topology administrator accounts. The contents of the `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file are shown below:

```
# Although setup automatically creates an initial root user account that can
# be used to manage the server, we strongly recommend creating a separate
# account for each administrator rather than using a single shared account.
# This offers several benefits, including:
#
# * It is easier to determine which administrator performed a given action.
# * There is no need to share credentials or coordinate password changes.
```

```

# * It is easier to use strong authentication options like certificates or
#   two-factor mechanisms.
# * You can customize the level of access that each administrator has.
#
# We also recommend creating topology admin user accounts rather than root
# user accounts. If you create a root user account, then it is only created
# in that one instance. If you create a topology admin user, then that
# account will be available in all instances in the topology.
#
# Because administrative accounts are very powerful, they are high-priority
# targets for attackers to try to compromise. They should be required to
# have
# strong credentials, and you may wish to require that they use strong
# authentication mechanisms (see other dsconfig batch files for configuring
# password validators and other password policy features). You may also
# want
# to give them usernames that are not likely to be guessed by an attacker,
# even if they know information about the individuals administering the
# service. For example, you may not want to use their name in the DN or
# username, choosing instead something that is less predictable or even
# completely random like a UUID.
#
# Once each administrator has their own account, we recommend that you
# disable
# or remove the initial root user created during setup. See the
# disable-or-remove-the-initial-root-user.dsconfig batch file for more
# information about that.

#
# NOTE: Do not edit this file directly. Changing this file could prevent
# it
# from being updated during a server upgrade. If you want to alter the
# dsconfig commands below before applying the configuration changes, copy
# this
# file to another directory and edit that copy.
#

# Create a new topology administrator account. In this example, the user
# will
# be able to read the configuration but will not be allowed to update it,
# and
# will be given the bypass-read-acl privilege rather than bypass-acl, which
# only ensures they will be able to read entries but they will not be
# permitted to update them unless permitted by the server's access control
# configuration. They will also only be permitted to communicate with the
# server over a secure connection, and they will only be permitted to
# authenticate with the EXTERNAL or UNBOUNDID-TOTP mechanisms.
dsconfig create-topology-admin-user \
  --user-name "[USER_NAME]" \
  --set "password:[PASSWORD]" \
  --set "first-name:[FIRST_NAME]" \
  --set "last-name:[LAST_NAME]" \
  --set "user-id:[USER_NAME]" \
  --set inherit-default-root-privileges:true \
  --set privilege:bypass-read-acl \
  --set privilege:-bypass-acl \
  --set privilege:-config-write \
  --set search-result-entry-limit:0 \
  --set time-limit-seconds:0 \
  --set look-through-entry-limit:0 \
  --set idle-time-limit-seconds:0 \
  --set require-secure-authentication:true \

```

```
--set require-secure-connections:true \
--set "allowed-authentication-type:SASL EXTERNAL" \
--set "allowed-authentication-type:SASL UNBOUNDID-TOTP"
```

## Initializing data on all servers

### About this task

Skip this step if you are using one of the following methods to load data during the initial setup:

- Each server instance imports the same user data from one or more LDIF backup files
- Data is synchronized from another source, such as an Active Directory server, to all servers
- No data is imported initially

Data must be imported and available on a single server only. Servers that do not feature user data must be initialized reliably and quickly.

### Note:

The absence of user data during the initial setup does not prevent the the environment from being set up correctly.

### Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. Import data into one of the server instances, as follows:

```
import-ldif --backendID userRoot \
--ldifFile userData0.ldif \
--ldifFile userData1.ldif
```

3. Initialize data on each server by using this server as the initial source:

```
dsreplication initialize \
--topologyFilePath /path/to/topology.json \
--retryTimeoutSeconds 120
```

For the sake of simplicity, other `dsreplication` options are not shown.

## Replacing crashed instances and scaling up

### About this task

The automation for this scenario is identical to the automation for [Setting up the initial topology](#) on page 1046.

### Scaling down

### About this task

### Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.

2. If the server is not present in the topology JSON file, remove it from the topology, as follows:

```
remove-defunct-server --topologyFilePath /path/to/topology.json \
  --ignore-online \
  --serverInstanceName instance-name
--retryTimeoutSeconds 120
```

For the sake of simplicity, LDAP bind options are omitted.

## Rolling updates

### About this task

The presence of the file `server.uuid` in the server's `config` directory indicates whether the server is being set up initially or being updated.

### Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the **manage-topology export** subcommand.
2. Extract the new server bits to a directory.
3. From the same directory's `bin` directory, replace the new server profile, as follows:

```
manage-profile replace-profile \
  --profile /path/to/server-profile \
  --profileVariablesFile /path/to/instance-specific-variables.properties \
  --serverRoot /path/to/existing/server
```

## Troubleshooting PingDirectory Server

---

The PingDirectory Server provides a highly-reliable service that satisfies your company's objectives. However, if problems do arise (whether from issues in the server itself or a supporting component, like the JVM, operating system, or hardware), then it is essential to be able to diagnose the problem quickly to determine the underlying cause and the best course of action to take towards resolving it.

This chapter provides information about how to perform this analysis to help ensure that the problem is resolved as quickly as possible. This chapter presents the following information:

## Directory Server gauges

The Directory Server provides a number of built-in gauges to monitor Directory Server performance. These gauges are listed in the following table:

### Directory Server Gauges

Gauge Name	Enabled by default?	Description
Active Cleaner Threads (Percent)	true	Monitors the percentage of database cleaner threads that are active in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the <code>list-backends</code> command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends may be included or excluded from monitoring by specifying its backend ID in the <code>include</code> resource and <code>exclude</code> resource properties respectively. To keep the database from growing on disk, database cleaner threads copy database information from older, mostly obsolete database files to new database files. At a single point in time, 100% of the cleaner threads might be active, but when averaged over time, the percentage of active cleaner threads should remain relatively low. Even environments that sustain a very high write load do not typically see an average cleaner percent busy over 50%. If the percentage exceeds 90% for over an hour, it is a sign that the database cleaner is not progressing and the act of cleaning is producing as much garbage as it cleans. This typically occurs in environments that are not fully cached, and have not given sufficient memory to the database cache. Either increase the memory available to the database cache (by increasing the JVM size or increasing the <code>db-cache-percent</code> setting on the backend) or reduce the <code>db-cleaner-min-utilization</code> setting, which reduces the burden on the cleaner thread(s).
Authentication Failure Rate	false	Rate of LDAP bind failures per second. A high rate of failures may indicate a misconfigured client application or a malicious attack.
Available File Descriptors	true	Monitors the number of file descriptors available to the server process. The server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. The number of file descriptors that the server will use can be configured by either using a <code>NUM_FILE_DESCRIPTOR</code> environment variable, or by creating a <code>config/num-file-descriptors</code> file with a single line such as <code>NUM_FILE_DESCRIPTOR=12345</code> . If these are not set, the default of 65535 is used. Running out of available file descriptors can lead to unpredictable behavior and severe system instability.

Gauge Namee	Enabled by default?	Description
Certificate Expiration (Days)	true	Monitors the expiration dates of key server certificates. A server certificate expiring may cause server unavailability, degradation, or loss of key server functionality. Certificates nearing the end of their validity should be replaced as soon as possible. See the status tool, or Status in the Administrative Console, for more information about server certificates and how they are managed.
Changelog Database Target Size (Percent)	true	Monitors the size of a changelog database on disk relative to the configured <b>target-database-size</b> value for the Replication Server changelog and the LDAP Changelog Backend (cn=changelog). The resource identifier indicates the changelog environment that is being monitored. The server aims to keep the disk usage of the changelog to between 95% and 100% of the target-database-size value. The most common reason that the server exceeds this limit is that there are no more changes that are old enough to purge. This is controlled with the replication-purge-delay setting on the Replication Server configuration object and the <b>changelog-maximum-age</b> setting on the 'changelog' Backend configuration object. If this is the case, the effective-purge-delay monitor attribute will match the configured purge delay. To eliminate the alarm in this case reduce the purge delay or increase the target-database-size value. Another reason that the disk usage could exceed this limit is that an export-ldif or online backup of the corresponding backend is running since database files on disk cannot be deleted while this operation is in progress. In practice, this will not occur unless the purge delay and target-database-size setting are configured to very small values and/or the backup is throttled with the <b>--maxMegabytesPerSecond</b> option so that it takes an especially long time to complete. The final reason that the limit could be exceeded is that the target-database-size setting is unreasonably small like less than one gigabyte.

Gauge Name	Enabled by default?	Description
Cleaner Backlog (Number Of Files)	true	Monitors the cleaner backlog in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the list-backends command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends may be included or excluded from monitoring by specifying its backend ID in the include resource and exclude resource properties respectively. The backlog is the number of database files that need to be cleaned to reach the target level of utilization. The value over time should stay close to zero. If it remains high or continues to grow, then consider updating the backend configuration to increase the <code>db-num-cleaner-threads</code> setting or reduce the <code>db-cleaner-min-utilization</code> setting. Temporary spikes in cleaner backlog are common during rebuild-index, export-ldif, and backup operations. The backlog should decrease automatically once these commands complete.
CPU Usage (Percent)	true	Monitors server CPU use and provides an averaged percentage for the interval defined. The monitored resource is the host system's CPU, which does not include a resource identifier. If CPU use is high, check the server's current workload and other processes on this system and make any needed adjustments. Reducing the load on the system will lead to better response times.
Database Cache Full (Percent)	true	Monitors the percentage capacity of the database cache currently populated with entries, per backend. The resource identifier for this gauge is a backend ID. Use the list-backends command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends may be included or excluded from monitoring by specifying its backend ID in the include-resource and exclude-resource properties respectively. Server performance can drop off dramatically when the database cache can no longer hold the entire data set. Most deployments are designed to keep the database cache usage comfortably within the configured limits. If this server is intentionally disk-bound, this gauge should be disabled.
Disk Busy (Percent)	true	Monitors disk busy percentage over the update interval. This gauge requires that the Host System Monitor Provider be enabled and that any monitored disks be registered using the disk-devices property of that Monitor Provider. The resource identifier for this gauge is the disk device name. Use the iostat command or a similar system utility to see a list of disk device names. A separate gauge monitor entry will be created for each monitored disk. High disk usage may be indicative of a Directory Server whose database cache and/or JVM heap size are not large enough to contain the entire data set.

Gauge Name	Enabled by default?	Description
HTTP Processing (Percent)	true	Monitors the percentage of time that request handler threads spend processing HTTP requests. This percentage represents the inverse of the server's ability to handle new requests without queueing.
JVM Memory Usage (Percent)	true	Monitors the percentage of Java Virtual Machine memory that is in use. This value naturally fluctuates due to garbage collection, so the minimum value within an interval is reported since it is a better indication of overall memory growth. When the memory usage exceeds 90%, this should be reported to customer support since the server is either misconfigured or has a memory leak. As memory usage approaches 100%, the server is more and more likely to experience garbage collection pauses, which leave the server unresponsive for a long time. Restarting the server is likely the only remedy for this situation. Prior to restarting the server, please run <code>collect-support-data</code> and capture the output of <code>jmap -histo</code> to provide to customer support. The pid of the server can be found from <code>/logs/server.pid</code> .
LDAP Operation Average Response Time (Milliseconds)	false	Monitors the average response time across all LDAP operations processed by this server since it was started. There is no resource identifier associated with this gauge. The monitored resource is overall response time of all LDAP operations processed by this server since it was started. High response times may be indicative of a number of factors including a disk-bound server, network latency, or misconfiguration. Enabling the Stats Logger plugin may help isolate problems. See the administration guide for more information on common problems and solutions.
LDAP Operations Failed (Percent)	false	Monitors the percentage of all LDAP operations processed by this server that have failed since it was started. There is no resource identifier associated with this gauge. The monitored resource is overall number of failed LDAP operations processed by this server since it was started. A high percentage of failed operations may indicate misconfiguration of a client or server in a topology.
License Expiration (Days)	true	Monitors the expiration date of the product license. An expired license will cause warnings to appear in the server's logs and in the status tool output. Request a license key through the Ping Identity licensing website <a href="https://www.pingidentity.com/en/account/request-license-key.html">https://www.pingidentity.com/en/account/request-license-key.html</a> or contact <a href="mailto:sales@pingidentity.com">sales@pingidentity.com</a> . Use the <code>dsconfig</code> tool to update the License configuration's license key property.

Gauge Name	Enabled by default?	Description
Memory Usage (Percent)	false	Monitors the percentage of memory use averaged over the update interval defined. The monitored resource is the host system's memory use, which does not have a resource identifier. Some operating systems, including Linux, use the majority of memory for file system cache, which is freed as applications need it. If memory use is high, check the applications that are running on the server.
Purge Expired Data Backlog (Number of Entries)	true	Monitors the backlog of entries that need to be purged by a Purge Expired Data Plugin. The resource identifier for this gauge is the name of the configured plugin. Increasing the max-updates-per-second configuration property on the plugin can increase the rate that the plugin purges expired data. It might also be necessary to refine the search that the plugin performs to be more efficient.
Recent Changes Database-to-JVM Heap Size Ratio (Percent)	true	The recent changes database keeps a number of recent changes made by update operations in changelog change entry form. This database is used by replication and the changelog backends, and unexpected growth affects server start time, memory consumption and space on disk. The ratio of the recent changes database to the overall heap size is used to track the impact on memory consumption. If you expect large changes and the server isn't experiencing issues, increase the alarm threshold. After processing large changes the alarm should clear itself, if not, it may necessary to perform an export and re-import of the data to resolve the issue.
Replication Conflict Growth Rate	false	Growth rate of the number of unresolved conflicts per second over the update interval. The resource identifier for this gauge is the base DN of the replica. Use the dsreplication status command to see a list of replicated base DNs. A separate gauge monitor entry will be created for each monitored replica. Replicas may be included or excluded from monitoring by specifying a replication base DN in the include resource and exclude resource properties respectively. Updates to Directory Server entries in a replication topology may happen independently, since replication guarantees only eventual consistency, not strong consistency. The eventual consistency model means that conflicting changes can be applied at different Directory Server instances. In most cases, the Directory Server is able to resolve these conflicts automatically and in a consistent manner. However, in some scenarios, manual administrative action is required. Attention should be paid to the origin of client write requests to prevent conflicts.

Gauge Name	Enabled by default?	Description
Replication Connection Status	false	Indicates the connection status of remote replication servers this servers replication topology. The 'cn=schema' backend as well as the local replication server, are excluded using the include-filter property. For all other remote servers in the topology, separate monitor entries will be created per server and replication base DN. The resource identifier for this gauge is a concatenated string containing the data set name, the host and port of the replication server and the replication server ID. A replicated data set depends upon the availability of servers replicating the data. So long as there are other replicas available in a replication topology, a single replica being unavailable should not affect the overall performance of the replication topology. However, unavailable replicas may increase the likelihood of data loss or performance degradation.
Replication Latency (Milliseconds)	false	Average amount of time it takes a modification on one replica to propagate and commit on another replica, in milliseconds. The resource identifier for this gauge is the base DN of the replica. Use the dsreplication status command to see a list of replicated base DNs. A separate gauge monitor entry will be created for each monitored replica. Replicas may be included or excluded from monitoring by specifying its base DN in the include-resource and exclude-resource properties respectively. Replication latency can be reported as high after the server starts, if the global configuration property startup-min-replication-backlog-count is not set. That property limits the number of outstanding changes any replica can have before the server will complete the startup process and begin accepting connections. This limits how out of the sync the server is at start up.
Replication Purge Delay (Hours)	true	For the replication server indicates the effective purge delay. In order to protect against missing changes the effective purge delay should be large enough to accommodate servers that have been offline as well as the need to restore from backups.
Replication Servers Available	false	Strong Encryption Not Available
Strong Encryption Not Available	true	The JVM does not appear to support strong encryption algorithms, like 256-bit AES. The server will fall back to using weaker algorithms, like 128-bit AES. To enable support for strong encryption, update your JVM to a newer version that supports it by default, or install or enable the unlimited encryption strength jurisdiction policy files in your Java installation.

Gauge Name	Enabled by default?	Description
Undeletable Database Files (Percent)	true	Monitors the percentage of undeletable database files in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the <code>list-backends</code> command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends may be included or excluded from monitoring by specifying its backend ID in the <code>include resource</code> and <code>exclude resource</code> properties respectively. The percentage of undeletable database files tracks the percentage of database files that have been cleaned but cannot be deleted because they are being used by a database maintenance operation. This could be a separate, offline process such as <code>export-ldif</code> or <code>verify-index</code> , or it could be a task running within the server such as a backup or replication initialization. A small percentage of undeletable files is expected when these commands are running, but a high percentage could indicate that one of these operations is having problems and should be canceled and restarted to avoid the database growing too large on disk.
Work Queue Size (Number Of Requests)	true	Number of requests in the server's work queue waiting to be processed, averaged over the update interval. There is no resource identifier associated with this gauge. The monitored resource is the server's work queue. If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available.

## Working with the `collect-support-data` tool

The Directory Server provides a significant amount of information about its current state including any problems that it has encountered during processing. If a problem occurs, the first step is to run the `collect-support-data` tool in the `bin` directory. The tool aggregates all relevant support files into a zip file that administrators can send to your authorized support provider for analysis. The tool also runs data collector utilities, such as `jps`, `jstack`, and `jstat` plus other diagnostic tools, and bundles the results in the zip file.

The tool may only archive portions of certain log files to conserve space, so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

The data collected by the `collect-support-data` tool varies between systems. However, the tool always tries to get the same information across all systems for the target Directory Server. The data collected includes the configuration directory, summaries and snippets from the `logs` directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

### Server commands used in the `collect-support-data` tool

The following presents a summary of the data collectors that the `collect-support-data` tool archives in zip format. If an error occurs during processing, you can re-run the specific data collector command and send the results to your authorized support provider.

**Directory Server Commands Used in the Collect-Support-Data Tool**

Data Collector	Description
status	Runs <code>status -F</code> to show the full version information of the Directory Server (Unix, Windows).
server-state	Runs <code>server-state</code> to show the current state of the Directory Server process (Unix, Windows).

**JDK commands used in the collect-support-data tool****JDK Commands Used in the Collect-Support-Data Tool**

Data Collector	Description
jps	Java Virtual Machine Process status tool. Reports information on the JVM (Linux, Windows, Mac OS).
jstack	Java Virtual Machine Stack Trace. Prints the stack traces of threads for the Java process (Linux, Windows, Mac OS).
jstat	Java Virtual Machine Statistics Monitoring Tool. Displays performance statistics for the JVM (Linux, Windows, Mac OS).
jjinfo	Displays the Java configuration information for the Java process (Linux, Windows, Mac OS).

**Linux commands used in the collect-support-data tool****Linux Commands Used in the Collect-Support-Data Tool**

Data Collector	Description
tail	Displays the last few lines of a file. Tails the <code>/var/logs/messages</code> directory.
uname	Prints system, machine, and operating system information.
ps	Prints a snapshot of the current active processes.
df	Prints the amount of available disk space for file systems in 1024-byte units.
cat	Concatenates the following files and prints to standard output: <ul style="list-style-type: none"> <li>▪ <code>/proc/cpuinfo</code></li> <li>▪ <code>/proc/meminfo</code></li> <li>▪ <code>/etc/hosts</code></li> <li>▪ <code>/etc/nsswitch.conf</code></li> <li>▪ <code>/etc/resolv.conf</code></li> </ul>
netstat	Prints the state of network interfaces, protocols, and the kernel routing table.
ifconfig	Prints information on all interfaces.
uptime	Prints the time the server has been up and active.
dmesg	Prints the message buffer of the kernel.
vmstat	Prints information about virtual memory statistics.
iostat	Prints disk I/O and CPU utilization information.
mpstat	Prints performance statistics for all logical processors.

Data Collector	Description
pstack	Prints an execution stack trace on an active process specified by the pid.
top	Prints a list of active processes and how much CPU and memory each process is using.

### MacOS commands used in the collect-support-data tool

#### MacOS Commands Used in the Collect-Support-Data Tool

Data Collector	Description
uname	Prints system, machine, and operating system information.
uptime	Prints the time the server has been up and active.
ps	Prints a snapshot of the current active processes.
system_profiler	Prints system hardware and software configuration.
vm_stat	Prints machine virtual memory statistics.
tail	Displays the last few lines of a file. Tails the <code>/var/log/system.log</code> directory.
netstat	Prints the state of network interfaces, protocols, and the kernel routing table.
ifconfig	Prints information on all interfaces.
df	Prints the amount of available disk space for file systems in 1024-byte units.
sample	Profiles a process during an interval.

### Invoking the collect-support-data tool as an administrative task

You can invoke `collect-support-data` as an administrative task, including as a recurring task that can be automatically invoked on a regular basis.

For more information, see [About recurring tasks and task chains](#) on page 403.

### Available tool options

The `collect-support-data` tool has some important options that you should be aware of:

- **--noLdap**. Specifies that no effort should be made to collect any information over LDAP. This option should only be used if the server is completely unresponsive or will not start and only as a last resort.
- **--pid {pid}**. Specifies the ID of an additional process from which information is to be collected. This option is useful for troubleshooting external server tools and can be specified multiple times for each external server, respectively.
- **--sequential**. Use this option to diagnose “Out of Memory” errors. The tool collects data in parallel to minimize the collection time necessary for some analysis utilities. This option specifies that data collection should be run sequentially as opposed to in parallel. This action has the effect of reducing the initial memory footprint of this tool at a cost of taking longer to complete.
- **--reportCount {count}**. Specifies the number of reports generated for commands that supports sampling (for example, `vmstat`, `iostat`, or `mpstat`). A value of 0 (zero) indicates that no reports will be generated for these commands. If this option is not specified, it defaults to 10.
- **--reportInterval {interval}**. Specifies the number of seconds between reports for commands that support sampling (for example, `mpstat`). This option must have a value greater than 0 (zero). If this option is not specified, it default to 1.
- **--maxJstacks {number}**. Specifies the number of jstack samples to collect. If not specified, the default number of samples collected is 10.

- **--collectExpensiveData**. Specifies that data on expensive or long running processes be collected. These processes are not collected by default, because they will impact the performance of a running server.
- **--comment {comment}**. Provides the ability to submit any additional information about the collected data set. The comment will be added to the generated archive as a README file.
- **--includeBinaryFiles**. Specifies that binary files be included in the archive collection. By default, all binary files are automatically excluded in data collection.
- **--adminPassword {adminPassword}**. Specifies the global administrator password used to obtain `dsreplication status` information.
- **--adminPasswordFile {adminPasswordFile}**. Specifies the file containing the password of the global administrator used to obtain `dsreplication status` information.
- **--outputPath**. Specifies the path (and optionally, the name) for the support data archive file. If the path specifies a filename, the archive is written to that file. If the path specifies a directory, the file is written into that directory with a server-generated name.
- **--useRemoteServer**. Invokes the tool against a remote server instance and streams the output and resulting support data archive back to the client. This option can be especially useful when the server instance is running in a container because it might otherwise be difficult to invoke commands or access files in that container. See also: **--proxyToServerAddress** and **--proxyToServerPort**.
- **--proxyToServerAddress** and **--proxyToServerPort**. Use these options with **--useRemoteServer** to indicate that the support data archive should be retrieved from a server that is not directly accessible but can be accessed through a Directory Proxy Server.

## Running the collect-support-data tool

### Steps

1. Go to the server root directory.
2. Use the `collect-support-data` tool. Make sure to include the host, port number, bind DN, and bind password.

Example:

```
$ bin/collect-support-data --hostname 127.0.0.1 --port 389 \
  --bindDN "cn=Directory Manager" --bindPassword secret \
  --serverRoot /opt/PingDirectory --pid 1234
```

3. Email the zip file to your Authorized Support Provider.

## Directory Server Troubleshooting information

The Directory Server has a comprehensive default set of log files and monitor entries that are useful when troubleshooting a particular server problem.

### Error log

By default, this log file is available at `logs/errors` below the server install root and it provides information about warnings, errors, and other significant events that occur within the server. A number of messages are written to this file on startup and shutdown, but while the server is running there is normally little information written to it. In the event that a problem does occur, however, the server writes information about that problem to this file.

The following is an example of a message that might be written to the error log:

```
[11/Apr/2011:10:31:53.783 -0500] category=CORE severity=NOTICE msgID=458887
msg="The Directory Server has started successfully"
```

The category field provides information about the area of the server from which the message was generated. Available categories include:

ACCESS\_CONTROL, ADMIN, ADMIN\_TOOL, BACKEND, CONFIG, CORE, DSCONFIG, EXTENSIONS, PROTOCOL, SCHEMA, JEB, SYNC, LOG, PLUGIN, PROXY, QUICKSETUP, REPLICATION, RUNTIME\_INFORMATION, TASK, THIRD\_PARTY, TOOLS, USER\_DEFINED, UTIL, VERSION.

The severity field provides information about how severe the server considers the problem to be. Available severities include:

- **DEBUG** – Used for messages that provide verbose debugging information and do not indicate any kind of problem. Note that this severity level is rarely used for error logging, as the Directory Server provides a separate debug logging facility as described below.
- **INFORMATION** – Used for informational messages that can be useful from time to time but are not normally something that administrators need to see.
- **MILD\_WARNING** – Used for problems that the server detects, which can indicate something unusual occurred, but the warning does not prevent the server from completing the task it was working on. These warnings are not normally something that should be of concern to administrators.
- **MILD\_ERROR** – Used for problems detected by the server that prevented it from completing some processing normally but that are not considered to be a significant problem requiring administrative action. Administrator
- **NOTICE** – Used for information messages about significant events that occur within the server and are considered important enough to warrant making available to administrators under normal conditions.
- **SEVERE\_WARNING** – Used for problems that the server detects that might lead to bigger problems in the future and should be addressed by administrators.
- **SEVERE\_ERROR** – Used for significant problems that have prevented the server from successfully completing processing and are considered important.
- **FATAL\_ERROR** – Used for critical problems that arise which might leave the server unable to continue processing operations normally.

The messages written to the error log may be filtered based on their severities in two ways. First, the error log publisher has a `default-severity` property, which may be used to specify the severity of messages logged regardless of their category. By default, this includes the NOTICE, SEVERE\_WARNING, SEVERE\_ERROR, and FATAL\_ERROR severities.

You can override these severities on a per-category basis using the `override-severity` property. If this property is used, then each value should consist of a category name followed by an equal sign and a comma-delimited set of severities that should be logged for messages in that category. For example, the following override severity would enable logging at all severity levels in the PROTOCOL category:

```
protocol=debug,information,mild-warning,mild-error,notice,severe-
warning,severe-error,fatal-error
```

AdmNote that for the purposes of this configuration property, any underscores in category or severity names should be replaced with dashes. Also, severities are not inherently hierarchical, so enabling the DEBUG severity for a category will not automatically enable logging at the INFORMATION, MILD\_WARNING, or MILD\_ERROR severities.

The error log configuration may be altered on the fly using tools like `dsconfig`, the Administrative Console, or the LDIF connection handler, and changes will take effect immediately. You can configure multiple error logs that are active in the server at the same time, writing to different log files with different configurations. For example, a new error logger may be activated with a different set of default severities to debug a short-term problem, and then that logger may be removed once the problem is resolved, so that the normal error log does not contain any of the more verbose information.

### server.out log

The `server.out` file holds any information written to standard output or standard error while the server is running. Normally, it includes a number of messages written at startup and shutdown, as well as information about any administrative alerts generated while the server is running. In most cases, this information is also written to the error log. The `server.out` file can also contain output generated by the

JVM. For example, if garbage collection debugging is enabled, or if a stack trace is requested via "kill -QUIT" as described in a later section, then output is written to this file.

## Debug log

The debug log provides a means of obtaining information that can be used for troubleshooting problems but is not necessary or desirable to have available while the server is functioning normally. As a result, the debug log is disabled by default, but it can be enabled and configured at any time.

Some of the most notable configuration properties for the debug log publisher include:

- **enabled** – Indicates whether debug logging is enabled. By default, it is disabled.
- **log-file** – Specifies the path to the file to be written. By default, debug messages are written to the `logs/debug` file.
- **default-debug-level** – Specifies the minimum log level for debug messages that should be written. The default value is "error," which only provides information about errors that occur during processing (for example, exception stack traces). Other supported debug levels include warning, info, and verbose. Note that unlike error log severities, the debug log levels are hierarchical. Configuring a specified debug level enables any debugging at any higher levels. For example, configuring the info debug level automatically enables the warning and error levels.
- **default-debug-category** – Specifies the categories for debug messages that should be written. Some of the most useful categories include caught (provides information and stack traces for any exceptions caught during processing), database-access (provides information about operations performed in the underlying database), protocol (provides information about ASN.1 and LDAP communication performed by the server), and data (provides information about raw data read from or written to clients).

As with the error and access logs, multiple debug loggers can be active in the server at any time with different configurations and log files to help isolate information that might be relevant to a particular problem.

### Note:

Enabling one or more debug loggers can have a significant impact on server performance. We recommend that debug loggers be enabled only when necessary, and then be scoped so that only pertinent debug information is recorded.

Debug targets can be used to further pare down the set of messages generated. For example, you can specify that the debug logs be generated only within a specific class or package. If you need to enable the debug logger, you should work with your authorized support provider to best configure the debug target and interpret the output.

## Replication repair log

The replication repair log is written to `logs/replication` by default and records information about processing performed by the replication repair service. This log is used to resolve replication conflicts that can arise. For example, if the same entry is modified at the same time on two different systems, or if an attempt is made to create entries with the same DN at the same time on two different systems, the Directory Server records these events.

## Config audit log and the configuration archive

The configuration audit log provides a record of any changes made to the server configuration while the server is online. This information is written to the `logs/config-audit.log` file and provides information about the configuration change in the form that may be used to perform the operation in a non-interactive manner with the `dsconfig` command. Other information written for each change includes:

- Time that the configuration change was made.
- Connection ID and operation ID for the corresponding change, which can be used to correlate it with information in the access log.

- DN of the user requesting the configuration change and the method by which that user authenticated to the server.
- Source and destination addresses of the client connection.
- Command that can be used to undo the change and revert to the previous configuration for the associated configuration object.

In addition to information about the individual changes that are made to the configuration, the Directory Server maintains complete copies of all previous configurations. These configurations are provided in the `config/archived-configs` directory and are gzip-compressed copies of the `config/config.ldif` file in use before the configuration change was made. The file names contain timestamps that indicate when that configuration was first used.

### Access and audit log

The access log provides information about operations processed within the server. The default access log file is written to `logs/access`, but multiple access loggers can be active at the same time, each writing to different log files and using different configurations.

By default, a single access log message is generated, which combines the elements of request, forward, and result messages. If an error is encountered while attempting to process the request, then one or more forward-failed messages may also be generated.

```
[01/Jun/2011:11:10:19.692 -0500] CONNECT conn=49 from="127.0.0.1"
to="127.0.0.1"
  protocol="LDAP+TLS" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.764 -0500] BIND RESULT conn=49 op=0 msgID=1 version="3"
  dn="cn=Directory Manager" authType="SIMPLE" resultCode=0 etime=0.401
  authDN="cn=Directory Manager,cn=Root DNs,cn=config"
  clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.769 -0500] SEARCH RESULT conn=49 op=1 msgID=2
  base="ou=People,dc=example,dc=com" scope=2 filter="(uid=1)" attrs="ALL"
  resultCode=0 etime=0.549 entriesReturned=1
[01/Jun/2011:11:10:19.788 -0500] DISCONNECT conn=49 reason="Client Unbind"
```

Each log message includes a timestamp indicating when it was written, followed by the operation type, the connection ID (which is used for all operations processed on the same client connection), the operation ID (which can be used to correlate the request and response log messages for the operation), and the message ID used in LDAP messages for this operation.

The remaining content for access log messages varies based on the type of operation being processed, and whether it is a request or a result message. Request messages generally include the most pertinent information from the request, but generally omit information that is sensitive or not useful.

Result messages include a `resultCode` element that indicates whether the operation was successful or if failed and an `etime` element that indicates the length of time in milliseconds that the server spent processing the operation. Other elements that might be present include the following:

- **origin=replication** – Operation that was processed as a result of data synchronization (for example, replication) rather than a request received directly from a client.
- **message** – Text that was included in the `diagnosticMessage` field of the response sent to the client.
- **additionalInfo** – Additional information about the operation that was not included in the response sent back to the client.
- **authDN** – DN of the user that authenticated to the server (typically only included in bind result messages).
- **authzDN** – DN of an alternate authorization identify used when processing the operation (for example, if the proxied authorization control was included in the request).
- **authFailureID** – Unique identifier associated with the authentication failure reason (only included in non-successful bind result messages).

- **authFailureReason** – Information about the reason that a bind operation failed that might be useful to administrators but was not included in the response to the client for security reasons.
- **responseOID** – OID included in an extended response returned to the client.
- **entriesReturned** – Number of matching entries returned to the client for a search operation.
- **unindexed=true** – Indicates that the associated search operation could not be sufficiently processed using server indexes and a significant traversal through the database was required.

Note that this is not an exhaustive list, and elements that are not listed here may also be present in access log messages. The LDAP SDK for Java provides an API for parsing access log messages and provides access to all elements that they may contain.

The Directory Server provides a second access log implementation called the *audit log*, which is used to provide detailed information about write operations (add, delete, modify, and modify DN) processed within the server. If the audit log is enabled, the entire content of the change is written to the audit log file (which defaults to `logs/audit`) in LDIF form.

The PingDirectory Server also provides a very rich classification system that can be used to filter the content for access log files. This can be helpful when debugging problems with client applications, because it can restrict log information to operations processed only by a particular application (for example, based on IP address and/or authentication DN), only failed operations, or only operations taking a long time to complete, etc.

### Setup log

The **setup** tool writes a log file providing information about the processing that it performs. By default, this log file is written to `logs/setup.log` although a different name may be used if a file with that name already exists, because the **setup** tool has already been run. The full path to the setup log file is provided when the **setup** tool has completed.

### Tool log

Many of the administrative tools provided with the Directory Server (for example, **import-ldif**, **export-ldif**, **backup**, **restore**, etc.) can take a significant length of time to complete write information to standard output or standard error or both while the tool is running. They also write additional output to files in the `logs/tools` directory (for example, **logs/tools/import-ldif.log**). The information written to these log files can be useful for diagnosing problems encountered while they were running. When running via the server tasks interface, log messages generated while the task is running may alternately be written to the server error log file.

### je.info and je.config files

The primary datastore used by the Directory Server is the Oracle Berkeley DB Java Edition (JE). The Directory Server provides two primary sources of information about processing within the database.

The first is logging performed by the JE code itself, and is written into the `je.info.0` file in the server containing the database files (for example, `db/userRoot/je.info.0`). In the event of a problem within JE itself, useful information about the nature of the problem may be written to this log. The level of information written to this log file is controlled by the `db-logging-level` property in the backend configuration object. It uses the standard Java logging framework for logging messages, so the standard SEVERE, WARNING, INFO, CONFIG, FINE, FINER, and FINEST levels are available.

The second is configuration information used when opening the database environment. When the backend database environment is opened, then the Directory Server will also write a file named `je.config` in the server containing the database files (for example, `db/userRoot/je.config`) with information about the configuration used.

### LDAP SDK debug log

This log can be used to help examine the communication between the Directory Server and the Directory Proxy Server. It contains information about exceptions that occur during processing, problems establishing and terminating network connections, and problems that occur during the reading and writing of LDAP

messages and LDIF entries. You can configure the types of debugging that should be enabled, the debug level that should be used, and whether debug messages should include stack traces. As for other file-based loggers, you can also specify the rotation and retention policies.

## About the monitor entries

While the Directory Server is running, it generates a significant amount of information available through monitor entries. Monitor entries are available over LDAP in the `cn=monitor` subtree. The types of monitor entries that are available include:

- **General Monitor Entry (cn=monitor)** – Provides a basic set of general information about the server.
- **Active Operations Monitor Entry (cn=Active Operations,cn=monitor)** – Provides information about all operations currently in progress in the server.
- **Backend Monitor Entries (cn={id} Backend,cn=monitor)** – Provides information about the backend, including the number of entries, the base DN(s), and whether it is private.
- **Client Connections Monitor Entry (cn=Client Connections,cn=monitor)** – Provides information about all connections currently established to the server.
- **Connection Handler Monitor Entry (cn={name},cn=monitor)** – Provides information about the configuration of each connection handler and the client connections established to it.
- **Database Environment Monitor Entries (cn={id} Database Environment,cn=monitor)** – Provides statistics and other data from the Oracle Berkeley DB Java Edition database environment used by the associated backend.
- **Disk Space Usage Monitor Entry (cn=Disk Space Usage,cn=monitor)** – Provides information about the amount of usable disk space available to server components.
- **JVM Memory Usage Monitor Entry (cn=JVM Memory Usage,cn=monitor)** – Provides information about garbage collection activity, the amount of memory available to the server, and the amount of memory consumed by various server components.
- **JVM Stack Trace Monitor Entry (cn=JVM Stack Trace,cn=monitor)** – Provides a stack trace of all threads in the JVM.
- **LDAP Statistics Monitor Entries (cn={name} Statistics,cn=monitor)** – Provides information about the number of each type of operation requested and bytes transferred over the connection handler.
- **Processing Time Histogram Monitor Entry (cn=Processing Time Histogram,cn=monitor)** – Provides information about the number of percent of operations that completed in various response time categories.
- **SSL Context Monitor Entry (cn=SSL Context,cn=monitor)** – Provides information about the available and supported SSL Cipher Suites and Protocols on the server.
- **System Information Monitor Entry (cn=System Information,cn=monitor)** – Provides information about the underlying JVM and system.
- **Version Monitor Entry (cn=Version,cn=monitor)** – Provides information about the Directory Server version.
- **Work Queue Monitor Entry (cn=Work Queue,cn=monitor)** – Provides information about the state of the Directory Server work queue, including the number of operations waiting on worker threads and the number of operations that have been rejected because the queue became full.

## Directory Server troubleshooting tools

The PingDirectory Server provides a set of tools that can also be used to obtain information for diagnosing and solving problems.

### Server version information

If it becomes necessary to contact your authorized support provider, then it will be important to provide precise information about the version of the Directory Server software that is in use. If the server is running, then this information can be obtained from the `"cn=Version,cn=monitor"` entry. It can also be obtained using the command:

```
$ bin/status --fullVersion
```

This command outputs a number of important pieces of information, including:

- Major, minor, point and patch version numbers for the server.
- Source revision number from which the server was built.
- Build information including build ID with timestamp, OS, user, Java and JVM version for the build.
- Auxiliary software versions: Jetty, JZlib, SNMP4j (SNMP4J, Agent, Agentx), Groovy, LDAP SDK for Java, and the Server SDK.

### LDIF connection handler

The Directory Server provides an LDIF connection handler that provides a way to request operations that do not require any network communication with the server. This can be particularly helpful if a configuration problem or bug in the server has left a connection handler unusable, or if all worker threads are busy processing operations.

The LDIF connection handler is enabled by default and looks for LDIF files to be placed in the `config/auto-process-ldif` directory. This Directory Server does not exist by default, but if it is created and an LDIF file is placed in it that contains one or more changes to be processed, then those changes will be applied.

Any changes that can be made over LDAP can be applied through the LDIF connection handler. It is primarily intended for administrative operations like updating the server configuration or scheduling tasks, although other types of changes (including changes to data contained in the server) can be processed. As the LDIF file is processed, a new file is written with comments for each change providing information about the result of processing that change.

### dbtest tool

The `dbtest` tool provides a utility that can be used to obtain general information about the data in a backend database. The tool dumps information about entries or keys, and raw data from the database. It can also find keys that have exceeded the entry limit.

For example, the following command can be used to dump a list of all keys in the `objectClass.equality` that have exceeded the entry threshold:

```
$ bin/dbtest dump-database-container \
  --backendID userRoot \
  --baseDN "dc=example,dc=com" \
  --databaseName objectClass.equality \
  --onlyExceedingLimit
```

On a large database, many `dbtest` operations may take a long time to complete, since every record in the associated database is examined. Use the database name option to list a specific database. The following command displays information about the `uid.equality` database in the `dc=example,dc=com` entry container in the `userRoot` backend.

```
$ bin/dbtest list-database-containers -n userRoot -b "dc=example,dc=com" -d
uid.equality
```

### Index key entry limit

Indexes have keys that maintain a list of matching entries, up to the index entry limit. When that limit is reached, the key will not contain or maintain that list, and will just maintain a count of matching entries. To determine if index keys are approaching their limit, use either the `dbtest` tool or the `verify-index` tool.

While the `dbtest` tool can be used to gather general information, the `verify-index` tool provides statistical data about the percent of entries covered by the keys.

For example, the following command can be used to retrieve a list of keys that have exceeded the entry threshold:

```
$ bin/verify-index \
  --baseDN dc=example,dc=com \
  --listKeysExceedingIndexEntryLimit
```

The following is a sample of the data returned:

```
[12:06:05] Checked 6003 entries and found 0 error(s) in 2 seconds (average
rate 2453.2/sec)
[12:06:05] Statistics for records that have exceeded the entry limit:
[12:06:05] The st.equality index has 48 such record(s) limit=100 min=103
max=152 median=118
[12:06:05] 1. or (152 entries / 2.53% of all entries)
[12:06:05] 2. ma (132 entries / 2.20% of all entries)
.....
[12:06:05] The id2subtree index has 2 such record(s) limit=4000 min=6000
max=6002 median=6001
[12:06:05] 1. 1 => dc=example,dc=com (6002 entries / 99.98% of all entries)
.....
[12:06:05] The id2children index has 1 such record(s) limit=4000 min=6000
max=6000 median=6000
[12:06:05] 1. 2 => ou=People,dc=example,dc=com (6000 entries / 99.95% of all
entries)
[12:06:05] The objectClass.equality index has 4 such record(s) limit=4000
min=6001 max=6003 median=6001
[12:06:05] 1. top (6003 entries / 100.00% of all entries)
.....
```

### Embedded profiler

If the Directory Server appears to be running slowly, then it is helpful to know what operations are being processed in the server. The JVM Stack Trace monitor entry can be used to obtain a point-in-time snapshot of what the server is doing, but in many cases, it might be useful to have information collected over a period of time.

The embedded profiler is configured so that it is always available but is not active by default so that it has no impact on the performance of the running server. Even when it is running, it has a relatively small impact on performance, but it is recommended that it remain inactive when it is not needed. It can be controlled using the `dsconfig` tool or the Administrative Console by managing the "Profiler" configuration object in the "Plugin" object type, available at the standard object level. The `profile-action` property for this configuration object can have one of the following values:

- **start** – Indicates that the embedded profiler should start capturing data in the background.
- **stop** – Indicates that the embedded profiler should stop capturing data and write the information that it has collected to a `logs/profile{timestamp}` file.
- **cancel** – Indicates that the embedded profiler should stop capturing data and discard any information that it has collected.

Any profiling data that has been captured can be examined using the `profiler-viewer` tool. This tool can operate in either a text-based mode, in which case it dumps a formatted text representation of the profile data to standard output, or it can be used in a graphical mode that allows the information to be more easily understood.

### Invoking the profile viewer in text-based mode

#### Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option.  
Example:

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z
```

## Invoking the profile viewer in GUI mode

### Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option. To invoke GUI mode, add the option `--useGUI`.

Example:

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z --useGUI
```

## Oracle Berkeley DB Java Edition utilities

The Oracle Berkeley DB Java Edition (JE) itself provides a number of utilities that can be used for performing various types of low-level debugging in the database environment. These utilities should generally not be used unless you are advised to do so by your authorized support provider, but they provide access to information about the underlying database environment that is not available through any other means.

## Troubleshooting resources for Java applications

Because the PingDirectory Server is written entirely in Java, it is possible to use standard Java debugging and instrumentation tools when troubleshooting problems with the Directory Server. In many cases, obtaining the full benefit of these tools requires access to the Directory Server source code. These Java tools should be used under the advisement of your authorized support provider.

### Java troubleshooting tools

The Java Development Kit provides a number of very useful tools to obtain information about Java applications and diagnosing problems. These tools are not included with the Java Runtime Environment (JRE), so the full Java Development Environment (JDK) should always be installed and used to run the PingDirectory Server.

#### jps

The `jps` tool is a Java-specific version of the UNIX `ps` tool. It can be used to obtain a list of all Java processes currently running and their respective process identifiers. When invoked by a non-root user, it will list only Java processes running as that user. When invoked by a root user, then it lists all Java processes on the system.

This tool can be used to see if the Directory Server is running and if a process ID has been assigned to it. This process ID can be used in conjunction with other tools to perform further analysis.

This tool can be run without any arguments, but some of the more useful arguments that include:

- `-v` – Includes the arguments passed to the JVM for the processes that are listed.
- `-m` – Includes the arguments passed to the main method for the processes that are listed.
- `-l` – (lowercase L). Include the fully qualified name for the main class rather than only the base class name.

#### jstack

The `jstack` tool is used to obtain a stack trace of a running Java process, or optionally from a core file generated if the JVM happens to crash. A stack trace can be extremely valuable when trying to debug a problem, because it provides information about all threads running and exactly what each is doing at the point in time that the stack trace was obtained.

Stack traces are helpful when diagnosing problems in which the server appears to be hung or behaving slowly. Java stack traces are generally more helpful than native stack traces, because Java threads can have user-friendly names (as do the threads used by the PingDirectory Server), and the frame of the stack trace may include the line number of the source file to which it corresponds. This is useful when diagnosing problems and often allows them to be identified and resolved quickly.

To obtain a stack trace from a running JVM, use the command:

```
jstack {processID}
```

where {processID} is the process ID of the target JVM as returned by the `jps` command. To obtain a stack trace from a core file from a Java process, use the command:

```
jstack {pathToJava} {pathToCore}
```

where {pathToJava} is the path to the java command from which the core file was created, and {pathToCore} is the path to the core file to examine. In either case, the stack trace is written to standard output and includes the names and call stacks for each of the threads that were active in the JVM.

In many cases, no additional options are necessary. The `-l` option can be added to obtain a long listing, which includes additional information about locks owned by the threads. The `-m` option can be used to include native frames in the stack trace.

### jmap

The `jmap` tool is used to obtain information about the memory consumed by the JVM. It is very similar to the native `pmap` tool provided by many operating systems. As with the `jstack` tool, `jmap` can be invoked against a running Java process by providing the process ID, or against a core file, like:

```
jmap {processID}
jmap {pathToJava} {pathToCore}
```

Some of the additional arguments include:

- **-dump:live,format=b,file=filename** – Dump the live heap data to a file that can be examined by the `jhat` tool
- **-heap** – Provides a summary of the memory used in the Java heap, along with information about the garbage collection algorithm in use.
- **-histo:live** – Provides a count of the number of objects of each type contained in the heap. If the `:live` portion is included, then only live objects are included; otherwise, the count include objects that are no longer in use and are garbage collected.

### jhat

The `jhat` (Java Heap Analysis Tool) utility provides the ability to analyze the contents of the Java heap. It can be used to analyze a heap dump file, which is generated if the Directory Server encounters an out of memory error (as a result of the `-XX:+HeapDumpOnOutOfMemoryError` JVM option) or from the use of the `jmap` command with the `-dump` option.

The `jhat` tool acts as a web server that can be accessed by a browser in order to query the contents of the heap. Several predefined queries are available to help determine the types of objects consuming significant amounts of heap space, and it also provides a custom query language (OQL, the Object Query Language) for performing more advanced types of analysis.

The `jhat` tool can be launched with the path to the heap dump file, like:

```
jhat /path/to/heap.dump
```

This command causes the `jhat` web server to begin listening on port 7000. It can be accessed in a browser at `http://localhost:7000` (or `http://address:7000` from a remote system). An alternate port number can be specified using the `-port` option, like:

```
jhat -port 1234 /path/to/heap.dump
```

To issue custom OQL searches, access the web interface using the URL `http://localhost:7000/oql/` (the trailing slash must be provided). Additional information about the OQL syntax may be obtained in the web interface at `http://localhost:7000/oqlhelp/`.

## jstat

The `jstat` tool is used to obtain a variety of statistical information from the JVM, much like the `vmstat` utility that can be used to obtain CPU utilization information from the operating system. The general manner to invoke it is as follows:

```
jstat {type} {processID} {interval}
```

The `{interval}` option specifies the length of time in milliseconds between lines of output. The `{processID}` option specifies the process ID of the JVM used to run the Directory Server, which can be obtained by running `jps` as mentioned previously. The `{type}` option specifies the type of output that should be provided. Some of the most useful types include:

- **-class** – Provides information about class loading and unloading.
- **-compile** – Provides information about the activity of the JIT complex.
- **-printcompilation** – Provides information about JIT method compilation.
- **-gc** – Provides information about the activity of the garbage collector.
- **-gccapacity** – Provides information about memory region capacities.

## Java diagnostic information

In addition to the tools listed in the previous section, the JVM can provide additional diagnostic information in response to certain events.

### JVM crash diagnostic information

If the JVM itself should happen to crash for some reason, then it generates a fatal error log with information about the state of the JVM at the time of the crash. By default, this file is named `hs_err_pid{processID}.log` and is written into the base directory of the Directory Server installation. This file includes information on the underlying cause of the JVM crash, information about the threads running and Java heap at the time of the crash, the options provided to the JVM, environment variables that were set, and information about the underlying system.

## Troubleshooting resources in the operating system

The underlying operating system also provides a significant amount of information that can help diagnose issues that impact the performance and the stability of the Directory Server. In some cases, problems with the underlying system can be directly responsible for the issues seen with the Directory Server, and in others system, tools can help narrow down the cause of the problem.

### Identifying problems with the underlying system

If the underlying system itself is experiencing problems, it can adversely impact the function of applications running on it. To look for problems in the underlying system view the system log file (`/var/log/messages` on Linux). Information about faulted or degraded devices or other unusual system conditions are written there.

### Examining CPU utilization

Observing CPU utilization for the Directory Server process and the system as a whole provides clues as to the nature of the problem.

#### *System-Wide CPU utilization*

To investigate CPU consumption of the system as a whole, use the `vmstat` command with a time interval in seconds, like:

```
vmstat 5
```

The specific output of this command varies between different operating systems, but it includes the percentage of the time the CPU was spent executing user-space code (user time), the percentage of time spent executing kernel-space code (system time), and the percentage of time not executing any code (idle time).

If the CPUs are spending most of their time executing user-space code, the available processors are being well-utilized. If performance is poor or the server is unresponsive, it can indicate that the Directory Server is not optimally tuned. If there is a high system time, it can indicate that the system is performing excessive disk and/or network I/O, or in some cases, there can be some other system-wide problem like an interrupt storm. If the system is mostly idle but the Directory Server is performing poorly or is unresponsive, there can be a resource constraint elsewhere (for example, waiting on disk or memory access, or excessive lock contention), or the JVM can be performing other tasks like stop-the-world garbage collection that cannot be run heavily in parallel.

#### *Per-CPU utilization*

To investigate CPU consumption on a per-CPU basis, use the `mpstat` command with a time interval in seconds, like:

```
mpstat 5
```

On Linux systems, it might be necessary to add `"-P ALL"` to the command, like:

```
mpstat -P ALL 5
```

Among other things, this shows the percentage of time each CPU has spent in user time, system time, and idle time. If the overall CPU utilization is relatively low but `mpstat` reports that one CPU has a much higher utilization than the others, there might be a significant bottleneck within the server or the JVM might be performing certain types of garbage collection which cannot be run in parallel. On the other hand, if CPU utilization is relatively even across all CPUs, there is likely no such bottleneck and the issue might be elsewhere.

#### *Per-process utilization*

To investigate CPU consumption on a per-process basis, use a command such as the `top`. Directory Server is consuming a significant amount of available CPU, it might be interfering with the ability of the Directory Server to run effectively.

### **Examining disk utilization**

If the underlying system has a very high disk utilization, it can adversely impact Directory Server performance. It could delay the ability to read or write database files or write log files. It could also raise concerns for server stability if excessive disk I/O inhibits the ability of the cleaner threads to keep the database size under control.

The `iostat` tool may be used to obtain information about the disk activity on the system.

On Linux systems, `iostat` should be invoked with the `"-x"` argument, like:

```
iostat -x 5
```

A number of different types of information will be displayed, but to obtain an initial feel for how busy the underlying disks are, look at the `"%util"` column on Linux. This field shows the percentage of the time that the underlying disks are actively servicing I/O requests. A system with a high disk utilization likely exhibits poor Directory Server performance.

If the high disk utilization is on one or more disks that are used to provide swap space for the system, the system might not have enough free memory to process requests. As a result, it might have started swapping blocks of memory that have not been used recently to disk. This can cause very poor server performance. It is important to ensure that the server is configured appropriately to avoid this condition. If this problem occurs on a regular basis, then the server is likely configured to use too much memory. If swapping is not normally a problem but it does arise, then check to see if there are any other processes running, which are consuming a significant amount of memory, and check for other potential causes of significant memory consumption (for example, large files in a `tmpfs` file system).

### **Examining process details**

There are a number of tools provided by the operating system that can help examine a process in detail.

### *ps*

The standard `ps` tool can be used to provide a range of information about a particular process. For example, the command can be used to display the state of the process, the name of the user running the process, its process ID and parent process ID, the priority and nice value, resident and virtual memory sizes, the start time, the execution time, and the process name with arguments:

```
ps -fly -p {processID}
```

Note that for a process with a large number of arguments, the standard `ps` command displays only a limited set of the arguments based on available space in the terminal window.

### *pstack*

The `pstack` command can be used to obtain a native stack trace of all threads in a process. While a native stack trace might not be as user-friendly as a Java stack trace obtained using `jstack`, it includes threads that are not available in a Java stack trace. For example, the command displays those threads used to perform garbage collection and other housekeeping tasks. The general usage for the `pstack` command is:

```
pstack {processID}
```

### *dbx / gdb*

A process debugger provides the ability to examine a process in detail. Like `pstack`, a debugger can obtain a stack trace for all threads in the process, but it also provides the ability to examine a process (or core file) in much greater detail, including observing the contents of memory at a specified address and the values of CPU registers in different frames of execution. The GNU debugger `gdb` is widely-used on Linux systems.

Note that using a debugger against a live process interrupts that process and suspends its execution until it detaches from the process. In addition, when running against a live process, a debugger has the ability to actually alter the contents of the memory associated with that process, which can have adverse effects. As a result, it is recommended that the use of a process debugger be restricted to core files and only used to examine live processes under the direction of your authorized support provider.

### *pfiles / lsof*

To examine the set of files that a process is using (including special types of files, like sockets), you can use a tool such as `lsof` on Linux systems, (

```
lsof -p {processID}
```

)

### **Tracing process execution**

If a process is unresponsive but is consuming a nontrivial amount of CPU time, or if a process is consuming significantly more CPU time than is expected, it might be useful to examine the activity of that process in more detail than can be obtained using a point-in-time snapshot. For example, if a process is performing a significant amount of disk reads and/or writes, it can be useful to see which files are being accessed. Similarly, if a process is consistently exiting abnormally, then beginning tracing for that process just before it exits can help provide additional information that cannot be captured in a core file (and if the process is exiting rather than being terminated for an illegal operation, then no core file may be available).

This can be accomplished using the `strace` tool on Linux (

```
strace -f -p {processID}
```

).

Consult the `strace` manual page for additional information.

## Problems with SSL communication

Enable TLS debugging in the server to troubleshoot SSL communication issues:

```
$ dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name
com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
  --set debug-level:verbose \
  --set include-throwable-cause:true
```

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true \
  --set default-debug-level:disabled
```

In the `java.properties` file, add `-Djavax.net.debug=ssl` to the `start-server` line, and run `bin/dsjavaproperties` to make the option take effect on a scheduled server restart.

## Examining network communication

Because the PingDirectory Server is a network-based application, it can be valuable to observe the network communication that it has with clients. The Directory Server itself can provide details about its interaction with clients by enabling debugging for the protocol or data debug categories, but there may be a number of cases in which it is useful to view information at a much lower level. A network sniffer, like the `tcpdump` tool on Linux, can be used to accomplish this.

There are many options that can be used with these tools, and their corresponding manual pages will provide a more thorough explanation of their use. However, to perform basic tracing to show the full details of the packets received for communication on port 389 with remote host 1.2.3.4, the following command can be used on Linux:

```
tcpdump -i {interface} -n -XX -s 0 host 1.2.3.4 and port 389
```

It does not appear that the `tcpdump` tool provides support for LDAP parsing. However, it is possible to write capture data to a file rather than displaying information on the terminal (using `-w {path}` with `tcpdump`), so that information can be later analyzed with a graphical tool like Wireshark, which provides the ability to interpret LDAP communication on any port.

Note that enabling network tracing generally requires privileges that are not available to normal users and therefore may require root access.

## Common problems and potential solutions

This section describes a number of different types of problems that can occur and common potential causes for them.

### General troubleshooting methodology

When a problem is detected, Ping Identity recommends using the following general methodology to isolate the problem:

1. Run the `bin/status` tool or look at the server status in the Administrative Console. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts.
2. Look in the server logs. In particular, view the following logs:
  - `logs/errors`
  - `logs/failed-ops`
  - `logs/expensive-ops`
3. Use system commands, such as `vmstat` and `iostat` to determine if the server is bottle-necked on a system resource like CPU or disk throughput.

4. For performance problem (especially intermittent ones like spikes in response time), enabling the `periodic-stats-logger` can help to isolate problems, because it stores important server performance information on a per-second basis. The `periodic-stats-logger` can save the information in a csv-formatted file that can be loaded into a spreadsheet. The information this logger makes available is very configurable. You can create multiple loggers for different types of information or a different frequency of logging (for example, hourly data in addition to per-second data). For more information, see "Profiling Server Performance Using the Periodic Stats Logger".
5. For replication problem, run `dsreplication status` and look at the `logs/replication` file.
6. For more advanced users, run the `collect-support-data` tool on the system, unzip the archive somewhere, and look through the collected information. This is often useful when administrators most familiar with the PingData Platform do not have direct access to the systems where the production servers are running. They can examine the `collect-support-data` archive on a different server. For more information, see Using the Collect Support Data Tool.

#### Important:

Run the `collect-support-data` tool whenever there is a problem whose cause is not easily identified, so that this information can be passed back to your authorized support provider before corrective action can be taken.

### The Server will not run setup

If the `setup` tool does not run properly, some of the most common reasons include the following:

#### *A suitable Java environment is not available*

The PingDirectory Server requires that Java be installed on the system and made available to the server, and it must be installed prior to running `setup`. If the `setup` tool does not detect that a suitable Java environment is available, it will refuse to run.

To ensure that this does not happen, the `setup` tool should be invoked with an explicitly-defined value for the `JAVA_HOME` environment variable that specifies the path to the Java installation that should be used. For example:

```
env JAVA_HOME=/ds/java ./setup
```

If this still does not work for some reason, then it can be that the value specified in the provided `JAVA_HOME` environment variable can be overridden by another environment variable. If that occurs, try the following command, which should override any other environment variables that can be set:

```
env UNBOUNDID_JAVA_HOME="/ds/java" UNBOUNDID_JAVA_BIN="" ./setup
```

#### *Oracle Berkeley DB Java Edition is not available*

If the version of the Directory Server that you are using was not provided with the Oracle Berkeley DB Java Edition library, then it must be manually downloaded and the appropriate JAR file placed in the `lib` directory before running `setup`. See the `lib/downloading-je.txt` file for instructions on obtaining the appropriate library.

#### *Unexpected arguments provided to the JVM*

If the `setup` script attempts to launch the `java` command with an invalid set of Java arguments, it might prevent the JVM from starting. By default, no special options are provided to the JVM when running `setup`, but this might not be the case if either the `JAVA_ARGS` or `UNBOUNDID_JAVA_ARGS` environment variable is set. If the `setup` tool displays an error message that indicates that the Java environment could not be started with the provided set of arguments, then invoke the following command before trying to re-run `setup`:

```
unset JAVA_ARGS UNBOUNDID_JAVA_ARGS
```

*The Server has already been configured or used*

The **setup** tool is only intended to provide the initial configuration for the Directory Server. It refuses to run if it detects that the **setup** tool has already been run, or if an attempt has been made to start the Directory Server prior to running the **setup** tool. This protects an existing Directory Server installation from being inadvertently updated in a manner that could harm an existing configuration or data set.

If the Directory Server has been previously used and if you want to perform a fresh installation, it is recommended that you first remove the existing installation, create a new one and run **setup** in that new installation. However, if you are confident that there is nothing of value in the existing installation (for example, if a previous attempt to run **setup** failed to complete successfully for some reason but it will refuse to run again), the following steps can be used to allow the **setup** program to run:

- Remove the `config/config.ldif` file and replace it with the `config/update/config.ldif.{revision}` file containing the initial configuration.
- If there are any files or subdirectories below the `db` directory, then remove them.
- If a `config/java.properties` file exists, then remove it.
- If a `lib/setup-java-home` script (or file on Microsoft Windows) exists, then remove it.

**The Server will not start**

If the Directory Server does not start, then there are a number of potential causes.

*The Server or other administrative tool is already running*

Only a single instance of the Directory Server can run at any time from the same installation root. If an instance is already running, then subsequent attempts to start the server will fail. Similarly, some other administrative operations can also prevent the server from being started. In such cases, the attempt to start the server should fail with a message like:

```
The Directory Server could not acquire an exclusive lock on file
/ds/PingDirectory/locks/server.lock: The exclusive lock requested for file
/ds/PingDirectory/locks/ server.lock was not granted, which indicates
that another process already holds a shared or exclusive lock on that
file. This generally means that another instance of this server is already
running
```

If the Directory Server is not running (and is not in the process of starting up or shutting down) and there are no other tools running that could prevent the server from being started, and the server still believes that it is running, then it is possible that a previously-held lock was not properly released. In that case, you can try removing all of the files in the `locks` directory before attempting to start the server.

If you wish to have multiple instances running at the same time on the same system, then you should create a completely separate installation in another location on the file system.

*There is not enough memory available*

When the Directory Server is started, the JVM attempts to allocate all memory that it has been configured to use. If there is not enough free memory available on the system, then the Directory Server generates an error message that indicates that the server could not be started with the specified set of arguments. Note that it is possible that an invalid option was provided to the JVM (as described below), but if that same set of JVM arguments has already been used successfully to run the server, then it is more likely that the system does not have enough memory available.

There are a number of potential causes for this:

- If the amount of memory in the underlying system has changed (for example, system memory has been removed, or if the Directory Server is running in a zone or other type of virtualized container and a change has been made to the amount of memory that container will be allowed to use), then the Directory Server might need to be re-configured to use a smaller amount of memory than had been previously configured.
- Another process running on the system is consuming a significant amount of memory so that there is not enough free memory available to start the server. If this is the case, then either terminate the other

process to make more memory available for the Directory Server, or reconfigure the Directory Server to reduce the amount of memory that it attempts to use.

- The Directory Server was just shut down and an attempt was made to immediately restart it. In some cases, if the server is configured to use a significant amount of memory, then it can take a few seconds for all of the memory that had been in use by the server, when it was previously running, to be released back to the operating system. In that case, run the `vmstat` command and wait until the amount of free memory stops growing before attempting to restart the server.
- If the system is configured with one or more memory-backed file systems, verify whether any large files might be consuming a significant amount of memory in any of those locations. If so, remove them or relocate them to a disk-based file system.
- For Linux systems only, if a mismatch exists between the huge pages setting for the JVM and the huge pages reserved in the operating system.

If nothing else works and there is still not enough free memory to allow the JVM to start, then as a last resort, try rebooting the system.

#### *An invalid Java Environment or JVM option was used*

If an attempt to start the Directory Server fails with an error message indicating that no valid Java environment could be found, or indicates that the Java environment could not be started with the configured set of options, then you should first ensure that enough memory is available on the system as described above. If there is a sufficient amount of memory available, then other causes for this error can include the following:

- The Java installation that was previously used to run the server no longer exists (for example, an updated Java environment was installed and the old installation was removed). In that case, update the `config/java.properties` file to reference to path to the new Java installation and run the `bin/dsjavaproperties` command to apply that change.
- The Java installation used to run the server has been updated and the server is trying to use the correct Java installation but one or more of the options that had worked with the previous Java version no longer work with the new version. In that case, it is recommended that the server be re-configured to use the previous Java version, so that it can be run while investigating which options should be used with the new installation.
- If an `UNBOUNDID_JAVA_HOME` or `UNBOUNDID_JAVA_BIN` environment variable is set, then its value may override the path to the Java installation used to run the server as defined in the `config/java.properties` file. Similarly, if an `UNBOUNDID_JAVA_ARGS` environment variable is set, then its value might override the arguments provided to the JVM. If this is the case, then explicitly unset the `UNBOUNDID_JAVA_HOME`, `UNBOUNDID_JAVA_BIN`, and `UNBOUNDID_JAVA_ARGS` environment variables before trying to start the server.

Note that any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration. If a problem with the previous Java configuration prevents the `bin/dsjavaproperties` tool from running properly, then it can be necessary to remove the `lib/set-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) and invoke the `bin/dsjavaproperties` tool with an explicitly-defined path to the Java environment, like:

```
env UNBOUNDID_JAVA_HOME=/ds/java bin/dsjavaproperties
```

#### *An invalid command-line option was provided*

There are a small number of arguments that are provided when running the `bin/start-server` command, but in most cases, none are required. If one or more command-line arguments were provided for the `bin/start-server` command and any of them is not recognized, then the server provides an error message indicating that an argument was not recognized and displays version information. In that case, correct or remove the invalid argument and try to start the server again.

#### *The Server has an invalid configuration*

If a change is made to the Directory Server configuration using an officially-supported tool like `dsconfig` or the Administrative Console, the server should validate that configuration change before applying it.

However, it is possible that a configuration change can appear to be valid at the time that it is applied, but does not work as expected when the server is restarted. Alternately, a change in the underlying system can cause a previously-valid configuration to become invalid.

In most cases involving an invalid configuration, the Directory Server displays (and writes to the error log) a message that explains the problem, and this can be sufficient to identify the problem and understand what action needs to be taken to correct it. If for some reason the startup failure does not provide enough information to identify the problem with the configuration, then look in the `logs/config-audit.log` file to see what recent configuration changes have been made with the server online, or in the `config/archived-configs` directory to see if there might have been a recent configuration change resulting from a direct change to the configuration file itself that was not made through a supported configuration interface.

If the server does not start as a result of a recent invalid configuration change, then it can be possible to start the server using the configuration that was in place the last time that the server started successfully (for example, the "last known good" configuration). This can be achieved using the `--useLastKnownGoodConfig` option:

```
$ bin/start-server --useLastKnownGoodConfig
```

Note that if it has been a long time since the last time the server was started and a number of configuration changes have been made since that time, then the last known good configuration can be significantly out of date. In such cases, it can be preferable to manually repair the configuration.

If there is no last known good configuration, if the server no longer starts with the last known good configuration, or if the last known good configuration is significantly out of date, then manually update the configuration by editing the `config/config.ldif` file. In that case, you should make sure that the server is offline and that you have made a copy of the existing configuration before beginning. You might wish to discuss the change with your authorized support representative before applying it to ensure that you understand the correct change that needs to be made.

#### Note:

In addition to manually-editing the config file, you can look at previous archived configurations to see if the most recent one works. You can also use the `ldif-diff` tool to compare the configurations in the archive to the current configuration to see what is different.

*You do not have sufficient permissions*

The Directory Server should only be started by the user or role used to initially install the server. In most cases, if an attempt is made to start the server as a user or role other than the one used to create the initial configuration, then the server will fail to start, because the user will not have sufficient permissions to access files owned by the other user, such as database and log files. However, if the server was initially installed as a non-root user and then the server is started by the root account, then it can no longer be possible to start the server as a non-root user because new files that are created would be owned by root and could not be written by other users.

If the server was inadvertently started by root when it is intended to be run by a non-root user, or if you wish to change the user account that should be used to run the server, then it should be sufficient to simply change ownership on all files in the Directory Server installation, so that they are owned by the user or role under which the server should run. For example, if the Directory Server should be run as the "ds" user in the "other" group, then the following command can be used to accomplish this (invoked by the root user):

```
chown -R ds:other /ds/PingDirectory
```

#### The Server has crashed or shut itself down

You can first check the current server state by using the `bin/server-state` command. If the Directory Server was previously running but is no longer active, then the potential reasons include the following:

- The Directory Server was shut down by an administrator. Unless the server was forcefully terminated (for example, using “kill -9”), then messages are written to the `error` and `server.out` logs explaining the reason for the shutdown.
- The Directory Server was shut down when the underlying system crashed or was rebooted. If this is the case, then running the `uptime` command on the underlying system shows that it was recently booted.
- The Directory Server process was terminated by the underlying operating system for some reason (for example, the out of memory killer on Linux). If this happens, then a message will be written to the system error log.
- The Directory Server decided to shut itself down in response to a serious problem that had arisen. At present, this should only occur if the server has detected that the amount of usable disk space has become critically low, or if significant errors have been encountered during processing that left the server without any remaining worker threads to process operations. If this happens, then messages are written to the `error` and `server.out` logs (if disk space is available) to provide the reason for the shutdown.
- The JVM in which the Directory Server was running crashed. If this happens, then the JVM should dump a fatal error log (a `hs_err_pid{processID}.log` file) and potentially a core file.

In the event that the operating system itself crashed or terminated the process, then you should work with your operating system vendor to diagnose the underlying problem. If the JVM crashed or the server shut itself down for a reason that is not clear, then contact your authorized support provider for further assistance.

### Conditions for automatic server shutdown

All PingDirectory Server servers will shutdown in an out of memory condition, a low disk space error state, or for running out of file descriptors. The Directory Server will enter lockdown mode on unrecoverable database environment errors, but can be configured to shutdown instead with this setting:

```
$ dsconfig set-global-configuration-prop \
    --set unrecoverable-database-error-mode:initiate-server-shutdown
```

### The Server will not accept client connections

You can first check the current server state by using the `bin/server-state` command. If the Directory Server does not appear to be accepting connections from clients, then potential reasons include the following:

- The Directory Server is not running.
- The underlying system on which the Directory Server is installed is not running.
- The Directory Server is running but is not reachable as a result of a network or firewall configuration problem. If that is the case, then connection attempts should time out rather than be rejected.
- If the Directory Server is configured to allow secure communication via SSL or StartTLS, then a problem with the key manager and/or trust manager configuration can cause connections to be rejected. If that is the case, then messages should be written to the server access log for each failed connection attempt.
- If the Directory Server has been configured with a maximum allowed number of connections, then it can be that the maximum number of allowed client connections are already established. If that is the case, then messages should be written to the server access log for each rejected connection attempt.
- If the Directory Server is configured to restrict access based on the address of the client, then messages should be written to the server access log for each rejected connection attempt.
- If a connection handler encounters a significant error, then it can stop listening for new requests. If this occurs, then a message should be written to the server error log with information about the problem. Another solution is to restart the server. A third option is to restart the connection handler using the LDIF connection handler to make it available again. To do this, create an LDIF file that disables and then re-enables the connection handler, create the `config/auto-process-ldif` directory if it does not already exist, and then copy the LDIF file into it.

## The Server is unresponsive

You can first check the current server state by using the `bin/server-state` command. If the Directory Server process is running and appears to be accepting connections but does not respond to requests received on those connections, then potential reasons for this behavior include:

- If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available. If this is the case, then a stack trace obtained using the `jstack` command shows that all of the worker threads are busy and none of them are waiting for new requests to process.

A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the `ldapsearch` command for example, use the `--useAdministrativeSession` option. The requester must have the `use-admin-session` privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

### Note:

If all of the worker threads are tied up processing the same operation for a long time, the server will also issue an alert that it might be deadlocked, which may not actually be the case. All threads might be tied up processing unindexed searches.

- If a request handler is stuck performing some expensive processing for a client connection, then other requests sent to the server on connections associated with that request handler is forced to wait until the request handler is able to read data on those connections. If this is the case, then only some of the connections can experience this behavior (unless there is only a single request handler, in which it will impact all connections), and stack traces obtained using the `jstack` command shows that a request handler thread is continuously blocked rather than waiting for new requests to arrive. Note that this scenario is a theoretical problem and one that has not appeared in production.
- If the JVM in which the Directory Server is running is not properly configured, then it can be forced to spend a significant length of time performing garbage collection, and in severe cases, could cause significant interruptions in the execution of Java code. In such cases, a stack trace obtained from a `pstack` of the native process should show that most threads are idle but at least one thread performing garbage collection is active. It is also likely that one or a small number of CPUs is 100% busy while all other CPUs are mostly idle. The server will also issue an alert after detecting a long JVM pause (due to garbage collection). The alert will include details of the pause.
- If the JVM in which the Directory Server is running has hung for some reason, then the `pstack` utility should show that one or more threads are blocked and unable to make progress. In such cases, the system CPUs should be mostly idle.
- If a network or firewall configuration problem arises, then attempts to communicate with the server cannot be received by the server. In that case, a network sniffer like `snoop` or `tcpdump` should show that packets sent to the system on which the Directory Server is running are not receiving TCP acknowledgement.
- If the system on which the Directory Server is running has become hung or lost power with a graceful shutdown, then the behavior is often similar to that of a network or firewall configuration problem.

If it appears that the problem is with the Directory Server software or the JVM in which it is running, then you need to work with your authorized support provider to fully diagnose the problem and determine the best course of action to correct it.

## The Server is slow to respond to client requests

If the Directory Server is running and does respond to clients, but clients take a long time to receive responses, then the problem can be attributable to a number of potential problems. In these cases, use the Periodic Stats Logger, which is a valuable tool to get per-second monitoring information on the Directory Server. The Periodic Stats Logger can save the information in csv format for easy viewing in a

spreadsheet. For more information, see "Profiling Server Performance Using the Periodic Stats Logger". The potential problems that cause slow responses to client requests are as follows:

- The server is not optimally configured for the type of requests being processed, or clients are requesting inefficient operations. If this is the case, then the access log should show that operations are taking a long time to complete and they will likely be unindexed. In that case, updating the server configuration to better suit the requests, or altering the requests to make them more efficient, could help alleviate the problem. In this case, view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second. You can also run the `bin/status` command or view the status in the Administrative Console to see the Directory Server's Work Queue information (also see the next bullet point).
- The server is overwhelmed with client requests and has amassed a large backlog of requests in the work queue. This can be the result of a configuration problem (for example, too few worker thread configured), or it can be necessary to provision more systems on which to run the Directory Server software. Symptoms of this problem appear similar to those experienced when the server is asked to process inefficient requests, but looking at the details of the requests in the access log show that they are not necessarily inefficient requests. Run the `bin/status` command to view the Work Queue information. If everything is performing well, you should not see a large queue size or a server that is near 100% busy. The %Busy statistic is calculated as the percentage of worker threads that are busy processing operations.

```

--- Work Queue ---
: Recent : Average : Maximum
-----:-----:-----:-----
Queue Size : 10   : 1     : 10
% Busy      : 17   : 14    : 100

```

You can also view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second.

- The server is not configured to fully cache all of the data in the server, or the cache is not yet primed. In this case, `iostat` reports a very high disk utilization. This can be resolved by configuring the server to fully cache all data, and to load database contents into memory on startup. If the underlying system does not have enough memory to fully cache the entire data set, then it might not be possible to achieve optimal performance for operations that need data which is not contained in the cache. For more information, see Disk-Bound Deployments.
- If the JVM is not properly configured, then it will need to perform frequent garbage collection and periodically pause execution of the Java code that it is running. In that case, the server error log should report that the server has detected a number of pauses and can include tuning recommendations to help alleviate the problem.
- If the Directory Server is configured to use a large percentage of the memory in the system, then it is possible that the system has gotten low on available memory and has begun swapping. In this case, `iostat` should report very high utilization for disks used to hold swap space, and commands like `cat /proc/meminfo` on Linux can report a large amount of swap memory in use. Another cause of swapping is if `swappiness` is not set to 0 on Linux. For more information, see Disable File System Swapping.
- If another process on the system is consuming a significant amount of CPU time, then it can adversely impact the ability of the Directory Server to process requests efficiently. Isolating the processes (for example, using processor sets) or separating them onto different systems can help eliminate this problem.

### The Server returns error responses to client requests

If a large number of client requests are receiving error responses, then view the `logs/failed-ops` log, which is an access log for only failed operations. The potential reasons for the error responses include the following:

- If clients are requesting operations that legitimately should fail (for example, they are targeting entries that do not exist, are attempting to update entries in a way that would violate the server schema, or are

performing some other type of inappropriate operation), then the problem is likely with the client and not the server.

- If a portion of the Directory Server data is unavailable (for example, because an online LDIF import or restore is in progress), then operations targeting that data will fail. Those problems will be resolved when the backend containing that data is brought back online. During the outage, it might be desirable to update proxies or load balancers or both to route requests away from the affected server. As of Directory Server version 3.1 or later, the Directory Server will indicate that it is in a degraded status and the Directory Proxy Server will route around it.
- If the Directory Server work queue is configured with a maximum capacity and that capacity has been reached, then the server begins rejecting all new requests until space is available in the work queue. In this case, it might be necessary to alter the server configuration or the client requests or both, so that they can be processed more efficiently, or it might be necessary to add additional server instances to handle some of the workload.
- If an internal error occurs within the server while processing a client request, then the server terminates the connection to the client and logs a message about the problem that occurred. This should not happen under normal circumstances, so you will need to work with your authorized support provider to diagnose and correct the problem.
- If a problem is encountered while interacting with the underlying database (for example, an attempt to read from or write to disk failed because of a disk problem or lack of available disk space), then it can begin returning errors for all attempts to interact with the database until the backend is closed and re-opened and the database has been given a change to recover itself. In these cases, the `je.info.*` file in the database directory should provide information about the nature of the problem.

### The Server must disconnect a client connection

If a client connection must be disconnected due to the expense of the client's request, such as an unindexed search across a very large database, perform the following:

- Find the client's connection ID by looking in the `cn=Active Operations,cn=monitor monitor` entry.

```
$ bin/ldapsearch -baseDN cn=monitor "cn=active operations" \
  --bindDN "cn=directory manager" \
  --bindPassword password
```

- The monitor entry will contain attribute values for `operation-in-progress`, which look like an access log message. Look for the value of `conn` in the client request that should be disconnected. In the following example, the client to be disconnected is requesting a search for `(description=expensive)`, which is on connection 6.

```
dn: cn=Active Operations,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-active-operations-monitor-entry
objectClass: extensibleObject
cn: Active Operations
num-operations-in-progress: 2
operation-in-progress: [15/Dec/2014:10:55:35 -0600] SEARCH conn=6 op=3
msgID=4
  clientIP="10.8.4.21"
  authDN="cn=apl,ou=applications,dc=example,dc=com" base="dc
    =example,dc=com" scope=wholeSubtree filter="(description=expensive)"
  attrs="A
    LL" unindexed=true
operation-in-progress: [15/Dec/2014:10:56:11 -0600] SEARCH conn=7 op=1
msgID=2
  clientIP="127.0.0.1" authDN="cn=Directory Manager,cn=Root
  DNs,cn=config" base="c
    n=monitor" scope=wholeSubtree filter="(cn=active operations)"
  attrs="ALL"
  num-persistent-searches-in-progress: 0
```

- With the connection ID value, create a file with the following contents, named **disconnect6.ldif**.

```
dn: ds-task-id=disconnect6,cn=scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-disconnect
ds-task-disconnect-connection-id: 6
ds-task-id: disconnect6
ds-task-class-name:
  com.unboundid.directory.server.tasks.DisconnectClientTask
```

- This LDIF file represents a task entry. The connection ID value 6 is assigned to **ds-task-disconnect-connection-id**. The value for **ds-task-id** value does not follow a specific convention. It must be unique among other task entries currently cached by the server.
- Disconnect the client and cancel the associated operation by adding the task entry to the server:

```
$ bin/ldapmodify --filename disconnect6.ldif \
  --defaultAdd --bindDN "cn=directory manager" \
  --bindPassword password
```

### The Server is experiencing problems with replication

If replication does not appear to be functioning properly, then first check the **dsreplication status** command, which shows all of the servers that are replicating and whether they are back-logged or not. Next, you can check the server error log, replication repair log, and replication monitor entries may provide information about the nature of the underlying problem. Potential reasons that replication may not be functioning as expected include the following:

- Replication has not yet been configured between systems or has been disabled.
- If a server has been offline for a period of time or has fallen far enough behind such that it is missing changes, which are no longer present in any of the replication databases, then that server must be re-initialized with an up-to-date copy of the data from another server.
- If the environment is comprised of a heterogeneous set of systems, then it is possible that some of the systems might not be able to keep up with the maximum throughput achieved by other servers in the topology. In such cases, the slower servers might not be fast enough to remain in sync with the other servers in the environment.
- If the environment contains systems in multiple data centers and the network links between the data centers are insufficient for the volume of changes that must be processed, then servers might not be able to remain in sync under a high volume of changes.
- A network or firewall configuration problem has arisen, which prevents or interferes with communication between servers.
- An internal problem within the server has caused replication to stop functioning properly. The Directory Server logs the event in the error log in this case. Run the **collect-support-data** tool, so that the details of the problems can be passed to your authorized support provider. Then, try restarting the Directory Server.

### How to regenerate the Server ads-certificate

At setup time, the server generates a private key and certificate for use when secure communication between servers is required. This certificate, **ads-certificate**, is stored in `config/ads-truststore` and should typically remain unchanged for the life of the server deployment. If the need arises for a new ads-certificate to be created, say because the server-root has been copied to a new host, then the private key and certificate will be recreated by the startup process if the `config/ads-truststore` and `config/ads-truststore.pin` files are first manually removed while the server is offline. Note that if replication is enabled, the server must have replication disabled before regeneration of the ads-certificate.

For example, the Directory Server allows easy copying of its installation, which can then be used to install another server instance. If a server (`ldap1.example.com:389`) is enabled with its own copy (`ldap2.example.com:389`), **dsreplication** will exit with the following error message:

Replication cannot be enabled between servers `ldap1.example.com:389` and `ldap2.example.com:389` because they are using the same instance key.

The solution is to stop the server, remove `config/adtruststore` and `config/adtruststore.pin` and re-start the server. Upon startup, a new `adtruststore`, containing the server's instance key, will be generated. Then, you can re-run `dsreplication enable` to set up replication between the two servers.

### The Server behaves differently from Sun/Oracle

After migrating from a Sun/Oracle configuration to a PingDirectory Server, follow the tuning procedures in [Sun/Oracle Compatibility](#) if the Directory Server behaves differently from the Sun/Oracle server.

### Troubleshooting ACI evaluation

The Directory Server provides the ability to collect debug information related to ACI evaluation for any operation by enabling the Debug ACI Logger. The Debug ACI Logger is highly configurable and can be scoped to trace very specific request operations in order to narrow on any ACI issue that may arise in the field. Parameters for non-request operations, such as `log-connects`, `log-disconnects`, `log-security-negotiation`, `log-results`, `log-assurance-completed`, `log-search-entries`, `log-search-references`, `log-intermediate-responses` are set to false by default and should remain so.

Here is an example to enable the Debug ACI Logger:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Debug ACI Logger" \
  --set enabled:true
```

Using this debug tracer is often more efficient by limiting the output using request and result criteria to match specific types of operations. An example result criteria for operations that fail due to insufficient access rights can be added to the logger as follows:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Debug ACI Logger" \
  --set "result-criteria:Insufficient Access Rights"
```

Once the logger is enabled, all matching operations begin writing ACI evaluation traces to the log file. The amount of information is quite large for each evaluation that is done. However, this information is useful if there is an ACI issue that is difficult to resolve. Most operations result in multiple "ACI DEBUG" traces in the log, since it usually requires multiple ACI rights to perform an operation, each of which requires a separate evaluation. In particular, you can expect a lot of debug tracing when dealing with ACIs for controls, extended operations, and proxied authorization.

The ACI DEBUG traces contain the following pieces of information:

- **Operation.** Specifies a dump of the operation object that you can use to correlate to the original request operation.
- **ACI Container.** Specifies the context of the ACI evaluation being performed.
  - **Client Entry.** Specifies an LDIF dump of the client request access.
  - **Resource Entry.** Specifies an LDIF dump of the target resource.
  - **isProxiedAuth.** Specifies if the client is attempting to proxy as another user.
  - **Original Auth.** Specifies the original client DN if authorization is currently via the proxy.
  - **Rights.** Specifies a list of the ACI rights being requested on the resource entry.
  - **Control.** Specifies the OIDs when evaluating ACIs for a control.
  - **ExtOp.** Specifies the OIDs when evaluating ACIs for an extended operation.
- **ACI Candidates.** Specifies a list of all the ACIs known to this operation, sorted by origin.
- **Applicable ACIs.** Specifies a list of ACIs relevant to the current evaluation. These ACIs are separated by type into "Denies" and "Allows".

- **Deny ACI Evaluations.** Specifies the results of evaluating each "deny" ACI. If any of these evaluate to TRUE, then the operation will be denied.
- **Allow ACI Evaluations.** Specifies the results of evaluating each "allow" ACI. At least one of these must evaluate to "TRUE" or the operation will be denied.

For users with the `bypass-acl` privilege, the Debug ACI Logger will not provide any ACI debug tracing since evaluations are not done for those operations. However, you will see the following trace if you have ACI debugging enabled (`debug-aci-enabled` is set to TRUE) for those operations:

```
Bypassing ACL Evaluation for Operation
```

To avoid unnecessary tracing of these operations, the "Debug ACI Logger" uses a "Client Connection Criteria" called "Clients subject to Access Control" that excludes requests from users with the `bypass-acl` privilege. It is recommended that you create and use your own criteria which specifically targets the clients that you are trying to debug in order to make analyzing the tracing output easier.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Restricted Clients" \
  --type simple \
  --set none-included-user-privilege:bypass-acl
```

#### Note:

Do not use Result Criteria with the Debug ACI Logger. Result criteria is evaluated after ACIs, so it will not be taken into consideration for this type of debugging.

### Problems with the Administrative Console

If a problem arises when trying to use the Administrative Console, then potential reasons for the problem may include the following:

- The web application container used to host the console is not running. If an error occurs while trying to start it, then consult the logs for the web application container.
- If a problem occurs while trying to authenticate to the web application container, then make sure that the target Directory Server is online. If it is online, then the access log may provide information about the reasons for the authentication failure.
- If a problem occurs while attempting to interact with the Directory Proxy Server instance using the Administrative Console, then the access and error logs for that Directory Server instance might provide additional information about the underlying problem.

### Problems with the Administrative Console: JVM memory issues

**Console runs out of memory (PermGen).** An inadequate PermSize setting in the server, while hosting web applications like the Administrative Console may result in errors like this in the error log:

```
[02/Mar/2016:07:50:27.017 -0600] threadID=2 category=UTIL
severity=SEVERE_ERROR msgID=-1 msg="The server experienced an unexpected
error. Please report this problem and include this log file.
OutOfMemoryError: PermGen space
() \ncom.unboundid.directory.server.core.DirectoryServer.uncaughtException
(DirectoryServer.java:15783) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1057) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1052) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1052) \njava.lang.Thread.dispatchUncaughtException
(Thread.java:1986) \nBuild revision: 22496\n"
```

This is only relevant for servers running Java 7.

### Problems with the HTTP Connection Handler

When problems with the HTTP Connection Handler occur, first look at the HTTP connection handler log to diagnose the issue. The following section shows HTTP log examples when various errors occur.

- **Failed Request Due to a Non-Existent Resource.** The server receives a status code 404, which indicates the server could not match the URI.

```
[15/Mar/2012:17:39:39 -0500] RESULT requestID=0 from="10.2.1.113:52958"
method="GET" url="https://10.2.1.113:443/Aleph/Users/uid=user.1,ou=people,
dc=example,dc=com" requestHeader="Host: x2270-11.example.lab"
requestHeader="Accept: */*" requestHeader="User-Agent: curl/7.21.6
(i386-pc-centos2.10) libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.2.2
libssh2/1.2.7" authorizationType="Basic" statusCode=404 etime=81.484
responseContentLength=103 responseHeader="Access-Control-Allow-
Credentials:true"
responseContentType="application/json"
```

- **Failed Request due to a Malformed Request Body.** The server receives a status code 400, which indicates that the request had a malformed syntax in its request body.

```
[15/Mar/2012:17:47:23-0500] RESULT requestID=10 from="10.2.1.113:55284"
method="POST" url="https://10.2.1.113:443/Aleph/Users" requestHeader="Host:
x2270-11.example.lab" requestHeader="Expect: 100-continue"
requestHeader="Accept: */*" requestHeader="Content-Type: application/json"
requestHeader="User-Agent: curl/ 7.21.6 (i386-pc-centos2.10) libcurl/7.21.6
OpenSSL/1.0.0d zlib/1.2.5 libidn/1.2.2 libssh2/1.2.7"
authorizationType="Basic"
requestContentType="application/json" requestContentLength=5564
statusCode=400
etime=15.272 responseContentLength=133 responseContentType="application/
json"
```

- **Failed Request due to an unsupported HTTP method.** The server receives a status code 405, which indicates that the specified method (e.g., "PATCH") in the request line is not allowed for the resource identified in the URI.

```
[15/Mar/2012:17:48:59-0500] RESULT requestID=11 from="10.2.1.113:55763"
method="PATCH" url="https://10.2.1.113:443/Aleph/Users"
requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: */*" requestHeader="Content-
Type:
application/json" requestHeader="User-Agent: curl/7.21.6 (i386-pc-
centos2.10)
libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.2.2 libssh2/1.2.7"
authorizationType="Basic" requestContentType="application/json"
statusCode=405
etime=6.807 responseContentLength=0 responseHeader="Allow: POST, GET,
OPTIONS, HEAD"
```

- **Failed Request due to an Unsupported Media Type.** The server receives a status code 415, which indicates that the request entity is in a format that is not supported by the requested resource.

```
[15/Mar/2012:17:44:45-0500] RESULT requestID=4 from="10.2.1.113:54493"
method="POST" url="https://10.2.1.113:443/Aleph/Users"
requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: */*" requestHeader="Content-
Type:
application/atom+xml" requestHeader="User-Agent: curl/7.21.6 (i386-pc-
centos2.10)
libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.2.2 libssh2/1.2.7"
authorizationType="Basic" requestContentType="application/atom+xml"
requestContentLength=3 statusCode=415 etime=6.222
responseContentLength=1402
responseHeader="Cache-Control: must-revalidate,no-cache,no-store"
responseContentType="text/html; charset=ISO-8859-1"
```

- **Failed Request due to an Authentication Error.** The server receives a status code 401, which indicates that the request requires user authentication.

```
[15/Mar/2012:17:46:06-0500] RESULT requestID=8 from="10.2.1.113:54899"
method="GET" url="https://10.2.1.113:443/Aleph/Schemas"
requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: */*" requestHeader="User-
Agent:
curl/7.21.6 (i386-pc-centos2.10) libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5
libidn/1.22 libssh2/ 1.2.7" authorizationType="Basic" statusCode=401
etime=2.751 responseContentLength=63 responseHeader="WWW-Authenticate:
Basic
realm=SCIM" responseHeader="Access-Control-Allow-Credentials: true"
responseContentType="application/json"
```

### Virtual process size on RHEL6 Linux is much larger than the heap

Red Hat Linux introduced a change in glib 2.11 that creates larger per-thread address spaces aligned at 64MB. This change results in a virtual process size much larger than those seen in previous versions of `glibc`. This is not considered a bug by RedHat, as noted in [https://bugzilla.redhat.com/show\\_bug.cgi?id=640286](https://bugzilla.redhat.com/show_bug.cgi?id=640286), and does not affect the physical memory needed by the server process. To see the version of `glibc` on your system, use the command `yum info glibc`.

### Providing information for support cases

If a problem arises that you are unable to fully diagnose and correct on your own, then contact your authorized support provider for assistance. To ensure that the problem can be addressed as quickly as possible, be sure to provide all of the information that the support personnel may need to fully understand the underlying cause by running the `collect-support-data` tool, and then sending the generated zip file to your authorized support provider. It is good practice to run this tool and send the ZIP file to your authorized support provider before any corrective action has taken place.

## Command-Line Tools

---

The PingDirectory Server provides a full suite of command-line tools necessary to administer the server. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

### Available command-line tools

PingDirectory provides the following command-line tools, which you can run in interactive, non-interactive, or script mode.

#### Tools Help

For	Use this option	Example
Information about arguments and subcommands Usage examples	<code>--help</code>	<code>dsconfig --help</code>
A list of subcommands	<code>--help-subcommands</code>	<code>dsconfig --help-subcommands</code>
More information about a subcommand	<code>--help</code> with the subcommand	<code>dsconfig list-log-publishers --help</code>

**Note:**

For detailed information and examples of the command-line tools, see the *Ping Identity Directory Server Command-Line Tool Reference*.

**Command-Line Tools**

audit-data-security	<p>Invoke data security audit processing in order to identify potential risks or other notable security characteristics contained in directory data.</p> <p>This tool schedules an internal task with the server that examines all or a subset of entries in the server, writing a series of reports on potential risks with the data. Reports are written to the output directory organized by backend name and audit items. The list of available auditors can be obtained using <code>dsconfig list-data-security-auditors --advanced --property name</code>. Either the <code>--includeAuditor</code> or the <code>--excludeAuditor</code> arguments may be used to limit the scope of the audit.</p> <p>Additionally, the entries scanned can be limited by specifying the backends to scan, or by specifying an LDAP filter that is used to selected entries to be processed.</p> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
authrate	<p>Perform repeated authentications against Directory Server, where each authentication consists of a search to find a user followed by a bind to verify the credentials for that user.</p>
backup	<p>Back up one or more directory server backends.</p> <p>Each backend backup is stored in a separate backend backup directory. A backend backup directory may contain multiple backups of the backend. Each backend backup directory contains a <code>backup.info</code> file providing information about each backup in the directory and an archive file for each backup. The name of the archive file includes both the backend ID and the backup ID. The backup ID may be provided to the backup command, or an ID is generated from a current timestamp.</p> <p>Backups may be full or incremental. The archive file for incremental backups contains the incremental changes since a previous backup. Each backup can be optionally compressed, encrypted, hashed or signed. A backup taken on one system can be restored on another system.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the directory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
base64	<p>Encode raw data using the base64 algorithm or decode base64-encoded data back to its raw representation.</p>

collect-support-data	<p>Collect and package system information useful in troubleshooting problems. The information is packaged as a zip archive that can be sent to a technical support representative.</p> <p>Information collected may include configuration files, server monitor entries, portions of log files, JVM thread stack dumps, system metrics, and other data that may be helpful in diagnosing problems, understanding server performance, or otherwise assisting with support requests. Although the tool will do its best to obscure or omit sensitive data, and the entire archive may be encrypted if you desire, you may wish to review the resulting support data archive to ensure verify its contents. Further, the archive will include a summary of any potential problems or concerns that are identified in the course of collecting the support data.</p>
config-diff	<p>Compares Directory Server configurations and produces a <code>dsconfig</code> batch file needed to bring the source inline with the target.</p> <p>Its uses include comparing multiple servers for configuration differences, producing a batch file to reconfigure a server from scratch from the out-of-the-box configuration, and comparing a local server against an expected configuration.</p> <p>Both the source and the target configurations can be retrieved over LDAP, accessed from the local server's file system, extracted from a specific file, or retrieved from every server in a configuration server group. Also, with the exception of accessing a configuration from a specific file, the source and/or target configurations can be compared as they existed at any point in the past, including the baseline, pre-installation configuration.</p> <p>Some configuration differences (those that will always differ between instances, like instance-name) are excluded by default to reduce the amount of spurious output, but these can be included by specifying the <code>--includeExpectedDifferences</code> command. Further differences can be excluded with the <code>--exclude</code> option.</p> <p>This tool attempts to generate a batch file that can be applied to the source server without any errors. However, there are some edge case configurations that the tool is not sophisticated enough to handle. For example, it cannot handle two peer configuration objects that would require swapping values for a property (for example, evaluation-order-index) that must be unique within the server. It will still generate a <code>dsconfig</code> batch file that includes these changes, but they might be rejected by the server. In these rare cases, the batch file can be hand edited so that it can be applied to a running server or it can be applied with the server shut down using <code>dsconfig --offline</code>.</p>
create-rc-script	<p>Create a Run Control (RC) script that you can use to start, stop, and restart the Directory Server on UNIX-based systems.</p>

create-systemd-script	<p>Create a systemd script to start and stop the Directory Server on Linux-based systems.</p> <p>Each local DB backend has a root container, identified by backend ID. Each root container has an entry container for each base DN in the backend, identified by base DN. Each entry container has a number of database containers that store entries, attribute indexes and system indexes. The <code>dbtest</code> command allows the contents of root containers, entry containers and database containers to be inspected.</p>
dbtest	<p>Inspect the contents of Directory Server local DB backends that store their information in Berkeley DB Java Edition databases. Only backends of type local DB can be inspected by this tool.</p> <p>Each local DB backend has a root container, identified by backend ID. Each root container has an entry container for each base DN in the backend, identified by base DN. Each entry container has a number of database containers that store entries, attribute indexes and system indexes. The <code>dbtest</code> command allows the contents of root containers, entry containers and database containers to be inspected.</p>
deliver-one-time-password	<p>Generate and deliver a one-time password to a user through some out-of-band mechanism. That password can then be used to authenticate via the UNBOUNDID-DELIVERED-OTP SASL mechanism.</p>
deliver-password-reset-token	<p>Generate and deliver a single-use token to a user through some out-of-band mechanism. The user can provide that token to the password modify extended request in lieu of the user's current password in order to select a new password.</p>
dsconfig	<p>View and edit the Directory Server configuration.</p> <p>This utility offers three primary modes of operation, the interactive mode, the non-interactive mode and batch mode. The interactive mode supports viewing and editing the configuration via an intuitive, menu driven environment. Running <code>dsconfig</code> in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the server. To start <code>dsconfig</code> in interactive command-line mode, simply invoke the <code>dsconfig</code> shell script or batch file without any arguments.</p> <p>The <code>dsconfig</code> non-interactive command-line mode provides a simple way to make arbitrary changes to the PingDirectory Server by invoking it on the command-line. If you want to use administrative scripts to automate the configuration process, then run the <code>dsconfig</code> command in non-interactive mode.</p> <p>The <code>dsconfig</code> tool provides a batching mechanism that reads multiple <code>dsconfig</code> invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting in that it minimizes LDAP connections and JVM invocations that normally occur with each <code>dsconfig</code> call. You can view the <code>logs/config-audit.log</code> file to review the configuration changes made to the PingDirectory Server and use them in the batch file.</p>

dsjavaproperties	<p>Configure the JVM arguments used to run the Directory Server and associated tools.</p> <p>The options managed by this tool are stored in <code>config/java.properties</code>. Typically you should not edit that file directly but rather run this tool specifying <code>--jvmTuningParameter</code> arguments to customize JVM options appropriate for this system. It is necessary however that this tool be run in the event that <code>config/java.properties</code> must be edited by hand. Note that the changes will only apply to this Directory Server installation. No modifications will be made to your environment variables.</p> <p>Memory and other settings for the tool JVMs including the start-server tool can be tuned during initialization by specifying one or more instances of the <code>--jvmTuningParameter</code> option when invoking this tool. Supported values are as follows:</p> <ul style="list-style-type: none"> <li>▪ <code>NONE</code> Explicitly specify no parameters</li> <li>▪ <code>AGGRESSIVE</code> This system is dedicated to running only this server. The amount of memory allocated to this server will be computed accordingly</li> <li>▪ <code>SEMI_AGGRESSIVE</code> This system is shared by multiple server processes. The amount of memory allocated to this server will be computed accordingly</li> </ul> <p>If no parameters are specified the parameters specified by the previous invocation of this tool or setup will be used. Use the <code>NONE</code> option to explicitly specify no parameters.</p>
dsreplication	<p>Manage data replication between two or more Directory Server instances.</p> <p>For replication to work, you must first enable replication using the <code>enable</code> option. Then, you initialize the contents of one of the servers with the contents of the other using the 'initialize' subcommand.</p>
dump-dns	<p>Obtain a listing of all of the DNSs for all entries below a specified base DN in the Directory Server.</p>
encode-password	<p>Encode user passwords with a specified storage scheme or determine whether a given clear-text value matches a provided encoded password.</p>
encrypt-file	<p>Encrypt or decrypt data using a key generated from a user-supplied passphrase, a key generated from an encryption settings definition, or a key shared among servers in the topology. The data to be processed can be read from a file or standard input, and the resulting data can be written to a file or standard output. You can use this command to encrypt and subsequently decrypt arbitrary data, or to decrypt encrypted backups, LDIF exports, and log files generated by the server.</p>
encryption-settings	<p>Manage the server encryption settings database.</p> <p>More information about the cipher algorithms and transformations available for use may be found in the Java Cryptography Architecture Reference Guide, as well as the Standard Algorithm Name Documentation for your chosen JDK implementation used by this server.</p>

enter-lockdown-mode	<p>Request that the Directory Server enter lockdown mode, during which it only processes operations requested by users holding the <code>lockdown-mode</code> privilege.</p> <p>While in lockdown mode, the Directory Server rejects all requests from users that do not hold the <code>lockdown-mode</code> privilege.</p>
export-ldif	<p>Export data from the Directory Server backend in LDIF form.</p> <p>To export data from a remote Directory Server, the Directory Server must be running and connection parameters must be supplied. You can specify options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The data may be appended to an existing file instead of overwriting it, and the output may be optionally compressed.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
export-reversible-passwords	<p>Requests that the server export entries from a specified backend in LDIF form, including clear-text representations of any passwords encoded with a reversible storage scheme. This tool may only be used over a secure connection and when authenticated as a user with the <code>permit-export-reversible-passwords</code> privilege. The output will be encrypted using a key generated from either a user-supplied passphrase or an encryption settings definition.</p>

<p>extract-data-recovery-log-changes</p>	<p>Extract changes matching a given set of criteria from a Directory Server audit log so that they can be replayed (for example, as part of a disaster recovery process) or reverted (for example, to back out changes made in error).</p> <p>This tool is designed to be used in conjunction with the server's data recovery log files (in the logs/data-recovery directory). It may be used in conjunction with other audit log files, but for best results, the logger should be configured to operate in reversible form, to include the requester DN and IP address, and to include information about any intermediate client control that may have been provided in the request.</p> <p>This tool must not be used with a log file that the server may update while the tool is running, or that may have some content stored in an unwritten buffer (which is especially likely if the log is compressed or encrypted). To use this tool with the server online, you should only specify a log file that has already been rotated to ensure that no more writes will be made to that file. If necessary, you may use the rotate-log tool to force the current active file to be rotated.</p> <p>To use this tool to revert an inappropriate set of changes, run it with '--direction revert' and an additional set of arguments that identify which changes should be reverted (for example, based on the address of the client, the authorization DN of the requester, the time frame in which the changes were applied, etc.).</p> <p>To use this tool to replay changes that were previously applied (for example, after restoring an old backup or importing an old LDIF file), run it with <code>--direction replay</code> and an appropriate set of arguments to select the desired set of changes. Also, make sure to use <code>dsreplication pre-external-initialization</code> before performing the restore or import and applying the changes, and then use <code>dsreplication post-external-initialization</code> after the changes have been applied. See the Directory Server Administration Guide for additional information.</p> <p>This tool will extract changes from the selected log file (and any previously rotated files, unless the <code>--doNotFollowRotationChain</code> argument is provided) and output them in LDIF change format. If the <code>--outputFile</code> argument is provided, then the changes will be written to that file; otherwise, they will be written to standard output. If changes are to be written to a file, then the output will be compressed if the input files were compressed (unless the <code>--doNotCompressOutput</code> argument was provided), and the output will be encrypted if the input files were encrypted (unless <code>--doNotEncryptOutput</code> was provided). You may wish to first run the tool without specifying an output file so that you can verify that the selected changes are correct. Once you are certain that the appropriate changes have been selected, then you can use a tool like <code>ldapmodify</code> or <code>parallel-update</code> to apply those changes to the server.</p>
<p>generate-totp-shared-secret</p>	<p>Generate a shared secret that you can use to generate time-based one-time password (TOTP) authentication codes for use in authenticating with the UNBOUNDID-TOTP SASL mechanism or with the validate TOTP password extended operation.</p>

identify-references-to-missing-entries	This tool may be used to identify entries containing one or more attributes which reference entries that do not exist. This may require the ability to perform unindexed searches and/or the ability to use the simple paged results control.
identify-unique-attribute-conflicts	This tool may be used to identify unique attribute conflicts. That is, it may identify values of one or more attributes which are supposed to exist only in a single entry but are found in multiple entries.
import-ldif	<p>Import LDIF data into a Directory Server backend.</p> <p>Connection parameters are not required when importing to a local Directory Server that is not running. However, connection parameters are required if the Directory Server is remote, or if the Directory Server is running locally and it is inconvenient to have to stop it for the import. You can use the options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The input file may be compressed.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.</p>
indent-ldap-filter	Parse a provided LDAP filter string and display it a multiline form that makes it easier to understand its hierarchy and embedded components. If possible, it might also simplify the provided filter in certain ways (for example, by removing unnecessary levels of hierarchy, like an AND embedded in an AND).
ldap-debugger	Intercept and decode LDAP communication.

`ldap-diff`

Compare the contents of two LDAP servers.

The `ldap-diff` tool outputs the difference between data stored in two LDAP servers into an LDIF file. This file could be used with the `ldapmodify` command to bring the source directory server in sync with the target directory server. The specific entries to compare can be controlled with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. Specific attributes can also be excluded by prepending a `^` character to the attribute. On Windows operating systems, excluded attributes must be quoted, for example, `"^attrToExclude"`. When retrieving entries from a PingDirectory Server, the `@objectClassName` notation can be used to compare only attributes that are defined for a given objectclass.

This command can be used on servers actively being modified, without reporting false positives due to replication delays, by checking differing entries multiple times. By default, it will re-check each differing entry twice, pausing two seconds between checks. These settings can be configured with the `--numPasses` and `--secondsBetweenPass` options. The output is formatted so that delete operations come first, modify operations come next, and add operations come last. This gives the best chance that the resulting output file can be used to bring the source server into sync with the target server without causing any conflicts. This takes into account attribute uniqueness constraints as well as that child entries must be deleted before parents and parents must be added before children.

The directory user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the PingDirectory Server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry:

- `ds-cfg-default-root-privilege-name: unindexed-search`
- `ds-cfg-default-root-privilege-name: bypass-acl`
- `ds-rlim-size-limit: 0`
- `ds-rlim-time-limit: 0`
- `ds-rlim-idle-time-limit: 0`
- `ds-rlim-lookthrough-limit: 0`

For servers from other vendors, consult their documentation for configuring the proper privileges.

The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For directories that contain tens of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by `ldap-diff` can be customized by editing the `ldap-diff.java-args` setting in the `config/java.properties` file and running the `dsjavaproperties` command.

ldap-result-code	<p>Display and query LDAP result codes.</p> <p>This tool may be used to list all known defined LDAP result codes, retrieve the name of the result code with a given integer value, or search for all result codes with names containing a given substring.</p> <p>At most one of the <code>--list</code>, <code>--int-value</code>, and <code>--search</code> arguments may be provided. If none of them is provided, then the <code>--list</code> option will be chosen by default.</p>
ldapcompare	<p>Perform compare operations in an LDAP Directory Server. Compare operations can be used to efficiently determine whether a specified entry has a given value.</p> <p>The exit code for this tool will indicate whether processing was successful or unsuccessful, and to provide a basic indication of the reason for unsuccessful attempts. By default, it will use an exit code of zero (which corresponds to the LDAP 'success' result) if all compare operations completed with a result code of either 'compare false' or 'compare true' (integer values 5 and 6, respectively), but if the <code>--useCompareResultCodeAsExitCode</code> argument is provided, only one compare assertion is performed, and it yields an exit code of 'compare false' or 'compare true', then the numeric value for that result code will be used as the exit code. If any error occurs during processing, then the exit code will be a nonzero value that reflects the first error result that was encountered.</p> <p>The attribute type and assertion value to use for the compare operations will typically be provided as the first unnamed trailing argument provided on the command line. It should be formatted with the name or OID of the target attribute type followed by a single colon and the string representation of the assertion value. Alternatively, the attribute name or OID may be followed by two colons and the base64-encoded representation of the assertion value, or it may be followed by a colon and a less-than symbol to indicate that the assertion value should be read from a file (in which case the exact bytes of the file, including line breaks, will be used as the assertion value).</p> <p>The DNs of the entries to compare may either be provided on the command line as additional unnamed trailing arguments after the provided attribute-value assertion, or they may be read from a file whose path is provided using the <code>--dnFile</code> argument.</p> <p>If the attribute-value assertion is provided on the command line as an unnamed trailing argument, then the same assertion will be performed for all operations. If multiple types of assertions should be performed, then you may use the <code>--assertionFile</code> argument to specify the path to a file containing both attribute-value assertions and entry DNs.</p>
ldapdelete	<p>Apply a set of add, delete, modify, and/or modify DN operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the <code>ldifFile</code> argument. Change records must be separated by at least one blank line.</p>
ldapmodify	<p>Apply a set of add, delete, modify, and/or modify DN operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the <code>ldifFile</code> argument. Change records must be separated by at least one blank line.</p>

ldappasswordmodify	<p>Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in RFC 3062), a standard LDAP modify operation, or an Active Directory-specific modification.</p> <p>Unless the password change method is explicitly specified (using the <code>--passwordChangeMethod</code> argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password change method will be selected, using a regular LDAP modify to update the <code>unicodePwd</code> attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute.</p> <p>Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in RFC 3062), a standard LDAP modify operation, or an Active Directory-specific modification.</p> <p>Unless the password change method is explicitly specified (using the <code>--passwordChangeMethod</code> argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password change method will be selected, using a regular LDAP modify to update the <code>unicodePwd</code> attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute.</p> <p>The new password to set for the user may be specified in one of several ways. It may be directly provided on the command line, read from a specified file, interactively prompted from the user, or automatically generated by this tool. If the new password is not specified using any of those methods, and if the password is to be updated using the password modify extended operation, then the new password field of the request will be left blank to indicate that the server should generate a new password for the user and include it in the response to the client. If no new password is specified and some other password change method is selected, then the tool will exit with an error.</p> <p>The current password for the user may also be specified. This is optional, although some servers may require a user to provide their current password when setting a new one. If a current password is provided (whether given as a command-line argument, read from a specified file, or interactively requested from the user), and if a regular LDAP modify operation is used to change the password, then the resulting modify request will include a delete of the current value and an add of the new value. If no current password is provided, then the modify request will replace any existing password(s) with the new value.</p>
--------------------	--

ldapsearch	<p>Process one or more searches in an LDAP directory server.</p> <p>The criteria for the search request can be specified in a number of different ways, including providing all of the details directly via command-line arguments, providing all of the arguments except the filter via command-line arguments and specifying a file that holds the filters to use, or specifying a file that includes a set of LDAP URLs with the base DN, scope, filter, and attributes to return.</p>
ldif-diff	<p>Compare the contents of two files containing LDIF entries. The output will be an LDIF file containing the add, delete, and modify change records needed to convert the data in the source LDIF file into the data in the target LDIF file.</p> <p>This tool works best with small LDIF files because it reads the entire contents of the source and target LDIF files into memory so they can be quickly compared. If you encounter an out of memory error while running the tool, you may need to increase the amount of memory available to the JVM used to invoke it.</p> <p>The amount of memory available to the JVM may be customized by invoking the JVM with the <code>-Xms</code> and <code>-Xmx</code> arguments (which specify the initial and maximum amounts of memory that it may use, respectively). These arguments should be immediately followed (without any intervening space) by an integer and a unit to specify the amount of memory that may be used. The unit may be either <code>m</code> to indicate that the size is in megabytes, or <code>g</code> to indicate that it is in gigabytes. For example, <code>-Xms512m</code> indicates that the JVM should be given an initial heap size of 512 megabytes, while <code>-Xmx2g</code> indicates that it should be given a maximum heap size of two gigabytes.</p> <p>When invoking the <code>ldif-diff</code> tool included in the installation of a Ping Identity server product, you may edit the <code>config/java.properties</code> file to specify the arguments to use when invoking the JVM. After modifying the file, run the <code>dsjavaproperties</code> tool to ensure that those changes will be used for subsequent tool invocations.</p>

ldifmodify	<p>Apply a set of changes (including add, delete, modify, and modify DN operations) to a set of entries contained in an LDIF file. The changes will be read from a second file (containing change records rather than entries), and the updated entries will be written to a third LDIF file. Unlike <code>ldapmodify</code>, the <code>ldifmodify</code> command cannot read the changes to apply from standard input.</p> <p>All of the change records will be read into memory before processing begins, so it is important to ensure that the tool is given enough memory to hold those change records. However, it will only operate on a single source entry at a time, so the size of the source LDIF file does not significantly impact the amount of memory that the tool requires.</p> <p>Note that the tool will attempt to correctly handle multiple changes affecting the same entry. However, because it only operates on one entry at a time, it cannot always behave in exactly the same way as if it were applying the changes over LDAP to a server populated with the source LDIF file. For example, it is not possible to reject an attempt to delete an entry that has subordinates, so any delete will be treated as a subtree delete.</p> <p>Further, not all types of modify DN change records are supported. In particular, modify DN change records are not permitted if they target any entry that has been targeted by a previous change record (for example, renaming an entry that was created by a previous add change record).</p> <p>Finally, it cannot perform other types of validation, like ensuring that all of the necessary superior entries exist when adding a new entry, or ensuring that a modify DN will not introduce a conflict with an existing entry.</p>
ldifsearch	Search one or more LDIF files to identify entries matching a given set of criteria.
leave-lockdown-mode	<p>Request that the Directory Server leave lockdown mode and resume normal operation.</p> <p>While in lockdown mode, the Directory Server rejects all requests from users that do not hold the lockdown-mode privilege.</p> <p>Note that the Directory Server may place itself in lockdown mode under certain conditions (for example, if it detects a security problem like a malformed access control rule that may have otherwise resulted in exposure of sensitive data).</p>
list-backends	List the backends and base DN's configured in Directory Server.
load-ldap-schema-file	Loads the schema definitions contained in a specified LDIF file into the schema for a running server. This tool may only be used in conjunction with a server instance running on the local system.
make-ldif	Generate LDIF data based on a definition in a template file. See the server's <code>config/MakeLDIF</code> directory for example template files. In particular, the <code>examples-of-all-tags.template</code> file shows how to use all of the tags for generating values.

manage-account	Retrieve or update information about the current state of a user account. Processing will be performed using the password policy state extended operation, and you must have the password-reset privilege to use this extended operation.
manage-certificates	Manage certificates and private keys in a JKS, PKCS #12, PKCS #11, or BCFKS key store.
manage-extension	Install or update PingDirectory Server extension bundles.  An extension bundle is a package of extension(s) that utilize the Server SDK to extend the functionality of PingDirectory Server. Extension bundles are installed from a zip archive or file system directory. PingDirectory Server will be restarted if running to activate the extension(s).
manage-profile	Generate, compare, install, and replace server profiles.  Server profiles define a format for the configuration of a server, including <b>dsconfig</b> , initial DIT, setup arguments, server SDK extensions, and other files. These are combined into one concrete structure. This tool provides subcommands that can be used to generate a new profile from an existing server, to set up a new server, and to replace an existing server's profile with a different profile.  A template server profile file structure can be found in the resource/ directory.
manage-tasks	Access information about pending, running, and completed tasks scheduled in the Directory Server.
manage-topology	Tool to manage the topology registry.  The topology registry is a branch of the configuration DIT (cn=Topology,cn=config). It stores all metadata about server instances, including their instance and listener certificates, secret keys, server groups and administrative user accounts. In addition, it also stores information about the replication topology (replication server ID and replication domain ID) when replication is enabled among servers in a Directory topology. Last but not least, it stores the license key required to install the server. Changes to the topology registry on one server are automatically mirrored to other servers in the topology. The <b>dsconfig</b> tool, configuration API or the management console may be used to make changes to the topology registry. This tool allows some additional capability such as exporting the contents of the registry as a JSON file.
migrate-ldap-schema	Migrate schema information from an existing LDAP server into a PingDirectory Server instance.  This tool may be used to migrate schema information from an existing LDAP server into this PingDirectory Server instance. The source server may be any standards-compliant LDAPv3 server. All attribute type and objectclass definitions which are contained in the source LDAP server but not in the target PingDirectory Server instance will be either added to the target instance or written to a schema file.

migrate-sun-ds-config	<p>Update an instance of the PingDirectory Server to match the configuration of an existing Sun Java System Directory Server 5.x, 6.x, or 7.x.</p> <p>This tool may be used to compare the configuration of Sun Java System Directory Server 5.x, 6.x, or 7.x and PingDirectory Server instances in order to identify any differences and update the PingDirectory Server configuration to more closely match that of the Sun server instance.</p>
modrate	Perform repeated modifications against an LDAP directory server.
move-subtree	Move all entries in a specified subtree from one server to another.
oid-lookup	<p>Search the OID registry to retrieve information about items that match a given OID or name.</p> <p>The string to use to search the OID registry should be provided as an unnamed trailing argument. All items in the OID registry will be examined, and any items that contain the provided string in its OID, name, type, origin, or URL will be matched. If no search string is provided, the entire OID registry will be displayed.</p>
parallel-update	<p>Use multiple concurrent threads to apply a set of add, delete, modify, and modify DN operations read from an LDIF file.</p> <p>As with other tools like <code>ldapmodify</code>, changes in the LDIF file to be processed should be ordered such that if there are any dependencies between changes (for example, if one add change record creates a parent entry and another add change record creates a child of that parent), prerequisite changes come before the changes that depend on them. When this tool is preparing to process a change, it will determine whether the new change depends on any other changes that are currently in progress, and if so, will delay processing that change until its dependencies have been satisfied. If a change does not depend on any other changes that are currently being processed, then it can be processed in parallel with those changes.</p> <p>This tool will keep track of any changes that fail in a way that indicates they succeed if re-tried later (for example, an attempt to add an entry that fails because its parent does not exist, but its parent may be created later in the set of LDIF changes), and can optionally re-try those changes after processing is complete. Any changes that are not retried, as well as changes that still fail after the retry attempts, will be written to a rejects file with information about the reason for the failure so that an administrator can take any necessary further action upon them.</p>

<p>populate-composed-attribute-values</p>	<p>Populate entries in one or more backends with attribute values generated by one or more composed attribute plugins.</p> <p>This tool uses the configuration from a specified set of composed attribute plugin instances to identify which entries to update and what changes to apply. It may be used as an alternative to exporting the data to LDIF and re-importing to ensure that existing entries have an appropriate set of composed attribute values.</p> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <b>manage-tasks</b> tool.</p>
<p>profile-viewer</p>	<p>View information in data files captured by the Directory Server profiler.</p> <p>Profiler data files are generated by the Profiler plugin. To create these data files, set the profile-action attribute of the Profiler configuration object to 'start' to begin collection. Set the <b>profile-action</b> attribute to <code>stop</code> to end collection and have the plugin write the file to <code>logs/profile.{timestamp}</code>.</p>
<p>re-encode-entries</p>	<p>Re-encode all or a specified portion of the entries in a local DB backend.</p> <p>This tool may be used to initiate a task that will cause a local DB backend to re-encode all or a specified subset of the entries that it contains. The contents of the entries will not be altered, but this provides a useful mechanism for applying significant changes to the way that entries are actually stored in the backend (for example, to apply encoding changes if a feature like data encryption or uncached attributes or entries is enabled).</p> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <b>manage-tasks</b> tool.</p>

rebuild-index	<p>Rebuild index data within a backend based on the Berkeley DB Java Edition. Note that this tool uses different approaches to rebuilding indexes based on whether it is running in online mode (as a task) rather than with the server offline. Running in offline mode will often provide significantly better performance and require significantly less database cleaning, particularly for indexes containing keys that match a large number of entries and have high index entry limit and exploded index entry threshold values. Also note that rebuilding an index with the server online will prevent the server from using that index while the rebuild is in progress, so some searches may behave differently while a rebuild is active than when it is not.</p> <p>An index must be rebuilt if the database already contains data when the index is configured. The backend containing the provided base DN must be a local DB backend. The types of indexes that can be rebuilt include attribute indexes, VLV indexes, and JSON field indexes.</p> <div data-bbox="592 674 1464 915" style="border: 1px solid black; padding: 5px;"> <p> <b>Note:</b></p> <p>PingDirectory does not support the rebuilding of system indexes, regardless of whether the rebuild is attempted online or offline. If you need to rebuild a system index, you must export the backend to LDIF and re-import it.</p> </div> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <b>manage-tasks</b> tool.</p>
register-yubikey-otp-device	<p>Registers a YubiKey OTP device with the Directory Server for a specified user so that the device may be used to authenticate that user in conjunction with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. Alternately, it may be used to deregister one or more YubiKey OTP devices for a user so that they may no longer be used to authenticate that user.</p>
reload-http-connection-handler-certificates	<p>Reload HTTPS Connection Handler certificates.</p> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <b>manage-tasks</b> tool.</p>

<pre>remove-attribute-type- from-schema</pre>	<p>Safely remove an attribute type definition from the server schema.</p> <p>The tool will perform an appropriate set of validation before actually removing the attribute type from the schema. The below conditions must be satisfied before the attribute type may be removed.</p> <ul style="list-style-type: none"> <li>▪ The requester must have the update-schema privilege.</li> <li>▪ The attribute type must not be referenced by any other schema element.</li> <li>▪ The attribute type must not be defined in any schema file that is included with the Directory Server. Only custom attribute types may be removed from the schema.</li> <li>▪ The attribute type must not be referenced in the server configuration (for example, it must not be indexed by any backend).</li> <li>▪ The attribute type must not be present in any entry that exists in any backend.</li> </ul> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <b>manage-tasks</b> tool.</p>
<pre>remove-backup</pre>	<p>Safely remove a backup and optionally all of its dependent backups from the specified Directory Server backend.</p> <p>This tool deletes the specified backup archive and updates the backup descriptor accordingly. If there are other (incremental) backups that depend on this backup, they will need to be removed before the base backup can be removed, unless you choose the <code>--force</code> option.</p> <p>If you choose the <code>--force</code> option, the specified backup and all other backups depending on it are removed. You can use the <code>--showDependencies</code> option to see what incremental backups depend on a given base backup.</p> <p>As an alternative to removing a specific backup, you can automatically remove backups outside of specified count or age criteria. The <code>--retainFullBackupCount</code> argument can be used to indicate that the specified number of full backups should be retained, and any other full backups in the directory are eligible to be removed (along any incremental backups that depend on them). The <code>--retainFullBackupAge</code> argument can be used to indicate that any full backups (and dependent incremental backups) older than the specified age are eligible to be removed.</p>
<pre>remove-defunct-server</pre>	<p>Remove a server from this server's topology.</p> <p>This tool will remove the specified server from the topology. In general, the <b>uninstall</b> tool should be used to remove a server from the topology. The <b>remove-defunct-server</b> tool should only be used if a prior attempt to uninstall a server was unsuccessful or the system where the server was installed is no longer available, leaving the server permanently inaccessible from the topology. If the defunct server is online and is able to reach other servers in the topology, running <b>remove-defunct-server</b> from it will cleanly remove it from the topology. If it cannot reach the other servers, then <b>remove-defunct-server</b> must also be run from one of the online servers.</p>

remove-object-class-from-schema	<p>Safely remove an object class definition from the server schema.</p> <p>The tool will perform an appropriate set of validation before actually removing the object class from the schema. The below conditions must be satisfied before the object class may be removed.</p> <ul style="list-style-type: none"> <li>▪ The requester must have the update-schema privilege.</li> <li>▪ The object class must not be referenced by any other schema element.</li> <li>▪ The object class must not be defined in any schema file that is included with the Directory Server. Only custom object classes may be removed from the schema.</li> <li>▪ The object class must not be referenced in the server configuration.</li> <li>▪ The object class must not be present in any entry that exists in any backend.</li> </ul> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <b>manage-tasks</b> tool.</p>
replace-certificate	<p>Replace the listener certificate for this PingDirectory Server server instance.</p>
restore	<p>Restore a backup of a Directory Server backend.</p> <p>Only one backend may be restored at a time by the restore command. The Directory Server should be stopped unless task connection options are supplied for a running server. You can list the backups contained in a particular backend backup directory. A backup taken on one system can be restored on another system.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <b>manage-tasks</b> tool.</p>
revert-update	<p>Revert this server package's most recent update.</p>
review-license	<p>Review and/or indicate your acceptance of the license agreement defined in <code>legal/LICENSE.txt</code>.</p>

rotate-log	<p>Trigger the rotation of one or more log files.</p> <p>If the file argument is provided one or more times to specify the target log file paths, then only those log files will be rotated. If the file argument is not given, then the server will trigger rotation for all supported log files.</p> <p>You must have the config-read and config-write privileges to run this tool, and you must have the necessary access control rights to create and monitor entries in the task backend.</p> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
sanitize-log	<p>Sanitize the contents of a server log file to remove potentially sensitive information while still attempting to retain enough information to make it useful for diagnosing problems or understanding load patterns. The sanitization process operates on fields that consist of name-value pairs. The field name is always preserved, but field values might be tokenized or redacted if they might include sensitive information. Supported log file types include the file-based access, error, sync, and resync logs, as well as the operation timing access log and the detailed HTTP operation log. Sanitize the audit log using the <code>scramble-ldif</code> tool.</p>
schedule-exec-task	<p>Schedule an exec task to run a specified command in the server. To run an exec task, a number of conditions must be satisfied: the server's global configuration must have been updated to include <code>com.unboundid.directory.server.tasks.ExecTask</code> in the set of allowed-task values, the requester must have the <code>exec-task</code> privilege, and the command to execute must be listed in the <code>exec-command-whitelist.txt</code> file in the server's <code>config</code> directory. The absolute path (on the server system) of the command to execute must be specified as the first unnamed trailing argument to this program, and the arguments to provide to that command (if any) should be specified as the remaining trailing arguments. The server root is used as the command's working directory, so any arguments that represent relative paths are interpreted as relative to that directory.</p>
search-and-mod-rate	<p>Perform repeated searches against an LDAP directory server and modify each entry returned.</p>
search-logs	<p>Search across log files to extract lines matching the provided patterns, like the <code>grep</code> command-line tool. The benefits of using this tool over <code>grep</code> are its ability to handle multiline log messages, extract log messages within a given time range, and the inclusion of rotated log files.</p>
searchrate	<p>Perform repeated searches against an LDAP directory server.</p>
server-state	<p>View information about the current state of the Directory Server process.</p>
set-delegated-admin-aci	<p>Request that the Directory Server assign appropriate ACI for configured delegated administrators of the Delegated Admin API.</p>

setup	<p>Perform the initial setup for a server instance.</p> <p>This tool features both interactive and non-interactive modes for accepting the product license terms and initially configuring a server instance.</p>
start-server	<p>Start the Directory Server.</p>
status	<p>Display basic server information.</p> <p>This tool prints information about the server, such as version, connection handlers, and data sources. Some information may not be available if the server is not running, or if authentication credentials are missing or do not have sufficient privileges, or if the invoking user does not have sufficient file system access rights.</p>
stop-server	<p>Stop or restart the server.</p> <p>This tool is used to stop or restart the local instance of the server (by omitting LDAP connection options), or a remote server (by interacting with it over LDAP). In addition, this tool is used to schedule the server for shutdown at a later time using the server's task interface.</p>
subtree-accessibility	<p>List or update the set of subtree accessibility restrictions defined in the Directory Server.</p>
sum-file-sizes	<p>Calculate the sum of the sizes for a set of files.</p> <p>This tool is used to find the sum of the sizes of one or more files. If any of the files specified is a directory then it will be recursively processed.</p>
summarize-access-log	<p>Examine one or more access log files from Ping Identity, UnboundID, or Nokia/Alcatel-Lucent 8661 server products to display a number of metrics about operations processed within the server.</p>
transform-ldif	<p>Apply one or more changes to entries or change records read from an LDIF file, writing the updating records to a new file. This tool can apply a variety of transformations, including scrambling attribute values, redacting attribute values, excluding attributes or entries, replacing existing attributes, adding new attributes, renaming attributes, and moving entries from one subtree to another.</p>
uninstall	<p>Uninstall the Directory Server.</p> <p>This tool removes the entire server or individual server components from the file system. If this server is a member of a replication topology, you must first remove references to this server in the other servers using the <b>dsreplication disable</b> command.</p>
update	<p>Update a deployed server so its version matches the version of this package.</p>

<code>validate-acis</code>	This tool may be used to validate a set of access control definitions contained in an LDAP server (including Sun/Oracle DSEE instances) or an LDIF file to determine whether they are acceptable for use in the PingDirectory Server. Note that output generated by this tool will be LDIF, but each entry in the output will have exactly one ACI, so entries which have more than one ACI will appear multiple times in the output with different ACI values.
<code>validate-file-signature</code>	Validate file signatures. For best results, file signatures should be validated by the same instance used to generate the file. However, it might be possible to validate signatures generated on other instances in a replicated topology.
<code>validate-ldap-schema</code>	Validate an LDAP schema read from one or more LDIF files.
<code>validate-ldif</code>	Validate the contents of an LDIF file against the server schema.
<code>verify-index</code>	Verify that indexes in a backend using the Berkeley DB Java Edition are consistent with the entry data contained in the database.
<code>watch-entry</code>	Launch a window to watch an LDAP entry for changes. If the entry changes, the background of modified attributes will temporarily be red. Attributes can be modified as well. This tool is primarily intended to demonstrate replication or synchronization functionality.

## Saving options in a file

Directory Server supports the use of a tools properties file (`config/tools.properties`) to simplify command-line invocations by reading in a set of options for each tool from a text file.

Properties files are convenient when quickly testing Directory Server in multiple environments.

Each property takes the form of a name-value pair that defines predetermined values for a tool's options.

Directory Server supports the following types of properties:

- Default properties that apply to all command-line utilities
- Tool-specific properties

### Creating a tools properties file

You can set properties that apply to all tools or are tool-specific. These properties serve as defaults for the command-line options they represent.

#### Steps

1. Use a text editor to open the default tools properties file (`config/tools.properties`) or a different properties file.

#### Note:

If you use a file other than `config/tools.properties`, invoke the tool with the `--propertiesFilePath` option to specify the path to your properties file.

## 2. Set or change properties that apply to all tools.

Use the standard Java properties file format (name=value) to set properties. For example, the following properties define a set of LDAP connection parameters.

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
baseDN=dc=example,dc=com
```

### Note:

Properties files do not allow quotation marks of any kind around values.

Escape spaces and special characters.

Whenever you specify a path, do not use ~ to refer to the home directory. The server does not expand the ~ value when read from a properties file.

## 3. Set or change properties that apply to specific tools.

Tool-specific properties start with the name of the tool followed by a period. These properties take precedence over properties that apply to all tools. The following example sets two ports: one that applies to all tools (`port=1389`) and a tool-specific one that **ldapsearch** uses instead (`ldapsearch.port=2389`).

```
hostname=server1.example.com
port=1389
ldapsearch.port=2389
bindDN=cn=Directory\ Manager
```

## 4. Save your changes and close the file.

### Evaluation of command-line options and file options

You can specify options for a command-line tool on the command line, in a properties file, or both.

Options you specify on a tool's command line take priority over options in a properties file.

Consider the following scenarios.

Command-line options	Directory Server uses ...
No command-line options	The options in the default <code>&lt;server-root&gt;/config/tools.properties</code> file
Command-line options other than the <code>--propertiesFilePath &lt;my-properties-file&gt;</code> option	The command-line options, which take priority if the options are also in the <code>&lt;server-root&gt;/config/tools.properties</code> file The file options for options that are only in the default <code>&lt;server-root&gt;/config/tools.properties</code> file
Only the <code>--propertiesFilePath &lt;my-properties-file&gt;</code> option	The options in <code>&lt;my-properties-file&gt;</code>
The <code>--propertiesFilePath &lt;my-properties-file&gt;</code> option and other command-line options	The command-line options, which take priority if the options are also in <code>&lt;my-properties-file&gt;</code> The file options for options that are only in <code>&lt;my-properties-file&gt;</code>
The <code>--noPropertiesFile</code> option and other command-line options	Only the options you specify on the command line, ignoring the default properties file

## Example

Consider this example properties file that is saved as `<server-root>/bin/tools.properties`:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

Directory Server checks command-line options and file options to determine the options to use, as explained below.

- All options presented with the tool on the command line take precedence over any options in a properties file.

In the following example, the command runs with the options specified on the command line (`--port` and `--baseDN`). With the `port` value both on the command line and in the properties file, the command-line value takes priority. The command uses the `bindDN` and `bindPassword` values specified in the properties file.

```
$ bin/ldapsearch --port 2389 --baseDN ou=People,dc=example,dc=com \
  --propertiesFilePath bin/tools.properties "(objectclass=*)"
```

- If you specify the properties file using the `--propertiesFilePath` option and no other command-line options, Directory Server uses only the options in the specified properties file:

```
$ bin/ldapsearch --propertiesFilePath bin/tools.properties \
  "(objectclass=*)"
```

- If do not specify any command-line options, Directory Server attempts to locate the default properties file in the following location:

```
<server-root>/config/tools.properties
```

By moving your `tools.properties` file from `<server-root>/bin` to `<server-root>/config`, you do not have to specify the `--propertiesFilePath` option. That change shortens the previous command to the following command.

```
$ bin/ldapsearch "(objectclass=*)"
```

## Sample dsconfig batch files

The `config/sample-dsconfig-batch-files` directory contains **dsconfig** batch files that you can use to configure various aspects of the server. For example, these files can enable additional security capabilities or take advantage of features that might require customization from one environment to another.

Each file includes comments that describe the purpose and benefit of its configuration change. You can choose which of the changes you want to apply.

You need to customize some of the batch files to provide values that might vary from one environment to another. To apply a batch file that requires changes, copy it to another directory and edit the copy. Leave the files in the `config/sample-dsconfig-batch-files` directory unchanged so that they can be updated when you upgrade the server. To specify the path to the file that contains the changes to apply, use the **dsconfig** tool (`bin/dsconfig` on UNIX-based systems or `bat\dsconfig.bat` on Windows) with the `--batch-file` argument.

You should also provide the arguments needed to connect and authenticate to the server. The `--no-prompt` argument ensures that the tool does not block while waiting for input if any necessary arguments are missing. Consider this example.

```
bin/dsconfig --hostname localhost \
  --port 636 --useSSL --trustStorePath config/truststore \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPasswordFile admin-password.txt \
  --batch-file config/hardening-dsconfig-batch-files/reject-insecure-
request.dsconfig \
  --no-prompt
```

## Running task-based tools

Directory Server has a Tasks subsystem that allows you to schedule basic operations, such as **backup**, **restore**, **rotate-log**, **schedule-exec-task**, **stop-server**, and others. All task-based tools require the `--task` option that explicitly indicates the tool is to run as a task rather than in offline mode.

The following table shows the options that you can use for task-based operations:

### Options for task-based operations

Option	Description
<code>--task</code>	Indicates that the tool is invoked as a task. The <code>--task</code> option is required. If you invoke a tool as a task without this <code>--task</code> option, then a warning message is displayed stating that it must be used. If the <code>--task</code> option is provided but the tool was not given the appropriate set of authentication arguments to the server, then an error message is displayed and the tool exits with an error.
<code>--start &lt;startTime&gt;</code>	Indicates the date and time, expressed in the format 'YYYYMMDDhhmmss', when the operation is to start.  A value of '0' causes the task to be scheduled for immediate execution.  After the scheduled run, the tool exits immediately.
<code>--dependency &lt;taskID&gt;</code>	Specifies the ID of a task upon which this task depends.  A task does not start execution until all its dependencies have completed execution.  You can use this option multiple times in a single command.
<code>--failedDependencyAction &lt;action&gt;</code>	Specifies the action this task takes if one of its dependent tasks fail.  Valid action values are: <ul style="list-style-type: none"> <li>▪ CANCEL (the default) Cancels the task.</li> <li>▪ DISABLE Disables the task so that it is not eligible to run until you manually enable it again.</li> <li>▪ PROCESS Runs the task.</li> </ul>

Option	Description
<code>--startAlert</code>	Generates an administrative alert when the task starts running.
<code>--errorAlert</code>	Generates an administrative alert when the task fails to complete successfully.
<code>--successAlert</code>	Generates an administrative alert when the task completes successfully.
<code>--startNotify</code> <emailAddress>	Specifies an email address to notify when the task starts running. You can use this option multiple times in a single command.
<code>--completionNotify</code> <emailAddress>	Specifies an email address to notify when the task completes, regardless of whether it succeeded or failed. You can use this option multiple times in a single command.
<code>--errorNotify</code> <emailAddress>	Specifies an email address to notify if an error occurs when this task executes. You can use this option multiple times in a single command.
<code>--successNotify</code> <emailAddress>	Specifies an email address to notify when this task completes successfully. You can use this option multiple times in a single command.

## PingDirectoryProxy Server Administration Guide

---

PingDirectoryProxy is a fast and scalable LDAPv3 gateway for the PingDirectory server. Administrators can configure the PingDirectoryProxy server architecture to control how client requests are routed to backend servers.

### Introduction to PingDirectoryProxy Server

---

This section gives an overview of the PingDirectoryProxy features and components.

PingDirectoryProxy is a fast and scalable LDAPv3 gateway for the PingDirectory. Administrators can configure the PingDirectoryProxy architecture to control how client requests are routed to backend servers.

### Overview of the PingDirectory Server features

The following overview describes PingDirectory Servers features and capabilities.

The PingDirectory Server is a fast, scalable, and easy-to-use LDAP proxy server that provides high availability and additional security for the PingDirectory Server while remaining largely invisible to client applications. From a client perspective, request processing is the same, whether communicating with the Directory Server directly or going through the Directory Server.

The PingDirectory Server provides the following features:

- High availability

The Directory Server allows you to transparently fail over between servers if a problem occurs as well as ensuring that the workload is balanced across the topology. If a client does not support following referrals, the Directory Server can follow them on the client's behalf.

#### Data mapping and transformation

The Directory Server can perform distinguished name (DN) mapping and attribute mapping to allow clients to interact with the server using older names for directory content. It allows clients to continue working when they would not be able to work directly with the Directory Server, either because of changes that have occurred at the data layer or to inherent design limitations in the clients.

#### Horizontal scalability and performance

Reads can be horizontally scaled using load balancing. In large data centers, if the data set is too large to be cached or to provide horizontal scalability for writes, the Directory Server can automatically split the data across multiple systems. This feature allows the Directory Server to improve scalability and performance of the Directory Server environment.

#### Load balancing and failover

You can spread the workload across multiple proxies in a large data center using load-balancing algorithms. Load balancing is also useful when a server becomes degraded or non-responsive because client process requesting directs to a different server.

#### Security and access control

The Directory Server can add additional firewall capabilities as well as constraints and filtering to help protect the Directory Server from attacks. You can use a Directory Server in a DMZ as opposed to allowing clients to directly access the Directory Server in the internal network or providing the data in the DMZ. It can help provide secure access to the data and you can define what actions clients are allowed to do. For example, you can prevent clients from making modifications to data when connected through a VPN no matter what their identity or permissions.

#### Tracking of operations across the environment

In the past, administrators have complained that when they see a request in the access log they have no idea where it came from and cannot track it back to a particular client. The Directory Server contains controls that allow administrators to track requests back to the client that issued them. Whenever the Directory Server forwards a request to the Directory Server, it includes a control in the request so that the Directory Server's access log has the IP address of the client, address and connection ID of the Directory Server. In the response back to the client, it similarly includes information about the Directory Server that processed the request, such as the connection ID and operation ID. This feature makes it easier for administrators to monitor in their environment.

#### Monitoring and management tools

Because the Directory Server uses many of the components of PingDirectory Server, it can leverage them to provide protocol support, logging, management tools for configuration and monitoring, and schema. You can use the DataMetricsServer, the `dsconfig` tool, and the administrative console to manage the Directory Server.

## Overview of the Directory Server components and terminology

This section describes each Directory Server component in more detail.

The Directory Server provides the following components and functionalities for the proxy capabilities:

- Locations
- LDAP External Servers
- LDAP Health Checks
- Load-Balancing Algorithms

- Data Transformations
- Request Processors
- Server Affinity Providers
- Subtree Views
- Connection Pools
- Client Connection Policies
- Entry Balancing

### **About locations**

You can assign a location to the Directory Server and each of the backend LDAP external servers for routing requests and failover response preferences.

Locations define a group of servers with similar response time characteristics. Each location consists of a name and an ordered list of preferred failover locations. These locations can determine how to route requests so that the server forwards requests to Directory Server in the same data center over those in remote locations.

For example, a deployment consists of three data centers, one in New York, one in Chicago, and one in Los Angeles. In the New York data center, applications that reside in this data center prefer communicating with directories in this data center. If none of the servers are available, it prefers to failover to the data center in Chicago rather than the data center in Los Angeles, so the New York location contains an ordered list in which the Chicago location is preferred over the Los Angeles data center for failover.

Follow these guidelines for assigning locations in Directory Server:

- If you have multiple data centers, assign a separate location for each one.
- In most environments, all Directory Proxy Server instances should have the same configuration except for the attribute that specifies the location of the Directory Proxy Server itself.

For more information about configuring locations, see [Configuring Locations](#).

### **About LDAP external servers**

PingDirectory Server allows you to configure different types of LDAP external servers.

You can configure information about the directory server instances accessed by PingDirectory Server. The default configuration for each type is tuned to be the best possible configuration for each.

The configuration information includes the following:

- Server connection information, such as IP address, port, and security layer
- Location
- Authentication information
- Methods for authenticating and authorizing clients
- Server-specific health checks
- Types of operations allowed

For example, some LDAP external servers might allow only reads and others allow reads and writes so that the Directory Server can recognize this and accommodate it.

For more information about configuring LDAP external servers, see [Configuring LDAP External Servers](#).

### **About LDAP health checks**

LDAP health checks provide information about the status and availability of LDAP external servers. Configure the Directory Proxy Server health checks that work best for your environment.

PingDirectory Server provides the following health checks:

Measure the response time for searches and examine the entry contents

The health check might retrieve a monitoring entry from a server and base the health check result on whether the entry was returned, how long it took to be returned, and whether the value of the returned entry matches what was expected.

#### Monitor the replication backlog

If a server falls too far behind in replication, then the Directory Proxy Server can stop sending requests to it. A server is classified as `degraded` or `unavailable` if the threshold is reached for the number of missing changes, the age of the oldest missing change, or both.

#### Consume Directory Server administrative alerts

If the Directory Server indicates there is a problem, such as an index that must be rebuilt, then it flags itself as `degraded` or `unavailable`. When the Directory Proxy Server detects this, it stops sending requests to the server. The Directory Proxy Server detects administrative alerts as soon as they are issued by maintaining an LDAP persistent search for changes within the `cn=alerts` branch of the Directory Server.

When the Directory Proxy Server is notified by the Directory Server of a new alert, it immediately retrieves the base `cn=monitor` entry of the Directory Server. If this entry has a value for the `unavailable-alert-type` attribute, then the Directory Proxy Server considers it unavailable. If this entry has a value for the `degraded-alert-type` attribute, then the Directory Proxy Server considers it `degraded`. Clients of the Directory Proxy Server can use a similar mechanism to detect and react when a Directory Proxy Server flags itself as `degraded` or `unavailable`.

#### Monitor the busyness of the server

If a server becomes too busy, you can mark it as `degraded` or `unavailable` so that less heavily-loaded servers are preferred.

## Results

The health check results contain the following server states:

#### Available

Completely accessible for use.

#### Degraded

The server can be used if necessary but has a condition which can make it less desirable than other servers. For example, it is slow to respond or has fallen behind in replication.

#### Unavailable

Completely unsuitable for use. For example, the server is offline or is missing critical data.

Health check results include a numeric score that has a value between 1 and 10. This score helps rank servers with the same state. For example, two servers are available and one has a score of 8 and the other a score of 7, you can configure the Directory Proxy Server to prefer the server with the higher score.

The results of health checks are made available to the load-balancing algorithms to help determine where to send requests. The Directory Server attempts to use servers with a state of `available` before trying servers with a state of `degraded`. It never attempts to use servers with a state of `unavailable`.

Some load-balancing algorithms also take the health check score into account, such as the health-weighted load-balancing algorithm that prefers servers with higher scores over those with lower scores. You should configure the algorithms that work best for you environment.

## Frequency

The Directory Server periodically invokes health checks to monitor each LDAP external server and initiates health checks in response to failed operations. It checks the health of the LDAP external servers at

intervals configured in the LDAP server's `health-check-frequency` property. The Directory Proxy Server contains safeguards to ensure that only one health check is in progress at any time against a backend server to avoid affecting its ability to process other requests.

To associate a health check with an LDAP external server and set the health check frequency, you must configure the `health-check` and `health-check-frequency` properties of the LDAP external server.

For more information about configuring the properties of the external server, see [Configuring an external server using `dsconfig`](#) on page 1198.

#### Server states and search response times

In some cases, an LDAP health check defines different sets of criteria for promoting and demoting the state of a server. A `degraded` server might need to meet more stringent requirements to be reclassified as `available` than originally for it to be considered `degraded`.

If response time is used in the process of determining the health of a server, then the Directory Server might have a faster response time threshold for transitioning a server from `degraded` back to `available` than the threshold used to consider it `degraded` in the first place. This threshold difference helps avoid cases in which a server repeatedly transitions between the two states because it is operating near the threshold.

For example, the health check used to measure search response time is configured to mark any server as `degraded` when the search response time is greater than 1 second. You can configure that the response time must be less than 500 ms before the server is made available again so that the Directory Server does not flip back and forth between `available` and `degraded`.

For more information about configuring health checks, see [Configuring Server Health Checks](#).

#### About load-balancing algorithms

Load-balancing algorithms determine which server in a set of similar servers to use to process a client request.

The PingDirectory Server provides the following load-balancing algorithms:

##### Fewest operations

Forwards request to the backend server with the fewest operations currently in progress.

##### Single server

Sends requests to the same server and doesn't attempt to fail over to another server if the target server is unavailable.

##### Weighted

Administrators explicitly assign numeric weights to individual servers or sets of servers to control how likely they are to be selected for processing requests relative to other servers.

##### Health-based weighting

Uses the health check score to assign weights to each of the servers so that a server with a higher score gets a higher percentage of the traffic than a server with a lower score. The proportion of traffic received is the difference between their health check scores.

##### Failover

Sends requests to a given server first. If that server fails, then the request sends to another specified server as specified in the ordered failover server list.

For more information about configuring load balancing, see [Configuring Load Balancing](#).

#### Algorithm criteria

The algorithm takes the following criteria into account:

#### Location of the server

Servers in the same location as the Directory Server are preferred over those in alternate locations.

#### Health of the server

Servers that are `available` are preferred over those that are `degraded`. In some cases, the health check score can be used to further differentiate between servers with the same health check state.

#### Route requests consistency

Requests from a single client can be consistently routed to the same directory server instance to avoid problems such as propagation delay from replication.

#### Operation retries

Retries the operation in an alternate server if the request fails or the operation times out. You can control if the retry is allowed and, if so, how many times to retry and the time out interval.

### About proxy transformations

Proxy transformations are used to rewrite requests and responses as they pass through the Directory Server. Proxy data transformations are helpful for clients that use an old schema or that contain a hard-coded schema.

Use the Directory Server proxy transformations to:

- Provide a distinguished name (DN) and attribute mapping altering both requests to the server as well as responses from the server.

For example, a client sends a request to `o=example.com` even though the directory server handling the request uses `dc=example,dc=com`. The Directory Server can transparently remap the request so that the server can process it and map it back to the original DN of the client request when the value is returned.

- Alternatively, if a client tries to use the attribute `userID`, the Directory Server can map it to `uid` before sending the request on to the backend LDAP server. The Directory Server then remaps the response to `userID` when the value is returned.
- Suppress a specified attribute so that it is never returned to clients. Also, it can cause the server to reject requests which target that particular attribute.
- Prevent entries that match a given search filter from being returned to clients.

For more information about configuring proxy transformations, see [Configuring Proxy Transformations](#).

### About request processors

A request processor encapsulates the logic for handling an operation, ensuring that a given operation is handled appropriately.

The request processor can:

- Process the operation directly
- Forward the request to another server
- Hand off the request to another request processor

Directory Proxy Server request processors can be used to forward certain controls, including the batch transaction control and the LDAP join control. The batch transaction control must target a single Berkley DB backend. For more information about the controls, see [LDAP SDK for Java documentation](#).

PingDirectory Server provides the following types of request processors:

#### Proxying request processors

Forwards operations received by the Directory Server to other LDAP external servers.

#### Entry-balancing request processors

Splits data across multiple servers. They determine which set of servers are used to process a given operation. They then hand off operations to proxying request processors so that requests can be forwarded to one of the servers in the set.

#### Failover request processors

Perform ordered failover between other types of request processors, sometimes with different behavior for different types of operations.

For information about configuring request processors, see [Configuring Request Processors](#).

#### About server affinity providers

The Directory Server supports the ability to forward a sequence of requests to the same external server if specific conditions are met, called server affinity.

Use the server affinity provider to establish an affinity to a particular backend server for certain operations.

The following provider configurations and server affinity methods are available in the Directory Proxy Server:

##### Client connection Server Affinity

Requests from the same client connection consistently route to the same backend server.

##### Client IP address Server Affinity

All requests coming from the same client system consistently route to the same backend server.

##### Bind DN Server Affinity

All requests from the same user consistently route to the same backend server.

For information about configuring server affinity, see [Configuring Server Affinity](#).

#### About subtree views

A subtree view can be used to make a portion of the directory information tree (DIT) available to a client by associating a request processor with a base distinguished name (DN).

A subtree views allow you to route operations concerning one set of data to a particular set of data sources and operations concerning another set of data to another set of data sources. Multiple subtree views are involved in processing a request, such as searches that have a scope that is larger than the subtree view.

The subtree view includes using a single base DN to identify the portion of the DIT. They might have hierarchical relationships: for example, one subtree view is configured for `dc=example, dc=com` and another for `ou=People, dc=example, dc=com`.

For information about configuring a subtree view, see [Configuring Subtree Views](#).

#### About the connection pools

PingDirectory Server maintains either one or two connection pools to the backend server, depending on the type of backend server you use.

PingDirectory Server maintains either one pool for all types of operations or two separate pools for processing bind and non-bind operations from clients. When PingDirectory Server establishes connections, it authenticates them using the authentication mechanism defined in the configuration of the external server.

These connections are re-used for all types of operations forwarded to the backend server. You can configure the bind distinguished name (DN) and password in the Directory Proxy Server.

When a client sends a bind request to the Directory Server, the server looks at the type of bind request that was sent:

- If the bind request is a SASL bind request, authentication is processed by the Directory Server itself and does not forward to the backend server, however, the Directory Server can use information contained in the backend server as needed.
- If the bind request is a simple bind request, and the bind DN is within the scope of data supplied by the backend server, the Directory Server forwards the client request to the backend server so that it uses the credentials provided by the client.

Regardless of the authentication method the client uses, the Directory Server remembers the identity of the client after the authentication completes. For any subsequent requests sent by that client, the Directory Server uses the configured authorization method to identify the client to the backend server.

Even though the operation is forwarded over a connection that is authenticated as a user defined in the Directory Proxy Server configuration, the request processes through the backend server under the authority of the end client.

### About client connection policies

Client connection policies define the general behavior the server exhibits when communicating with a set of clients.

Each policy contains the following:

- A set of connection criteria that define which client is associated with the policy based on information the server has about the client, including:
  - Client address
  - Protocol used
  - Secure communication mechanism
  - Location of the client's entry in the Directory Server
  - Contents of the client's entry

These criteria are the same as those used for filtered logging. For example, different client connection policies could be established for different classes of users, such as root and non-root users.

- A set of constraints on the type of operations a client can request. You can specify whether a particular type of operation is allowed for clients.

For some operation types, such as extended operations, you can allow only a particular subset of an operation type, such as a particular extended operation.

- A set of subtree views that define information about the parts of the directory information tree (DIT) the client can access.

When a client connection is established, only one client connection policy is applied. If the criteria for several policies match the same client connection, the evaluation order index is used as a tiebreaker. If no policy matches, the client connection is terminated. If the client binds, changing its identity, or uses StartTLS to convert from an insecure connection to a secure connection, then the connection is evaluated again to determine if it matches the same or a different client connection policy. The connection is terminated if it no longer matches any policy.

For more information about configuring a client connection policy, see [Configuring Client Connection Policies](#).

### About entry balancing

Entry balancing allows you to automatically spread entries below a common parent among multiple sets of directory servers for improved scalability and performance.

Entry balancing can take advantage of a global index. A global index is an in-memory cache used for quickly determining which set or sets of servers to use to process a request based on the entry distinguished names (DNs) and attribute values.

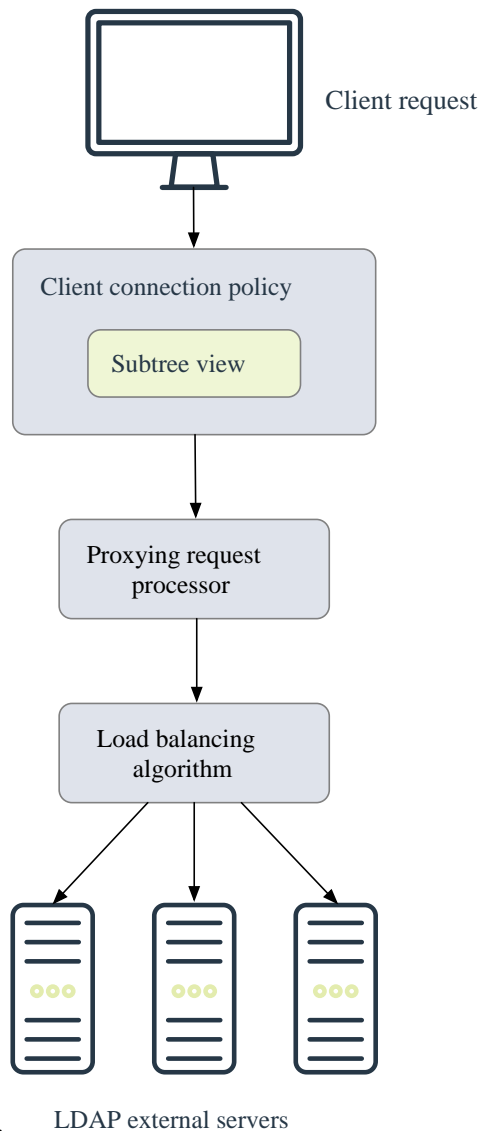

For information about configuring entry balancing, see [Deploying an entry-balancing proxy configuration](#) on page 1361.

## Server component architecture

This section provides an overview of the process flow between the Directory Server components for a simple proxy deployment and an entry-balancing deployment.

### Architecture of a simple Directory Server deployment

A simple Directory Server deployment is illustrated in figure 1.

### Process Flow for Directory Proxy Server

#### Processing steps

1. A client request is initiated.
2. The client connection policy processes the client request.
3. The client connection policy contains a subtree view, which defines the portion of the directory information tree (DIT) available to clients and determines if the DIT is available.
4. After the Directory Server determines that the DIT is available, it passes the request to the request processor, which defines the logic for processing the request.
5. The request processor passes the request to a load-balancing algorithm, which determines the server in a set of servers responsible for handling the request.

6. The request is passed to the LDAP external server.

**Note:**

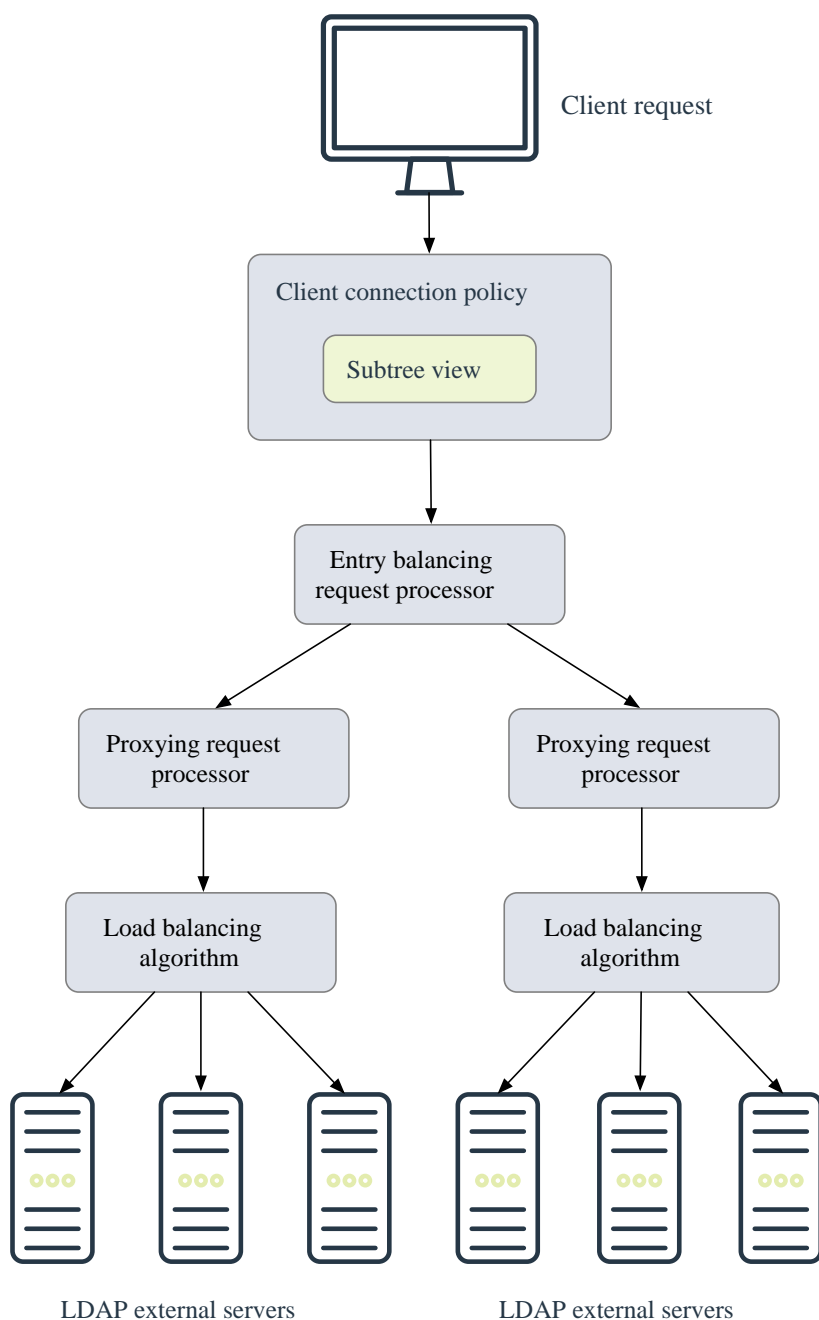

The LDAP external server contains properties that define the server's location in a topology and the health checks used to determine if the server is functioning properly.

This information can be used by the load-balancing algorithm for determining how to route requests.

**Architecture of an entry-balancing Directory Server deployment**

Entry balancing is used when the data set is too large to fully cache on a single server or when the write performance requirements of an environment are higher than can be achieved with a single replicated set of servers. In such cases, the data can be split across multiple sets of servers, increasing the memory available for caching and the overall write performance in proportion to the number of server sets.

The following figure shows how a client request is treated in an entry-balancing Directory Server deployment.

1. A client request is initiated.
2. The client connection policy processes the client request.
3. The client connection policy contains a subtree view, which determines how the Directory Proxy Server communicates with a set of clients. It contains a subtree view that represents the base distinguished name (DN) for the entire deployment. The data set splits beneath this base DN.
4. The Directory Server passes the request to the entry-balancing request processor.

The entry-balancing request processor contains a global attribute index property, which helps the request processor determine which server set contains the entry and how to properly route the request. It also contains a placement algorithm, which helps it select the server set in which to place new entries created by add requests.

5. The entry-balancing request processor has beneath it multiple proxying request processors that handle multiple unique sets of data.

6. The proxying request processors passes the request to a load-balancing algorithm, which determines which LDAP external server should handle the request.

**Note:**

As with a simple proxy deployment, this LDAP external server contains properties that define the server's location and the health checks that determine if the server is functioning properly.

7. The request is passed to the LDAP external server.

For information about entry-balancing replication, see [Overview of replication in an entry-balancing environment](#) on page 1386.

## Directory Server configuration overview

The following topic provides an overview of the component configurations for your Directory Server deployment.

### Configuring locations for your deployment

A location is a collection of servers that share access and latency characteristics. For example, your deployment might include two data centers, one in the east and one in the west. These data centers are configured as two locations in the Directory Server. Each location is associated with a name and an ordered list of failover locations to use if none of the servers in the preferred location are available.

### Configuring the Directory Server location

You update the configuration to specify the location of the Directory Server instance.

### Configuring health checks for the LDAP external servers

You configure at what point the Directory Proxy Server considers an LDAP external server to be available, of degraded availability, or unavailable. Each health check can be configured to be used automatically for all LDAP external servers or for a specified set of servers.

### Configuring the LDAP external servers

You define each of the external directory servers, including the server type. You can configure Ping Identity Directory Servers, Java System Directory Servers, or generic LDAP servers. You also assign the server-specific health checks configured previously.

### Configuring the load-balancing algorithm

You configure the load-balancing algorithm that the Directory Server uses to determine which server in a set of similar servers to use to process a client request. The Directory Server provides default algorithms. You can create new algorithms either using an existing algorithm as a template or creating one from scratch.

### Configuring the proxying request processor

You configure proxying request processors that forward operations received by the Directory Server to other LDAP external servers.

### Configuring subtree views

A subtree view defines the portion of the directory information tree (DIT) available to a client. Each subtree view can be associated with a load-balancing algorithm to help distribute the work load.

Configuring the client connection policy

You configure policies to classify how the Directory Server manages different client connections. The client connection policy can be used to control the types of operations that a client might perform and the portion of the DIT that the client can access. Restrictions configured in a client connection policy take precedence over any capabilities granted by access control or privileges.

## Installing PingDirectoryProxy Server

---

This section describes how to install PingDirectoryProxy Server and includes pre-installation requirements and considerations.

It includes the following sections:

- [Before you begin](#) on page 1123
- [Preparing the operating system](#) on page 1127
- [teo1564011417715Getting the installation packages](#) on page 340
- [Signing on to the Administrative Console](#) on page 340
- [Ping license keys](#) on page 355
- [Installing the Directory Proxy Server](#) on page 1134
- [Directory Server folder layout](#) on page 1140

### Before you begin

Review requirements and considerations before installing the software and configuring the PingDirectory Server objects.

#### Important:

Each server deployment requires an execution of `setup`. Duplicating a server-root is not supported. The installation of the server doesn't write or require any data outside of the server-root directory.

After you run the `setup` tool, do not copy the server-root to another location or system to duplicate the installation because this isn't a supported method of deployment. If a host or file system change is needed, you can move the server-root to another host or disk location.

Make sure a Network Time Protocol (NTP) system is in place so that multi-server environments are synchronized and timestamps are accurate.

### System requirements

The PingDirectory server requires certain software packages to operate properly.

Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software are suspected of causing issues.

The following system requirements are qualified and certified to be compatible with the PingDirectory server.

#### Running PingDirectory on Amazon Web Services (AWS)

To take advantage of snapshots for backing up any important files, install the PingDirectory server on an Elastic Block Store (EBS) file system. You should also move any databases, logs, and other files to a high-performance file system that is separate from the rest of the server image and create an S3 bucket for storing backups, schema, and other artifacts.

The following guidelines and considerations can help you avoid environmental constraint issues:

- PingDirectory does not support the Elastic File System (EFS) for database persistence.
- For the lowest cost, use t3.medium or t3a.medium and up.

- For the best performance, use m5dn, c5dn, or r5dn instance types (size xlarge and up) and the local SSD for PingDirectory database persistence.
- The A1 and M6g instance types, Ampere and Graviton, are not qualified by Ping at this time.
- Using network load balancers (NLBs) can lead to severed connections, which could cause issues that are difficult to diagnose.

## Platforms

The following operating systems support PingDirectory server, PingDirectoryProxy server, and PingDataSync server's installation and deployment:

- Amazon Linux 2
- Canonical Ubuntu 18.04 LTS and 20.04 LTS
- CentOS 7.7 and 8.1
- Microsoft Windows Server 2016 and 2019
- Oracle Linux 7.9 and 8.2
- Red Hat Enterprise Linux ES 7.7, 8.1, and 8.2
- SUSE Linux Enterprise 12 SP5 and 15 SP1

### Attention:

This product has been tested with the default configurations of all operating system components. Customized implementations or installed third-party plugins from your organization might affect the deployment of this product.

## Docker

The following Docker version and operating systems are a pre-installation requirement:

- Version: Docker 19.03.5
- Base image operating system: Ubuntu 18.04 LTS
- Base image operating system: Alpine Linux 3.11
- Base image operating system: Oracle Linux 7.9

For more information, view the Directory Server Docker Image on DockerHub at [pingidentity/pingdirectory](https://hub.docker.com/r/pingidentity/pingdirectory) and visit the [PingIdentity DevOps documentation](#).

### Note:

Only the Directory Server software is licensed under Ping Identity's end user license agreement, and any other software components contained within the image are licensed solely under the terms of the applicable open source/third-party license.

Ping Identity accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

## Java Runtime Environment

The following [Java Development Kit \(JDK\)](#) versions are a pre-installation requirement:

- Oracle JDK 8 64-bit
- Oracle JDK 11 LTS 64-bit
- OpenJDK 8 64-bit
- OpenJDK 11
- Corretto 8

- Corretto 11

**Note:**

The [Ping Identity Java Support Policy](#) applies to your [Java Runtime Environment \(JRE\)](#).

## Browsers

The following are the browsers supported by the PingDirectory server administrative console:

- Chrome
- Firefox
- Edge

## Platforms

The following operating systems support PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server's installation and deployment.

- Amazon Linux 2
- Canonical Ubuntu 18.04 LTS and 20.04 LTS
- CentOS 7.7 and 8.1
- Microsoft Windows Server 2016 and 2019
- Oracle Linux 7.9 and 8.2
- Red Hat Enterprise Linux ES 7.7, 8.1, and 8.2
- SUSE Linux Enterprise 12 SP5 and 15 SP1

**Attention:**

This product has been tested with the default configurations of all operating system components. Customized implementations or installed third-party plugins from your organization might affect the deployment of this product.

## Docker

The following Docker version and operating systems are a pre-installation requirement.

- Version: Docker 19.03.5
- Base image operating system: Ubuntu 18.04 LTS
- Base image operating system: Alpine Linux 3.11
- Base image operating system: Oracle Linux 7.9

For more information, view the Directory Server Docker Image on DockerHub at [pingidentity/pingdirectory](#) and visit the [PingIdentity DevOps documentation](#).

**Note:**

Only the Directory Server software is licensed under Ping Identity's end user license agreement, and any other software components contained within the image are licensed solely under the terms of the applicable open source/third-party license.

Ping Identity accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

## Java Runtime Environment

The following Java Development Kit versions are a pre-installation requirement.

- Oracle JDK 8 64-bit

- Oracle JDK 11 LTS 64-bit
- OpenJDK 8 64-bit
- OpenJDK 11
- Corretto 8
- Corretto 11

**Note:**

The [Ping Identity Java Support Policy](#) applies to your Java Runtime Environment.

## Browsers

### Administration Console

- Chrome
- Firefox
- Internet Explorer 11 or later

### End users

- Chrome
- Edge
- Firefox
- Internet Explorer 11 or later
- Safari

## Defining a naming strategy for server locations

The various objects defined in the PingDirectory Server are specific to a particular location.

Location names can define a grouping of PingDirectory Server products based on physical proximity.

A location is usually associated with a single datacenter location. During the installation, assign a location to each server for optimal inter-server behavior. The location assigned to a server within Global Configuration can be referenced by components within the server as well as processes external to the server to satisfy "local" versus "remote" decisions used in replication, load balancing, and failover.

## Installing Java

### About this task

For optimized performance, the requires Java for 64-bit architectures. You can view the minimum required Java version on your Customer Support Center portal or contact your authorized support provider for the latest software versions supported.

Even if your system already has Java installed, you can create a separate Java installation for use by the to ensure that updates to the system-wide Java installation do not inadvertently impact the . This setup requires that you download the 64-bit version of the Java Development Kit (JDK) instead of the Java Runtime Environment (JRE).

### Steps

1. Go to the [Oracle download site](#).
2. Click JDK Download.
3. On the download page, select the download file for your operating system and accept the license agreement to start the download.

## Preparing the operating system

You should make the following changes to your operating system depending on the production environments on which the Directory Proxy Server server will run:

- [Configure the file descriptor limits](#)
- [Enable the server toPre listen on privileged ports \(Linux\)](#)
- [Set the file system flushes](#)
- [Disable file system swapping](#)
- [About editing OS-level environment variables](#)
- [Install sysstat and pstack \(RedHat\)](#)
- [Install dstat \(SUSE Linux\)](#)
- [Omit vm.overcommit\\_memory](#)
- [Manage system entropy](#)
- [Set file system event monitoring \(inotify\)](#)
- [Tune the I/O scheduler](#)

### Configuring the file descriptor limits

Operating system default file descriptor limits restrict the number of PingDirectory Server connections. Change the descriptor limits to allow more connections.

About this task

The Directory Server allows for an unlimited number of connections by default, but the file descriptor limit on the operating system restrict the number of connections. Many Linux distributions have a default file descriptor limit of 1024 per process, which might be too low for the server if it needs to handle a large number of concurrent connections.

If the operating system relies on `systemd`, see the Linux operating system documentation for instructions on setting the file descriptor limit.

After you set the operating system limit, you can configure the number of file descriptors that the server will use either by using a `NUM_FILE_DESCRIPTOR` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as `NUM_FILE_DESCRIPTOR=12345`. If these are not set, the operating system uses the default of 65535 descriptors. This is an optional change you can make if you want to ensure that the server shuts down safely prior to reaching the file descriptor limit.

Steps

1. Display the current `fs.file-max` limit of the system.

```
sysctl fs.file-max
```

The `fs.file-max` limit is the maximum server-wide file limit you can set without tuning the kernel parameters in the `proc` file system.

2. Edit the `/etc/sysctl.conf` file.

If there is a line that sets the value of the `fs.file-max` property, make sure that its value is set to at least 1.5 times the per-process limit.

If there is no line that sets a value for this property, add the following to the end of the file:

```
fs.file-max = 100000
```

**Note:**

100000 is just an example here. Specify a value of at least 1.5 times the per-process limit.

3. Display the current hard limit of the system.

```
ulimit -aH
```

The `open files (-n)` value is the maximum number of open files per process limit.

The value should be set to at least 65535.

4. Edit the `/etc/security/limits.conf` file.

If the file has lines that set the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines before `#End of file`, making certain to insert a tab between the columns.

```
* soft nofile 65535
* hard nofile 65535
```

#### Note:

The number of open file descriptors is limited by the physical memory available to the host. You can determine this limit with the following command.

```
cat /proc/sys/fs/file-max
```

If the `file-max` value is significantly higher than the 65535 limit, consider increasing the file descriptor limit to between 10% and 15% of the system-wide file descriptor limit. For example, if the `file-max` value is 810752, you could set the file descriptor limit to 100000. If the `file-max` value is lower than 65535, the host is likely not sized appropriately.

5. Reboot your system, and then use the `ulimit` command to verify that the file descriptor limit is set to 65535.

```
# ulimit -n
```

## Result

#### Note:

For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits.

```
/etc/security/limits.d/20-nproc.conf
```

Add or edit the following lines if they do not already exist:

```
* soft nproc 65536
* soft nofile 65536
* hard nproc 65536
* hard nofile 65536
root soft nproc unlimited
```

## Enabling the server to listen on privileged ports (Linux)

For your convenience, enable the server to listen on privileged ports while running as a non-root user.

### About this task

Linux systems have a mechanism called capabilities that is used to grant specific commands the ability to do things that are normally only allowed for a root account:

- The `setcap` command assigns capabilities to an application.
- The `cap_net_bind_service` capability enables a service to bind a socket to privileged ports (port numbers less than 1024).

### Steps

1. If Java is installed in `/ds/java` (and the Java command to run the server is `/ds/java/bin/java`), you can grant the `cap_net_bind_service` capability to the Java binary with the following command.

```
$ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
```

2. Create the file `/etc/ld.so.conf.d/libjli.conf` with the path to the directory that contains the `libjli.so` file.

The java binary needs an additional shared library (`libjli.so`) as part of the Java installation. Because this process imposes stricter limits on where the operating system looks for shared libraries to load for commands that have capabilities assigned, it is also necessary to tell the operating system where to look for this library.

Example: For example, if the Java installation is in `/ds/java`, the contents of that file should be:

```
/ds/java/lib/amd64/jli
```

3. To apply the changes, run the following command.

```
$ sudo ldconfig -v
```

## Setting the file system flushes

Improve Directory Server performance by reducing the span between file system flushes.

### About this task

By default, Linux servers running the ext3 file system flush the data to disk every five seconds.

### Steps

1. If the Directory Server is running on a Linux server using the ext3 file system, consider editing the mount options for that file system to include the following command.

```
commit=1
```

This variable changes the flush frequency from five seconds to one second.

2. You should also set the flush frequency in the `/etc/fstab` file.  
Changing the mount command alone does not survive across reboots.

## Disabling file system swapping

Because file system swapping can interfere with PingDirectory, disable performance tuning tools like **tuned**.

About this task

### Steps

1. Sign on as the root user.
2. Add the line `vm.swappiness = 0` to the file `/etc/sysctl.conf`.
3. Restart the system to apply the change.
4. Optional: If you need to tune performance after disabling file system swapping, do the following:
  - a. Clone the existing performance profile.
  - b. Run **tuned**.
  - c. Add the line `vm.swappiness = 0` to the file `/usr/lib/tuned/profile-name/tuned.conf`.
  - d. To select the updated profile, run **tuned-adm profile customized\_profile**.
  - e. Restart the system to apply the changes.

### About editing OS-level environment variables

Certain environment variables might affect the Directory Server in unexpected ways. This is particularly true for environment variables that are used by the underlying operating system to control how it uses non-default libraries.

For this reason, the Directory Server explicitly overrides the values of key environment variables like `<PATH>`, `<LD_LIBRARY_PATH>`, and `<LD_PRELOAD>` to ensure that environment settings used to start the server do not inadvertently impact its behavior.

If you need to edit any of these environment variables, set the values of those variables by manually editing the `<set_environment_vars>` function of the `lib/_script-util.sh` script.

You must stop (`bin/stop-server`) and re-start (`bin/start-server`) the server for the change to take effect.

### Installing sysstat and pstack (Red Hat)

If you plan to run PingDirectory on a Red Hat Linux system, install a couple of packages, **sysstat** and **pstack**, that are disabled by default, but are useful for troubleshooting.

About this task

The troubleshooting tool **collect-support-data** uses the **iostat**, **mpstat**, and **pstack** utilities to collect monitoring, performance, and stack trace information on the server's processes.

### Steps

- To install **sysstat** on your Red Hat system, run the following command.

```
$ sudo yum install sysstat gdb dstat -y
```

### Installing dstat (SUSE Linux)

**dstat** is a system monitoring tool that can help you troubleshoot PingDirectory servers on SUSE distributions.

About this task

The **collect-support-data** tool uses the **dstat** utility for system monitoring. **dstat** can be obtained from the OpenSUSE project website. The following process shows how to install the **dstat** utility on SUSE Enterprise Linux 11 SP2:

Steps

1. Sign on as the root user.
2. Add the appropriate repository using the **zypper** tool.
3. Install the **dstat** utility.

```
$ zypper install dstat
```

### Omitting vm.overcommit\_memory

An improperly configured value for the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file might cause the **setup** or **start-server** tool to fail.

About this task

For Linux systems, the `vm.overcommit_memory` property sets the kernel policy for memory allocations. The default value of 0 indicates that the kernel determines the amount of free memory to grant a `malloc` call from an application. If the property is set to a value other than zero, the operating system might grab too much memory, reducing the amount of available memory for the **setup** or **start-server** tools.

Steps

Omit the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file to ensure that enough memory is available for these tools.

### Managing system entropy

Linux uses entropy to calculate random data that is used by the system in cryptographic operations.

About this task

Some environments with low entropy might have intermittent performance issues with SSL-based communication. This is more typical on virtual machines but can occur in physical instances as well.

Steps

- Monitor the `kernel.random.entropy_avail` in `sysctl` value for best results.

### Setting file system event monitoring (inotify)

An event monitoring tool such as **inotify** can be configured for notifying processes about file system events, including file creation, deletion, and updates.

About this task

Linux limits the number of **inotify** watches a user can receive.

## Steps

- To increase the limit, edit `etc/sysctl.conf` to add the following line.

```
fs.inotify.max_user_watches = 524288
```

- Run the following command.

```
$ sudo sysctl -w fs.inotify.max_user_watches=524288
```

## Tuning the I/O scheduler

Using the correct I/O scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load.

### About this task

For file systems running on an SSD or in a virtualized environment, use the recommended `noop` scheduler. For all other systems, use the `deadline` scheduler.

The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

## Steps

1. To determine which scheduler is configured on your system, run the following command.

```
$ cat /sys/block/<block-device>/queue/scheduler
```

2. To change the scheduler on a running system, run the following command.

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

3. To apply the change, restart the system.

## Getting the installation packages

Obtain the latest `.zip` release bundle from Ping Identity and extract it to a folder of your choice to begin the installation process.

### About this task

The release bundle contains the Directory Server code, tools, and package documentation.

Complete the following steps to unpack the build distribution.

## Steps

1. Download the latest `.zip` distribution of the Directory Server software.
2. Extract the compressed `.zip` archive file to a directory of your choice.

Example:

```
$ unzip PingDirectory-<version>.zip
```

Result:

You can set up the Directory Server.

## Signing on to the Administrative Console

After the server is installed, access the Administrative Console, <https://<host>/console/login>, to verify the configuration and manage the server. The root user DN or the common name of a root user

DN is required to log into the Administrative Console. For example, if the DN created when the server was installed is `cn=Directory Manager,directory manager` can be used to log into the Administrative Console.

If the Administrative Console needs to run in an external container, such as Tomcat, a separate package can be installed according to that container's documentation. Contact Ping Identity Customer Support for the package location and instructions.

**Note:**

The session timeout for the console is 24 hours by default. When this duration is exceeded, all inactive users are logged off automatically.

To set a different timeout value, configure the `server.sessionTimeout` application parameter, which specifies the timeout duration in seconds. You can set the value as an init parameter either in the console or on the command line, as shown below.

- Console

Select **Web Application Extensions # Console** and then use the **Init Parameter** field.

- Command line

The following example uses a value of 1800 seconds (30 minutes).

```
dsconfig set-web-application-extension-prop --no-prompt \
--extension-name Console \
--add init-parameter:server.sessionTimeout=1800
```

For the change to take effect, restart the HTTP(S) Connection Handler or the server itself.

## Ping license keys

License keys are required to install, update, and renew all Ping products.

How to obtain a license

To obtain a license key, contact your account representative or use the [Ping Identity licensing portal](#).

When do you need a license

A license is required for setting up a new single server instance and can be used site-wide for all servers in an environment. Additionally, you must obtain a new license when updating a server to a new major version, such as when upgrading from 7.3 to 8.0. When cloning a server instance with a valid license, you do not need a new license.

**Note:**

The update process displays a prompt for a new license.

How to specify a license

- Specify a license at setup

You have these options:

- Use the `--licenseKeyFile <path-to-license>` option with `setup`.
- Copy the license file to the server root directory and then run the `setup` tool. The tool discovers the license file.

- Specify a license after setup

Use the Administrative Console or `dsconfig` (in the Topology section, select License).

**Note:**

Placing the new license file in the server root directory does not work in this case.

How to view the license status

To view the details of a license, including its expiration, you have these options:

- The server's `status` tool
- The Administrative Console's **Status** page (On the **Monitors** tab, search for License.)

License expiration

The server provides a notification as the expiration date approaches.

Before a license expires, obtain a new one and install it by using `dsconfig` or the Administrative Console.

**Note:**

An expiring license causes alerts and alarms but does not affect the functionality of the product.

## Installing the Directory Proxy Server

To help administrators install identical proxies, the Directory Server lets you clone a proxy configuration.

About this task

When you deploy PingDirectory Server in a topology, you generally deploy them in pairs. These pairs have identical configurations except for their host name, port name, and possibly their location.

The following sections describe the `setup` tool in more detail, explaining how to install the first and subsequent proxies in your topology:

- [About the setup tool](#) on page 1134
- [Installing Directory Proxy Server in interactive mode](#) on page 1135
- [Installing the first Directory Proxy Server in non-interactive mode](#) on page 1138
- [Installing additional Directory Proxy Server in non-interactive mode](#) on page 1139
- [Installing the Directory Proxy Server with a truststore in non-interactive mode](#) on page 1139

Steps

1. To install a Directory Server, run the `setup` tool.
2. To configure the server, run the `create-initial-proxy-config` tool.  
For more information, see [Using the create-initial-proxy-config Tool](#).
3. To clone the configuration, run the `setup` tool on subsequent servers and clone the configuration on a peer server.

### About the setup tool

The `setup` tool lets you quickly install and configure a stand-alone Directory Server instance.

One of the strengths of the PingDirectory Server is the ease with which you can install a server instance using the `setup` tool.

To install a server instance, run the `setup` tool in one of the following modes:

### Interactive command-line mode

Interactive command-line mode prompts for information during the installation process.

To start the installation in this mode, run the `setup --cli` command.

### Non-interactive command-line mode

Non-interactive command-line mode is designed for setup scripts to automate installations or for command-line usage.

To start the installation in this mode, run `setup` with the `--no-prompt` option as well as the other arguments required to define the appropriate initial configuration.

Perform all installation and configuration steps while signed on to the system as the user or role under which the Directory Server runs.

## Installing Directory Proxy Server in interactive mode

The `setup` tool provides an interactive text-based interface to install a Directory Server instance.

### Installing the first Directory Proxy Server in interactive mode

#### Steps

1. Change to the server root directory.

Example:

```
cd Directory Proxy Server
```

2. Use the `setup` command.

Example:

```
$ ./setup
```

3. Read the Ping Identity End-User License Agreement, and type `yes` to continue.
4. Press **Enter** to accept the default of `no` in response to adding this new server to an existing topology.

Example:

```
Would you like to add this server to an existing Directory Proxy Server
topology? (yes / no) [no]:
```

5. Enter the fully qualified host name for this server, or press **Enter** to accept the default.
6. Create the initial root user DN for this server, or press **Enter** to accept the default.
7. Enter and confirm a password for this account.
8. To enable the Directory Proxy Server services (Configuration, Documentation, and Directory REST API) and Administrative Console over HTTPS, press **Enter** to accept the default. After setup, individual services can be enabled or disabled by configuring the HTTPS Connection Handler.
9. Enter the port on which the Directory Proxy Server should accept connections from HTTPS clients, press **Enter** to accept the default.
10. Enter the port on which the Directory Proxy Server should accept connections from LDAP clients, press **Enter** to accept the default.
11. The next two options enable LDAPS and StartTLS. Press **Enter** to accept the default (yes), or type **no**. If either are enabled, certificate options are required. To use the Java Keystore or the PKCS#12 keystore, the keystore path and the key PIN are required. To use the PKCS#11 token, only the key PIN is required.

## 12. Choose a certificate server option:

Example:

```
Certificate server options:
```

- ```
1) Generate self-signed certificate (recommended for testing purposes
only)
2) Use an existing certificate located on a Java Keystore (JKS)
3) Use an existing certificate located on a PKCS#12 keystore
4) Use an existing certificate on a PKCS#11 token
```

## 13. Choose the desired encryption for backups and log files from the choices provided:

Choose from:

- Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments, and you should use the same encryption passphrase when setting up each server in the topology.
- Encrypt data with a key generated from a passphrase read from a file.
- Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
- Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
- Do not encrypt server data.

14. To configure your Directory Server to use entry balancing, type `yes`, or accept the default `no`. In an entry balancing environment, entries immediately beneath the balancing base DN are divided into disjoint subsets. Each subset of data is handled by a separate set of one or more directory server instances, which replicate this subset of data between themselves. Choosing `yes` will enable more memory be allocated to the server and tools.

## 15. Choose the option for the amount of memory to assign to this server.

## 16. Enter an option to set up the server with the current configuration, provide new parameters, or cancel.

## 17. After setup is complete, choose the next configuration option.

Example:

```
This server is now ready for configuration What would you like to do?
```

- ```
1) Start 'create-initial-proxy-config' to create a basic
initial configuration (recommended for new users)
2) Start 'dsconfig' to create a configuration from scratch
3) Quit
```

```
Enter choice [1]:
```

## Installing additional Directory Proxy Server instances in interactive mode

### About this task

The `setup` tool provides an interactive text-based interface to install a Directory Server instance that clones a previously installed Directory Proxy Server instance.

### Steps

## 1. Change to the server root directory.

Example:

```
cd Directory Proxy Server
```

2. Use the **setup** command.

Example:

```
$ ./setup
```

3. Read the Ping Identity End-User License Agreement, and type **yes** to continue.

4. Enter **yes** in response to add this new server to an existing topology.

Example:

```
Would you like to add this server to an existing Directory Proxy Server topology? (yes / no) [no]: yes
```

5. Enter the host name of the Directory Proxy Server from which configuration settings are copied during setup.

Example:

```
Enter the host name of the peer Directory Proxy Server from which you would like to copy configuration settings. [proxy.example.com]:
```

6. Type the port number of the peer Directory Proxy Server from which configuration settings are copied during setup. You can press **Enter** to accept the default port, which is 389.

Example:

```
Enter the port of the peer Directory Proxy Server [389]:
```

7. Enter the option corresponding to the type of connection you want to use to connect to the peer Directory Proxy Server.

Example:

```
How would you like to connect to the peer Directory Proxy Server?
1) None
2) SSL
3) StartTLS
```

```
Enter choice [1]:
```

8. Type the root user DN of the peer Directory Proxy Server, or press **Enter** to accept the default (cn=Directory Manager), and then type and confirm the root user password.

Example:

```
Enter the manager account DN for the peer Directory Proxy Server [cn=Directory Manager]:
Enter the password for cn=Directory Manager:
```

9. Enter the host name of the new local Directory Proxy Server.

Example:

```
Enter the fully qualified host name or IP address of the local host [proxy.example.com]:
```

10. Choose the location of your new Directory Proxy Server instance or enter a new one.
11. Enter an option to set up the server with the current configuration, provide new parameters, or cancel.
12. After setup is complete, choose the next configuration option.

## Installing the first Directory Proxy Server in non-interactive mode

Run the `setup` tool in non-interactive mode to automate the installation process using a script or to run the command directly from the command line.

### About this task

The `setup` tool automatically chooses the maximum heap size. You can manually tune the maximum amount of memory devoted to the server's process heap using the `--maxHeapSize` option. The `--maxHeapSize` argument is only valid if the `--entryBalancing` or `--aggressiveJVMTuning` options are also present.

For example, use the `--aggressiveJVMTuning` option to set the maximum amount of memory used by the Directory Proxy Server and tools as follows.

```
--aggressiveJVMTuning --maxHeapSize 256m
```

If you are using entry balancing, tune the amount of memory devoted to the Directory Proxy Server using the `--entryBalancing` option as follows.

```
--entryBalancing --maxHeapSize 1g
```

The amount of memory allowed when using the `--entryBalancing` option is calculated and depends on the amount of system memory available. If you are using entry balancing and also want the tools to get more memory, include both the `--entryBalancing` and the `--aggressiveJVMTuning` options.

```
--entryBalancing --aggressiveJVMTuning --maxHeapSize 1g
```

If you already configured a truststore, you can run the `setup` tool to enable security. The following example enables both SSL and StartTLS security. It also specifies a Java Keystore (JKS) and Truststore that define the server certificate and trusted CA. The passwords for the keystore files are defined in the corresponding `.pin` files, where the password is written on the first line of the file. The values in the `.pin` files are copied to the `server-root/config` directory in the `keystore.pin` file.

```
$ env JAVA_HOME=/ds/java ./setup --cli \
  --no-prompt --rootUserDN "cn=Directory Manager" \
  --rootUserPassword "password" --ldapPort 389 \
  --enableStartTLS --ldapsPort 636 \
  --useJavaKeystore /path/to/devkeystore.jks \
  --keyStorePasswordFile /path/to/devkeystore.pin \
  --certNickName server-cert \
  --useJavaTrustStore /path/to/devtruststore.jks \
  --trustStorePasswordFile /path/to/devtruststore.pin \
  --acceptLicense
```

### Note:

The password to the private key within the keystore is expected to be the same as the password to the keystore. If this is not the case, you can define the private key password within the Administrative Console or `dsconfig` by editing the Trust Manager Provider standard configuration object.

## Steps

- Run **setup** with the `--no-prompt` option.

Example:

The command uses the default root user distinguished name (DN) (`cn=Directory Manager`) with the specified `--rootUserPassword` option. You must include the `--acceptLicense`, `--instanceName`, and `--location` options or the **setup** tool will generate an error message.

```
$ env JAVA_HOME=/ds/java ./setup --no-prompt \
--rootUserDN "cn=Directory Manager" \
--rootUserPassword "password" --ldapPort 389 \
--acceptLicense \
--instanceName ds1 --location Denver
```

## Installing additional Directory Proxy Server in non-interactive mode

Run the **setup** tool in non-interactive mode to automate the installation process using a script or to run the command directly from the command line.

### About this task

## Steps

- Run the **setup** tool with the `--no-prompt` option.

Example:

```
$ env JAVA_HOME=/ds/java ./setup --cli --no-prompt \
--rootUserDN "cn=Directory Manager" \
--rootUserPassword "password" --ldapPort 1389 \
--localHostName proxy2.example.com \
--peerHostName proxy1.example.com --peerPort 389 \
--peerUseNoSecurity --acceptLicense --instanceName ds1 \
--location austin1
```

## Installing the Directory Proxy Server with a truststore in non-interactive mode

### About this task

If you've already configured a trust store, you can use the **setup** tool to enable security. The following example enables SSL security and specifies a Java KeyStore (JKS) and truststore that define the server certificate and trusted certificate authority (CA). The passwords for the keystore files are defined in the corresponding `.pin` files, where the password displays on the first line of the file. The values in the `.pin` files are copied to the `server-root/config` directory in the `keystore.pin` and `truststore.pin` files.

## Steps

- To install with a truststore, run the **setup** tool.

Example:

```
$ env JAVA_HOME=/ds/java ./setup --cli \
--no-prompt --rootUserDN "cn=Directory Manager" \
--rootUserPassword "password" \
--ldapPort 389 --ldapsPort 636 \
--useJavaKeystore /path/to/devkeystore.jks \
--keyStorePasswordFile /path/to/devkeystore.pin \
--certNickName server-cert \
--useJavaTrustStore /path/to/devtruststore.jks \
--acceptLicense \
```

```

--instanceName ds1 --location Denver

In order to update the trust store, the password must be provided

See 'prepare-external-server --help' for general overview

Testing connection to ds-east-01.example.com:1636 ..... Done
Testing 'cn=Proxy User,cn=Root DNs,cn=config' access .....
Created 'cn=Proxy User,cn=Root DNs,cn=config'

Testing 'cn=Proxy User,cn=Root DNs,cn=config' access ..... Done
Testing 'cn=Proxy User,cn=Root DNs,cn=config' privileges ..... Done
Verifying backend 'dc=example,dc=com' ..... Done

```

## Directory Server folder layout

After extracting the Directory Server distribution file, a variety of folders and command-line utilities are available.

### Layout of the Directory Server Folders

Directories, Files, or Tools	Description
License.txt	Licensing agreement for the Directory Server.
README	README file that describes the steps to set up and start the Directory Server.
bak	Stores the physical backup files used with the <b>backup</b> command-line tool.
bat	Stores Windows-based command-line tools for the Directory Server.
bin	Stores UNIX/Linux-based command-line tools for the Directory Server.
classes	Stores any external classes for server extensions.
collector	Used by the server to make monitored statistics available to the Data Metrics Server.
config	Stores the configuration files for the backends ( <code>admin</code> , <code>config</code> ) as well as the directories for messages, schema, tools, and updates.
docs	Provides the product documentation.
import-tmp	Stores temporary imported items.
ldif	Stores any LDIF files that you create or import.
legal-notice	Stores any legal notices for dependent software used with the Directory Server.
lib	Stores any scripts, jar, and library files needed for the server and its extensions.
locks	Stores any lock files in the backends.

Directories, Files, or Tools	Description
logs	Stores log files for the Directory Server.
metrics	Stores the metrics that can be gathered for this server and surfaced in the Data Metrics Server.
resource	Stores the management information base (MIB) files for SNMP and can include <code>ldif</code> files, <code>make-ldif</code> templates, schema files, <code>dsconfig</code> batch files, and other items for configuring or managing the server.
revert-update	The <code>revert-update</code> tool for UNIX/Linux systems.
revert-update.bat	The <code>revert-update</code> tool for Windows systems.
setup	The <code>setup</code> tool for UNIX/Linux systems.
setup.bat	The <code>setup</code> tool for Windows systems.
scim-data-tmp	Used to create temporary files containing SCIM request data.
uninstall	The <code>uninstall</code> tool for UNIX/Linux systems.
uninstall.bat	The <code>uninstall</code> tool for Windows systems.
update	The <code>update</code> tool for UNIX/Linux systems.
update.bat	The <code>update</code> tool for Windows systems.
Velocity	Stores any customized Velocity templates and other artifacts, such as CSS, Javascript, and images, or Velocity applications hosted by the server.

## Uninstalling the Server

The Directory Server provides an `uninstall` command-line utility for quick removal of the code base.

To uninstall a server instance, run the `setup` tool in interactive command-line, or non-interactive command-line mode.

### Interactive command-line mode

Interactive command-line mode is a text-based interface that prompts the user for input. To run this mode, use the `bin/uninstall` command with the `--cli` option.

### Non-interactive command-line mode

Non-interactive command-line mode suppresses progress information from being written to standard output during processing, except for fatal errors. To run this mode, use the `bin/uninstall` command with the `--no-prompt` option.

**Note:**

For standalone installations with a single Directory Server instance, you can also manually remove the Directory Server by stopping the server and recursively deleting the directory and subdirectories, as in the following example.

```
$ rm -rf /ds/PingDirectory
```

## Uninstalling the server in interactive mode

Interactive mode uses a text-based, command-line interface to help you remove your instance.

### About this task

If `uninstall` cannot remove all of the Directory Server files, the `uninstall` tool generates a message with a list of the files and directories that must be manually deleted. The `uninstall` command must be run as either the root user or the same user (or role) that installed the Directory Server.

### Steps

1. From the server root directory, run the `uninstall` command.

Example:

```
$ ./uninstall --cli
```

2. Select the components to be removed.

Choose from:

- Remove all components - If you want to remove all components, press **Enter** to accept the default (remove all).
- Select the components to be removed - If you do not want to remove all components, enter the option to specify the removal of only specific components.

For each type of server component, press **Enter** to remove it or enter `no` to keep it.

3. If the Directory Server is part of a replication topology, enter `yes` to provide your authentication credentials (Global Administrator ID and password). If you are uninstalling a standalone server, continue to step 7.
4. Enter the Global Administrator ID and password to remove the references to this server in other replicated servers, and then enter or verify the host name or IP address for the server that you are uninstalling.
5. Select how you want to trust the server certificate if you have set up SSL or StartTLS. Press **Enter** to accept the default.

Example:

```
How do you want to trust the server certificate for the Directory Server
on server.example.com:389?
```

- ```
1) Automatically trust
2) Use a trust store
3) Manually validate
```

```
Enter choice [3]:
```

6. View the logs for any remaining files and manually remove any remaining files or directories.

If your Directory Server is running, the server shuts down before continuing the uninstall process. The uninstall action processes the removal requests before completing.

## Uninstalling the server in non-interactive mode

The `uninstall` utility provides a non-interactive method to enter the command with the `--no-prompt` option.

### About this task

Another useful argument is the `--forceOnError` option that continues the uninstall process when an error is encountered. If an option is incorrectly entered or if a required option is omitted and the `--forceOnError` option is not used, the command fails and aborts.

### Steps

1. From the server root directory, run `uninstall` tool with the `--remove-all` option to remove all of the Directory Server's libraries.

The optional `--quiet` option suppresses output information.

#### Example:

The following command assumes that the Directory Server is standalone and not part of a replication topology.

```
$ ./uninstall --cli --remove-all --no-prompt --quiet --forceOnError
```

2. If any files or directories remain, manually remove them.

## Uninstalling selected components in non-interactive mode

### Steps

1. From the server root directory, run `uninstall` with the `--backup-files` option to remove the Directory Server's backup files.

#### Example:

```
$ ./uninstall --cli --backup-files --no-prompt --quiet --forceOnError
```

2. To view the other options available to remove specific components, use the `--help` or `-H` option.

## Upgrading the PingDirectoryProxy Server

Administrators can use the Directory Proxy Server's `update` utility to update the current server code with the latest features and bug fixes.

Ping Identity issues new software builds periodically and distributes the software package in `.zip` format. To update the Directory Proxy Server to a newer version, download the build package, and then extract the new server package on the same host as the server you want to update.

#### Note:

Before upgrading a server, ensure that it is capable of starting without severe or fatal errors. For more information, see [Planning your upgrade](#).

During the update process, the updater checks a manifest file that contains a MD5 checksum of each file in its original state when installed from `.zip`. Next, it compares the checksum of the new server files to that of the old server. Any files that have different checksums are updated. For files that predates the manifest file generation, the file is backed up and replaced. The updater also logs all file changes in the history directory to tell what files have been changed.

For schema updates, the `update` tool preserves any custom schema definitions (`99-user.ldif`). For any default schema element changes (if any), the updater warns the user about this condition and then creates a patch schema file and copies it into the server's schema directory. For configuration files, the `update` tool preserves the configuration file, `config.ldif`, unless you need to add new configuration options to the Directory Proxy Server.

When the updater finishes processing, it checks if the newly updated server starts without any fatal errors. If an error occurs during the update process, the `update` tool reverts the server root instance to the server state prior to the update.

## Upgrade overview and considerations

Considerations when upgrading to 8.2.0.0

This upgrade moves to Jetty 9.4. As a result, the HTTPS connection handler no longer supports TLS\_RSA ciphers by default. If you use any legacy HTTPS clients that still require TLS\_RSA ciphers, modify the `ssl-cipher-suite` property of the HTTPS connection handler to include them.

## Upgrading servers in a topology

An update to the current PingDirectory Server release includes the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts.

Before you begin

Before you can update and migrate the admin backend, the following conditions must be satisfied:

- Run the `update` tool and provide LDAP authentication options to the peer servers of the server being updated. The `update` tool connects to the peer servers of the server being updated to obtain the necessary information to populate the topology registry.
- On every server in the topology, configure the encryption protocol requested, either plain, TLS, StartTLS, or SASL, for an LDAP connection.
- Ensure the LDAP credentials are present on every server in the topology.
- Ensure the users related to the LDAP credentials have permissions to read from the admin backend and the config backend of every server in the topology. For example, you can use a root DN user that has `inherit-default-privileges` set to true, such as the `cn=Directory Manager` user, that exists on every server.
- The instance name is set on every server and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server is uniquely identified by its instance name. After the name is set, it cannot be changed.

### Tip:

If needed, use the following command to set the instance name of a server prior to the update.

```
$ bin/dsconfig set-global-configuration-prop \
  --set instance-name:uniqueName
```

### Important:

This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than a 7.x to a 7.x version and is not applicable to any updates to a server version of 8.x or later.

### About this task

Upgrade to a server that uses a topology registry to store network configuration, administrator user accounts, and keys information, as well as migrate the information from the previous server version. The following requirements must be met:

- When the first server is being updated, all other servers in the topology are online.
- When updating additional servers, all topology information was obtained from one of the servers that has already been updated.
- The users related to the provided LDAP credentials have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server and is unique across all servers in the topology.

### Steps

1. To make clustered configuration changes in a mixed-version cluster, choose one of the following options:

Choose from:

- Update each server to the same version.
- Temporarily split up the cluster by changing the `cluster-name` property on the server instance configuration objects.

#### Note:

Changes to clustered configurations are not allowed in mixed-version clusters. This applies to configuration in the `cn=Cluster, cn=config` subtree and only applies to servers with matching cluster names.

2. Make clustered configuration changes again to mirror these changes across the topology.

Result:

When all of these conditions are met, the cluster-wide configuration is synchronized on all servers in the topology.

#### Note:

Older versions have some topology configuration under the `cn=cluster, cn=config` JSON attribute and field constraints. These items do not support mirrored cluster-wide configuration data. In an update, avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree master. If additional configuration steps are needed, see step 4.

3. To synchronize the cluster-wide configuration data across all servers in the topology, run the `config-diff` tool on each pair of servers to determine the differences, and use `dsconfig` to update each instance using the `config-diff` output.

Example:

```
$ bin/config-diff --sourceHost hostName \  
  --sourcePort port \  
  --sourceBindDN bindDN \  
  --sourceBindPassword password \  
  --targetHost hostName \  
  --targetPort port \  
  --targetBindDN bindDN \  
  --targetBindPassword password
```

## Upgrading the Directory Proxy Server

### About this task

Assume that an existing version of the Directory Proxy Server is stored at `PingDirectory-old` directory, which you want to update.

### Steps

1. Make a complete, readable backup of the existing system.

 **Note:**

Make sure you have a clear backout plan and schedule.

2. Download the latest version of the PingDirectory Server software and extract the file.  
Assume the new server is located in the `PingDirectory-new` directory.
3. Use the `--version` option on any command-line utility to check the version number of the Directory Proxy Server instance that you downloaded in step 2.

Example:

You should see the latest revision number.

```
$ PingDirectory-new/setup --version PingDirectory Server
                        8.1.0.0
Build 2011043200609Z Revision 9235
```

4. Run the **update** tool of the newly extracted build to update the Directory Proxy Server code.

Use the `--serverRoot` option to specify the Directory Proxy Server instance that you're upgrading.

Example:

```
$ PingDirectory-new/update --serverRoot PingDirectory-old
```

 **Note:**

The PingDirectory Server provides a web-based Administrative Console for configuring and monitoring the server. If you update the Directory Proxy Server version, you should also update the Administrative Console.

 **Note:**

You must stop the Directory Proxy Server to apply this update.

5. To see which files are changed, go to the `<server-root>/history` directory and open the log file.  
Example:

The file is labelled with the version number and revision.

```
$ view <server-root>/history/1272307020420-8.1.0.0.9235/update.log
```

## Reverting an update

After PingDirectory Server has been updated, you can revert to the last version or one level back using the **revert-update** tool.

### About this task

The **revert-update** tool accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the **revert-update** tool multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing PingDirectory Server, you can run the **revert-update** command to revert to its previous state, then run the **revert-update** command again to return to its original state. The following steps detail reverting from 7.x to a version prior to 7.0.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server displays warnings about "offline configuration changes," but they are not critical and do not appear on subsequent start ups.

To revert to the most recent server version:

### Steps

- Use **revert-update** in the server root directory to revert back to the most recent version of the server.

Example:

```
$ PingDirectory-old/revert-update
```

### Next steps

Reverting from the 7.0 version or later to a version earlier than 7.0 using the **revert-update** command might require extra steps. This is also the case when updating or reverting from a version earlier than 6.2.0.2 to a 6.2.0.2 version or later. These steps are listed when the **update** and **revert-update** tool are run as well. Depending on your installation and configuration, you might need to perform one or more of the following tasks:

- When updating or reverting from 6.2.0.2 or later to a version earlier than 6.2.0.2, indexes might need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and rebuild the indexes using the **rebuild-index** tool. The command for recreating an index is in the **Undo** portion of the `logs/config-audit.log` file. To later revert to an older version, delete and recreate those composite indexes again after the revert process completes.
- When updating to 7.x for the first time, instance names must be set for each server in the topology if they were not previously set. This is done with the following **dsconfig** command.

```
$ bin/dsconfig --bindDN "cn=Directory Manager" \
  --bindPassword secret \
  --no-prompt set-global-configuration-prop \
  --set instance-name:<name>
```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the **admin** backend. As long as new servers are not added to the topology after this update, you can use the **revert-update** command to return to the previous version. However, if new servers are added, then the restored **admin** backend of this server does not contain information about the new servers, and the local server cannot communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.

- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a version earlier than 7.x, any servers in the topology using the topology portion of the configuration rather than the `admin` backend must know that the reverted server was downgraded to the `admin` backend. To do this, run the following `dsconfig` command on one of the servers that has not been reverted.

```
$ bin/dsconfig set-server-instance-prop \
  --instance-name <Reverted server instance name> \
  --set server-version:<Version to which server is reverted>
```

- If the topology does not have a master server when this command is run, the `revert-update` will not succeed. In this case, you must make one of the remaining updated servers in the topology the master with the following command. This enables the chosen instance to run the `revert-update` command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
  --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions, such as 6.x or earlier. To later revert to an older version, you must export the data to LDIF before performing the reversion. Then, re-import the data after the revert process completes. In addition, you must delete the `changelogDb/` and `db/changelog/` directories in the reverted server root after the revert process completes.

## Getting Started with Directory Server

---

- [Running the server](#) on page 371
- [Stopping the Directory Server](#) on page 373
- [Scheduling a server shutdown](#) on page 374
- [Restarting the server](#) on page 374
- [Running the server as a Microsoft Windows service](#) on page 374

### Running the server

Run the server as a background or foreground process.

#### Steps

1. To start the Directory Server, run the `bin/start-server` command on UNIX or Linux systems.

An analogous command is in the `bat` folder on Microsoft Windows systems.

#### Note:

The `bin/start-server` command starts the Directory Server as a background process when no options are specified.

2. Optional: To run the Directory Server as a foreground process, use the `bin/start-server` command with the `--nodetach` option.

## Starting the Directory Server

Start the directory server using the terminal.

### Steps

- To start the server, on the terminal run `bin/start-server`.

Example:

```
$ bin/start-server
```

## Running the server as a foreground process

Use the terminal to run the PingDirectory service as a foreground process.

### Steps

1. To launch the Directory Server as a foreground process, open the terminal and enter `bin/start-server` with the `--nodetach` option.

Example:

```
$ bin/start-server --nodetach
```

2. To stop the Directory Server:

Choose from:

- Press **CTRL+C** in the terminal window where the server is running.
- Run the `bin/stop-server` command from another terminal window.

## Starting the server at boot time

By default, PingDirectory Server does not start automatically when the system is booted. Instead, you must manually start it with the `bin/start-server` command.

### About this task

To configure the Directory Server to start automatically when the system boots, use the `create-systemd-script` utility to create a script, or create the script manually.

### Steps

1. Create the service unit configuration file in a temporary location, where "ds" is the user running PingDirectory.

Example:

```
$ bin/create-systemd-script \
  --outputFile /tmp/ping-directory.service \
  --userName ds
```

2. As a root user, copy the `ping-directory.service` configuration file into the `/etc/systemd/system` directory.
3. To read the new configuration file, reload `systemd`.

Example:

```
$ systemctl daemon-reload
```

4. To start the PingDirectory, run the `start` command.

Example:

```
$ systemctl start ping-directory.service
```

- To configure the PingDirectory to start automatically when the system boots, run the `enable` command.

Example:

```
$ systemctl enable ping-directory.service
```

- Log out as root.

To perform this task on an RC system, create the startup script with `bin/create-rc-script` and move it to the `/etc/init.d` directory.

#### Note:

Create symlinks to this script from the `/etc/rc3.d` directory (starting with an "S" to ensure that the server is started) and `/etc/rc0.d` directory (starting with a "K" to ensure that the server is stopped).

### Signing on to the Administrative Console

After the server is installed, access the administrative console, `https://hostname:HTTPport/console/login`, to verify the configuration and manage the server.

To sign on to the administrative console, use the initial root user DN specified during setup (by default `cn=Directory Manager`).

You can use the `dsconfig` command or the administrative console to create additional root DN users in `cn=Root DNs`, `cn=config`. These new users require the fully qualified DN as the username, such as `cn=new-admin, cn=Root DNs, cn=config`. To use a simple username (without the `cn=` prefix) for signing on to the administrative console, the root DN user must have the `alternate-bind-dn` attribute configured with an alternate name, such as "admin."

The default link to the administrative console is `https://hostname:HTTPport/console/login`.

If you need to run the administrative console in an external container, such as Tomcat, you can install a separate package (`/server-root/resource/admin-console.zip`) according to that container's documentation.

#### Note:

The default session timeout for the console is 24 hours. When this duration is exceeded, all inactive users are signed off automatically.

To set a different timeout value, configure the `server.sessionTimeout` application parameter, which specifies the timeout duration in seconds. You can set the value as an init parameter either in the console or on the command line, as shown below.

For changes to take effect, restart the HTTP(S) Connection Handler or the server.

#### Console

- Go to **Web Application Extensions # Console**.
- Use the **Init Parameter** field.

#### Command line

- The following example uses a value of 1800 seconds (30 minutes).

```
dsconfig set-web-application-extension-prop --no-prompt \
--extension-name Console \
--add init-parameter:server.sessionTimeout=1800
```

## Stopping the Directory Server

The Directory Server provides a simple shutdown script, `bin/stop-server`, to stop the server. Run it manually from the command line or within a script.

### About this task

If the Directory Server has been configured to use a large amount of memory, then it might take several seconds for the operating system to fully release the memory and make it available again. If you try to start the server too quickly after shutting it down, then the server might fail because the system does not yet have enough free memory. On UNIX systems, run the `vmstat` command and watch the values in the "free" column increase until all memory held by the Directory Server is released back to the system.

You can also set a configuration option that specifies the maximum shutdown time a process might take.

### Steps

- Use the `bin/stop-server` tool to shut down the server.

Example:

```
$ bin/stop-server
```

## Scheduling a server shutdown

Schedule a server shutdown.

### Steps

- To schedule a server shutdown, use the `bin/stop-server` tool with the `--stopTime YYYYMMDDhhmmss` option .

The Directory Server schedules the shutdown and sends a notification to the `server.out` log file. The following example sets up a shutdown task that is scheduled to be processed on June 6, 2012 at 8:45 A.M. CDT. The server uses the UTC time format if the provided timestamp includes a trailing "Z", for example, `20120606134500Z`. The command also uses the `--stopReason` option that writes the reason for the shut down to the logs.

Example:

```
$ bin/stop-server --stopTime 20120606134500Z --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --stopReason "Scheduled offline maintenance"
```

## Restarting the server

Restart the Directory Server.

### About this task

Running the command is equivalent to shutting down the server, exiting the Java Virtual Machine (JVM) session, and then starting up again.

### Steps

- Go to the server root directory, and run the `bin/stop-server` command with the `-R` or `--restart` options.

Example:

```
$ bin/stop-server --restart
```

## Running the server as a Microsoft Windows service

The server can run as a Windows service on Windows Server 2012 R2 and Windows Server 2016. This enables signing-out of a machine without stopping the server.

### Registering the server as a Windows service

Register the server as a Windows service using the Windows command prompt.

About this task

Perform the following steps to register the server as a service:

#### Steps

1. Stop the server with `bin/stop-server`.  
You cannot register a server while it is running.
2. To register the server as a service, from a Windows command prompt, run `bat/register-windows-service.bat`.
3. After registration, start the server from the Windows Services Control Panel or with the `bat/start-server.bat` command.

Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

### Running multiple service instances

Only one instance of a particular service can run at one time.

About this task

Services are distinguished by the `wrapper.name` property in the `<server-root>/config/wrapper-product.conf` file.

#### Steps

1. To run additional service instances, change the `wrapper.name` property on each additional instance.
2. Add or change descriptions of the service in the `wrapper-product.conf` file.

### Deregistering and uninstalling services

To uninstall a service, you must first deregister it.

About this task

While a server is registered as a service, it cannot run as a non-service process or be uninstalled.

#### Steps

1. To remove the service from the Windows registry, use the `bat/deregister-windows-service.bat` file.
2. To uninstall the server, run the `uninstall.bat` script.

### Configuring log files for services

About this task

The log files are stored in `<server-root>/logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or the file reaches its maximum size. Only the last three log files are retained.

## Steps

These configurations can be changed in the `<server-root>/config/wrapper.conf` file.

## Configuring the Directory Proxy Server

---

After you have set up PingDirectory Server, you can manage your deployment using the configuration framework and management tools.

### About the configuration tools

You can access and modify your PingDirectory Server in two ways.

#### Administrative Console

PingDirectory Server provides an Administrative Console for graphical server management and monitoring. The console functions are equivalent to the `dsconfig` tool for viewing or editing configurations.

All configuration changes using the administrative console are recorded in `logs/config-audit.log`, which also has the equivalent reversion commands if you need to undo a configuration.

#### `dsconfig` Command-Line Tool

The `dsconfig` tool is a text-based menu-driven interface to the underlying configuration. The tool runs the configuration using three operational modes:

- Interactive command-line mode
- Non-interactive command-line mode
- Batch mode

All configuration changes made using this tool are recorded in `logs/config-audit.log`.

### Using the `create-initial-proxy-config` tool

The `create-initial-proxy-config` tool can be used to initially configure the Directory Server. We strongly recommend that you use the `create-initial-proxy-config` tool for your initial Directory Server configuration. This tool prompts you for basic information about your topology, including external servers, their locations, and credentials for communicating with them. Once the configuration is complete, the tool writes the configuration to a `dsconfig` batch file and allows you to apply the configuration to the local Directory Server. The tool assumes the following about your topology:

- All servers are accessible through a single user account. This user account must be a root user that is not generally accessible to clients to avoid inadvertent changes, deletions, or backend server availability issues due to reimporting data.
- All servers support the same type of communication security.
- All external servers are any combination of Ping Identity Directory Server, Sun Directory Server, or Red Hat (including Fedora and 389) instances.

If your topology does have these characteristics, you can use the tool to define a basic configuration that is saved to a `dsconfig` batch file. You can then run the `dsconfig` tool to fine-tune the configuration. You can also use this tool to configure an entry balancing configuration, which allows you to automatically spread entries below a common parent among multiple sets of directory servers for improved scalability and performance.

The `create-initial-proxy-config` tool produces a log file called `create-initial-proxy-config.log` that is stored in the local Directory Proxy Server's `logs` directory.

You can only run the `create-initial-proxy-config` tool once for the initial configuration of each Directory Proxy Server instance. To tune your configuration, use the `dsconfig` tool. When installing a second Directory Proxy Server, it will not be necessary to run the `create-initial-proxy-config` tool again, as the Directory Proxy Server setup has the ability to clone the settings from an existing Directory Proxy Server.

This section describes how to use this tool to configure a standard Directory Proxy Server deployment as well as an entry balancing configuration.

## Configuring a standard Directory Proxy Server deployment

Install a standard Directory Proxy Server deployment using the `create-initial-proxy-config` tool.

About this task

### Note:

Remember that you deploy Directory Proxy Server in pairs. Each pair should be configured identically except for their host name, port, and possibly their location.

### Steps

1. After initial installation, select the number to start the `create-initial-proxy-config` tool automatically, or run it manually at the command line from the server root directory, `<server-root>/PingDirectory`.

```
$ ./bin/create-initial-proxy-config
```

2. If the servers do not meet the displayed configuration requirements, you can enter `no` to quit the process.

```
Some assumptions are made about the topology in order to keep this tool simple:
```

- 1) all servers will be accessible via a single user account
- 2) all servers support the same communication security type
- 3) all servers are PingDirectory Server, Directory Server, Java System 5.x, 6.x, or 7.x, or Red Hat (including Fedora and 389) directory servers

```
If your topology does not have these characteristics you can use this tool to define a basic configuration and then use the 'dsconfig' tool or the Administrative Console to fine tune the configuration.
```

```
Continue? (yes / no) [yes]:
```

3. Enter the distinguished name (DN) for the Directory Proxy Server user account, and then enter and confirm the password for this account.

```
Enter the DN of the proxy user account [cn=Proxy User,cn=Root DNs,cn=config]:
```

```
Enter the password for 'cn=Proxy User,cn=Root DNs,cn=config':
```

Confirm the password for 'cn=Proxy User,cn=Root DNs,cn=config':

**Note:**

You should not use `cn=Directory Manager` account for communication between the Directory Proxy Server and the Directory Server.

For security reasons, the account used to communicate between the Directory Proxy Server and the Directory Server should not be directly accessible by clients accessing the Directory Proxy Server.

For more information about this account, see [Configuring LDAP external servers](#) on page 1196.

- Specify whether to use secure communication with the Directory Server instances.

```
>>>> External Server Communication Security

Specify the type of security that the Directory Proxy Server will use
when communicating with directory server instances:

    1) None
    2) SSL
    3) StartTLS

    b) back
    q) quit

Enter choice [1]:
```

- Enter the base DN of the Directory Server instances that will be accessed through the Directory Proxy Server. Press Enter when you have finished specifying the DNs.

```
Enter a base DN of the directory server instances that will be accessed
through the Identity Proxy:

    b) back
    q) quit

Enter a DN or choose a menu item [dc=example,dc=com]:
```

The Directory Proxy Server will create subtree views using each base DN to define portions of the external servers' directory information tree (DIT) available for client access. You can specify more than one base DN.

- Specify whether the entries under your defined subtree view will be split across multiple servers in an entry balanced deployment.

Press Enter to accept the default setting of no.

- Define a location for your server, such as the name of your data center or the city where the server is located.

```
Enter a location name or choose a menu item: east
```

- Optional: If you defined more than one location, specify the location that contains the Directory Proxy Server itself.

```
Choose the location for this Directory Proxy Server

    1) east
    2) west

    b) back
```

```
q) quit
Enter choice [1]: 1
```

9. Define the host:port used by the LDAP external servers.

```
Enter a host:port or choose a menu item [localhost:389]: ldap-
east-01.example.com:389
```

**Note:**

If you have specified more than one location, you will complete this process for each location.

10. Select the option **Yes, and all subsequent servers** to indicate that you want the tool to create a proxy user account on all of your LDAP external servers within that location.

```
Would you like to prepare ldap-east-01.example.com:389 for access by the
Directory Proxy Server?

1) Yes
2) No
3) Yes, and all subsequent servers
4) No, and all subsequent servers

Enter choice [1]: 3
```

11. If the proxy user account does not already exist on your LDAP external server, create the account by connecting as `cn=Directory Manager`.

```
Would you like to create or modify root user 'cn=Proxy User' so that it
is available for this Directory Proxy Server? (yes / no) [yes]:
Enter the DN of an account on ldap-east-01.example.com:389 with which to
create or manage the 'cn=Proxy
User' account [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':

Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User' privileges ..... Done
Verifying backend 'dc=example,dc=com' ..... Done
```

12. Repeat steps 9-12 for the servers in the other location. When finished, press Enter to finish configuring the location.
13. Review the configuration summary. After you have confirmed that the changes are correct, press Enter to write the configuration.

```
>>>> Configuration Summary

External Server Security:  SSL
Proxy User DN:            cn=Proxy User,cn=Root DNs,cn=config

Location east
  Failover Order: west
  Servers: localhost:1636

Location west
  Failover Order: east
  Servers: localhost:2636

Base DN: dc=example,dc=com
```

```
Servers: localhost:1636, localhost:2636
```

```
b) back
q) quit
w) write configuration file
```

```
Enter choice [w]:
```

14. Enter `yes` to apply the configuration changes locally to the Directory Proxy Server.

```
This tool can apply the configuration changes to the local Identity
Proxy. This requires any configured Server SDK extensions to be in
place. Do you want to do
this? (yes / no) [yes]:
```

#### Note:

If you have any Server SDK extensions, be sure to run the `manage-extension` tool first, then press Enter to apply the changes to the Directory Proxy Server.

Alternatively, you can quit and run the `dsconfig` batch file at a later time.

Once the changes have been applied, you cannot use the `create-initial-proxy-config` tool to configure this Directory Proxy Server again. Use the `dsconfig` tool to modify your configuration instead.

#### Result

If you open the generated `proxy-cfg.txt` file or the `logs/config-audit.log` file, you see that a configuration element hierarchy has been created, listing locations, health checks, external servers, load-balancing algorithms, request processors, and subtree views.

## About the `dsconfig` configuration tool

The `dsconfig` tool is the text-based management tool used to configure the underlying Directory Server configuration.

The `dsconfig` tool has three operational modes: interactive mode, non-interactive mode, and batch mode.

The `dsconfig` tool offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, you should keep the server running when you access the configuration for the server to give the user feedback about the validity of the configuration.

## Using `dsconfig` in interactive command-line mode

In interactive mode, the `dsconfig` tool offers a filtering mechanism that only displays the most common configuration elements.

#### About this task

The user can specify that more expert level objects and configuration properties be shown using the menu system.

Running `dsconfig` in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the PingDirectory Server.

## Steps

1. To start `dsconfig` in interactive command-line mode, invoke the `dsconfig` script without any arguments.  
Result: You are prompted for connection and authentication information to the Directory Server, and then a menu displays the available operation types.
2. To accept the default values, press **Enter**.

### Note:

In some cases, a default value is provided in square brackets. For example, [389] indicates that the default value for that field is port 389.

3. To skip the connection and authentication prompts, provide the connection and authentication information using the command-line options of `dsconfig`.

## Changing the dsconfig object menu

The purpose of object levels is to present only those properties that an administrator will likely use.

### About this task

Because some configuration objects are more likely to be modified than others, the PingDirectory Server provides four different object menus that hide or expose configuration objects to the user. The `object` type is a convenience feature designed to improve menu readability.

The following object menus are available:

#### Basic

Only includes the components that are configured most frequently.

#### Standard

Includes all components in the Basic menu plus other components that might occasionally need to be altered in many environments.

#### Advanced

Includes all components in the Basic and Standard menus plus other components that might require configuration under special circumstances or that might be harmful if configured incorrectly.

#### Expert

Includes all components in the Basic, Standard, and Advanced menus plus other components that almost never require configuration, or that could seriously impact the functionality of the server if not properly configured.

To change the `dsconfig` object menu:

## Steps

1. Using `dsconfig`, repeat steps 1–6 in [To Install the Directory Server in Interactive Mode](#).
2. On the **PingDirectory Server configuration** main menu, enter the letter `o` to change the object level.  
Basic objects are displayed by default.

3. Enter a number corresponding to an object level of your choice.  
Choose from:
  - Enter 1 for Basic.
  - Enter 2 for Standard.
  - Enter 3 for Advanced.
  - Enter 4 for Expert.

4. Review the menu at the new object level.

Additional configuration options for the Directory Server components are displayed.

## Using dsconfig in non-interactive mode

The **dsconfig** non-interactive command-line mode provides a simple way to make arbitrary changes to the Directory Server by invoking it from the command line.

### Steps

1. To use administrative scripts to automate configuration changes, run the **dsconfig** command in non-interactive mode.

Non-interactive mode is convenient for scripting applications.

#### Note:

If you plan to make changes to multiple configuration objects at the same time, then the batch mode might be more appropriate.

2. Use the **dsconfig** tool to update a single configuration object using command-line arguments to provide all of the necessary information.

Example:

The following shows the general format for the non-interactive command line.

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

#### Note:

The **--no-prompt** argument indicates that you want to use non-interactive mode. The **{subcommand}** is used to indicate which general action to perform. The **{globalArgs}** argument provides a set of arguments that specify how to connect and authenticate to the Directory Server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on your setup. For example, using standard LDAP connections, you can invoke the **dsconfig** tool, as shown.

```
$ bin/dsconfig --no-prompt list-backends \  
  --hostname server.example.com \  
  --port 389 \  
  --bindDN uid=admin,dc=example,dc=com \  
  --bindPassword password
```

3. If your system uses SASL GSSAPI (Kerberos), invoke **dsconfig** as shown.

```
$ bin/dsconfig --no-prompt list-backends \  
  --saslOption mech=GSSAPI \  
  --saslOption authid=admin@example.com \  
  --saslOption ticketcache=/tmp/krb5cc_1313 \  
  \
```

```
--sasloption useticketcache=true
```

4. To always display the advanced properties, use the `--advanced` command-line option.

#### Note:

The `{subcommandArgs}` argument contains a set of arguments specific to the particular subcommand that you want to invoke.

Global arguments can appear anywhere on the command line, including before the subcommand and after or intermingled with subcommand-specific arguments. The subcommand-specific arguments can appear anywhere after the subcommand.

### Getting the equivalent `dsconfig` non-interactive mode command

Find the command you want to use in non-interactive command-line mode by looking it up in interactive mode.

#### Steps

1. Use `dsconfig` in interactive mode to make changes to a configuration, but do not enter the letter `f` to apply the changes.
2. To view the equivalent non-interactive command, enter `d`.
3. View the equivalent command, and then press `Enter` to continue.

#### Result:

Based on an example in the previous section, changes made to the `db-cache-percent` returns the following message.

```
Command line to apply pending changes to this Local DB Backend: dsconfig
set-backend-prop --backend-name userRoot --set db-cache-percent:40
```

The command does not contain the LDAP connection parameters required for the tool to connect to the host because the command is presumed to be used to connect to a different remote host.

## Using `dsconfig` batch mode

Configure the Directory Server in `dsconfig` batch mode.

#### About this task

The PingDirectory Server provides a `dsconfig` batching mechanism that reads multiple `dsconfig` invocations from a file and executes them sequentially.

The batch file provides advantages over standard scripting by minimizing LDAP connections and Java virtual machine (JVM) invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

If a `dsconfig` command has a missing or incorrect argument, the command fails and aborts the batch process without applying any changes to the Directory Server. The `dsconfig` command supports a `--batch-continue-on-error` option that instructs `dsconfig` to apply all changes and skip any errors.

You can view the `logs/config-audit.log` file to review the configuration changes made to the Directory Server and use them in the batch file. The batch file can have blank lines for spacing and lines starting with a pound sign (`#`) for comments. The batch file also supports a `\` line continuation character for long commands that require multiple lines.

The Directory Server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Oracle to PingDirectory Server machines.

### Steps

1. Create a text file that lists each `dsconfig` command with the complete set of properties that you want to apply to the Directory Server.

#### Note:

The items in this file should be in the same format as those accepted by the `dsconfig` command. The batch file can have blank lines for spacing and lines starting with a pound sign (#) for comments. The batch file also supports a `"\"` line continuation character for long commands that require multiple lines.

#### Example:

```
# This dsconfig operation creates the exAccountNumber global attribute
index.
dsconfig create-global-attribute-index
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--index-name exAccountNumber --set prime-index:true

# Here we create the entry-count placement algorithm with the
# default behavior of adding entries to the smallest backend
# dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name example_com_entry_count
--type entry-counter
--set enabled:true
--set "poll-interval:1 m"

# Note that once the entry-count placement algorithm is created
# and enabled, we can delete the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then delete the
# original round-robin algorithm created during the setup
# procedure.

dsconfig delete-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin
```

2. To read and execute the commands, run `dsconfig` with the `--batch-file` option.

## Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth tokens

Configure an access token validator to use PingFederate OAuth tokens with PingDirectory.

Before you begin

You need the following information:

- The runtime engine service port of the PingFederate server, usually 9031
- The client ID of an OAuth 2.0 client configured on the PingFederate server
- The client secret of the OAuth 2.0 client
- The IP address of the PingFederate server

## About this task

After you configure a PingFederate server to issue OAuth 2 tokens, you must make these tokens compatible with SCIM 2.0 operations on PingDirectory Server or PingDirectoryProxy.

This section explains how to set up an access token validator to handle this task.

## Steps

1. Register the PingFederate server using the following command.

```
dsconfig create-external-server \
  --server-name PingFederateInstance \
  --type http \
  --set base-url:https://<PingFed IP address>:<PingFed port> \
  --set hostname-verification-method:allow-all \
  --set "trust-manager-provider:Blind Trust"
```

### Note:

In this example, the hostname verification method is set to **allow-all** and the Blind Trust manager provider is used for the sake of simplicity. You should not use these settings for production environments.

2. Create the access token validator using the following command.

```
dsconfig create-access-token-validator \
  --validator-name PingFederateValidator \
  --type ping-federate \
  --set enabled:true \
  --set authorization-server:PingFederateInstance \
  --set client-id:client-id \
  --set client-secret:client-secret
```

### Note:

Take the *client-id* and *client-secret* values from the PingFederate OAuth 2 client that will be used with the PingDirectory Server or PingDirectoryProxy.

3. Add the access token validator to the SCIM 2 HTTP Servlet configuration with the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set access-token-validator:PingFederateValidator
```

4. Test the validator by sending a GET request to `/scim/v2/ServiceProviderConfig`.

This endpoint does not require any scopes to access, just a valid bearer token. The sever should return a response similar to the following.

```
{
  "schemas": [
    "urn:ietf:params:scim:schemas:core:2.0:ServiceProviderConfig"
  ],
  "patch": {
    "supported": true
  },
  "bulk": {
    "supported": false,
    "maxOperations": 0,
  }
}
```

```

    "maxPayloadSize": 0
  },
  "filter": {
    "supported": true,
    "maxResults": 0
  },
  "changePassword": {
    "supported": true
  },
  "sort": {
    "supported": false
  },
  "etag": {
    "supported": false
  },
  "authenticationSchemes": [
    {
      "name": "OAuth 2.0 Bearer Token",
      "description": "The OAuth 2.0 Bearer Token Authentication
scheme. OAuth enables clients to access protected resources by obtaining
an access token, which is defined in RFC 6750 as \"a string representing
an access authorization issued to the client\", rather than using the
resource owner's credentials directly.",
      "specUri": "http://tools.ietf.org/html/rfc6750",
      "type": "oauthbearertoken",
      "primary": true
    }
  ],
  "meta": {
    "resourceType": "ServiceProviderConfig",
    "location": "https://localhost:8443/scim/v2/
ServiceProviderConfig"
  }
}

```

## Topology configuration

Topology configuration enables automatic server grouping and configuration change mirroring. It uses a master and slave architecture for mirroring shared data across the topology.

All writes and updates are forwarded to the master, which forwards them to all other servers. Reads can be served by any server in the group, and servers can be added to an existing topology at installation.

### Note:

To remove a server from the topology, you must uninstall it with the uninstall tool.

### Topology master requirements and selection

A topology master server receives configuration changes from other servers in the topology, verifies the changes, and then makes the changes available to all connected servers.

When updating, the master sends a digest of its subtree contents. If the node's digest differs from the master's, the server node knows it is not synchronized. The servers pull the entire subtree from the master if they detect that they are not synchronized.

A server detects it is not synchronized with the master under the following conditions:

- The server's subtree digest differs from the master's digest at the end of its periodic polling interval.
- One or more servers have been added to or removed from the topology.

The master of the topology is selected by prioritizing servers based on:

- Minimum supported product version
- Availability
- Server version
- Earliest start time
- Startup UUID (smaller is preferred)

After determining a master, the topology data is reviewed from all available servers, every five seconds by default, to determine if any new information identifies a better server master. If a new server can be the master and no other servers have indicated that they should be the master, it will communicate its eligibility to the other servers. This ensures that all servers accept the same master at approximately the same time, within a few milliseconds of each other. If there is no better master, the initial master maintains the role.

After the best master has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that master.
  - The master server itself is considered while determining this majority.
- There is only a single master in the entire topology.

If either of these conditions is not met, the topology is without a master and the peer polling frequency is reduced to 100 milliseconds to find a new master as quickly as possible. If there is no master in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as master with the `force-as-master-for-mirrored-data` option in the Global Configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as masters, then a `multiple-servers-forced-as-masters` alarm is raised.

### Topology components

When you install a server, you can add it to an existing topology, cloning the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

#### Server configuration settings

Configuration settings for the topology are configured in the global configuration and in the config file handler backend. They are topology settings, but they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The global configuration object contains a single topology setting, `force-as-master-for-mirrored-data`. This should be set to `true` on only one of the servers in the topology, and is used only if the topology cannot determine a master because most of the servers are not available. A server with this setting enabled is assigned the role of master if no suitable master can be determined.

The config file handler backend defines three topology `mirrored-subtree` settings:

#### `mirrored-subtree-peer-polling-interval`

Specifies the frequency at which the server polls its topology peers to identify any changes warranting a new master selection. A lower value ensures a faster failover, but it also causes more traffic among the peers. The default value is 5 seconds. If no suitable master is found, the polling frequency adjusts to 100 milliseconds until a new master is selected.

#### `mirrored-subtree-entry-update-timeout`

Specifies the maximum length of time to wait for an entry update operation, such as add, delete, modify or modify-dn, to be applied by the master on all of the servers in the topology. The default is 10 seconds, but updates can take up to twice as long if master selection is in progress at the time the update operation is received.

#### `mirrored-subtree-search-timeout`

Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

#### Topology settings

Topology metadata is stored under the `cn=topology,cn=config` subtree and cluster data is stored under the `cn=cluster,cn=config` subtree. The only setting that can be changed is the cluster name.

#### Monitor data for the topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to identify changes in the topology.

Topology data includes the following:

- The server ID of the current master, if the master is not known
- The instance name of the current master or if a master is not set, a description stating why a master is not set
- A flag indicating which server thinks that it should be the master
- A flag indicating which server is the current master
- A flag indicating a server that was forced as master
- The total number of configured peers in the topology group
- The peers connected to this server
- The current availability of this server
- A flag indicating that a server is not synchronized with its master or another node in the topology if the master is unknown
- The amount of time in milliseconds that multiple masters were detected by this server
- The amount of time in milliseconds that no suitable server is found to act as master
- A SHA-256 digest encoded as a base-64 string for the current subtree contents

The following metrics are included if this server has processed any operations as master:

- The number of operations processed by this server as master
- The number of successful operations processed by this server as master
- The number of operations processed by this server as master that failed to validate
- The number of operations processed by this server as master that failed to apply
- The average amount of time taken in milliseconds by this server to process operations as the master
- The maximum amount of time taken in milliseconds by this server to process an operation as the master

## Using the Configuration API

PingDirectory Server provides a Configuration API when updating the server configuration with LDAP is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers allow the `application/json` content type.

#### About this task

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP.

#### Steps

- To add the extension to one of the server's HTTP Connection Handlers, run the following code.

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
```

```
--add http-servlet-extension:Configuration
```

#### Note:

By default, the extension is enabled for new installations. You can enable the extension for existing deployments.

Result: The API is made available on the HTTPS Connection Handler's host:port in the `/config` context. Due to the potentially sensitive nature of the server's configuration, use the HTTPS Connection Handler for hosting the configuration extension.

### Authentication and authorization with the Configuration API

Use this topic for how to make changes for customizing authentication and authorization access with the Configuration API.

#### Authentication

Clients must use HTTP basic authentication to authenticate to the Configuration API. If the username value is not a distinguished name (DN), then it resolves to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a username. To customize this behavior, either customize the default identity mapper or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. The following code provides an example.

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Configuration \
  --set "identity-mapper:Alternative Identity Mapper"
```

#### Authorization

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACI.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

### The Configuration API and the dsconfig tool relationship

The Configuration API is designed to mirror the `dsconfig` tool, using the same names for properties and object types.

Property names are presented as hyphen case in `dsconfig` and as camel-case attributes in the API. In API requests that specify property names, case is not important. `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the `dsconfig list-connection-handlers` command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a local database backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the `dsconfig` tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the System for Cross-domain Identity Management (SCIM) specification. Request specific attributes using the `attributes` query parameter, whose value must be a comma-delimited list of properties to be returned, such as `attributes=baseDN,description`. You can exclude attributes from responses by specifying the `excludedAttributes` parameter.

**Configuration API operations supported in REST APIs**

| HTTP Method | Description                                                                                                                                                                                                                                                                                                                                                                                 | Related dsconfig Example                                                                                                                                                      |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GET         | Lists the properties of an object when used with a path representing an object, such as <code>/config/global-configuration</code> or <code>/config/backends/userRoot</code> .<br><br>Can also list objects when used with a path representing a parent relation, such as <code>/config/backends</code> .                                                                                    | <ul style="list-style-type: none"> <li>▪ <code>get-backend-prop</code></li> <li>▪ <code>list-backends</code></li> <li>▪ <code>get-global-configuration-prop</code></li> </ul> |
| POST        | Creates a new instance of an object when used with a relation parent path, such as <code>/config/backends</code> .                                                                                                                                                                                                                                                                          | <code>create-backend</code>                                                                                                                                                   |
| PUT         | Replaces the existing properties of an object. A PUT operation is similar to a PATCH operation, except that the PATCH identifies the difference between an existing target object and a supplied source object. Only those properties in the source object are modified in the target object. The target object is specified using a path, such as <code>/config/backends/userRoot</code> . | <ul style="list-style-type: none"> <li>▪ <code>set-backend-prop</code></li> <li>▪ <code>set-global-configuration-prop</code></li> </ul>                                       |
| PATCH       | Updates the properties of an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .                                                                                                                                                                                                                                                 | <ul style="list-style-type: none"> <li>▪ <code>set-backend-prop</code></li> <li>▪ <code>set-global-configuration-prop</code></li> </ul>                                       |
| DELETE      | Deletes an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .                                                                                                                                                                                                                                                                   | <code>delete-backend</code>                                                                                                                                                   |

**Note:**

The `OPTIONS` method can also be used to determine the operations permitted for a particular path.

Object names, such as `userRoot` in the description column, must be URL-encoded for use in the path segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent, `%`, character. The following URL is for accessing the HTTP Connection Handler object.

```
/config/connection-handlers/http%20connection%20handler
```

## GET example

This topic provides an example of a GET request and response concerning the `userRoot` backend for reference.

## GET request

The following code example is a GET request for information about the `userRoot` backend.

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

## GET response

The following code example is the response.

```

    ...

```

**PATCH example**

Modify the Configuration API using the HTTP PATCH method.

The PATCH request body is a JSON object formatted according to the System for Cross-domain Identity Management (SCIM) patch request. The Configuration API supports a subset of possible values for the path attribute that indicates the configuration attribute to modify.

Modify the configuration object's attributes according to the information in the following table, which details the comparable `dsconfig modify-[object]` options to each PATCH request.

**Operations and PATCH requests to modify the configuration object's attributes**

| Operation                                                                                                                                                                       | PATCH request                                                                                          | Comparable <code>dsconfig modify-[object]</code> options                                                               |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Set the single-valued <code>description</code> attribute to a new value.                                                                                                        | <pre>{   "op" : "replace",   "path" :   "description",   "value" : "A new   backend." }</pre>          | <pre>\$ dsconfig set-backend- prop   --backend-name   userRoot \   --set "description:A   new backend"</pre>           |
| Add a new value to the multi-valued <code>jeProperty</code> attribute.                                                                                                          | <pre>{   "op" : "add",   "path" :   "jeProperty",   "value" :   "je.env.backgroundReadLimit" }</pre>   | <pre>\$ dsconfig set- backend-prop --backend- name userRoot \   --add je- property:je.env.backgroundReadLimit</pre>    |
| Remove a value from a multi-valued property. In this case, path specifies a SCIM filter identifying the value to remove.                                                        | <pre>{   "op" : "remove",   "path" :   "[jeProperty eq   \"je.cleaner.adjustUtilizati   on\"]" }</pre> | <pre>\$ dsconfig set-backend- prop --backend-name   userRoot \   --remove je- property:je.cleaner.adjustUtilizat</pre> |
| Second operation to remove a value from a multi-valued property, where the path specifies both an attribute to modify and a SCIM filter whose attribute is the following value. | <pre>{   "op" : "remove",   "path" :   "jeProperty[value eq   \"je.nodeMaxEntries=32\"]" }</pre>       | <pre>\$ dsconfig set-backend- prop --backend-name   userRoot \   --remove je- property:je.nodeMaxEntries=32</pre>      |
| Option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value.                                   | <pre>{   "op" : "remove",   "path" :   "id2childrenIndexEntryLimit" }</pre>                            | <pre>\$ dsconfig set-backend- prop --backend-name   userRoot \   --reset   id2childrenIndexEntryLimit</pre>            |

## Example

The following is the full example request.

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json

{
  "schemas" : [ "urn:ietf:params:scim:api:messages:2.0:PatchOp" ],
  "Operations" : [ {
    "op" : "replace",
    "path" : "description",
    "value" : "A new backend."
  }, {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }, {
    "op" : "remove",
    "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
  }, {
    "op" : "remove",
    "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
  }, {
    "op" : "remove",
    "path" : "id2childrenIndexEntryLimit"
  } ]
}
```

## Example

The API responds with the entire modified configuration object, which can include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions. The following is an example response.

```
{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],
  "id": "userRoot2",
  "meta": {

                allow the new limit to be used for any id2children keys
                that had already hit the previous limit."
  }
]
}
}
}

```

### Configuration API paths

The Configuration API and supported sub-paths are available under the `/config` path.

A full listing of supported sub-paths is available when you access the base `/config/ResourceTypes` endpoint.

```

GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json

```

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted or created. These paths can be differentiated from others by their singular, rather than plural, relation name, such as `global-configuration`.

### Example

The following sample response is abbreviated.

```

{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 520,
  "Resources": [
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "dsee-compat-access-control-handler",
      "name": "DSEE Compat Access Control Handler",
      "description": "The DSEE Compat Access Control
                    Handler provides an implementation that uses syntax
                    compatible with the Sun Java System Directory Server
                    Enterprise Edition access control handler.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/dsee-
compat-access-control-handler"
      }
    },
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "access-control-handler",
      "name": "Access Control Handler",
      "description": "Access Control Handlers manage the
                    application-wide access control. The server's access

```

```

        control handler is defined through an extensible
        interface, so that alternate implementations can be created.
        Only one access control handler may be active in the server
            at any given time.",
    "endpoint": "/access-control-handler",
    "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/access-
control-handler"
    }
},
{
    ...

```

The response's `endpoint` elements enumerate all available sub-paths. You can use the path `/config/access-control-handler` in the example to get a list of existing access control handlers and create new ones. You can use a path containing an object name, such as `/config/backends/{backendName}` (where `{backendName}` corresponds to an existing backend like `userRoot`) to obtain an object's properties, update the properties, or delete the object.

### Sort and filter objects

The Configuration API supports System for Cross-domain Identity Management (SCIM) parameters for filter, sorting, and pagination.

Search operations can specify a SCIM filter to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters, or paging parameters. Include or exclude attributes can be specified in both GET and list operations.

| GET Parameter     | Description                                                                                                                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>filter</b>     | Values can be simple SCIM filters, such as <code>id eq "userRoot"</code> , or compound filters like <code>meta.resourceType eq "Local DB Backend"</code> and <code>baseDn co "dc=example,dc=com"</code> . |
| <b>sortBy</b>     | Specifies a property value by which to sort.                                                                                                                                                              |
| <b>sortOrder</b>  | Specifies either <code>ascending</code> or <code>descending</code> alphabetical order.                                                                                                                    |
| <b>startIndex</b> | 1-based index of the first result to return.                                                                                                                                                              |
| <b>count</b>      | Indicates the number of results per page.                                                                                                                                                                 |

### Update properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH.

With PUT, the server computes the differences between the object in the request with the current version in the server and performs modifications where necessary. The server never removes attributes that are not specified in the request. The API responds with the entire modified object.

### Example

Sample request:

```

PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
    "description" : "A new description."
}

```

}

**Sample response:**

```

{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],
  "id": "userRoot",
  "meta": {
    "resourceType": "Local DB Backend",
    "location": "http://example.com:5033/config/backends/userRoot"
  },

"writabilityMode": "enabled"
}

```

### Administrative actions

Updating a property might require an administrative action before changes can take effect.

If you need administrative actions to update a property, the server returns 200 Success. Any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

### Example

For example, changing the `jeProperty` of a backend results in the following:

```

"urn:unboundid:schemas:configuration:messages:2.0": {
  "required-actions": [
    {
      "property": "baseContextPath",
      "type": "componentRestart",
      "synopsis": "In order for this modification to take effect, the
component
must be restarted, either by disabling and re-enabling it,
or
by restarting the server"
    },
    {
      "property": {
        "property": {
          "type": "other",
          "synopsis": "If this limit is increased, then the
contents of the backend must be exported to LDIF
and re-imported to allow the new limit to be used
for any id2children keys that had already hit the
previous limit."
        }
      }
    }
  ]
}

```

### Updating servers and server groups

You can configure servers as part of a server group so that configuration changes applied to a single server are applied to all servers in a group.

When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query attribute. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `single-server` or `server-group` can be specified.

#### Example

```
http://localhost:8082/config/backends/userRoot?applyChangeTo=single-server
```

### Configuration API responses

Clients of the API should examine the HTTP response code to determine the success or failure of a request.

The following are response codes and their meanings.

| Response Code    | Description                                                                                                                                                                                                                                              | Response Body                                                 |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| 200 Success      | The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the <code>urn:unboundid:schemas:configuration:messages:2.0</code> object.   | List of objects, object properties, or administrative actions |
| 204 No Content   | The requested operation succeeded and no further information has been provided, as in the case of a DELETE operation.                                                                                                                                    | None                                                          |
| 400 Bad Request  | The request contents are incorrectly formatted or a request is made for an invalid API version.                                                                                                                                                          | Error summary and optional message                            |
| 401 Unauthorized | User authentication is required. Some user agents, such as browsers, might respond by prompting for credentials. If the request specified credentials in an Authorization header, they are invalid.                                                      | None                                                          |
| 403 Forbidden    | The requested operation is forbidden, either because the user does not have sufficient privileges or some other constraint, such as an object is edit-only and cannot be deleted.                                                                        | None                                                          |
| 404 Not Found    | The requested path does not refer to an existing object or object relation.                                                                                                                                                                              | Error summary and optional message                            |
| 409 Conflict     | The requested operation could not be performed due to the current state of the configuration. For example, an attempt was made to create an object that already exists, or an attempt was made to delete an object that is referenced by another object. | Error summary and optional message                            |

| Response Code                 | Description                                                                                                    | Response Body                      |
|-------------------------------|----------------------------------------------------------------------------------------------------------------|------------------------------------|
| 415<br>Unsupported Media Type | The request is such that the Accept header does not indicate that JSON is an acceptable format for a response. | None                               |
| 500 Server Error              | The server encountered an unexpected error. Report server errors to Customer Support.                          | Error summary and optional message |

**Note:**

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages can change, and their presence can depend on server configuration. Use the HTTP return code and the context of the request to create a client error message.

**Example**

The following is an example encoded error message.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": 404,
  "scimType": null,
  "detail": "The Local DB Index does not exist."
}
```

**Working with the Directory REST API**

The Directory REST API is the native interface for client access to the PingDirectory Server. Instead of trying to manage directory hierarchy or require attribute mapping, the Directory REST API provides direct access to directory data in a way that is dynamic, discoverable, and efficient.

**Before you begin**

The Directory REST API gives developers who are more comfortable with REST than LDAP access to arbitrary directory data in a way that ensures directory data remains consistent regardless of whether it is accessed from LDAP or REST. The Directory API is enabled during server setup. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.

While both the Directory REST API and System for Cross-domain Identity Management (SCIM) provide REST access to directory data, the goals of the two protocols are different. SCIM is useful to generic, external clients that require simple, narrow access to identity data, but because it is a less common standard for identity stores, it might not offer as much functionality or be as user-friendly as the Directory REST API.

The Directory REST API can be used for the following operations.

| HTTP operation | Resource endpoint               | Description      | Allowed query parameters |
|----------------|---------------------------------|------------------|--------------------------|
| DELETE         | <code>/directory/v1/{dn}</code> | Delete an entry. |                          |

| HTTP operation | Resource endpoint                            | Description                                           | Allowed query parameters                                                                                                                                                                                                 |
|----------------|----------------------------------------------|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GET            | /directory/v1                                | Get metadata about the API and server.                |                                                                                                                                                                                                                          |
| GET            | /directory/v1/{dn}                           | Retrieve a single entry.                              | <ul style="list-style-type: none"> <li>▪ <b>expand</b></li> <li>▪ <b>includeAttributes</b></li> <li>▪ <b>excludeAttributes</b></li> </ul>                                                                                |
| GET            | /directory/v1/{dn}/subtree                   | Search an entry's descendants.                        | <ul style="list-style-type: none"> <li>▪ <b>filter</b></li> <li>▪ <b>searchScope</b></li> <li>▪ <b>cursor</b></li> <li>▪ <b>limit</b></li> <li>▪ <b>includeAttributes</b></li> <li>▪ <b>excludeAttributes</b></li> </ul> |
| GET            | /directory/v1/schemas                        | Retrieve the schemas of all available object classes. |                                                                                                                                                                                                                          |
| GET            | /directory/v1/schemas/{objectclass}          | Retrieve schema for a specific object class.          |                                                                                                                                                                                                                          |
| GET            | /directory/v1/schemas/_operationalAttributes | Retrieve schema for operational attributes.           |                                                                                                                                                                                                                          |
| GET            | /directory/v1/me                             | Alias for retrieving the current user.                |                                                                                                                                                                                                                          |
| PATCH          | /directory/v1/{dn}                           | Modify an entry (add or delete values).               | <b>expand</b>                                                                                                                                                                                                            |
| POST           | /directory/v1                                | Create a new entry.                                   | <b>expand</b>                                                                                                                                                                                                            |
| PUT            | /directory/v1/{dn}                           | Modify or rename an entry.                            | <b>expand</b>                                                                                                                                                                                                            |

### Steps

- Configure the Directory REST API with any of the following properties using **dsconfig**:

| Command                   | Description                                                                                                                                                                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>basic-auth-enabled</b> | Specifies whether users can connect to the service with HTTP Basic authentication. If disabled, users need a bearer token. If changed, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled. Basic authentication is enabled by default. |
| <b>identity-mapper</b>    | If HTTP Basic authentication is enabled, the identity mapper referenced by this distinguished name (DN) must be used to map the user names provided to user entries. By default, an identity mapper is provided, which maps a fully-qualified DN to an entry.                                      |

| Command                                   | Description                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | For changes to take effect, the server must be restarted, or any HTTP connection handlers referencing this service disabled and re-enabled.                                                                                                                                                                                                                           |
| <code>access-token-validator</code>       | Specifies the subset of this server's Access Token Validators (by DN), which can validate Bearer authentication tokens. By default, if no validators are specified, then any of the validators on the server can be used. For changes to take effect, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled. |
| <code>access-token-scope</code>           | The scope that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, Bearer token authentication is disabled, and only Basic authentication is used. By default, no value is provided. Changes to this value take effect immediately.                                                                                    |
| <code>audience</code>                     | A string or URI audience that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, any audience is acceptable. By default, no value is provided. Changes to this value take effect immediately.                                                                                                                         |
| <code>max-page-size</code>                | The maximum number of entries to be returned in one page from the search endpoint. Actual results returned might be lower due to the limit query parameter on the request and the actual number of available results. The value must be an integer between 1 and 1000. The default value is 100. Changes to this value take effect immediately.                       |
| <code>schemas-endpoint-objectclass</code> | The list of object classes that will be returned by the <code>/schemas/</code> endpoint in the REST API. By default, no schemas are returned. Changes to this value take effect immediately.                                                                                                                                                                          |

Example:

The following example uses `dsconfig` to configure an `objectClass` entity.

```
dsconfig set-http-servlet-extension-props --extension-name "Directory
REST API" \
  --add schemas-endpoint-objectclass:ubidPerson
```

## Generating a summary of configuration components

The `config-diff` tool generates a summary of the configuration in a local or remote directory server instance.

About this task

The `config-diff` tool is useful for comparing configuration settings on the directory server instance when troubleshooting issues or when verifying configuration settings on newly-added servers. The tool can interact with the local configuration regardless of whether the server is running.

Steps

- To generate a summary of configuration components, run `config-diff`  
Example: `$ bin/config-diff` generates a summary of a local online server.

- To generate a comparison of the current configuration with the pre-installation configuration, run the following.

```
$ bin/config-diff --sourceLocal \
  --sourceBaseline \
  --targetLocal \
  --exclude differs-after-install \
  --outputFile configuration-steps.dsconfig
```

This comparison ignores any changes that could be made by the installer and writes the output to a file called `configuration-steps.dsconfig`.

You can use this file as the basis for a script to configure a new server identical to the local server.

- To view other available tool options, run `config-diff --help`.

## Configuring server groups

The PingDirectoryProxy Server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group.

### About this task

After you have set up a server group, you can make an update on one server using `dsconfig`, then apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the `dsconfig` non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using `dsconfig` in interactive command-line mode, you are asked if you want to apply the change to a single server or to all servers in the server group.

You can create an administrative server group using the `dsconfig` tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group, as outlined in [Replication Configuration](#).

The following example procedure adds three PingDirectoryProxy Server instances into the server group labeled "group-one".

### Steps

1. Create a group called "group-one" using `dsconfig`.

Example:

```
$ bin/dsconfig create-server-group --group-name group-one
```

2. Add any PingDirectoryProxy Server to the server group.

If you have set up replication between a set of servers, these server entries are created by the `dsreplication enable` command.

Example:

```
$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server1

$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server2

$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server3
```

3. Set a global configuration property for each of the servers that should share changes in this group.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set configuration-server-group:group-one
```

4. Test the server group.

In this example, enable the log publisher for each PingDirectoryProxy Server in the group "server-group" by using the `--applyChangeTo server-group` option.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
  --applyChangeTo server-group
```

5. View the property on the first PingDirectoryProxy Server instance.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
-----:-----
enabled : true
```

6. Repeat step 5 on the second and third PingDirectoryProxy Server instances.
7. Test the server group by disabling the log publisher on the first PingDirectoryProxy Server instance by using the `--applyChangeTo single-server`.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:disabled \
  --applyChangeTo single-server
```

8. View the property on the first PingDirectoryProxy Server instance.

The first PingDirectoryProxy Server instance should be disabled.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
-----:-----
enabled : false
```

- View the property on the second PingDirectoryProxy Server instance.

Repeat this step on the third PingDirectoryProxy Server instance to verify that the property is still enabled on that server.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
-----:-----
enabled : true
```

## DNS caching

You can use two global configuration properties to control the caching of host name-to-numeric IP address or DNS lookup results returned from the name resolution services of the underlying operating system.

About this task

Steps

- To configure these properties, use the `dsconfig` tool.

### Global configuration properties and their descriptions

| Global configuration property        | Description                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| network-address-cache-ttl            | Sets the Java system property <code>networkaddress.cache.ttl</code> , and controls the length of time in seconds that a host name-to-IP address mapping can be cached. By default, it keeps resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.                                                                                                      |
| network-address-outage-cache-enabled | Caches host name-to-IP address results in the event of a DNS outage. By default, this is set to true, meaning name resolution results are cached. Unexpected service interruptions might occur during planned or unplanned maintenance, network outages, or an infrastructure attack. This cache can allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions. |

- To reduce delays due to unnecessary DNS lookups, follow these recommendations:
  - Maintain a connection pool in the client app rather than opening new connections for each bind.
  - Add appropriate records to DNS, including PTR records.
  - Add options `timeout:1` or options `single-request` in the `/etc/resolv.conf` file.
  - If IPv6 requests are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory Server's `config/java.properties` file, so that running `bin/dsjavaproperties` and restarting the server no longer issues IPv6 PTR requests.

## IP address reverse name lookups

The PingDirectory Server performs numeric IP address-to-host name lookups.

Numeric IP address-to-host name lookups

The following are some of the numeric IP address-to-host name lookups:

- Binding to the Directory: Decoding, examining, or evaluating a DNS bind rule
- Logging: Logging information to certain monitors or writing to the error log
- Java Management Extension (JMX): Creating a server socket
- Key Management: Generating a trust store
- Replication Server: Creating an SSL socket
- Replication Session Management: Obtaining a session or performing a handshake with a replication server
- Simple Authentication and Security Layer (SASL) Authentication: Applying configuration changes
- SMTP Alert Handler: Initializing or sending an alert notification

Configuring address masks

Address masks configured in Access control instructions (ACIs), connection handlers, connection criteria, and certificate handshake processing might trigger implicit reverse name lookups.

For more information about how address masks are configured in the server, see the following information for each server:

- ACI DNS: bind rules in [Managing Access Control](#) on page 718 for Directory Server and Directory Proxy Server
- `ds-auth-allowed-address`: [Restricting access through operational attributes in user entities](#) for Directory Server
- Connection Criteria: [Restricting server access based on client IP address](#) on page 500 for Directory Server and Directory Proxy Server
- Connection Handlers: [Restricting server access using the connection handlers](#) on page 500 for a configuration reference guide for all servers

## Configuring traffic through a load balancer

Configure the PingDirectory Server to get traffic through a load balancer and to record the actual client's IP address.

Before you begin

By default, when a PingDirectory Server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, it logs incoming requests as originating with the intermediate HTTP server instead of the client that sent the request.

Steps

1. To record the actual client's IP address to the trace log, enable **X-Forwarded-\*** handling in both the intermediate HTTP server and the PingDirectory Server.
2. Edit the appropriate connection handler object, HTTPS or HTTP, and set **use-forwarded-headers** to **true**.

### Note:

When **use-forwarded-headers** is set to **true**, the server uses the client IP address and port information in the **X-Forwarded-\*** headers instead of the address and port of the entity that's

sending the request, the load balancer. This client address information shows up in logs, such as in the `from` field of the HTTP REQUEST and HTTP RESPONSE messages.

3. On the load balancer, configure settings to provide the `X-Forwarded-*` information, such as `X-Forwarded-Host`.

## Managing root user accounts

PingDirectory Server provides a default root user, `cn=Directory Manager`, that is stored in the server's configuration file, such as under `cn=Root DNs,cn=config`.

About this task

The root user is the LDAP-equivalent of a UNIX superuser account and inherits its read-write privileges from the default root privilege set.

Steps

- To create or update root users, use the `dsconfig` tool.

Example:

```
bin/dsconfig create-root-dn-user --user-name "Joanne Smith" \
  --set last-name:Smith \
  --set first-name:Joanne \
  --set user-id:jsmith \
  --set 'email-address:jsmith@example.com' \
  --set mobile-telephone-number:8889997777 \
  --set home-telephone-number:5556667777 \
  --set work-telephone-number:4445556666
```

### Note:

Root user entries are stored in the server's configuration.

- To limit full access to all of Directory Server, create separate administrator accounts with limited privileges so that you can identify the administrator responsible for a particular change.

### Note:

Separate user accounts for each administrator make it possible to enable password policy functionality, such as password expiration, password history, and requiring secure authentication, for each administrator.

## Default root privileges

The PingDirectory Server contains a privilege subsystem that allows for a more fine-grained control of privilege assignments.

### Note:

Creating restricted root user accounts requires assigning privileges and necessary access controls for actions on specific data or backends. Access controls are determined by how the directory is configured and the structure of your data. See Chapter 16: Managing Access Controls for more information.

The following set of root privileges are available to each root user DN:

**Default Root Privileges**

| Privilege                               | Description                                                                                                                                                               |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| audit-data-security                     | Allows the associated user to execute data security auditing tasks.                                                                                                       |
| backend-backup                          | Allows the user to perform backend backup operations.                                                                                                                     |
| backend-restore                         | Allows the user to perform backend restore operations.                                                                                                                    |
| bypass-acl                              | Allows the user to bypass access control evaluation.                                                                                                                      |
| config-read                             | Allows the user to read the server configuration.                                                                                                                         |
| config-write                            | Allows the user to update the server configuration.                                                                                                                       |
| disconnect-client                       | Allows the user to terminate arbitrary client connections.                                                                                                                |
| ldif-export                             | Allows the user to perform LDIF export operations.                                                                                                                        |
| ldif-import                             | Allows the user to perform LDIF import operations.                                                                                                                        |
| lockdown-mode                           | Allows the user to request a server lockdown.                                                                                                                             |
| manage-topology                         | Allows the user to modify topology setting.                                                                                                                               |
| metrics-read                            | Allows the user to read server metrics.                                                                                                                                   |
| modify-acl                              | Allows the user to modify access control rules.                                                                                                                           |
| password-reset                          | Allows the user to reset user passwords but not their own. The user must also have privileges granted by access control to write the user password to the target entry.   |
| permit-get-password-policy-state-issues | Allows the user to access password policy state issues.                                                                                                                   |
| privilege-change                        | Allows the user to change the set of privileges for a specific user, or to change the set of privileges automatically assigned to a root user.                            |
| server-restart                          | Allows the user to request a server restart.                                                                                                                              |
| server-shutdown                         | Allows the user to request a server shutdown.                                                                                                                             |
| soft-delete-read                        | Allows the user access to soft-deleted entries.                                                                                                                           |
| stream-values                           | Allows the user to perform a stream values extended operation that obtains all entry DNs and/or all values for one or more attributes for a specified portion of the DIT. |
| third-party-task                        | Allows the associated user to invoke tasks created by third-party developers.                                                                                             |
| unindexed-search                        | Allows the user to perform an unindexed search in the Oracle Berkeley DB Java Edition backend.                                                                            |
| update-schema                           | Allows the user to update the server schema.                                                                                                                              |
| use-admin-session                       | Allows the associated user to use an administrative session to request that operations be processed using a dedicated pool of worker threads.                             |

The Directory Server provides other privileges that are not assigned to the root user DN by default but can be added using the `ldapmodify` tool (see Modifying Individual Root User Privileges) for more information.

## Other Available Privileges

| Privilege                                  | Description                                                                                                                                                                                                 |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bypass-pw-policy                           | Allows the associated user bypass password policy rules and restrictions.                                                                                                                                   |
| bypass-read-aci                            | Allows the associated user to bypass access control checks performed by the server for bind, compare, and search operations. Access control evaluation may still be enforced for other types of operations. |
| jmx-notify                                 | Allows the associated user to subscribe to receive JMX notifications.                                                                                                                                       |
| jmx-read                                   | Allows the associated user to perform JMX read operations.                                                                                                                                                  |
| jmx-write                                  | Allows the associated user to perform JMX write operations.                                                                                                                                                 |
| permit-externally-processed-authentication | Allows the associated user accept externally processed authentication.                                                                                                                                      |
| permit-proxied-mschapv2-details            | Allows the associated user to permit MS-CHAP V2 handshake protocol.                                                                                                                                         |
| proxied-auth                               | Allows the associated user to accept proxied authorization.                                                                                                                                                 |

## Configuring locations

PingDirectory Server defines locations, both for the LDAP external servers and the proxy server instances themselves. A location defines a collection of servers that share access and latency characteristics. For example, your deployment might include two data centers, one in the east and one in the west. These data centers would be configured as two locations in the Directory Proxy Server. Each location is associated with a name and an ordered list of failover locations, which could be used if none of the servers in the preferred location are available. You can define these locations using the Administrative Console or the command line.

The Directory Proxy Server itself is also associated with a location. This location is specified in the global configuration properties of the Directory Proxy Server. If the load balancing algorithm's `use-location` property is set to true, then the load balancing component of the Directory Proxy Server refers to the Directory Proxy Server's location to determine the external servers it prefers to communicate with.

### Configuring locations using dsconfig

#### Steps

1. To configure the LDAP external server locations, use the `dsconfig` tool.

```
$ bin/dsconfig
```

2. Enter the host name or IP address for your Directory Proxy Server, or press Enter to accept the default, `localhost`.

```
Directory Proxy Server host name or IP address [localhost]:
```

3. Enter the number corresponding to how you want to connect to the Directory Proxy Server, or press Enter to accept the default, `LDAP`.

```
How do you want to connect?
1) LDAP
2) LDAP with SSL
3) LDAP with StartTLS
```

4. Enter the port number for your Directory Proxy Server, or press Enter to accept the default, 389.

```
Directory Proxy Server port number [389]:
```

5. Enter the administrator's bind distinguished name (DN) or press Enter to accept the default, cn=Directory Manager, and then enter the password.

```
Administrator user bind DN [cn=Directory Manager]:
Password for user 'cn=Directory Manager':
```

6. In the Directory Server main menu, enter the number corresponding to location configuration. Then enter the number to create a new location.
7. Enter the name of the new location.

Example:

This example demonstrates configuring a location called East.

```
>>>> Enter a name for the location that you want to create: east
>>>> Configure the properties of the location

Property                                Value(s)
-----
1) description                            -
2) preferred-failover-location            -

?) help
f) finish - create the new location
d) display the equivalent dsconfig arguments to
   create this object
b) back
q) quit

Enter choice [b]: f
```

8. To finish configuring the location, enter f.
9. Edit the configuration of an existing location, in this example a location named East.

Example:

```
>>>> Location menu
What would you like to do?

1) List existing locations
2) Create a new location
3) View and edit an existing location
4) Delete an existing location

b) back
q) quit

Enter choice [b]: 3

>>>> Select the location from the following list:
1) East
2) West

b) back
q) quit

Enter choice [b]: 1
```

10. Define the `preferred-failover-location` property for `East`.

This property provides alternate locations that can be used if servers in this location are not available. If more than one location is provided, Directory Proxy Server tries the locations in the order listed.

Example:

```
>>>> Configure the properties of the Location

  Property                                Value(s)
  -----
  1) description                            -
  2) preferred-failover-location            -

  ?) help
  f) finish - create the new location
  d) display the equivalent dsconfig arguments to create this object
  b) back
  q) quit

Enter choice [b]: 2

...

Do you want to modify the 'preferred-failover-location' property?

  1) Add one or more values

  ?) help
  q) quit

Enter choice [1]: 2

Select the locations you wish to add:

  1) East
  2) West
  3) Create a new location
  4) Add all locations

...

Enter one or more choices separated by commas[b]: 2
```

11. Verify and apply your change to the property.

Example:

```
Do you want to modify the 'preferred-failover-location' property?

  1) Use the value: West
  2) Add one or more values
  3) Remove one or more values
  4) Leave undefined
  5) Revert changes

  ?) help
  q) quit

Enter choice [1]:

>>>> Configure the properties of the location

  Property                                Value(s)
```

```

-----
1) description                -
2) preferred-failover-location West

?) help
f) finish - apply any changes to the Location
d) display the equivalent dsconfig command lines to either
   re-create this object or only to apply pending changes
b) back
q) quit

Enter choice [b]: f

```

## Modifying locations using dsconfig

### Steps

1. To configure existing LDAP external server locations, use the `dsconfig` tool.

```
$ bin/dsconfig
```

2. Enter the host name or IP address for your Directory Proxy Server, or press Enter to accept the default, `localhost`.

```
Directory Proxy Server host name or IP address [localhost]:
```

3. Enter the number corresponding to how you want to connect to the Directory Proxy Server, or press Enter to accept the default, `LDAP`.

```
How do you want to connect?
1) LDAP
2) LDAP with SSL
3) LDAP with StartTLS
```

4. Enter the port number for your Directory Proxy Server, or press Enter to accept the default, `389`.

```
Directory Proxy Server port number [389]:
```

5. Enter the administrator's bind distinguished name (DN) or press Enter to accept the default `cn=Directory Manager`, and then enter the password.

```
Administrator user bind DN [cn=Directory Manager]:
Password for user 'cn=Directory Manager':
```

6. In the Directory Proxy Server main menu, enter the number corresponding to **Global Configuration**. Then enter the number to view and edit the **Global Configuration**.

7. Enter the number associated with the location configuration property.

```
Enter choice [b]: 2
```

8. Specify a new location for this Directory Proxy Server instance, in this example the East location.  
Example:

Operations involving communications with other servers might prefer servers in the same location to ensure low-latency responses.

```
>>>> Configuring the 'location' property
...
Do you want to modify the 'location' property?
```

```

1) Leave undefined
2) Change it to the location: East
3) Change it to the location: West
4) Create a new location

b) back
q) quit

Enter choice [b]: 2

```

9. To finish the operation, enter `f`.

```
Enter choice [b]: f
```

## Configuring batched transactions

Configure Directory Server to use batched transactions in both simple and entry-balanced configurations.

About this task

The batched transactions feature supports two implementations: the standard LDAP transactions per RFC 5805 and the PingDirectory Server proprietary implementation, known as the multi-update extended operation.

Batched transactions can be used through the Directory Proxy Server in both simple and entry-balanced configurations, but only in cases where all operations within the transaction request can be processed within the same backend server and within the same Berkeley DB JE backend.

### Note:

Batched transactions can't be processed across multiple servers or multiple Directory Server backends.

You can submit multiple updates in a single request. These updates can be processed either as individual operations or as a single batch. When Directory Proxy Server receives a Start Batched Transaction request, it queues all associated operations in memory until the End Batched Transaction request is received with the intention to commit, at which point the set of operations is sent as a single multi-update extended request to the Directory Server.

You can include `add`, `delete`, `modify`, `modify DN`, and `password modify extended` operations to the set of operations processed during a batch transaction. The operations are processed sequentially in the order in which they were included in the extended request. If an error occurs while processing an operation in the set, then the server can be instructed to continue processing or to cancel any remaining operations. If the operations aren't canceled, you can configure the server to process all operations as a single unit.

Because of this use of multi-update, you must configure the external Directory Server to allow multi-update extended requests made by the Directory Proxy Server on behalf of the DN submitting the batched transaction.

For example, the following Directory Server `dsconfig` command grants anonymous access to the multi-update extended request.

```

$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(extop="1.3.6.1.4.1.30221.2.6.17") (version 3.0;
  acl "Anonymous access to multi-update extended request"; allow (read)
  userdn="ldap:///anyone");'

```

### Note:

The submitter of the request still needs access rights for the individual operations within the multiple-update.

Batched transactions are managed by the Batched Transactions Extended Operation Handler. You can use it to configure the start transaction and end transaction operations used to indicate the set of `add`, `delete`, `modify`, `modify DN`, or `password modify` operations as a single atomic unit.

### Steps

1. Configure batched transactions using the `dsconfig` command.

Example:

```
$ bin/dsconfig set-extended-operation-handler-prop \
  --handler-name "Batched Transactions" \
  --set enabled:true
```

2. Configure the external servers to allow the multi-update extended operation by granting access rights to the feature.

See example in the previous section.

## Configuring server health checks

You can use the PingDirectory Server to configure different types of health checks for your deployment. The health checks define external server availability as either being available, unavailable, or degraded. The external server health is given a value from 0 to 10, which is used to determine if the server is available and how that server compares to other servers with the same state. Load-balancing algorithms can be used to check the score and prefer servers with higher scores over those with lower scores.

An individual health check can be defined for use against all external servers or assigned to individual external servers, as determined by the `use-for-all-servers` parameter within the health check configuration object. If `use-for-all-servers` is set to `true`, the Directory Proxy Server applies the health check to all external servers in all locations. If `use-for-all-servers` is set to `false`, then the health check is only employed against an external server if the configuration object for that external server lists the health check.

For more information about health checks and the type of health checks supported by PingDirectory Server, see [About LDAP Health Checks](#).

### About the default health checks

By default, the Directory Proxy Server has two health check instances enabled for use on all servers:

- **Consume Admin Alerts.** This health check detects administrative alerts from the Directory Server, as soon as they are issued, by maintaining an LDAP persistent search for changes within the `cn=alerts` branch of the Directory Server. When the Directory Proxy Server is notified by the Directory Server of a new alert, it immediately retrieves the base `cn=monitor` entry of the Directory Server. If this entry has a value for the `unavailable-alert-type` attribute, then the Directory Proxy Server will consider it unavailable. If this entry has a value for the `degraded-alert-type` attribute, then the Directory Proxy Server will consider it degraded.
- **Get Root DSE.** This health check detects if the root DSE entry exists on the LDAP external server. As this entry always exists on a PingDirectory Server, the absence of the entry suggests that the LDAP external server may be degraded or unavailable.

### About creating a custom health check

You can create a new health check from scratch or use an existing health check as a template for the configuration of a new health check.

If you choose to create a custom health check, you can create one of the following types:

### Admin Alert Health Check

This health check watches for administrative alerts generated by the LDAP external server to determine whether the server has entered a degraded or unavailable state.

### Groovy Scripted LDAP Health Check

This health check allows you to create custom LDAP health checks in a dynamically-loaded Groovy script, which implements the `ScriptedLDAPHealthCheck` class defined in the Server SDK.

### Replication Backlog Health Check

While the Admin Alert Health Check consumes replication backlog alerts emitted from external servers, a finer definition of external server health based on replication backlog can be defined with this health check. If a server falls too far behind in replication, then the Directory Proxy Server can stop sending requests to it. A server is classified as degraded or unavailable if the threshold is reached for the number of backlogged changes, the age of the oldest backlogged change, or both.

### Search LDAP Health Check

This health check performs searches on an LDAP external server and gauges the health of the server depending on the response time in which the expected results were returned. For example, if an error occurs while attempting to communicate with the server, then the server is considered unavailable. You can also apply filters to the results to use values within the monitor entry as indicators of server health.

### Third Party LDAP Health Check

This health check allows you to define LDAP health check implementations in third-party code using the Server SDK.

### Work Queue Busyness Health Check

This health check can monitor the percentage of time that worker threads in backend servers devote to processing requests.

## Configuring a health check using dsconfig

### Steps

1. To configure the LDAP external server locations, use the `dsconfig` tool.

```
$ bin/dsconfig
```

2. Enter the host name or IP address for your Directory Proxy Server, or press Enter to accept the default, `localhost`.

```
Directory Proxy Server host name or IP address [localhost]:
```

3. Enter the number corresponding how you want to connect to the Directory Proxy Server, or press Enter to accept the default, `LDAP`.

```
How do you want to connect?
 1) LDAP
 2) LDAP with SSL
 3) LDAP with StartTLS
```

4. Enter the port number for your Directory Proxy Server, or press Enter to accept the default, `389`.

```
Directory Proxy Server port number [389]:
```

5. Enter the administrator's bind distinguished name (DN) or press Enter to accept the default `cn=Directory Manager`. Then enter the password.

```
Administrator user bind DN [cn=Directory Manager]:
Password for user 'cn=Directory Manager':
```

6. In the Directory Proxy Server main menu, enter the number corresponding to LDAP health checks.
7. Enter the number to create a new LDAP Health Check, and then press `n` to create a new health check from scratch.
8. Select the type of health check you want to create.

This example demonstrates the creation of a new search LDAP health check.

```
>>> Select the type of LDAP Health Check that you want to create:

    1) Admin Alert LDAP Health Check
    2) Custom LDAP Health Check
    3) Groovy Scripted LDAP Health Check
    4) Replication Backlog LDAP Health Check
    5) Search LDAP Health Check
    6) Third Party LDAP Health Check
    7) Work Queue Busyness LDAP Health Check

    ?) help
    c) cancel
    q) quit

Enter choice [c]: 5
```

9. Enter a name for the new health check.

In this example, the health check is named `Get example.com`.

```
>>>> Enter a name for the search LDAP Health Check that you want to
create: Get example.com
```

10. To enable the new health check, enter `1`.

```
>>>> Configuring the 'enabled' property

Indicates whether this LDAP health check is enabled for use in the
server.

Select a value for the 'enabled' property:

    1) true
    2) false

    ?) help
    c) cancel
    q) quit

Enter choice [c]: 1
```

## 11. Configure the properties of the health check.

You might need to modify the `base-dn` property as well as one or more response time thresholds for non-local external servers, accommodating WAN latency.

Example:

The following is a Search LDAP Health Check for the single entry `dc=example,dc=com`, which allows non-local responses of up to 2 seconds to still be considered healthy.

```
>>>> Configure the properties of the Search LDAP Health Check

Property                                     Value(s)
-----
1) description                               -
2) enabled                                   true
3) use-for-all-servers                      false
4) base-dn                                  "dc=example,dc=com"
5) scope                                     base-object
6) filter                                    (objectClass=*)
7) maximum-local-available-response-time    1 s
8) maximum-nonlocal-available-response-time  2 s
9) minimum-local-degraded-response-time     500 ms
10) minimum-nonlocal-degraded-response-time  1 s
11) maximum-local-degraded-response-time    10 s
12) maximum-nonlocal-degraded-response-time  10 s
13) minimum-local-unavailable-response-time  5 s
14) minimum-nonlocal-unavailable-response-time 5 s
15) allow-no-entries-returned               true
16) allow-multiple-entries-returned         true
17) available-filter                        -
18) degraded-filter                        -
19) unavailable-filter                      -

?) help
f) finish - create the new Search LDAP Health Check
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit
```

## Configuring LDAP external servers

The LDAP external server configuration element defines the connection, location, and health check information necessary for the Directory Proxy Server to communicate with the server properly.

PingDirectory Server includes a tool, **prepare-external-server**, for configuring communication between the Directory Proxy Server and the LDAP backend server. After you add a new LDAP external server to an existing installation, we strongly recommend that you run this tool to automatically create the user account necessary for communications. The **prepare-external-server** tool does not make configuration changes to the local Directory Proxy Server, only the external server is modified. When you run this tool, you must supply the user account and password that you specified for the Directory Proxy Server during configuration, `cn=Proxy User` by default.

### Important:

You should not use `cn=Directory Manager` as the account to use for communication between the Directory Proxy Server and the Directory Server. For security reasons, the account used to communicate between the Directory Proxy Server and the Directory Server should not be directly accessible by clients accessing the Directory Proxy Server. The account that you choose should meet the following criteria:

- For all server types, it should not exist in the Directory Proxy Server but only in the backend directory server instances.

- For Ping Identity Directory Server, this user should be a root user.
- For Ping Identity Directory Server, this user should not automatically inherit the default set of root privileges, but instead should have exactly the following set of privileges: `bypass-read-acl`, `config-read`, `lockdown-mode`, `proxied-auth`, and `stream-values`.
- For Sun Directory Servers, the account should be created below the `cn=Root DNs`, `cn=config` entry and the `nsSizeLimit`, `nsTimeLimit`, `nsLookThroughLimit`, and `nsIdleTimeout` values for the account should be set to -1. You also need to create access control rules to grant the user account appropriate permissions within the server. The `prepare-external-server` tool handles all of this work automatically.

### About the `prepare-external-server` tool

Use the `prepare-external-server` tool if you have added LDAP external servers using `dsconfig`.

The `create-initial-proxy-config` tool automatically runs the `prepare-external-server` tool to configure server communications so that you do not need to invoke it separately. The `create-initial-proxy-config` tool verifies that the proxy user account exists and has the correct password and required privileges. If it detects any problems, it prompts for manager credentials to rectify them.

If you want the `prepare-external-server` tool to add the LDAP external server's certificates to the Directory Proxy Server's trust store, you must include the `--proxyTrustStorePath` option and either the `--proxyTrustStorePassword` or the `--proxyTrustStorePasswordFile` option.

The default location of the Directory Proxy Server trust store is `config/truststore`. The pin is encoded in the `config/truststore.pin` file.

The following example prepares a PingDirectory Server on the remote host `ds-east-01.example.com`, listening on port 1389 for access by the Directory Proxy Server using the default user account `cn=Proxy User`, as shown in the following example.

```
prepare-external-server --hostname ds-east-01.example.com \
--port 1389 --baseDN dc=example,dc=com --proxyBindPassword secret
```

When the `prepare-external-server` command is executed, it creates the `cn=Proxy User Root` distinguished name (DN) entry as well as an access control rule in the Directory Server to grant the proxy user the proxy access right.

#### Important:

For non-Ping Identity servers, the `--baseDN` argument is required for the `prepare-external-server` tool. The base DN is used to create the global access control instruction (ACI) entries for these servers.

### Configuring server communication using the `prepare-external-server` tool

The following example illustrates how to run the `prepare-external-server` tool to prepare a Directory Server.

About this task

In this example, the server is configured on the remote host `ds-east-01.example.com`, listening on port 1636.

The Directory Server is being accessed by a Directory Server that uses the default user account `cn=Proxy User`, `cn=Root DNs`, `cn=config`. Because a password to the trust store is not provided, the trust store defined in the `--proxyTrustStorePath` is referenced in a read-only manner.

## Steps

- To prepare the Directory Server, use the **prepare-external-server** tool.

Example:

```
$ ./PingDirectory/bin/prepare-external-server \
  --baseDN dc=example,dc=com
  --proxyBindPassword password \
  --hostname ds-east-01.example.com \
  --useSSL \
  --port 1636
  --proxyTrustStorePath /full/path/to/trust/store \
  --proxyTrustStorePassword secret
```

- Follow the prompts to set up the external server.

```
Testing connection to ds-east-01.example.com:1636 .....

Do you wish to trust the following certificate?

Certificate Subject: CN=ds-east-01.example.com, O=Example Self-Signed
Certificate
Issuer Subject:      CN=ds-east-01.example.com, O=Example Self-Signed
Certificate
Validity:            Thu May 21 08:02:30 CDT 2009 to Wed May 16 08:02:30
CDT 2029

Enter 'y' to trust the certificate or 'n' to reject it.

y

The certificate was added to the local trust store

Done
Testing 'cn=Proxy User' access to ds-east-01.example.com:1636 .....
Failed to bind as
'cn=Proxy User'

Would you like to create or modify root user 'cn=Proxy User' so that it
is available
for this Directory Proxy Server? (yes / no) [yes]:

Enter the DN of an account on ds-east-01.example.com:1636 with which to
create or
manage the 'cn=Proxy User' account [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':

Created 'cn=Proxy User,cn=Root DNs,cn=config'

Testing 'cn=Proxy User' privileges ..... Done
```

### Configuring an external server using dsconfig

Use the **dsconfig** tool to create and configure external servers. Then, specify the host name, connection method, port number, and bind distinguished name (DN), as described in previous procedures.

## Steps

1. Run the **dsconfig** command.

```
$ bin/dsconfig
```

2. In the Directory Proxy Server main menu, enter the number corresponding to external servers.
3. Enter the number to create a new external server.
4. Select the type of server you want to create.

Example:

This example creates a new Ping Identity Directory Server.

```
>>>> Select the type of external server that you want to create:

1) Ping Identity DS external server
2) JDBC external server
3) LDAP external server
4) Sun DS external server

?) help
c) cancel
q) quit

Enter choice [c]: 1
```

5. Specify a name for the new external server.

Example:

In this example, the external server is named `east1`.

```
>>>> Enter a name for the Ping Identity DS external server that you want
to create: east1
```

6. Configure the host name or IP address of the target LDAP external server.

Example:

```
Enter a value for the 'server-host-name' property: east1.example.com
```

7. Configure the location property of the new external server.

Example:

```
Do you want to modify the 'location' property?

1) Leave undefined
2) Change it to the location: East
3) Change it to the location: West
4) Create a new location

?) help
q) quit

Enter choice [1]: 2
```

8. Define the bind DN and bind password.

Example:

```
Do you want to modify the 'bind-dn' property?

1) Leave undefined
2) Change the value

?) help
q) quit
```

```

Enter choice [1]: 2

Enter a value for the 'bind-dn' property [continue]: cn=Proxy
User,cn=Root DNs,cn=config

Enter choice [b]: 6

...

Do you want to modify the 'password' property?

  1) Leave undefined
  2) Change the value
  ?) help
  q) quit

Enter choice [1]: 2

Enter a value for the 'password' property [continue]:
Confirm the value for the 'password' property:

```

9. To finish the operation, enter `f`.

```
Enter choice [b]: f
```

## Result

```
The Ping Identity DS external server was created successfully.
```

## Next steps

After adding the server, run the `prepare-external-server` tool to configure communications between the Directory Proxy Server and the Ping Identity Directory Servers.

For more information, see [Preparing two new external servers using the prepare-external-server tool](#) on page 1347.

## Configuring authentication with a SASL external certificate

By default, the Server authenticates to the Server using LDAP simple authentication with a bind DN and a password. You can configure the Directory Proxy Server to use Simple Authentication and Security Layer (SASL) EXTERNAL to authenticate to the Directory Server with a client certificate.

### Before you begin

Install and configure Server instances to communicate with the backend Server instances using either SSL or StartTLS.

## Steps

1. Create a Java KeyStore (JKS) that includes a public and private key pair for a certificate that the Server instances will use to authenticate to the Directory Server instances.
  - a. Run the following command in the instance root of one of the Server instances.

```

$ keytool -genkeypair \
  -keystore config/proxy-user-keystore \
  -storetype JKS \
  -keyalg RSA \
  -keysize 2048 \
  -alias proxy-user-cert \

```

```
-dname "cn=Proxy User,cn=Root DNs,cn=config" \  
-validity 7300
```

- b. When prompted for a key store password, enter a strong password to protect the certificate.
  - c. When prompted for the key password, press Enter to use the key store password to protect the private key.
2. Use a text editor to create a `config/proxy-user-keystore.pin` file containing a single line that is the key store password provided in the previous step.
  3. If there are other Server instances in the topology, copy the `proxy-user-keystore` and `proxy-user-keystore.pin` files into the `config` directory for all instances.
  4. To export the public component of the proxy user certificate to a text file, run the following command.

```
$ keytool -export \  
-keystore config/proxy-user-keystore \  
-alias proxy-user-cert \  
-file config/proxy-user-cert.txt
```

5. Copy the `proxy-user-cert.txt` file into the `config` directory of all Directory Server instances.
  - a. Import that certificate into each server's primary trust store by running the following command from the server root.

```
$ keytool -import \  
-keystore config/truststore \  
-alias proxy-user-cert \  
-file config/proxy-user-cert.txt
```

- b. When prompted for the keystore password, enter the password contained in the `config/truststore.pin` file.
  - c. When prompted to trust the certificate, enter `yes`.
6. To update the configuration for each Server instance to create a new key manager provider that will obtain its certificate from the `config/proxy-user-keystore` file, run the following `dsconfig` command.

```
$ dsconfig create-key-manager-provider \  
--provider-name "Proxy User Certificate" \  
--type file-based \  
--set enabled:true \  
--set key-store-file:config/proxy-user-keystore \  
--set key-store-type:JKS \  
--set key-store-pin-file:config/proxy-user-keystore.pin
```

7. To update the configuration for each LDAP external server in each Server instance to use the newly-created key manager provider, and also to use SASL EXTERNAL authentication instead of LDAP simple authentication, run the following `dsconfig` command.

```
$ dsconfig set-external-server-prop \  
--server-name dsl.example.com:636 \  
--set authentication-method:external \  
--set "key-manager-provider:Proxy User Certificate"
```

Result: After these changes, the Server re-establishes connections to the LDAP external server and authenticates with SASL EXTERNAL.

8. Verify that the Server can communicate with all backend servers by running the `bin/status` command.

Result: All of the servers listed in the "--- LDAP External Servers ---" section are available.

## 9. Review the Directory Server access log.

The BIND RESULT log messages used to authenticate the connections from the Server include the following:

- `authType="SASL"`
- `saslMechanism="EXTERNAL"`
- `resultCode=0`
- `authDN="cn=Proxy User,cn=Root DNs,cn=config"`

## Servers and certificates

The following provides a detailed description of PingDirectory Server certificate types.

PingDirectory Server uses two main types of certificates:

### Listener certificates

Used to secure communication through TLS.

### Inter-server certificates

Used to authenticate between server instances in a topology.

### Listener certificates

When a client initiates TLS negotiation with the server, the server presents a certificate chain to the client and the certificate at the head of the chain functions as a listener certificate.

Because the client decides whether to trust the certificate chain, it is recommended that the chain be signed by an issuer whom the client is likely to trust or that the client can be easily configured to trust.

You can create self-signed certificates with long lifespans, but a certificate that a certification authority signs is likely to have a relatively short lifespan. Commercial authorities typically issue certificates that are valid for only one or two years, but some authorities use shorter validity windows.

Short certificate lifespans offer some security benefits. In particular, because most clients do not verify whether a certificate has been revoked, a shorter validity window minimizes the timeframe that a compromised certificate can be used. If the process for replacing certificates is streamlined or automated, administrative inconvenience can be kept to a minimum.

Listener certificates are stored in key stores that are referenced by key manager providers, which in turn provide the logic and configuration for accessing the key stores. If a server component, like a connection handler, requires access to a certificate that it presents to a peer during the TLS negotiation process, that component must reference the key manager provider that points to the key store containing the appropriate certificate. If the key store contains multiple certificates, and if the component referencing the key store includes a property specifying the certificate's nickname, the certificate with that alias is selected. Otherwise, the server lets the Java virtual machine (JVM) select a certificate that might not be well-defined.

The server also provides trust manager providers, which determine whether to trust the certificate chains with which it is presented. A trust manager provider can reference a specified trust store file, but other options include the JVM default trust store, which uses the Java installation's default set of trusted issuers, and the blind trust manager provider, which automatically trusts every certificate chain that is presented to it.

### Note:

Never use a blind trust manager in a production environment because it leaves the server vulnerable to impersonation and man-in-the-middle attacks. However, a blind trust manager can be convenient in test environments when troubleshooting certain types of problems.

## Replacing listener certificates

Certificate authorities typically restrict the lifespans of the certificates that they sign. If you use a certification authority to issue listener certificates, you are likely replacing the certificates on a regular basis.

About this task

The **replace-certificate** tool performs the following steps:

1. Obtain a new certificate chain.
2. Make necessary updates to the key manager provider and the connection handler configurations
3. Update the server instance listener configuration with the new certificate.

The **replace-certificate** tool offers the following modes of operation:

Interactive mode

Walks you through the process of obtaining a new certificate and installing it in the server.

Interactive mode also displays the non-interactive commands that are required to achieve the same result.

Non-interactive mode

Useful when scripting the process of replacing a certificate.

Steps

- To replace a listener certificate, run the **replace-listener-certificate** subcommand of the **replace-certificate** tool.

### Note:

You can replace certificates manually, but the **replace-certificate** tool automates the process. The **replace-certificate** tool provides information about multiple listener certificates during the transitional phase that occurs when you install them.

The **replace-listener-certificate** subcommand takes arguments that provide the following information:

- Arguments required to authenticate to PingDirectory Server, such as **--bindDN** and **--bindPasswordFile**
- Details about the key store that contains the new certificate
- Updates that must be made to the key and trust manager providers
- Whether to signal the HTTP connection handler to reload its certificates after the update is complete

The following arguments are available:

| Argument                                       | Description                                                                                                                                     |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>--source-key-store-file {path}</b>          | Path to the Java KeyStore (JKS) or PKCS #12 file that contains the private key entry with the new certificate chain. This argument is required. |
| <b>--source-key-store-password {password}</b>  | Clear-text password that is needed to access the contents of the source key store.                                                              |
| <b>--source-key-store-password-file {path}</b> | Path to the file that contains the password necessary to access the contents of the source key store. The file can contain the password in      |

| Argument                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                        | the clear or can be encrypted with a definition from the server's encryption settings database.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>--source-certificate-alias {alias}</code>        | Password that is required to access the appropriate private key in the source key store. If neither the <code>--source-private-key-password</code> nor the <code>--source-private-key-password-file</code> argument is provided, the key store password is used as the private key password.                                                                                                                                                                                                                                                        |
| <code>--source-private-key-password-file {path}</code> | Path to the file that contains the password needed to access the appropriate private key in the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database. If neither the <code>--source-private-key-password</code> nor the <code>--source-private-key-password-file</code> argument is provided, the key store password is used as the private key password.                                                                                          |
| <code>--key-manager-provider {name}</code>             | Name of the key manager provider that is updated to use the new certificate chain. The value must identify a file-based key manager provider, and the new certificate chain must be enabled. Defaults to <code>JKS</code> if a value is not specified.                                                                                                                                                                                                                                                                                              |
| <code>--trust-manager-provider {name}</code>           | Name of the trust manager provider that is updated with the information required to trust the new certificate chain. The value must identify a file-based trust manager provider, and the new certificate chain must be enabled. If neither this argument nor the <code>--use-jvm-default-trust-manager-provider</code> argument is provided, the tool assumes that the name of the trust manager provider is identical to the name of the key manager provider.                                                                                    |
| <code>--use-jvm-default-trust-manager-provider</code>  | Indicates that the server must be configured to use the JVM-default trust manager provider, which trusts certificates signed by issuers in the <code>cacerts</code> trust store provided with the Java virtual machine (JVM), rather than updating an existing trust manager provider.                                                                                                                                                                                                                                                              |
| <code>--target-certificate-alias {alias}</code>        | <p>Alias to use for the new certificate in the key manager provider's key store, and for appropriate updates in the trust manager provider's trust store. Defaults to an alias of <code>server-cert</code> if a value is not specified.</p> <div data-bbox="868 1795 1472 1932" style="border: 1px solid black; padding: 5px;"> <p> <b>Note:</b></p> <p>If the key manager provider's key store, or the trust manager provider's trust store, already</p> </div> |

| Argument                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                      | contains an entry with the given alias, the existing entry is renamed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>--reload-http-connection-handler-certificates</b> | <p data-bbox="873 321 1464 478">Indicates that the tool is requesting that the server cause any HTTPS-based connection handlers to reload their certificates, so that the connection handlers can use the updated certificate.</p> <p data-bbox="873 499 1464 751">LDAP connection handlers react to the change immediately and start presenting the new certificate chain during subsequent TLS negotiations. HTTPS connection handlers continue using the former certificate until the connection handler is restarted or until the connection handler is asked specifically to reload its certificates.</p> <div data-bbox="873 783 1464 966"> <p> <b>Note:</b></p> <p data-bbox="873 846 1464 945">This option might prevent clients with existing TLS sessions that were negotiated with the former certificate from being resumed.</p> </div> |

- To remove earlier certificates from the server instance listener configuration, run the **purge-retired-listener-certificates** subcommand.

 **Note:**

The **purge-retired-listener-certificates** subcommand does not take arguments other than the ones that are required to authenticate to the server.

By default, the **replace-certificate** tool updates the server instance listener configuration object to include the new listener certificate, and it merges the old and new certificates residing in the configuration object.

### Inter-server certificates

Each server instance in a topology has an inter-server certificate that is generated during the setup process.

The inter-server certificate is not exposed to clients, so a trusted issuer does not need to sign it. Instead, the topology registry, representing a mirrored portion of the configuration with information about every PingDirectory Server instance in the environment, contains the information that each instance needs to trust the inter-server certificates for all other instances.

Inter-server certificates can be used to protect certain secrets that are shared among servers within the topology, like the secrets that are used to digitally sign log files, backups, and LDIF exports. Inter-server certificates include the encryption keys that reversible password-storage schemes use.

The inter-server certificate is generated with a long lifespan. Replace it only when you suspect that its private key is compromised.

### Replacing the inter-server certificate

During the installation process, the inter-server certificate is generated with a long lifespan and does not require replacement under normal circumstances. You should replace the inter-server certificate only if you suspect that its private key is compromised.

#### About this task

The inter-server certificate is intended for use only between server instances within the same topology. Because it is not exposed to regular clients, the inter-server certificate does not need to be trusted.

The `replace-certificate replace-inter-server-certificate` command performs the following steps:

- Acquires the new inter-server certificate from a provided Java KeyStore (JKS) or PKCS #12 key store
- Makes the necessary updates to the `config/ads-truststore` file in the server key store
- Updates the server instance configuration object to include the new inter-server certificate

#### Note:

To avoid the need to replace the inter-server certificate on a regular basis, use a self-signed certificate with a long lifespan. Each server instance must possess its own, unique inter-server certificate that satisfies the following conditions:

- Uses an RSA key pair
- Has a minimum key size of 2048 bits

The following types of certificates are not allowed:

- Certificates with an elliptic curve key pair
- Certificates with an RSA key that is smaller than 2048 bits

#### Steps

- To replace the inter-server certificate, run the `replace-inter-server-certificate` subcommand of the `replace-certificate`.

The `replace-inter-server-certificate` subcommand takes a subset of the arguments that are used with the `replace-listener-certificate` subcommand, including the following arguments:

- `--source-key-store-file {path}--source-key-store-password {password}`
- `--source-key-store-password-file {path}`
- `--source-certificate-alias {alias}`
- `--source-private-key-password {password}`
- `--source-private-key-password-file {path}`
- To delete earlier values that are no longer needed, run the `purge-retired-inter-server-certificates` subcommand.

#### Note:

By default, the new inter-server certificate is merged with the existing values in the server instance configuration entry.

### X.509 certificates

The server supports X.509 certificates, the most common type of certificates. [RFC 5280](#) describes X.509v3, which provides the current version of the specification.

An X.509v3 certificate includes the following components:

#### X.509 encoding version

Enables the differentiation between an X.509v3 certificate and one that conforms to an earlier or later version of the specification.

#### Serial number of the certificate

Integer value that uniquely identifies a certificate as issued by a certification authority.

#### Subject DN

Distinguished name for the certificate, which often provides details about the context in which the certificate is to be used. For more information, see [Certificate subject DNs](#) on page 415.

#### Issuer DN

Distinguished name for the issuer certificate, which is the certificate used to sign the certificate. For a self-signed certificate, this value matches the subject DN.

#### Validity window

Indicates the timeframe during which the certificate is considered valid. This component includes the following elements:

- **notBefore**  
Specifies the earliest time at which the certificate is considered valid.
- **notAfter**  
Specifies the latest time at which the certificate is considered valid.

#### Public key

Public portion of a pair of cryptographically linked keys. For more information, see [Certificate key pairs](#) on page 416.

#### Signature

A type of cryptographic proof that the certificate truly was sent from the issuer and has remained unaltered. A self-signed certificate is signed with its own private key. Otherwise, it is signed with the issuer's private key.

An X.509v3 certificate might also include the following optional components:

#### Subject unique ID

Uniquely identifies the certificate. This component has been deprecated in favor of the subject key identifier extension, so it is generally omitted from X.509v3 certificates.

#### Issuer unique ID

Subject unique ID of the issuer certificate, if available. This component has been deprecated in favor of the authority key identifier extension.

#### Set of extensions

Provides additional context for the certificate and the manner in which it is used. For more information, see [Certificate extensions](#) on page 417.

### **Certificate subject DNs**

A certificate's subject distinguished name (DN) provides information about how the certificate should be used.

Like an LDAP DN, a certificate's subject DN consists of a comma-delimited series of attribute-value pairs. However, unlike an LDAP DN, the attribute names in a certificate subject DN are typically written in all uppercase characters.

A certificate's subject DN is also referred to as its subject. The following attributes commonly appear in a certificate subject.

| Attribute name | Attribute description                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CN             | Common name<br><br> <b>Note:</b><br>For a listener certificate, the CN attribute typically identifies the host name that clients use to access the certificate. However, the subject alternative name extension is recommended more highly for accomplishing the same task. Most certificate subject DNs include at least the CN attribute. |
| E              | Email address                                                                                                                                                                                                                                                                                                                                                                                                                |
| OU             | Name of the organizational unit, such as the relevant department                                                                                                                                                                                                                                                                                                                                                             |
| O              | Name of the organization or company                                                                                                                                                                                                                                                                                                                                                                                          |
| L              | Name of the locality, such as the appropriate city                                                                                                                                                                                                                                                                                                                                                                           |
| ST             | Full name of the state or province                                                                                                                                                                                                                                                                                                                                                                                           |
| C              | ISO 3166 country code                                                                                                                                                                                                                                                                                                                                                                                                        |

A certificate subject includes at least one attribute-value pair, and the CN attribute is typically present. Other attributes can be omitted, although the O and C attributes are also common. For example, a listener certificate for a server with an address of `ldap.example.com`, which is run by the US-based company Example Corp, might have a subject of `CN=ldap.example.com,O=Example Corp,C=US`.

### Certificate key pairs

Each certificate contains a key pair that consists of two keys that are linked cryptographically. If you encrypt data with one key, the data can be only decrypted with the other key.

Although a key pair can be created easily when both keys are generated simultaneously, the process of deriving one key from the other is extremely difficult, a process categorized in cryptographic terms as computationally infeasible.

When generating a key pair, one key is designated as the public key, and the other key is designated the private key. The public key can be made widely available, but the private key must be kept secret and not shared with anyone.

As long as the secrecy of the private key is maintained, the key pair can be used to perform the following functions:

- Encryption, sometimes referred to as confidentiality

If someone wants to send you a secret message without anyone else viewing it, the message can be encrypted with your public key. Only you possess the private key, so only you can decrypt the message.

- Digital signatures

If you encrypt data with your private key, it can be decrypted only with your public key. Because your public key can be made widely available, this encryption method does not actually protect the content.

However, digital signatures prove that a message came from you because only your private key could have generated it.

**Note:**

When generating a digital signature, the entire message is generally not encrypted. Only a hash of the message is encrypted, typically by using a digest algorithm like SHA-256.

This approach protects the integrity of a message. A decrypted signature that matches the digest of the original message guarantees that the message came from you and that it has remained unaltered since you signed it.

The following public key algorithms are used primarily in certificates that facilitate TLS communication:

- RSA, which is based on the multiplication of large prime numbers
- EC, which is based on computations that involve special types of elliptical curves

Although RSA is supported more widely than EC, it is slower and requires larger keys to achieve the same level of security. To support legacy clients, you should use an RSA certificate and choose a key size of at least 2,048 bits.

If all of your clients support EC certificates, you should use an EC certificate with a key size of at least 256 bits.

### Certificate extensions

Extensions provide additional context for a certificate.

Some of the more common extension types include the following:

#### Subject key identifier

Holds a unique identifier for the certificate, which is generally derived from the certificate's public key.

#### Authority key identifier

Holds the subject key identifier for the issuer certificate. This extension type helps to identify the issuer certificate, especially when presented with an incomplete certificate chain.

#### Subject alternative name

Holds a list of ways that clients are expected to reference a server when establishing a connection to it.

**Note:**

Clients must take this information into account when deciding whether to trust a server's certificate.

The most common types of values include DNS names, IP addresses, and URIs. DNS names must be fully qualified, but can optionally use an asterisk in the leftmost component to match any single name in that component. For example, `*.example.com` could match `www.example.com` or `ldap.example.com`, but would not match `ldap.east.example.com` or `example.com`.

#### Key usage

Provides information about the manner in which the certificate is expected to be used. The following key usages are allowed:

`digitalSignature`

Indicates that the certificate can be used for digitally signing data, excluding certificates and certificate revocation lists (CRL).

`nonRepudiation`

Indicates that the certificate can be used to prevent denying the authenticity of a message. `nonRepudiation` is also known as `contentCommitment`.

`keyEncipherment`

Indicates that the certificate can be used to protect encryption keys, such as symmetric keys that are derived during TLS key agreement.

`dataEncipherment`

Indicates that the certificate can be used for encrypting data directly.

`keyAgreement`

Indicates that the certificate's public key can be used for key agreement, such as deriving the symmetric key that protects TLS communication.

`keyCertSign`

Indicates that the certificate can act as a certification authority and be used for signing other certificates.

`cRLSign`

Indicates that the certificate can be used to sign CRLs.

`encipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for encrypting data during key agreement.

`decipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for decrypting data during key agreement.

**Extended key usage**

Acts as an alternative to the key usage extension and provides additional high-level functionality. The following extended key usages are allowed:

`serverAuth`

Indicates that the server can present the certificate to the client during TLS negotiation.

`clientAuth`

Indicates that the client can present the certificate to the server during TLS negotiation.

`codeSigning`

Indicates that the certificate can be used to sign source and compiled code.

`emailProtection`

Indicates that the certificate can be used to sign or encrypt email messages.

`timeStamping`

Indicates that the certificate can be used to assert the time that an event occurred.

`ocspSigning`

Indicates that the certificate can be used to sign an online certificate status protocol (OCSP) response.

**Basic constraints**

Indicates whether the certificate can act as a certification authority and, if so, the maximum number of intermediate certificates that can follow it in a certificate chain.

### Certificate chains

A certificate chain is an ordered list of one or more certificates. In such a chain, each subsequent certificate is the issuer of the previous certificate.

During TLS negotiation, the server presents a certificate chain to the client, which determines whether to trust the chain and continue with the negotiation. The client can also present its own certificate chain to the server.

If a certificate is self-signed, its chain contains only that single certificate. If a certificate is signed by a self-signed certificate authority (CA) certificate, such as a root CA, the chain contains two certificates: the server certificate and the CA certificate that follows it. If a single intermediate CA (a CA certificate that is signed by a root CA) is present, the chain contains the server certificate, followed by the intermediate CA, and then the root CA.

Intermediate certificate authorities are useful for security purposes, especially in commercial authorities. If a client trusts a root CA certificate, it is likely to trust anything with that root CA certificate at the base of its chain. Consequently, the root CA certificate must be kept secure.

#### Note:

If the root CA certificate is compromised, any certificate that is directly or indirectly signed by it can no longer be trusted.

With intermediate CA certificates, the root certificate can be kept offline in secure storage and used only when a new intermediate CA certificate must be signed. The intermediate CA certificates can be used to sign end-entity certificates, but must be protected to avoid compromising any of the certificates. A compromised certificate must be revoked along with all of the certificates that it signed. In such a scenario, the root CA can be used to sign a new certificate.

#### Note:

The certificate chain that the server presents to the client, or that the client presents to the server, during TLS negotiation does not always need to be the complete chain. If the root CA at the end of the chain is widely trusted, the server can assume that the client already has that root CA in its default set of trusted certificates. The server can leave that root CA off the chain with the assumption that the client will retrieve it from its default trust store. While the same assumption could theoretically be true for intermediate CA certificates, only the root CA certificate is commonly omitted. When a client receives an incomplete chain, the client looks in its default trust store to determine whether the trust store contains the issuer certificate, which it can identify by using properties like the issuer distinguished name (DN) or an authority key identifier extension.

The certificate at the head of a certificate chain, which appears as the first one in the list, is often called the end-entity certificate. If this certificate appears at the head of the chain that a server presents during TLS negotiation, it is referred to as the server certificate. If the certificate appears at the head of a chain that a client presents, it is referred to as a client certificate. The certificate at the end of a complete chain must be a root CA certificate. In the case of a self-signed certificate, the chain contains only a single certificate that serves both roles.

### About representing certificates, private keys, and certificate signing requests

X.509 is an encoding format that uses the ASN.1 distinguished encoding rules (DER), which exist in binary format. When writing a certificate to a file, either a raw DER format or a plaintext format called PEM can be used.

PEM encoding consists of a line that contains the text `-----BEGIN CERTIFICATE-----`, followed by a set of lines that contains the base64-encoded representation of the raw DER bytes (typically with no more than 64 characters per line), followed by a line that contains the text `-----END CERTIFICATE-----`.

The X.509 encoding contains a certificate's public key, but not its private key. The PKCS #8 specification in [RFC 5958](#) describes the encoding for private keys. This approach uses a DER encoding with a PEM variant that instead uses the following header and footer, respectively.

```
-----BEGIN PRIVATE KEY-----
-----END PRIVATE KEY-----
```

RFC 5958 also describes an encrypted representation of the private key, but that format is currently unsupported.

The PKCS #10 specification in [RFC 2986](#) describes the CSR format. This format uses a DER encoding with a PEM variant that uses the following header and footer, respectively.

```
-----BEGIN CERTIFICATE REQUEST-----
-----END CERTIFICATE REQUEST-----
```

Some implementations use the following alternate, nonstandard forms.

```
-----BEGIN NEW CERTIFICATE REQUEST-----
-----END NEW CERTIFICATE REQUEST-----
```

### Certificate trust

When a server presents its certificate chain to a client during TLS negotiation, the client decides whether to trust the certificate chain and concludes whether it is communicating with a legitimate server instead of an impostor.

If a client is tricked through DNS hijacking into communicating with a rogue application instead of with a legitimate server, the application can steal the client's credentials, or can fool the client into concluding that it has performed an action that it has not performed. If a rogue application acts as a broker between the client and the legitimate server, the client might be unable to detect the change, and the malicious application might be capable of stealing data or altering the communication. Consequently, you should avoid `trust all` or `blind trust` options in a production environment.

When determining whether to trust a server certificate chain, a client performs the following steps.

### Processing steps

1. Verifies that it has received the complete certificate chain.

If a server presents an incomplete chain, the client must ensure that it can complete the chain with information in an explicitly provided trust store or default trust store. If the client cannot complete the certificate chain, the chain is not trusted.

2. Verifies that each subsequent certificate in the chain is the issuer certificate for, and that its private key was used to sign, the certificate that precedes it.

**Note:**

If a certificate chain contains extraneous certificates, or if a subsequent certificate did not issue the certificate that precedes it, the chain is not trusted.

3. Confirms that it has a reason to trust the certificate at the root of the chain.

**Note:**

This step is generally performed by ensuring that the root certificate authority (CA) certificate can be found in either a default trust store or a trust store that is configured for use by the client. If the client has no prior knowledge of the root CA certificate, the chain is not trusted.

4. Verifies that the current time lies within the validity window for each certificate in the chain.

**Note:**

The chain is not trusted under the following conditions:

- When the `notBefore` value of any certificate in the chain is later than the current time.
- When the `notAfter` value of any certificate in the chain is earlier than the current time.

5. Verifies that the server certificate at the head of the chain is suitable for the server with which the client thinks it is communicating.

**Note:**

The client must verify that the address used to connect to the server matches one of the following values:

- The `CN` attribute of the certificate's subject.
- One of the values of any subject alternative name extension.

These steps represent a starting point. If necessary, the client can perform additional types of validation. For example, if a root or intermediate certification authority maintains a certificate revocation list (CRL) or supports the online certificate status protocol (OCSP), the client must verify that none of the certificates in the chain has been revoked. The client can also verify that the CA certificates include the basic constraints extension, and that the server certificate does not contain too many levels. Other checks, like those that use certificate policy extensions, can also be performed.

### Keystores and truststores

A keystore is a type of database that holds certificates.

The following examples represent the most common forms of keystores:

- File that uses the Java-specific Java KeyStore (JKS) format
- File that uses the standard PKCS #12 format
- Collection of files that holds certificates and private keys, typically in PEM or DER format
- Hardware security module (HSM) that makes the certificate information available through an interface like PKCS #11

The server supports file-based keystores by using the JKS and PKCS #12 formats and by using hardware security modules that are accessible through PKCS #11. The server does not currently support a keystore

format that consists of individual certificate and private key files. To import these files into a JKS or PKCS #12 keystore, use the **manage-certificates** tool.

A keystore also represents a collection of entries, each of which is identified by a name that an alias calls. Keystores can have the following entry types:

#### Private key entries

Contain a certificate chain and a private key. When a server accepts a TLS-based connection, it uses a private key entry to obtain the certificate chain that it presents to the client. The server can also use the private key from the same entry to process its key agreement. Similarly, a client uses a private key entry when presenting its own certificate chain to a server.

#### Trusted certificate entries

Contain a single certificate without a private key. As the name implies, a trusted certificate entry is intended primarily for use when determining whether to trust a certificate chain that is presented during TLS negotiation.

#### Secret key entries

Contain a secret key only, without an associated certificate. These types of entries are not used for TLS processing. Instead, they hold symmetric encryption keys or other types of secrets.

A password, sometimes called a PIN, protects the contents of a keystore. In some cases, like with JKS keystores, some content might be accessible without a password, and a password might be required only when trying to access private keys or secret keys. In other cases, like with PKCS #12 keystores, you might need a password for any interaction with the keystore.

Additional passwords can further protect private keys. This approach is often the same as with the keystore password, but the password can be different. This tactic is useful when a single keystore is shared for multiple purposes, for example, and when merely having access to the keystore does not guarantee access to all of the data that it contains.

#### Note:

A truststore is another name for a keystore that is intended primarily for use when determining whether to trust a certificate chain that has been presented. Truststores generally contain primarily trusted certificate entries, but that case is not required.

Java runtime environments typically include a default truststore, often `jre/lib/security/cacerts` or `lib/security/cacerts`, that is prepopulated with several widely trusted certification authority certificates. When presented with a certificate that one of these authorities has signed, the default truststore can allow the certificate to be trusted without any additional configuration. When presented with a self-signed certificate, or when presented with a certificate that is signed by an issuer not in the default truststore, such as a private corporate certification authority, a separate truststore is required.

### Transport Layer Security (TLS)

TLS describes a mechanism for securely communicating between two parties that might have no prior knowledge of each other.

TLS is the successor to SSL, and the two terms are often used interchangeably, even though such usage might not technically be correct.

#### Note:

SSL remains the more widely recognized term. The abbreviation TLS occasionally generates confusion with the StartTLS extended operation, particularly in LDAP.

TLS provides security in the form of the following main components:

## Certificate trust

Is about reassuring a connection-initiating client that it is communicating with the server to which it intended to connect. To ensure that the server shares the same degree of confidence in the identity and legitimacy of the client, it can ask the client to present its own certificate chain. For more information, see [Certificate Trust](#).

## Cipher selection

Involves choosing the cipher and the key to protect the bulk of the communication. Although a client can use a server certificate's public key to encrypt data before sending it, this approach can lead to the following issues:

- Unless the client presents its own certificate chain to the server, the server cannot encrypt the data that it sends back to the client.
- Public key encryption is considerably slower than symmetric encryption, in which the same key is used for both encryption and decryption. Public key encryption is also called asymmetric encryption because different keys are used to encrypt and decrypt data.
- If you rely entirely on the security of a private key to ensure the secrecy of a communication, and if the private key becomes compromised, data that has been encrypted with the private key must also be considered compromised.

Rather than relying solely on public key encryption to protect communication between a client and server, the TLS negotiation process allows a client and server to agree on the type of encryption and the secret key to use after completing the negotiation process.

### **TLS handshakes**

The process of negotiating the TLS is referred to as the handshake.

Although the exact process depends on the TLS version that is ultimately chosen, the following steps represent the basic components of a TLS 1.2 handshake:

### TLS processing steps

1. The client sends a `hello` message that provides the server with the following information:
  - Highest supported version of the TLS protocol
  - The cipher suites that the client uses
  - Set of extensions with additional information:
    - The address that the client uses to communicate with the server
    - The signature algorithms and elliptic curves that the client supports
    - Whether the client supports secure renegotiation
2. The server returns a `server hello` message that provides the client with the following information:
  - The TLS protocol version that the server uses
  - The cipher suite that the server selects

The server can also provide its own extensions to the client.
3. The server sends a `certificate` message that provides its certificate chain to the client.
4. The server can optionally send a `server key exchange` message with additional information that the client might need to securely derive the same symmetric encryption key that the server generates.
5. The server can optionally send a `certificate request` message that asks the client to present its own certificate chain to the server.

6. The server sends a `server hello done` message to inform the client that it has completed its `hello` sequence.
7. The client can optionally send a `certificate` message to the server with its own certificate chain.

**Note:**

The client sends a `certificate` message only when the server initially sends a certificate request. If the client receives such a request, it can refuse to, and probably will not, send a certificate chain. The server decides whether to require a client certificate chain. In LDAP, the server commonly asks the client to present a certificate, but continues with TLS negotiation even if the client does not present one. This approach supports authentication methods like SASL EXTERNAL, in which a client uses the certificate chain that it presents during TLS negotiation as proof of its identity.

8. The client derives a symmetric key to use for the remainder of the encrypted processing, and sends a `client key exchange` message to the server. The `client key exchange` message includes the information that the server needs to generate the same key. Only the client and server know the value of the key, even if another entity can observe the communication that passes between the client and the server.
9. If the client presents a certificate chain to the server, it also sends a `certificate verify` message to prove that the private key for the certificate is included at the head of the chain.
10. The client sends a `change cipher spec` message to the server, which informs the server that the client will use the agreed-upon symmetric key to encrypt everything else that it sends to the server.
11. The client sends a `finished` message to the server to indicate that it has completed its portion of the handshake.
12. The server sends a `change cipher spec` message to the client, which informs the client that the server will use the agreed-upon symmetric key to encrypt everything else that it sends to the client.
13. The server sends a `finished` message to the client to indicate that it has completed its portion of the handshake.

TLS 1.3 uses a different handshake sequence that can require only a single round-trip to exchange the necessary information between the client and the server. TLS 1.2 requires two round-trips. To accomplish this task, TLS 1.3 tries to guess the type of key agreement that the server wants to use, and sends the relevant information to the server up front instead of waiting to hear from the server.

Because an extra round of communication between the client and server is eliminated, the server finishes its portion of the negotiation before the client. The server must assume that the client trusts its certificate chain. Because the server might log a successful negotiation only to discover late, through a TLS alert, that the client rejected the certificate, this approach might complicate certain types of troubleshooting.

### Key agreement

Key agreement processing provides a critical component of TLS negotiation.

It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

#### RSA key exchange

The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.

#### Diffie-Hellman (DH) key exchange

The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE

versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, use ECHDE over DHE, and either of those options over RSA. The DH algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. The use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

### LDAP StartTLS extended operation

In most scenarios, a client that uses TLS establishes a connection to a port that is dedicated to its use, like 636 (LDAPS) or 443 (HTTPS).

The client begins the TLS-negotiation process by sending a `client hello` message over the connection. In some scenarios, the client establishes a non-secure connection and later converts it to a secure one. In LDAP, this task is accomplished by using the `StartTLS` extended operation.

The `StartTLS` extended operation provides the following advantages over a dedicated LDAPS connection:

- To enable secure as well as insecure communication, only one port needs to be opened through a firewall.
- A client can use opportunistic encryption, in which the client performs the following steps:
  1. Queries the root DSE to determine whether the server supports StartTLS.
  2. Secures the connection, if possible.

Opportunistic encryption is useful in scenarios like following referrals because LDAP URLs do not officially support LDAPS as a scheme.

To ensure that a communication is always secure, use LDAPS instead of establishing an insecure connection that you secure later with the `StartTLS` extended operation. If you enable support for unencrypted LDAP communication, as `StartTLS` requires, a client might send a password-containing bind request or other sensitive data over an unencrypted connection. A server can be configured to reject unencrypted communication, but it cannot prevent a client from sending an unencrypted request.

#### Note:

Although you can use `StartTLS` to temporarily secure a connection before falling back on an unencrypted LDAP communication, the server does not support this strategy.

### About the `manage-certificates` tool

PingDirectory Server offers a `manage-certificates` tool that enables interaction with Java KeyStore (JKS) and PKCS #12 key stores.

Although it behaves similarly to the `keytool` utility that accompanies most Java distributions, `manage-certificates` is easier to use, provides improved usage information, and offers additional functionality.

### Available subcommands

The `manage-certificates` tool uses the following subcommands to indicate which function to invoke:

| Subcommand                     | Function                              |
|--------------------------------|---------------------------------------|
| <code>list-certificates</code> | Lists the certificates in a keystore. |

| Subcommand                                            | Function                                                                                                                                                                             |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>import-certificate</code>                       | Imports a certificate into a trusted certificate entry or imports a certificate chain and private key into a private key entry.                                                      |
| <code>export-certificate</code>                       | Exports a certificate from a keystore.                                                                                                                                               |
| <code>export-private-key</code>                       | Exports a private key from a keystore.                                                                                                                                               |
| <code>generate-self-signed-certificate</code>         | Generates a self-signed certificate.                                                                                                                                                 |
| <code>generate-certificate-signing-request</code>     | Generates a certificate-signing request that can be provided to a certification authority.                                                                                           |
| <code>sign-certificate-signing-request</code>         | Signs a certificate-signing request with a specified issuer certificate.                                                                                                             |
| <code>check-certificate-usability</code>              | Checks a specified certificate in a keystore to verify whether it is suitable for use as a listener certificate.                                                                     |
| <code>trust-server-certificate</code>                 | Initiates the TLS-negotiation process with a specified server to obtain its certificate chain so that a truststore can be updated with the necessary information to trust the chain. |
| <code>display-certificate-file</code>                 | Displays the contents of a file that contains one or more PEM-encoded or DER-encoded X.509 certificates.                                                                             |
| <code>display-certificate-signing-request-file</code> | Displays the contents of a file that contains a PEM-encoded or DER-encoded PKCS #10 certificate-signing request (CSR).                                                               |
| <code>change-certificate-alias</code>                 | Changes the alias for an entry in a keystore.                                                                                                                                        |
| <code>change-keystore-password</code>                 | Changes the password for a keystore.                                                                                                                                                 |
| <code>change-private-key-password</code>              | Changes the password that protects the private key for a specified entry in a keystore.                                                                                              |

### Common arguments

Most of the `manage-certificates` subcommands require access to a Java KeyStore (JKS) or PKCS #12 keystore. In such instances, use the `--keystore` argument to specify the path to the keystore.

If the keystore already exists, the tool detects automatically whether it is a JKS or PKCS #12 keystore. If the operation creates a new keystore, you can specify the type explicitly by using the `--keystore-type` argument, followed by a value of `JKS` or `PKCS12`. If you do not specify the keystore type, a default value of `JKS` is used.

Some situations require you to provide the password that is needed to access the keystore. For a JKS keystore, you might need to provide a keystore password only for operations that involve creating a keystore or accessing a private key. However, you will likely need to provide the password for all operations that involve a PKCS #12 keystore.

To provide a keystore password, use one of the following arguments:

- **--keystore-password**, followed by the clear-text password for the keystore.
- **--keystore-password-file**, followed by the path to a file that contains the password for the keystore. The file might contain the password in the clear, or it might be encrypted with a definition from the server's encryption-settings database.
- **--prompt-for-keystore-password**. If this argument is provided, the tool prompts you interactively to provide the password.

If a private key is protected with a different password than the keystore itself, specify one of the following arguments to provide the private key password:

- **--private-key-password**, followed by the plaintext password.
- **--private-key-password-file**, followed by the path to a file that contains the clear-text or encrypted password.
- **--prompt-for-private-key-password**, which causes the tool to prompt interactively for the password.

Several operations require you to specify the keystore entry to target. In such scenarios, provide the **--alias** argument, followed by the name of the alias for that entry.

### Listing the certificates in a keystore

List the certificates available in a keystore.

#### Steps

- To list the certificates in a keystore, use the **list-certificates** subcommand.

This subcommand requires you to specify the path to the keystore file, and possibly the password that is needed to access the keystore. The following options are also available:

| Option                           | Description                                                                                                                                                                                      |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>--alias {alias}</b>           | Specifies the alias of the certificate to display. If this value is not provided, all certificates are displayed. To list more than one specific certificate, specify this value multiple times. |
| <b>--display-pem-certificate</b> | Includes a PEM-encoded representation of each certificate as part of the output.                                                                                                                 |
| <b>--verbose</b>                 | Includes details about each certificate.                                                                                                                                                         |

#### Example:

The following command demonstrates the basic listing of a keystore that contains a single certificate chain.

```
$ bin/manage-certificates list-certificates \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin

Alias: server-cert (Certificate 1 of 2 in a chain)
Subject DN: CN=ds1.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Certification Authority,O=Example Corp,C=US
Validity Start Time: Saturday, November 9, 2019 at 11:26:09 AM CST
                    (8 minutes, 15 seconds ago)
Validity End Time: Sunday, November 8, 2020 at 11:26:09 AM CST
                  (364 days, 23 hours, 51 minutes, 44 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
SHA-1 Fingerprint: 42:f8:85:97:bf:88:bc:74:4b:5b:ce:0c:54:43:9b:44:6b:
                   81:23:a3
```

```

SHA-256 Fingerprint: 4f:be:47:ed:36:68:13:38:ba:e8:c0:c5:6c:85:51:97:
                    8b:40:1b:76:10:c0:be:80:15:62:06:96:c5:71:30:df
Private Key Available: Yes
The certificate has a valid signature.

Alias: server-cert (Certificate 2 of 2 in a chain)
Subject DN: CN=Example Certification Authority,O=Example Corp,C=US
Issuer DN:  CN=Example Certification Authority,O=Example Corp,C=US
Validity Start Time: Saturday, November 9, 2019 at 11:26:08 AM CST
                    (8 minutes, 16 seconds ago)
Validity End Time:  Friday, November 4, 2039 at 12:26:08 PM CDT
                    (7299 days, 23 hours, 51 minutes, 43 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint: b8:d0:16:9b:5d:f2:e7:a1:80:79:95:a2:64:b5:aa:ad:80:
                    23:64:16
SHA-256 Fingerprint: cf:98:2a:66:35:6e:6d:f9:5d:25:c6:68:68:04:5a:a8:
                    88:43:ca:b5:c8:e5:c9:95:09:e9:fc:ab:b9:41:ec:71
The certificate has a valid signature.

```

**Example:**

The following sample represents the verbose version of the previous command.

```

$ bin/manage-certificates list-certificates \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --verbose

Alias: server-cert (Certificate 1 of 2 in a chain)
X.509 Certificate Version: v3
Subject DN: CN=ds1.example.com,O=Example Corp,C=US

### Generating self-signed certificates

The process of creating a self-signed certificate is straightforward because a self-signed certificate claims itself as its own issuer.

Although self-signed certificates are convenient for testing environments, clients do not trust them by default. Consequently, you should not use them as listener certificates in production environments.

The `manage-certificates` tool offers a `generate-self-signed-certificate` subcommand that can create a self-signed certificate. In addition to the arguments that provide information about the keystore, certificate alias, and optional private key password, the following arguments are available.

| Argument                                       | Description                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--subject-dn {subject}</code>            | Subject DN for the certificate to create. This value is required.                                                                                                                                                                                                                                                                                  |
| <code>--days-valid {number}</code>             | Number of days that the certificate remains valid. Defaults to 365 if no value is specified.                                                                                                                                                                                                                                                       |
| <code>--validity-start-time {timestamp}</code> | Indicates the time at which the certificate begins its validity window. This value is assumed to reflect the local time zone, and must be expressed in the form <code>YYYYMMDDhhmmss</code> , where a value of <code>20190102030405</code> indicates January 2, 2019, at 3:04:05 AM.<br><br>Defaults to the current time if no value is specified. |
| <code>--key-algorithm {name}</code>            | Name of the algorithm to use when generating the key pair. For a listener certificate, this value is typically <code>RSA</code> or <code>EC</code> .<br><br>Defaults to <code>RSA</code> if no value is specified.                                                                                                                                 |
|                                                |  <b>Note:</b><br>This argument cannot be used in conjunction with the <code>--replace-existing-certificate</code> argument.                                                                                                                                     |

| Argument                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>--key-size-bits {number}</pre>              | <p>Length of the key, in bits, to generate. If the <code>--key-algorithm</code> argument is given, then <code>--key-size-bits {number}</code> must also be specified. Conversely, if the <code>--replace-existing-certificate</code> argument is given, then <code>--key-size-bits {number}</code> must not be specified.</p> <p>Typical key sizes are:</p> <ul style="list-style-type: none"> <li>▪ RSA key – 2048 or 4096 bits</li> </ul> <p>If a default RSA key is used but this argument is not provided, a default key size of 2048 bits is used.</p> <ul style="list-style-type: none"> <li>▪ Elliptic curve key – 256 or 384 bits</li> </ul>                                                                             |
| <pre>--signature-algorithm {name}</pre>          | <p>Name of the algorithm to use to sign the certificate. If the <code>--key-algorithm</code> argument is used to specify an algorithm other than <b>RSA</b>, then <code>--signature-algorithm {name}</code> must also be specified.</p> <p>If the <code>--replace-existing-certificate</code> argument is used, then <code>--signature-algorithm {name}</code> must not be specified.</p> <p>Typical signature algorithms include <b>SHA256withRSA</b> for certificates with RSA keys, and <b>SHA256withECDSA</b> for certificates with elliptic curve keys. If a default key algorithm is used but the <code>--signature-algorithm {name}</code> argument is not provided, a default value of <b>SHA256withRSA</b> is used.</p> |
| <pre>--replace-existing-certificate</pre>        | <p>Uses the new certificate to replace an existing certificate in the key store (within the same alias), and reuses the key for that certificate.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <pre>--inherit-extensions</pre>                  | <p>Indicates that, when replacing an existing certificate, the new certificate contains the same set of extensions as the existing certificate. If the <code>--replace-existing-certificate</code> argument is provided, but the <code>--inherit-extensions</code> argument is omitted, the new certificate contains only arguments that are provided explicitly.</p>                                                                                                                                                                                                                                                                                                                                                            |
| <pre>--subject-alternative-name-dns {name}</pre> | <p>Indicates that the certificate is expected to have a subject alternative name extension with the provided DNS name. The given name must be fully qualified, although it can contain an asterisk (*) as a wildcard in the leftmost component.</p> <p>To include multiple DNS names in the subject alternative name extension, specify the <code>--subject-alternative-name-dns {name}</code> argument multiple times.</p>                                                                                                                                                                                                                                                                                                      |

### Example

For example, the following command can be used to generate a self-signed server certificate.

```
bin/manage-certificates generate-self-signed-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --keystore-type JKS \
  --alias server-cert \
  --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
  --key-algorithm EC \
  --key-length-bits 256 \
  --signature-algorithm SHA256withECDSA \
  --subject-alternative-name-dns ds.example.com \
  --subject-alternative-name-dns ds1.example.com \
  --subject-alternative-name-dns localhost \
  --subject-alternative-name-ip-address 1.2.3.4 \
  --subject-alternative-name-ip-address 127.0.0.1 \
  --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
  --key-usage digital-signature \
  --key-usage key-encipherment \
  --key-usage key-agreement \
  --extended-key-usage server-auth \
  --extended-key-usage client-auth
```

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:

Subject DN: CN=ds.example.com,O=Example Corp,C=US

Issuer DN: CN=ds.example.com,O=Example Corp,C=US

Validity Start Time: Monday, January 27, 2020 at 03:40:13 PM CST  
(0 seconds ago)

Validity End Time: Tuesday, January 26, 2021 at 03:40:13 PM CST  
(364 days, 23 hours, 59 minutes, 59 seconds from now)

Validity State: The certificate is currently within the validity window.

Signature Algorithm: SHA-256 with ECDSA

Public Key Algorithm: EC (secP256r1)

SHA-1 Fingerprint:

## Generating certificate signing requests

A certificate signing request (CSR) contains all of the information that a certification authority requires to issue a certificate.

[RFC 2986](#) defines the request format, also known as PKCS #10, and includes the following elements:

- Certificate signing request version
- Requested subject distinguished name (DN) for the certificate
- Public key for the requested certificate
- Requested set of extensions for the certificate
- Signature that proves the requester has the private key for the given public key

To create a certificate signing request, use the `manage-certificates generate-certificate-signing-request` command, which performs the following steps:

1. Generated a public and private key pair.
2. Stores the key pair in a key store with a given alias.
3. Outputs the certificate signing request to the terminal.
4. Optionally writes the certificate signing request to a file.

Because a certificate signing request contains many of the same elements as a certificate, the command to generate one takes most of the same arguments as for generating a self-signed certificate. The following arguments are unavailable when generating a CSR:

- `--replace-existing-certificate`
- `--days-valid {number}`
- `--validity-start-time {timestamp}`

The following arguments are available when generating a certificate signing request but not when generating a self-signed certificate:

`--output-file {path}`

Path to a file to which the certificate signing request is written. If this value is not provided, the request is written only to the terminal in PEM form.

`--output-format {value}`

Format to use when writing the certificate signing request. This value can be **PEM** or **DER**, but the DER format is used only in conjunction with the `--output-file` argument. Defaults to **PEM** if the `--output-format {value}` argument is not provided.

`--use-existing-key-pair`

Indicates that the CSR uses a key pair that already exists in the key store with the given alias, rather than generating a new key pair, in which case the specified alias must not already be in use in the key store.

The following example command creates a CSR.

```
bin/manage-certificates generate-certificate-signing-request \
  --output-file dsl-cert.csr \
  --output-format PEM \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --keystore-type JKS \
  --alias server-cert \
  --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
  --key-algorithm EC \
  --key-length-bits 256 \
  --signature-algorithm SHA256withECDSA \
  --subject-alternative-name-dns ds.example.com \
  --subject-alternative-name-dns dsl.example.com \
```

```

--subject-alternative-name-dns localhost \
--subject-alternative-name-ip-address 1.2.3.4 \
--subject-alternative-name-ip-address 127.0.0.1 \
--subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
--key-usage digital-signature \
--key-usage key-encipherment \
--key-usage key-agreement \
--extended-key-usage server-auth \
--extended-key-usage client-auth

```

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing request.

Successfully wrote the certificate signing request to file '/ds/build/package/PingDirectory/dsl-cert.csr'.

If the contents of the resulting CSR file are made available to a certification authority to be signed, the resulting signed certificate can be imported into the key store.

To print the contents of a certificate signing request file, use the **display-certificate-signing-request-file** subcommand, which supports the following arguments:

```
--certificate-signing-request-file {path}
```

Path to the file that contains the certificate signing request to display.

```
--verbose
```

Indicates that the command is expected to display verbose information about the request, rather than a basic information set.

The following example demonstrates the basic output from the command.

```

$ bin/manage-certificates display-certificate-signing-request-file \
  --certificate-signing-request-file dsl-cert.csr

PKCS #10 Certificate Signing Request Version:  v1
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)

```

The following example demonstrates the verbose output.

```

$ bin/manage-certificates display-certificate-signing-request-file \
  --certificate-signing-request-file dsl-cert.csr \
  --verbose

### Importing signed and trusted certificates

Use the **manage-certificates import-certificate** command to import certificates into a keystore.

This command is used to accomplish the following tasks:

- Import a certificate that a certification authority has signed into the keystore in which the key pair was generated. In this scenario, the certificate is imported into a private key entry and must be imported as a certificate chain rather than an end-entity certificate.
- Import a trusted issuer certificate into a trust store. In this scenario, the certificate is imported into a trusted certificate entry as a single certificate instead of as a chain.
- Import a certificate chain, along with the private key for the end-entity certificate. This approach imports certificates that were generated through another library, like OpenSSL.

In addition to the arguments that provide information about the key store and the alias into which the certificate or certificate chain is imported, the **manage-certificates import-certificate** command accepts the following arguments:

```
--certificate-file {path}
```

Path to the file that contains the certificate to import. The certificate can be in PEM or DER format and can be a single certificate or a certificate chain. If the certificates in the chain reside in separate files, specify the **--certificate-file {path}** argument multiple times when you import a certificate chain.

```
--private-key-file {path}
```

Path to the file containing the private key that corresponds to the certificate at the head of the imported chain. The private key can be in PEM or DER format.

```
--no-prompt
```

Indicates that the certificate is to be imported without prompting for confirmation. By default, a summary of the certificate is displayed, and you must confirm that you want to import it.

The following example command imports a signed certificate into the key store that generates the certificate signing request.

```
$ bin/manage-certificates import-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --certificate-file ds1-cert.pem \
  --certificate-file ca-cert.pem
```

The following certificate chain will be imported into the keystore into alias 'server-cert', preserving the existing private key associated with that alias:

```
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
                    (4 minutes, 16 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
                  (364 days, 23 hours, 55 minutes, 43 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
SHA-1 Fingerprint:
  02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb

```

Do you want to import this certificate chain into the keystore? yes

Successfully imported the certificate chain.

If you do not provide the `--no-prompt` argument, the `manage-certificates import-certificate` tool still displays information about the certificates to import. To view additional information about a certificate before you import it, use the `display-certificate-file` subcommand, which supports the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to view.

`--verbose`

Displays verbose information about the certificate.

The output of the `display-certificate-file` subcommand has the same format and content as the `list-certificates` subcommand.

### Exporting certificates

Use the `export-certificate` subcommand to export a single certificate or a certificate chain from a key store to a file in PEM or DER format.

The `export-certificate` subcommand supports the normal arguments about the key store and certificate alias, in addition to the following arguments:

#### `--output-file {path}`

Path to the file to which exported certificates are written. If this value is not provided, the certificates are written to standard output rather than a file.

#### `--output-format {format}`

Format in which exported certificates are written. The value can be `PEM` or `DER`, but the DER format can be used only if the output is written to a file. Defaults to `PEM` if no value is specified.

#### `--export-certificate-chain`

Indicates that a certificate chain, rather than the end-entity certificate only, is to be exported.

#### `--separate-file-per-certificate`

Indicates the use of separate output files for each exported certificate, rather than placing all of the certificates in a single file. If this argument is provided and multiple certificates are to be exported, then `.1` is appended to the path for the indicated output file for the first certificate in the chain, `.2` is appended for the second certificate, and so on.

The following example exports a certificate chain.

```
$ bin/manage-certificates export-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --output-file server-cert.pem \
  --output-format PEM \
  --export-certificate-chain \
  --separate-file-per-certificate

Successfully exported the following certificate to '/ds/server-cert.pem.1':
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
                    (3 hours, 26 minutes, 23 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
                    (364 days, 20 hours, 33 minutes, 36 seconds from
now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
SHA-1 Fingerprint:
02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb
SHA-256 Fingerprint:
1d:b5:eb:3c:f5:ff:bf:79:a2:a5:86:b8:e4:33:76:4d:d7:50:dc:a4:34:95:37:be:89:45:
86:1f:5d:79:c3:93

Successfully exported the following certificate to '/ds/server-cert.pem.2':
Subject DN: CN=Example Root CA,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:00:07 PM CST
                    (3 hours, 35 minutes, 39 seconds ago)
Validity End Time: Saturday, November 5, 2039 at 10:00:07 PM CDT
```

```

(7299 days, 20 hours, 24 minutes, 20 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP384r1)
SHA-1 Fingerprint:
  0e:5c:21:c9:a5:36:0a:24:eb:aa:55:b6:a5:94:0e:e0:56:03:22:e6
SHA-256 Fingerprint:
  77:cf:66:d7:3c:8a:fd:67:2d:b7:36:fd:60:1d:ca:eb:1b:03:b1:12:7b:10:1f:26:
  05:b7:b9:0d:02:e0:38:3e

```

The **export-certificate** subcommand exports only the public portion of a certificate. Its private key is not included. To export the private key, use the **export-private-key** subcommand, which supports the following arguments, in addition to the usual key store and alias arguments:

```
--output-file {path}
```

Path to the file to which the exported private key is written. If this value is not provided, the key is written to standard output rather than a file.

```
--output-format {format}
```

Format in which the exported private key is written. The value can be **PEM** or **DER**, but the **DER** format is used only if the output is written to a file. Defaults to **PEM** if no value is specified.

The following code provides an example of the **export-private-key** subcommand .

```

$ bin/manage-certificates export-private-key \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --output-file server-cert-key.pem \
  --output-format PEM

```

```
Successfully exported the private key.
```

### Using manage-certificates as a simple certification authority

If your server instances need to support an arbitrary or unknown set of clients, configure them with certificates from a trusted issuer, such as a commercial authority or the free Let's Encrypt service.

#### About this task

If you control every client that accesses the servers, you might want to create your own internal certification authority so that you have a common issuer for all servers. In such a scenario, the clients need to trust only the certificates that the issuer signs. Commercial and open-source software packages provide full-featured certification authority functionality, but you can use the **manage-certificates** tool to create a certificate authority (CA) certificate that you can use to sign certificate-signing requests.

#### Steps

1. Create a CA certificate.

A CA certificate is a self-signed certificate that possesses the following extensions:

- A key usage extension that includes at least the keyCertSign usage
- A basic constraints extension that identifies the certificate as a CA certificate

If you do not plan to use an intermediate CA certificate, the basic constraints extension must have a path length constraint of 0. If you plan to use an intermediate CA certificate, the path length constraint

must be 1. Because certificates that the CA certificate signs are valid only for as long as all certificates in the chain remain valid, we recommend that you specify a long lifespan for the CA certificate.

Example:

The following example creates a new root CA certificate.

```
$ bin/manage-certificates generate-self-signed-certificate \
  --keystore /ca/root-ca-keystore \
  --keystore-password-file /ca/root-ca-keystore.pin \
  --keystore-type JKS \
  --alias root-ca-cert \
  --subject-dn "CN=Example Root CA,O=Example Corp,C=US" \
  --days-valid 7300 \
  --key-algorithm RSA \
  --key-size-bits 4096 \
  --signature-algorithm SHA256withRSA \
  --basic-constraints-is-ca true \
  --basic-constraints-maximum-path-length 1 \
  --key-usage key-cert-sign \
  --key-usage crl-sign
```

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:

Subject DN: CN=Example Root CA,O=Example Corp,C=US

Issuer DN: CN=Example Root CA,O=Example Corp,C=US

Validity Start Time: Monday, January 27, 2020 at 03:47:29 PM CST (0 seconds ago)

Validity End Time: Sunday, January 22, 2040 at 03:47:29 PM CST (7299 days, 23 hours, 59 minutes, 59 seconds from now)

Validity State: The certificate is currently within the validity window.

Signature Algorithm: SHA-256 with RSA

Public Key Algorithm: RSA (4096-bit)

SHA-1 Fingerprint:

bc:8e:5b:30:52:ec:03:63:b4:9a:aa:1a:45:a0:fc:84:49:dd:e8:64

SHA-256 Fingerprint:

d5:47:06:cd:a2:95:42:61:1f:c7:aa:04:16:1e:c1:70:41:c4:44:48:bf:74:20:5f:1c:61:e2:aa:40:08:3a:ff

2. Export the public portion of the root CA certificate for future reference.

When you import a signed certificate, you can import the public portion of the root CA certificate as a standalone certificate into trust stores as well as into part of a certificate chain.

3. Create a new certificate signing request to create an intermediate CA certificate,

The certificate signing request uses essentially the same settings as the root CA. If you anticipate only a single intermediate CA, its basic constraints extension must have a path length constraint of 0, rather than 1, to indicate that it is used only to sign end-entity certificates and that it cannot create subordinate CA certificates by itself.

Example:

The following example command creates a certificate signing request.

```
$ bin/manage-certificates generate-certificate-signing-request \
  --keystore /ca/intermediate-ca-keystore \
  --keystore-password-file /ca/intermediate-ca-keystore.pin \
  --keystore-type JKS \
  --alias intermediate-ca-cert \
  --subject-dn "CN=Example Intermediate CA,O=Example Corp,C=US" \
  --key-algorithm RSA \
  --key-size-bits 4096 \
```

```
--signature-algorithm SHA256withRSA \
--basic-constraints-is-ca true \
--basic-constraints-maximum-path-length 0 \
--key-usage key-cert-sign \
--key-usage crl-sign \
--output-file /ca/intermediate-ca-cert.csr \
--output-format PEM
```

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing request.

Successfully wrote the certificate signing request to file '/ca/intermediate-ca-cert.csr'.

4. Use the root CA certificate to sign the certificate signing request for the intermediate CA certificate with the **sign-certificate-signing-request** subcommand.

The **sign-certificate-signing-request** subcommand takes most of the same arguments as generating a self-signed certificate. The primary differences between the argument sets are as follows:

- The key store that contains the certificate uses the provided key store arguments to sign the request. To specify the name of the certificate to use when signing the request, use the **--signing-certificate-alias** argument.
- To specify the path to the file that contains the certificate signing request file to generate, provide a **--request-input-file** argument.
- To specify the path to the file to which the signed certificate is written, provide a **--certificate-output-file** argument. If this argument is omitted, the PEM representation of the certificate is written to standard output.
- To specify the format, **PEM** or **DER**, in which the certificate is written to the output file, provide an **--output-format** argument.
- To specify the subject to use for the signed certificate, use the **--subject-dn** argument. To use the subject DN from the certificate signing request, omit this argument.
- To specify the name of the signature algorithm, use the **--signature-algorithm** argument.

 **Note:**

Because the requester generated the key, you cannot specify the key algorithm or the key length.

- To indicate that the signed certificate includes every extension that is listed in the certificate signing request, use the **--include-requested-extensions** argument. If this argument is not provided, explicitly specify the set of extensions to include.

Example:

The following example command signs the certificate signing request for an intermediate CA certificate.

```
$ bin/manage-certificates sign-certificate-signing-request \
--keystore /ca/root-ca-keystore \
--keystore-password-file /ca/root-ca-keystore.pin \
--signing-certificate-alias root-ca-cert \
--days-valid 7300 \
--include-requested-extensions \
--request-input-file /ca/intermediate-ca-cert.csr \
--certificate-output-file /ca/intermediate-ca-cert.pem \
--output-format PEM
```

Read the following certificate signing request:

```
PKCS #10 Certificate Signing Request Version: v1
Subject DN: CN=Example Intermediate CA,O=Example Corp,C=US
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
```

```
Do you really want to sign this request? yes
```

```
Successfully wrote the signed certificate to file
'/ca/intermediate-ca-cert.pem'.
```

5. After you obtain the intermediate CA certificate, create secure, offline backups of the root CA certificate.
6. Remove the root CA certificate, or at least its private key, from all systems.

#### Note:

Make certain that all end-entity certificates are signed with the intermediate CA certificate, and that the process is identical to the previous example. Restore the root CA certificate only if you need to sign another intermediate CA certificate.

### Enabling TLS support during setup

Enable TLS support in the server.

To enable TLS support in the server, you should complete one of the following tasks during the setup procedure:

- Provide a key store that contains the certificate to use.
- Make the installer generate a self-signed certificate.

When using the **setup** tool in interactive mode, it prompts you for the information that it needs to configure secure communication, as shown in the following example.

```
Do you want to enable the Directory Server services (Available State,
Available or Degraded State, Configuration, Consent, Directory REST API,
Documentation, SCIM2, and Swagger UI) and Administrative Console over
HTTPS? After setup, you can selectively enable or disable individual
services and applications by configuring the HTTPS Connection Handler
(yes / no) [yes]: yes
```

```
On which port should the Directory Server accept connections from HTTPS
clients? [443]: 443
```

```
On which port should the Directory Server accept connections from LDAP
clients? [389]: 389
```

```
Do you want to enable LDAPS? (yes / no) [yes]: yes
```

```
On which port should the Directory Server accept connections from LDAPS
clients? [636]: 636
```

```
Do you want to enable StartTLS? (yes / no) [yes]: yes
```

```
Certificate server options:
```

- 1) Generate self-signed certificate (recommended for testing purposes only)
- 2) Use an existing certificate located on a Java Keystore (JKS)
- 3) Use an existing certificate located on a PKCS12 keystore
- 4) Use an existing certificate on a PKCS11 token

```
Enter option [1]: 2
```

```

Java Keystore (JKS) path: /ca/dsl-keystore
Keystore PIN: {password}

Truststore options:

    1) Generate a default JKS truststore
    2) Use an existing JKS truststore
    3) Use an existing PKCS12 truststore

Enter option [1]: 2

JKS truststore path: /ca/truststore
Truststore password (can be blank): {password}

```

When using **setup** in non-interactive mode, use the following arguments to configure TLS support.

| Argument                                     | Description                                                                                                                                                                                                                                                                                                |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--ldapsPort {port}</code>              | Server enables support for LDAPS (LDAP over TLS) on the specified TCP port.                                                                                                                                                                                                                                |
| <code>--httpsPort {port}</code>              | Server enables support for HTTPS for SCIM, the Directory REST API, and the web-based administration console on the specified TCP port.                                                                                                                                                                     |
| <code>--enableStartTLS</code>                | LDAP connection handler enables support for the StartTLS extended operation.                                                                                                                                                                                                                               |
| <code>--generateSelfSignedCertificate</code> | <b>setup</b> generates a self-signed certificate that is presented to clients that use LDAPS, HTTPS, and the StartTLS extended operation.                                                                                                                                                                  |
| <code>--useJavaKeyStore {path}</code>        | Server uses the specified Java KeyStore (JKS) key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.                                                                                                                            |
| <code>--usePKCS12KeyStore {path}</code>      | Server uses the specified PKCS #12 key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.                                                                                                                                       |
| <code>--usePKCS11KeyStore</code>             | Server uses a PKCS #11 key store, like a hardware security module, to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation. The Java Virtual Machine (JVM) must already be configured to access the appropriate key store through PKCS #11. |
| <code>--keyStorePassword {password}</code>   | Password that is needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store. The <b>setup</b> tool assumes that the private key password matches the key store password.                                                                                                                   |

| Argument                                     | Description                                                                                                                                                                                                                            |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--keyStorePasswordFile {path}</code>   | Path to the file that contains the password needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store.                                                                                                                |
| <code>--certNickname {alias}</code>          | Alias of the private key entry in the specified key store that contains the certificate chain to present to clients during TLS negotiation. This argument is optional but recommended if the key store contains multiple certificates. |
| <code>--useJavaTrustStore {path}</code>      | Server uses the specified JKS trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation.                                                                                            |
| <code>--usePKCS12TrustStore {path}</code>    | Server uses the specified PKCS #12 trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation.                                                                                       |
| <code>--trustStorePassword {password}</code> | Password that is needed to interact with the specified JKS or PKCS #11 trust store.                                                                                                                                                    |
| <code>--trustStorePasswordFile {path}</code> | Path to the file that contains the password needed to interact with the specified JKS or PKCS #11 trust store.                                                                                                                         |

The following example command sets up PingDirectory Server in non-interactive mode with an existing certificate.

```
$ ./setup \
  --no-prompt \
  --acceptLicense \
  --ldapPort 389 \
  --ldapsPort 636 \
  --httpsPort 443 \
  --enableStartTLS \
  --useJavaKeyStore config/keystore \
  --keyStorePasswordFile config/keystore.pin \
  --certNickname server-cert \
  --useJavaTrustStore config/truststore \
  --trustStorePasswordFile config/truststore.pin \
  --baseDN dc=example,dc=com \
  --rootUserDN "cn=Directory Manager" \
  --rootUserPasswordFile root-pw.txt \
  --maxHeapSize 10g \
  --encryptDataWithPassphraseFromFile encryption-settings-password.txt \
  --instanceName dsl \
  --location Austin \
  --noPropertiesFile
```

```
Ping Identity Directory Server 8.0.0.0
```

```
Initializing ..... Done
Configuring Directory Server ..... Done
Configuring Certificates ..... Done
Starting Directory Server ..... Done
```

### Enabling TLS support after setup

If the server has been set up without support for TLS, enable TLS support later by completing the following tasks.

#### Steps

1. Obtain a certificate chain.

For more information about obtaining a certificate chain, see [Certificate chains](#) on page 418. To prepare a Java KeyStore JKS or PKCS #12 key store with an appropriate certificate chain and private key, use the `manage-certificates` tool. We also recommend that you create a trust store that the server can use.

2. Configure the key and trust manager providers.

For more information, see [Configuring key and trust manager providers](#) on page 447.

3. Configure connection handlers.

For more information, see [Configuring connection handlers](#) on page 447.

### Configuring key and trust manager providers

After you have a key store, configure a key manager provider to access it.

The server is preconfigured with key manager providers, `JKS` and `PKCS12`, that you can use with JKS or PKCS #12 key stores, respectively. You can update the appropriate key manager provider in most cases to reference the key store that you plan to use. The following code provides an example.

```
dsconfig set-key-manager-provider-prop \
  --provider-name JKS \
  --set enabled:true \
  --set key-store-file:config/keystore \
  --set key-store-pin-file:config/keystore.pin
```

A similar change configures a trust manager provider to reference the appropriate trust store. The following code provides an example.

```
dsconfig set-trust-manager-provider-prop \
  --provider-name JKS \
  --set enabled:true \
  --set include-jvm-default-issuers:true \
  --set trust-store-file:config/truststore \
  --set trust-store-pin-file:config/truststore.pin
```

#### Note:

If all clients and servers use certificates that are signed by issuers and are included in the JVM's default trust store, you can use the `JVM-Default` trust manager provider to accomplish this task.

## Configuring connection handlers

After you configure the key and trust manager providers, update the connection handlers to use the key and trust manager providers.

### Steps

- For the LDAP connection handler, use the following command to enable StartTLS with a configuration change. By default, the LDAP connection handler accepts non-secure connections.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --set allow-start-tls:true \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert \
  --set ssl-client-auth-policy:optional
```

- If you did not configure secure communication during setup, the LDAPS connection handler is disabled. To configure LDAPS support in this scenario, enable the connection handler and configure most of the same settings. You must set **allow-start-tls** to `false` and **use-ssl** to `true`. See the following code for an example configuration.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "LDAPS Connection Handler" \
  --set enabled:true \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert \
  --set ssl-client-auth-policy:optional
```

Example: The following example uses a similar configuration change to enable the HTTPS connection handler.

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true \
  --set listen-port:443 \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert
```

## Updating the topology registry

After the server connection handlers are updated to enable TLS, update the topology registry to provide information about the new configuration.

The topology registry holds information about server instances that are part of the environment, and it helps to facilitate inter-server communication, such as replication, mirroring portions of the configuration, and PingDirectory Server's automatic backend server-discovery functionality.

The following table details the two types of entries that require updating.

## Configuration types and their update descriptions

| Configuration Type                     | Update description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Server instance listener configuration | <ul style="list-style-type: none"> <li>▪ Provides information that is needed to trust the TLS certificates that instances in the topology present.</li> <li>▪ The server instance listener configuration must include the server certificate, which is defined as the certificate at the head of the chain. This version must be the multi-line, PEM-formatted representation of the certificate. You can use <b>dsconfig</b> to import the certificate from a file, as shown in the following example.</li> </ul> <pre data-bbox="906 617 1448 884">bin/dsconfig set-server-instance-listener-prop \   --instance-name ds1 \   --listener-name ldap-listener-mirrored-config \   --set server-ldap-port:636 \   --set connection-security:ssl \   --set 'listener-certificate&gt;/ca/ds1-cert.pem'</pre> <div data-bbox="906 932 1461 1247" style="border: 1px solid black; padding: 5px;"> <p> <b>Note:</b></p> <p>The less-than operator &gt; in the final line indicates that the value is read from a file rather than provided directly. In addition, you might not need to enclose the property name and path within single straight quotes to prevent the shell from interpreting the less-than symbol as an attempt to redirect input.</p> </div> |

### Troubleshooting TLS-related issues

Use this section for troubleshooting problems that might arise during TLS configuration, including communication and security issues that affect clients as well as PingDirectory Server.

- [Log messages](#)
- [manage-certificates check-certificate-usability](#)
- [ldapsearch](#)
- [Using low-level TLS debugging](#)

### Log messages

The following describes how to use the server's log messages to troubleshoot TLS-related issues.

To troubleshoot TLS-related issues, start by checking the server's access log. If the client can establish a TCP connection to the server, which must occur before TLS negotiation can start, the access log shows a `CONNECT` message with the following information:

- Source and destination address and port for the connection
- Protocol
- Selected client connection policy

The `CONNECT` message does not appear

If the `CONNECT` does not appear, the client might be unable to communicate with the server. The culprit can be a network problem, a firewall that is blocking attempts to communicate, or the client is trying to use an incorrect address or port.

The `CONNECT` message does appear

If the `CONNECT` message appears in the access log, it typically includes a `conn` element that specifies the connection ID. To view additional log messages for the client connection, use the `search-logs` tool. For example, if the connection ID is `12345`, the following command displays the complete set of associated log messages.

```
$ bin/search-logs --logFile logs/access conn=12345
```

If you are using LDAPS

If you are attempting to use LDAPS, one of the following log messages appears next:

- `SECURITY-NEGOTIATION` message – Indicates that the client and server successfully completed the negotiation process and that the issue likely occurred after the TLS session was established. This message also includes details about the negotiation, including the TLS protocol and the selected cipher suite.
- `DISCONNECT` message – The issue might involve a failure in the TLS-negotiation process. In such scenarios, the message usually includes a `reason` element that provides additional information about the reason for the disconnect.

If the failure occurred during TLS negotiation, the usefulness of the `DISCONNECT` message depends in part on whether the failure occurred on the client or the server. For example, if the server decided to abort the negotiation, the message ideally contains the specific reason. If the problem occurred on the client, the log message likely contains only the general category for the failure.

**Note:**

The TLS protocol does not provide a mechanism for conveying detailed error messages. Instead, it offers only a basic alert mechanism with a fixed set of alert types. For example, if a client does not trust the certificate chain that the server presents to it, the server might receive a generic alert like `certificate_unknown`, even if the client knows the precise reason for rejecting the chain. In such instances, you might need to determine whether the client can provide additional details about the issue.

If the access log does not provide useful information

If the access log does not provide useful information, check the server error log. Although the error log does not normally include information about issues that relate to client communication, it provides helpful information in certain circumstances, like when an internal error within the server interferes with communication attempts.

### **manage-certificates check-certificate-usability**

The `manage-certificates` tool offers a `check-certificate-usability` subcommand to examine a specified entry in a key store and to identify potential issues that might interfere with secure communication.

The `check-certificate-usability` tool completes the following tasks:

- Ensures that a specified entry in the key store includes a private key and a complete certificate chain
- Checks whether the certificate at the root of the chain is found in the Java virtual machine's (JVM's) default set of trusted certificates
- Ensures that the current time lies within the validity window for all certificates in the chain
- Validates the signatures for all certificates in the chain
- Warns if the end-entity certificate is self-signed
- Warns if the end-entity certificate does not contain an extended key usage extension with the `serverAuth` usage
- Warns if the issuer certificates do not have a key usage extension with the `keyCertSign` usage
- Warns if the issuer certificates do not have a basic constraints extension indicating that it can operate as a certification authority

If the chain violates a path length constraint, the `check-certificate-usability` tool reports an error.

- Ensures that the signature algorithm uses a strong message digest algorithm, like SHA-256

The `check-certificate-usability` tool reports an error for weak digest algorithms like MD5 or SHA-1, and reports a warning for unrecognized digest algorithms.

- Ensures that none of the certificates that use an RSA key pair have a key size less than 2048 bits

The following example demonstrates the usage for the `manage-certificates check-certificate-usability` command and its output when no problems are identified.

```
$ bin/manage-certificates check-certificate-usability \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert

Successfully retrieved the certificate chain for alias 'server-cert':

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' at the head of the chain includes an extended key usage extension, and that extension includes the serverAuth usage.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' includes a basic constraints extension, and the certificate chain satisfies those constraints.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' includes a key usage extension with the keyCertSign usage flag set to true.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes a basic constraints extension, and the certificate chain satisfies those constraints.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes a key usage extension with the keyCertSign usage flag set to true.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' has a 2048-bit RSA public key, which is considered strong.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a 4096-bit RSA public key, which is considered strong.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a 4096-bit RSA public key, which is considered strong.

No usability errors or warnings were identified while validating the certificate chain.

If any usability issues are identified, they might be responsible for communication problems.

## Idapsearch

The `ldapsearch` command-line utility is a powerful tool for issuing searches against an LDAP directory server. It also provides a convenient method for troubleshooting a variety of issues, including problems that are relevant to TLS communication.

The following table details arguments that are the most useful for TLS-related communication.

### TLS-related communication arguments and their descriptions

| Argument                                     | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--hostname {address}</code>            | Address of the server to which the connection is established                                                                                                                                                                                                                                                                                                                                     |
| <code>--port {port}</code>                   | TCP port of the server to which the connection is established. The standard port for non-secure LDAP, or LDAP to be secured with StartTLS, is <b>389</b> , and the standard port for secure LDAPS is <b>636</b> . Many deployments use alternate ports, especially non-privileged ports above <b>1024</b> .                                                                                      |
| <code>--useSSL</code>                        | The tool establishes an initially insecure LDAP connection, which is secured later with the StartTLS extended operation.                                                                                                                                                                                                                                                                         |
| <code>--trustStorePath {path}</code>         | Path to the trust store that is used when determining whether to trust the certificate chain that the server presents during TLS negotiation. If neither this argument nor the <code>--trustAll</code> argument is provided, the tool prompts you interactively whether to trust server certificates that are not signed by an issuer in the Java virtual machine's (JVM's) default trust store. |
| <code>--trustStoreFormat {format}</code>     | Format for the trust store, which is typically <b>JKS</b> or <b>PKCS12</b> .                                                                                                                                                                                                                                                                                                                     |
| <code>--trustStorePassword {password}</code> | Password that is required to access the contents of the trust store.                                                                                                                                                                                                                                                                                                                             |
| <code>--trustStorePasswordFile {path}</code> | Path to the file that contains the password that is required to access the contents of the trust store.                                                                                                                                                                                                                                                                                          |
| <code>--trustAll</code>                      | The tool blindly trusts all TLS certificate chains that are presented to it. Although this argument can prove useful for troubleshooting purposes, it is not recommended for general use.                                                                                                                                                                                                        |

| Argument                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--keyStorePath {path}</code>         | <p>Path to the key store to use if a client certificate chain is presented to the server.</p> <p> <b>Note:</b></p> <p>Use this argument only when one of the following conditions is satisfied:</p> <ul style="list-style-type: none"> <li>▪ The server is configured to require clients to present a certificate.</li> <li>▪ You intend to use the certificate to authenticate through SASL EXTERNAL.</li> </ul> |
| <code>--keyStoreFormat {format}</code>     | Format for the key store, which is typically <b>JKS</b> or <b>PKCS12</b> .                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>--keyStorePassword {password}</code> | Password to access the key store.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>--keyStorePasswordFile {path}</code> | Path to the file that contains the password necessary to access the key store.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>--certNickname {alias}</code>        | Alias of the private key entry in the key store. Use when obtaining the certificate chain to present to the server.                                                                                                                                                                                                                                                                                                                                                                                |
| <code>--useSASLExternal</code>             | The client authenticates with the EXTERNAL SASL mechanism, which typically identifies the client using the certificate chain that is presented during TLS negotiation.                                                                                                                                                                                                                                                                                                                             |
| <code>--enableSSLDebugging</code>          | The tool activates the low-level TLS-debugging feature that the JVM provides.                                                                                                                                                                                                                                                                                                                                                                                                                      |

The following command provides an example of the simplest method for testing TLS communication with PingDirectory Server.

#### Example

```
$ bin/ldapsearch \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --baseDN "" \
  --scope base \
  "(objectClass=*)"
```

The server presented the following certificate chain:

```
Subject: CN=ds1.example.com,O=Example Corp,C=US
Valid From: Tuesday, November 12, 2019 at 08:28:08 PM CST
Valid Until: Wednesday, November 11, 2020 at 08:28:08 PM CST
SHA-1 Fingerprint:
  6a:22:2a:bd:0b:1b:09:35:63:bc:12:3e:2c:9e:e7:70:bc:a4:73:de

34:34:a1:90:83:8a:d5:12

Do you wish to trust this certificate? Enter 'y' or 'n': y
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: 8d574122-4584-4522-96d9-0cdcb9d2e339
startTime: 20191113061149Z

# Result Code: 0 (success)
# Number of Entries Returned: 1

```

### Trust stores and trust-related arguments

If no trust-related arguments are provided, the tool uses the JVM's default trust store to verify whether to trust the certificate chain, based on the information that it contains. If a trusted authority has signed the server certificate, the negotiation process continues without further interaction.

If the chain cannot be trusted, based on the information in the JVM-default trust store, **ldapsearch** prompts you interactively about whether to trust the certificate. If you accept the chain, the client and server complete the negotiation process, and the client sends the search request to the server. If the search succeeds, the server can communicate over TLS.

To test with a trust store instead of being prompted interactively, use the **--trustStorePath** argument that points to the appropriate trust store. If you are using a Java Keystore (JKS) trust store, you might not need to provide the trust store password. If you are using a PKCS #12 trust store, you need to provide the trust store password. The following code provides an example.

### Example

```

$ bin/ldapsearch \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --trustStorePath config/truststore.p12 \
  --trustStorePasswordFile config/truststore.pin \
  --trustStoreFormat PKCS12 \
  --baseDN "" \
  --scope base \
  "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse

```

```

startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code: 0 (success)
# Number of Entries Returned: 1

```

### Client certificate chains and key stores

To present a client certificate chain to the server, either because the server's connection handler is configured with an `ssl-client-auth-policy` value of `required` or because you plan to use the certificate to authenticate by way of the SASL EXTERNAL mechanism, provide at least the key store and its corresponding password. You can also specify the alias of the certificate chain to present, which is recommended if your client key store contains multiple certificates. The following code provides an example.

### Example

```

$ bin/ldapsearch \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --trustStorePath config/truststore.p12 \
  --trustStorePasswordFile config/truststore.pin \
  --trustStoreFormat PKCS12 \
  --keyStorePath client-keystore \
  --keyStorePasswordFile client-keystore.pin \
  --certNickname client-cert \
  --useSASLExternal \
  --baseDN "" \
  --scope base \
  "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code: 0 (success)
# Number of Entries Returned: 1

```

If you need to further troubleshoot a TLS-related issue

If you encounter a TLS-related issue that you cannot resolve by examining the `ldapsearch` output or the server logs, use the `--enableSSLDebugging` option to enable the JVM's support for low-level debugging of TLS processing. For more information, see [Using low-level TLS debugging](#) on page 457.

### Using low-level TLS debugging

Use tools other than the command-line tools that are provided with PingDirectory Server for performing low-level TLS debugging.

Before you begin

#### Note:

If you need to use low-level debugging options, enable the Java Virtual Machine (JVM)'s support for TLS debugging. Many of the command-line tools that are provided with PingDirectory Server, such as `ldapsearch`, offer an `--enableSSLDebugging` argument that simplifies this process.

## Steps

1. In the `config/java.properties` file, add the following line to the set of properties for the appropriate tool.

```
-Djavax.net.debug=all
```

2. For the changes to take effect, run the `bin/dsjavaproperties` command.

## Next steps

The next time the tool is run, an output is generated detailing the TLS-related processing that the JVM is performing. You and the Ping Identity support team can use the output to identify the issue.

## Enabling low-level debugging

### About this task

#### Note:

Because this approach requires multiple server restarts, it is not a popular option. You might be able to obtain more information without a restart by using the debugging support that is built into the server. For more information and to enable this level of support, see [Using the debug log publisher](#).

To enable low-level debugging:

## Steps

1. In the `config/java.properties` file, add `-Djavax.net.debug=all` to the `start-server.java-args` property.
2. Run `bin/dsjavaproperties`.
3. Restart the server.

## Using the debug log publisher

To obtain more information for troubleshooting without a restart, use the server's built-in debugging support.

### About this task

To use the debug log publisher:

## Steps

1. To enable the debug log publisher and set the debug target, run the following configuration changes:
  - a. Run `dsconfig` with the `create-debug-target` option.

Example:

```
dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name
  com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider
  \
  --set debug-level:verbose
```

- b. Run `dsconfig` with the `set-log-publisher-prop` option.

Example:

```
dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
```

```
--set enabled:true
```

Result: The `logs/debug` file captures a substantial amount of information about the TLS-related processing that the server is performing. Although this file doesn't provide as much detail as the Java virtual machine's (JVM) built-in debugging information, it might help to pinpoint the cause of the problem and to identify potential solutions.

2. To disable the debug log publisher and remove the debug target, run the following configuration changes:
  - a. Run `dsconfig` with the `set-log-publisher-prop` option.

Example:

```
dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:false
```

- b. Run `dsconfig` with the `delete-debug-target` option.

Example:

```
dsconfig delete-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name
  com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider
```

#### Tip:

To troubleshoot TLS communication with a non-Java client that does not offer its own TLS debugging mechanism, and if the server-side debugging support is insufficient, use a network protocol analyzer to capture the communication between the client and the server and to examine its content. The free, open-source [Wireshark utility](#) is a graphical tool that runs on a variety of platforms and provides support for understanding TLS communication. Even if you can't decipher the encrypted content, you can view at least some of the handshake messages.

#### Note:

More of the handshake is encrypted in TLS 1.3 than in earlier versions of the protocol. Although this change improves security and privacy, it might interfere with troubleshooting attempts.

## Configuring load balancing

You can distribute the load on your Directory Proxy Server using one of the load-balancing algorithms provided with PingDirectory Server. By default, the Directory Proxy Server prefers local servers over non-local servers, unless you set the `use-location` property of the load-balancing algorithm to `false`. Within a given location, the Directory Proxy Server prefers available servers over degraded servers. This means that if at all possible, the Directory Proxy Server sends requests to servers that are local and available before considering selecting any server that is non-local or degraded.

#### Note:

If the `use-location` property is set to `true`, then the load is balanced only among available external servers in the same location. If no external servers are available in the same location, the Directory Proxy Server will attempt to use available servers in the first preferred failover location, and so on. The failover based on no external servers with AVAILABLE health state can be customized to allow the Directory Proxy Server to prefer local DEGRADED health servers to servers in a failover location. See the online [PingDirectory Server Configuration Reference Guide](#) for more information on the `prefer-degraded-servers-over-failover` property.

The Directory Proxy Server provides the following load-balancing algorithms:

- **Failover load balancing.** This algorithm forwards requests to servers in a given order, optionally taking the location into account. If the preferred server is not available, then it will fail over to the alternate server in a predefined order. This balancing method can be useful if certain operations, such as LDAP writes, need to be forwarded to a primary external server, with secondary external servers defined for failover if necessary.

This algorithm also offers load spreading to multiple failover servers. If the failover load-balancing algorithm is configured with one or more load-spreading base DNs, then requests that target entries below a load-spreading base DN can be balanced across any of the servers with the same health check state and location. Requests targeting a specific portion of the data will consistently be routed to the same server, but requests targeting a different portion of the data may be sent to a different server.

- **Fewest operations load balancing.** This algorithm forwards requests to the backend server with the fewest operations currently in progress and tends to exhibit the best performance.
- **Health weighted load balancing.** This algorithm assigns weights to servers based on their health scores and, optionally, their locations. For example, servers with a higher health check score will receive a higher proportion of the requests than servers with lower health check scores.
- **Single server load balancing.** This algorithm forwards all operations to a single external server that you specify.
- **Weighted load balancing.** This algorithm uses statically defined weights for sets of servers to divide load among external servers. External servers are grouped into weighted sets, the values of which, when added to all of the weighted sets for the load balancing algorithm, represent a percentage of the load the external servers should receive.
- **Criteria based load balancing.** This algorithm allows you to balance your load across a server topology depending on the types of operations received or the client issuing the request.

For example, ds1 and ds2 are assigned to a weighted set named Set-80 and assigned the weight 80. The external servers ds3 and ds4 are assigned to the weighted set Set-20 and assigned the weight 20. When both sets, Set-80 and Set-20, are assigned to the load balancing algorithm, 80 percent of the load will be forwarded to ds1 and ds2, while the remaining 20 percent will be forwarded to ds3 and ds4.

### Configure failover load-balancing for load spreading

If the failover load-balancing algorithm is configured with one or more load-spreading base distinguished names (DNs), then requests that target entries below a load-spreading base DN can be balanced across any of the servers with the same health check state and location.

Requests targeting a specific portion of the data are consistently routed to the same server, but requests targeting a different portion of the data might be sent to a different server.

Load spreading is useful for deployments:

- Where the directory information tree (DIT) contains a large number of branches below a common parent
- Where most operations (including search operations, as indicated by the search base DN) only target entries at least one level below that common parent.

For example, load spreading can be useful for a multi-tenant deployment in which all of the entries for a given tenant are within their own branch, and all of the tenant branches reside below a common parent.

Load spreading is configured with the `load-spreading-base-dn` property. The value or values of this property are the base DN or DN's below which the tenant entries reside.

In a deployment with a DIT as in the following example, the `load-spreading-base-dn` value would be set to `ou=customers,dc=example,dc=com`.

```
dc=example,dc=com
ou=customers,dc=example,dc=com
ou=Customer 1,ou=customers,dc=example,dc=com
```

```
ou=Customer 2,ou=customers,dc=example,dc=com
ou=Customer 3,ou=customers,dc=example,dc=com
...
```

If the `load-spreading-base-dn` property is not configured, the failover load-balancing algorithm uses the default behavior. If the property is configured with one or more values, but a client requests an operation that targets an entry that is not below any of the configured base DNs, then that operation is handled using the default behavior.

When the `load-spreading-base-dn` property is configured with one or more values, the load-balancing algorithm continues to generate the same list of lists, but the order of the servers within each list is determined using the following algorithm:

1. If the list is empty or contains only a single item, then leave it unchanged and skip the remaining steps.
2. Identify the Relative Distinguished Name (RDN) component from the target entry DN that is exactly one level below one of the `load-spreading-base-dn` values. If the targeted entry is not below any of the configured `load-spreading-base-dn` values, the order of servers in each of those lists is based only on the order in which they appear in the load-balancing algorithm's `backend-server` property. The remaining steps are skipped.
3. Compute a SHA-1 digest from the normalized string representation of the identified RDN component. SHA-1 is notably faster than more secure digest algorithms, and it does a good job at distributing bits across the entire range of the 160 bits that it generates.
4. Create a non-negative integer from the last 31 bits of the computed SHA-1 digest.
5. Compute a modulus using the integer value as the dividend and the number of servers in the current list as the divisor. This yields an integer value that is between 0 and  $(list.size() - 1)$ , inclusive.

**Note:**

$(list.size() - 1)$  is the number of servers minus 1.

6. If the modulus computed is equal to 0, no further action is necessary. If not, move a number of servers equal to the computed modulus from the beginning of the list to the end of the list. The order of the elements that are moved should be preserved.

For example, consider a `load-spreading-base-dn` value of `"ou=customers,dc=example,dc=com"`, a list that contains three servers (`ds1`, `ds2`, and `ds3`, in that order), and a modify request that targets the entry with DN `"uid=jdoe,ou=People,ou=Acme,ou=customers,dc=example,dc=com"`. The RDN component immediately below the `load-spreading-base-dn` is `"ou=Acme"`. The normalized string representation of that RDN component is `"ou=acme"`, and the hexadecimal representation of the SHA-1 digest of that is `"f0c69713535daf8816038f1bceab70380c92b83e"`. The last 31 bits of that SHA-1 digest are `0c92b83e` hex, which is 210942014. With 210942014 modulo 3 is 2, which means that the first two servers are moved from the beginning of the list to the end of the list, resulting in an order of `ds3`, `ds1`, `ds2`.

While this algorithm spreads the load across multiple backend servers, it does not mean that there will be an even distribution of the load across all of those servers. The load-balancing algorithm still prioritizes based on location and health check state, so the load is generally spread only across the available servers in the same location as the Directory Proxy Server. Assuming that the entries that are immediate children of a `load-spreading-base-dn` are the tops of the branches that define tenants, some tenants are targeted more heavily than others because they have more entries or because their entries are accessed more frequently. The modulo operation might not result in an even distribution across those servers.

### Configuring load balancing using `dsconfig`

Create and configure a load-balancing algorithm with `dsconfig`.

About this task

To create and configure a load-balance algorithm:

## Steps

1. Run the `dsconfig` tool.

When prompted, specify the host name, connection method, port number, and bind distinguished name (DN).

Example:

```
$ bin/dsconfig
```

2. In the Directory Proxy Server main menu, enter the selection for load-balancing algorithms.
3. To create the Load Balancing Algorithm, in the Load Balancing Algorithm menu, select an option.

Choose from:

- To use an existing load-balancing algorithm as a template, enter `t`.
- To create a new load-balancing algorithm from scratch, enter `n`.

Example:

In this example, a new Load Balancing Algorithm is created from scratch.

```
>>>>Choose how to create the new Load Balancing Algorithm:

n) new Load Balancing Algorithm created from scratch
t) use an existing Load Balancing Algorithm as a template
b) back
q) quit

Enter a choice [n]: n
```

4. In Select the type of Load Balancing Algorithm menu, select the type of load-balancing algorithm that you want to create.

Depending on type of algorithm you select, you're guided through a series of configuration properties, such as providing a name and selecting an LDAP external server.

Example:

```
>>>> Select the type of Load Balancing Algorithm that you want to
create:

1) Failover Load Balancing Algorithm
2) Fewest Operations Load Balancing Algorithm
3) Health Weighted Load Balancing Algorithm
4) Single Server Load Balancing Algorithm
5) Weighted Load Balancing Algorithm

?) help
c) cancel
q) quit

Enter choice [c]: 3
```

5. Review the configuration properties for your new load-balancing algorithm and enter `f`.

### Configuring criteria-based load-balancing algorithms

You can configure alternate load-balancing algorithms that determine how they function according to request or connection criteria.

These algorithms allow you to balance your load across a server topology depending on the types of operations received or the client issuing the request. They are called criteria-based load-balancing algorithms and are configured using at least one connection criteria or request criteria.

For example, you can configure criteria-based load-balancing algorithms to accomplish the following:

- Route write operations to a single server from a set of replicated servers to prevent replication conflicts while load balancing all other operations across the full set of servers.
- Route all operations from a specific client to a single server in a set of replicated servers, eliminating errors that arise from replication latency and load balancing operations from other clients across the full set of servers. This configuration is useful for certain provisioning applications that need to write and then immediately read the same data.

When a request is received, the proxying request processor first iterates through all of the criteria-based load-balancing algorithms in the order in which they are listed to determine whether the request matches the associated criteria. If there is a match, then the criteria-based load-balancing algorithm is selected. If there is not a match, then the default load-balancing algorithm is used.

### Preferring failover LBA for write operations

You can configure the Directory Proxy Server to use criteria-based load-balancing algorithms to balance providing a consistent view of directory server data for applications that require it with taking advantage of all servers in a topology for handling read-only operations, such as `search` and `bind`. The flexible configuration model supports a wide range of criteria for choosing which load-balancing algorithm to use for each operation.

In most Directory Proxy Server deployments, you should use a failover load-balancing algorithm for at least `add`, `delete`, and `modifyDN` operations

Each Proxying Request Processor configured in the Directory Proxy Server uses a load-balancing algorithm to choose which Directory Server to use for a particular operation.

The load-balancing algorithm takes several factors into account when choosing a server:

- The availability of the directory servers
- The location of the directory servers

By default, load-balancing algorithms prefer directory servers in the same location as the Directory Proxy Server.

- If the Directory Server is degraded for any reason, such as having a local database (DB) index being rebuilt
- The result of configured health checks

For instance, a server with a small replication backlog can be preferred over one with a larger backlog.

- Recent operation routing history

How these factors are used depends on the specific load-balancing algorithm. The two most commonly used load-balancing algorithms are:

- The failover load-balancing algorithm
- The fewest operations load-balancing algorithm

These two algorithms are similar when determining which Directory Servers are the possible candidates for a specific operation. The algorithms use the same criteria to determine server availability and health, and by default they prefer Directory Servers in the same location as the Directory Proxy Server. However, they differ in the criteria they use to choose between available servers. The following sections describe the algorithms in more detail.

### Choosing between available servers

The failover load-balancing algorithm sends all operations to a single server until it is unavailable, and then sends all operations to the next preferred server, and so forth. This algorithm provides the most consistent view of the topology to clients because all clients, at least those in the same location as the Directory Proxy Server, see the same, up-to-date view of the data, but it leaves unused capacity in the failover instances because most topologies include multiple Directory Server replicas within each data center.

The fewest operations load-balancing algorithm efficiently distributes traffic among multiple servers by choosing to send each operation to the server that has the fewest number of outstanding operations, which is the server from the Directory Proxy Server's point of view that is the least busy.

#### Note:

The fewest operations load-balancing algorithm routes traffic to the least loaded server, which, in a lightly-loaded environment, can result in an imbalance because the first server in the list of configured servers is more likely to receive a request.

This algorithm naturally routes to servers that are more responsive as well as limits the impact of servers that have become unreachable. However, this implies that consecutive operations that depend on each other can be routed to different Directory Servers, which can cause issues for some types of clients:

- If two entries are added in quick succession where the first entry is the parent of the second in the LDAP hierarchy, the addition of the child entry could fail if that operation is routed to a different Directory Server instance than the first `add` operation, and this happens within the replication latency.
- Some clients add or modify an entry and then immediately read the entry back from the server, expecting to see the updates reflected in the entry.

In these situations, you should configure the Directory Proxy Server to route dependent requests to the same server.

### The server affinity feature

The server affinity feature achieves this in some environments but not in all because the affinity is tracked independently by each Directory Proxy Server instance, and some clients send requests to multiple proxies. It is common for a client to not connect to the Directory Proxy Servers directly but instead to connect through a network load balancer, which in turn opens connections to the Directory Proxy Servers. Each individual client connection is established to a single Directory Proxy Server so that operations on that connection are routed to the same Directory Proxy Server, and server affinity configured within the Directory Proxy Server ensures those operations are routed to the same Directory Server.

However, many clients establish a pool of connections that are reused across operations, and within this pool, connections are established through the load balancer to different Directory Proxy Servers. Dependent operations sent on different connections could then be routed to different Directory Proxy Servers, and then on to different Directory Servers.

#### Note:

For more information about the server affinity feature, see [Configuring Server Affinity](#).

A failover load-balancing algorithm addresses this issue by routing all requests to a single server, but that leaves unused search capacity on the other instances. A criteria-based load-balancing algorithm enables the proxy to route certain types of requests (or requests from certain clients) using a different load-balancing algorithm than the default. For instance, all write operations (`add`, `delete`, `modify`, and `modifyDN`) could be routed using a failover load-balancing algorithm while all other operations (`bind`, `search`, and `compare`) use a fewest operations load-balancing algorithm.

If there are clients that are particularly sensitive to reading entries immediately after modifying them, additional connection criteria can be specified to all operations from those clients using the failover load-balancing algorithm.

#### Note:

Routing all write requests to a single server in a location instead of evenly across servers does not limit the overall throughput of the system because all servers ultimately have to process all write operations either from the client directly or through replication.

### Replication conflicts

Another benefit of using the failover load-balancing algorithm for write operations is reducing replication conflicts. The Ping Identity Directory Server follows the traditional LDAP replication model of eventual consistency. This provides high availability for handling write traffic even in the presence of network partitions, but it can lead to replication conflicts. Replication conflicts involving modify operations can be automatically resolved, leaving the servers in a consistent state where each attribute on each entry reflects the most recent update to that attribute. However, conflicts involving **add**, **delete**, and **modifyDN** operations cannot always be resolved automatically and might require manual involvement from an administrator. By routing all write operations (or at least **add**, **delete**, and **modifyDN** operations) to a single server, replication conflicts can be avoided.

#### Note:

When using a failover load-balancing algorithm, consider the following:

- When using the failover load-balancing algorithm in a configuration with multiple locations, the load-balancing algorithm fails over between local instances before failing over to servers in a remote location. The list of servers in the `backend-server` configuration property of the load-balancing algorithm should be ordered such that preferred local servers should appear before failover local servers, but the relative order of servers in different locations is unimportant as the `preferred-failover-location` of the Directory Proxy Server's configuration is used to decide which remote location to fail over to. It is also advisable that the order of local servers match the `gateway-priority` configuration settings of the Replication Server configuration object on the Directory Server instances. This can reduce the WAN replication delay because the Directory Proxy Server will then prefer to send writes to the Directory Server with the WAN Gateway role, avoiding an extra hop to the remote locations.
- For Directory Proxy Server configurations that include multiple Proxying Request Processors, including Entry-Balancing environments, each Proxying Request Processor should be updated to include its own criteria-based load-balancing algorithm.

## Routing operations to a single server

### About this task

The following example shows how to extend a Directory Proxy Server's configuration to use a criteria-based load-balancing algorithm to route all write requests to a single server using a failover load-balancing algorithm. This example can be extended to support alternate criteria and more complex topologies using multiple locations or entry balancing.

#### Note:

This example uses a basic deployment of a Directory Proxy Server fronting three Directory Servers: `ds1.example.com`, `ds2.example.com`, and `ds3.example.com`.

## Steps

1. To create a location, run **dsconfig** with the `create-location` option.

Example:

```
dsconfig create-location --location-name Austin
```

2. To update the failover location for your server, run **dsconfig** with the `set-location-prop` option.

Example:

```
dsconfig set-location-prop --location-name Austin
```

3. To set the location as a global configuration property, run **dsconfig** with the `set-global-configuration-prop` option.

Example:

```
dsconfig set-global-configuration-prop --set location:Austin
```

4. To set up the health checks for each external server, run **dsconfig** with the `create-ldap-health-check` option.

Example:

```
dsconfig create-ldap-health-check \
--check-name ds1.example.com:389_dc_example_dc_com-search-health-check \
--type search --set enabled:true --set base-dn:dc=example,dc=com

dsconfig create-ldap-health-check \
--check-name ds2.example.com:389_dc_example_dc_com-search-health-check \
--type search --set enabled:true --set base-dn:dc=example,dc=com

dsconfig create-ldap-health-check \
--check-name ds3.example.com:389_dc_example_dc_com-search-health-check \
--type search --set enabled:true --set base-dn:dc=example,dc=com
```

5. To create the external servers, run **dsconfig** with the `create-external-server` option.

Example:

```
dsconfig create-external-server --server-name ds1.example.com:389 \
--type Ping Identity-ds \
--set server-host-name:ds1.example.com --set server-port:389 \
--set location:Austin --set "bind-dn:cn=Proxy User,cn=Root DNs,cn=config" \
--set password:AADoPkhx22qpiBQJ7T0X4wH7 \
--set health-check:ds1.example.com:389_dc_example_dc_com-search-health-check

dsconfig create-external-server --server-name ds2.example.com:389 \
--type Ping Identity-ds \
--set server-host-name:ds2.example.com --set server-port:389 \
--set location:Austin --set "bind-dn:cn=Proxy User,cn=Root DNs,cn=config" \
--set password:AAoVqVYsEavey80T0QfR60I \
--set health-check:ds2.example.com:389_dc_example_dc_com-search-health-check

dsconfig create-external-server --server-name ds3.example.com:389 \
--type Ping Identity-ds \
--set server-host-name:ds3.example.com --set server-port:389 \
--set location:Austin --set "bind-dn:cn=Proxy User,cn=Root DNs,cn=config" \
--set password:AADOkveb0TtYR9xpkVrNgMtF \
```

```
--set health-check:ds3.example.com:389_dc_example_dc_com-search-health-check
```

6. To create a load-balancing algorithm, run **dsconfig** with the `create-load-balancing-algorithm` option.

Example:

This example creates a load-balancing algorithm for `dc=example,dc=com`.

```
dsconfig create-load-balancing-algorithm \
--algorithm-name dc_example_dc_com-fewest-operations \
--type fewest-operations --set enabled:true \
--set backend-server:ds1.example.com:389 \
--set backend-server:ds2.example.com:389 \
--set backend-server:ds3.example.com:389
```

7. To create a request processor, run **dsconfig** with the `create-request-processor` option.

Example:

This example creates a request processor for `dc=example,dc=com`.

```
dsconfig create-request-processor \
--processor-name dc_example_dc_com-req-processor \
--type proxying \
--set load-balancing-algorithm:dc_example_dc_com-fewest-operations
```

8. To create a subtree view, run **dsconfig** with the `create-subtree-view` option.

Example:

This example creates a subtree view for `dc=example,dc=com`.

```
dsconfig create-subtree-view \
--view-name dc_example_dc_com-view \
--set base-dn:dc=example,dc=com \
--set request-processor:dc_example_dc_com-req-processor
```

9. To update the client connection policy, run **dsconfig** with the `set-client-connection-policy-prop` option.

Example:

This example updates the client connection policy for `dc=example,dc=com`.

```
dsconfig set-client-connection-policy-prop \
--policy-name default \
--add subtree-view:dc_example_dc_com-view
```

10. To create a new request criteria object to match all write operations, run **dsconfig** with the `create-request-criteria` option.

Example:

```
dsconfig create-request-criteria \
--criteria-name any-write \
--type simple --set "description:All Write Operations" \
--set operation-type:add --set operation-type:delete \
--set operation-type:modify --set operation-type:modify-dn
```

11. To create a new failover load-balancing algorithm listing the servers that should be included, run **dsconfig** with the `create-load-balancing-algorithm` option.

Example:

In this example, the order that the servers are listed in is the failover order between servers.

```
dsconfig create-load-balancing-algorithm \
--algorithm-name dc_example_dc_com-failover \
--type failover --set enabled:true \
--set backend-server:ds1.example.com:389 \
--set backend-server:ds2.example.com:389 \
--set backend-server:ds3.example.com:389
```

12. To tie the request criteria and the failover load-balancing algorithm together into a criteria-based load-balancing algorithm, run **dsconfig** with the `create-criteria-based-load-balancing-algorithm` option.

Example:

```
dsconfig create-criteria-based-load-balancing-algorithm \
--algorithm-name dc_example_dc_com-write-traffic-lba \
--set "description:Failover_LBA For All Write Traffic" \
--set request-criteria:any-write \
--set load-balancing-algorithm:dc_example_dc_com-failover
```

13. To update the proxying request processor to use the criteria-based load-balancing algorithm, run **dsconfig** with the `set-request-processor-prop` option.

Example:

```
dsconfig set-request-processor-prop \
--processor-name dc_example_dc_com-req-processor \
--set criteria-based-load-balancing-algorithm:dc_example_dc_com-write-traffic-lba
```

## Result

The Directory Proxy Server routes all write operations to `ds1.example.com` as long as it's available and then to `ds2.example.com` if it's not. Directory Proxy Server routes other types of operations, such as searches and binds, to all three servers using the fewest operations load-balancing algorithm.

## Routing operations from a single client to a specific set of servers

### About this task

To create a type of server affinity where all operations from a single client are routed to a specific set of servers, follow a similar process as in the previous task, but configure connection criteria instead of request criteria. These connection criteria identify clients that could be impacted by replication latency. These clients use the failover load-balancing algorithm rather than the default fewest operations load-balancing algorithm.

For example, an administrative tool includes a `delete user` function. If the application immediately re-queries the directory for an updated list of users, the just-deleted entry must not be included.

To configure a criteria-based load balancing algorithm:

## Steps

1. Create the new failover load-balancing algorithm using **dsconfig** with the `create-load-balancing-algorithm` option.

### Note:

The failover load-balancing algorithm should list the same set of servers as the existing fewest operation load-balancing algorithm.

### Example:

```
dsconfig create-load-balancing-algorithm \
  --algorithm-name client_one_routing_algorithm \
  --type failover --set enabled:true \
  --set backend-server:east1.example.com:389 \
  --set backend-server:east2.example.com:389
```

2. To route operations from a single client to a single server in a set of replicated servers, create connection criteria using **dsconfig** with the `create-connection-criteria` option.

### Example:

```
dsconfig create-connection-criteria \
  --criteria-name "Client One" --type simple \
  --set included-user-base-dn:cn=Client One,ou=Apps,dc=example,dc=com
```

3. Configure a criteria-based load balancing algorithm and assign it to the proxying request processor, using **dsconfig** with the `create-criteria-based-load-balancing-algorithm` option.

Use the load balancing algorithm and connection criteria created in steps 1-2.

### Example:

```
dsconfig create-criteria-based-load-balancing-algorithm \
  --algorithm-name dc_example_dc_com-client-operations \
  --set load-balancing-algorithm:dc_example_dc_com-failover \
  --set "request-criteria:Client One Requests"
```

4. Assign the new criteria-based load balancing algorithm to the proxying request processor using **dsconfig** with the `set-request-processor-prop` option.

### Example:

```
dsconfig set-request-processor-prop \
  --processor-name dc_example_dc_com-req-processor \
  --add criteria-based-load-balancing-algorithm:dc_example_dc_com-client-operations
```

## Understanding failover and recovery

After a previously degraded or unavailable server has recovered, it should be eligible to start receiving traffic within the time configured for the `health-check-frequency` property that is 30 seconds by default. However, failover and recovery also depend on the load-balancing algorithm in use.

The load-balancing algorithm provides an ordered list of servers to check, with the number of servers in the list based on the maximum number of retry attempts. The server checks to see if affinity should be used and, if so, whether an affinity is set for that load-balancing algorithm.

### Note:

If there is an affinity to a particular server and that server is classified as available, that server is always the first in the list.

Next, the Directory Proxy Server creates a two-dimensional matrix of servers based on:

- The health check state, with available preferred over degraded and unavailable not considered at all
- Location, with backend servers in the same location as the Directory Proxy Server most preferred, then servers in the first failover location, then the second, and so forth

Within each of these sets, and ideally at least one server in the local data center is classified as available, the load-balancing algorithm selects the servers in the order of most preferred to least preferred based on whatever logic the load-balancing algorithm uses. The load-balancing algorithm keeps selecting servers until enough of them have been selected to satisfy the maximum number of possible retries.

The load-balancing algorithm includes a configuration option that allows you to decide whether to prefer location over availability or availability over location, such as specifying if a local degraded server is more or less preferred than a remote available server.

By default, the algorithm prefers available servers over degraded ones, even if it has to go to another data center to access them. You can change the load-balancing algorithm to try to stay in the same data center if at least one server is not unavailable.

The Directory Proxy Server does both proactive and reactive health checking.

#### Proactive health checking

The Directory Proxy Server periodically (by default, every 30 seconds) runs a full set of tests against each backend server. The result of these tests are used to determine the overall health check state (available, degraded, or unavailable) and score (an integer value from 10 to 0).

#### Reactive health checking

The Directory Proxy Server kicks off a lesser set of health checks against a server if an operation forwarded to that server did not complete successfully.

Proactive health checking can be used to promote and demote the health of a server. Reactive health checking can only be used to demote the health of a server. As a result, if a server is determined to be unavailable, then it will remain that way until a subsequent proactive health check determines that it has recovered. If a server is determined to be degraded, it might not become available until the next proactive health check, but it could be downgraded to unavailable by a reactive check if other failures are encountered against that server.

Both proactive and reactive health check assignments take effect immediately and are considered for all subsequent requests routed to the load-balancing algorithm. If a server is considered degraded, then it's immediately considered less desirable than available servers in the same data center, and possibly less desirable than available servers in more remote data centers. If a server is considered unavailable, then it's not eligible to be selected until it is reclassified as available or degraded.

## Configuring HTTP connection handlers

HTTP connection handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. They can also be used to host web applications on the server. Each HTTP connection handler must be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this will not prevent the entire Directory Server from starting. The Directory Server's **start-server** tool will output any errors to the error log. This allows the Directory Server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with an HTTP connection handler include:

- **listen-address.** Specifies the address on which the connection handler will listen for requests from clients. If not specified, then requests will be accepted on all addresses bound to the system.
- **listen-port.** Specifies the port on which the connection handler will listen for requests from clients. Required.
- **use-ssl.** Indicates whether the connection handler will use SSL/TLS to secure communications with clients (whether it uses HTTPS rather than HTTP). If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.
- **http-servlet-extension.** Specifies the set of servlet extensions that will be enabled for use with the connection handler. You can have multiple HTTP connection handlers (listening on different address/port combinations) with identical or different sets of servlet extensions. At least one servlet extension must be configured.
- **http-operation-log-publisher.** Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers will be used.
- **key-manager-provider.** Specifies the key manager provider that will be used to obtain the certificate presented to clients if SSL is enabled.
- **trust-manager-provider.** Specifies the trust manager provider that will be used to determine whether to accept any client certificates presented to the server.
- **num-request-handlers.** Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads will be automatically selected based on the number of CPUs available to the JVM.
- **web-application-extension.** Specifies the Web applications to be hosted by the server.

## Configuring an HTTP connection handler

About this task

An HTTP connection handler has two dependent configuration objects:

- One or more HTTP servlet extensions
- An optional HTTP log publisher.

You must configure the HTTP servlet extension and log publisher before configuring the HTTP connection handler. The log publisher is optional but in most cases, you should configure one or more logs to troubleshoot any issues with your HTTP connection.

### Steps

1. To configure your HTTP servlet extensions, run **dsconfig** with the `create-http-servlet-extension` option.

Example:

This example uses the `ExampleHTTPServletExtension` in the Server SDK.

```
$ bin/dsconfig create-http-servlet-extension \
  --extension-name "Hello World Servlet" \
  --type third-party \
  --set "extension-
class:com.unboundid.directory.sdk.examples.ExampleHTTPServletExtension" \
  --set "extension-argument:path=/" \
  --set "extension-argument:name=example-servlet"
```

2. To configure an HTTP log publisher, run **dsconfig** with the `create-log-publisher` option.

Example:

This example configures one log publisher for common access and one for detailed access. Both log publishers use the default configuration settings for log rotation and retention.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access Logger" \
  --type common-log-file-http-operation \
  --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Detailed Access Logger" \
  --type detailed-http-operation \
  --set enabled:true \
  --set log-file:logs/http-detailed-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

3. To configure the HTTP connection handler, run **dsconfig** with the `create-connection-handler` option to specify the HTTP servlet extension and log publishers.

**Note:**

Some configuration properties can be updated while the HTTP connection handler is enabled while others, such as `listen-port`, require that the HTTP connection handler be disabled and then re-enabled for the change to take effect.

Example:

```
$ bin/dsconfig create-connection-handler \
  --handler-name "Hello World HTTP Connection Handler" \
  --type http \
  --set enabled:true \
  --set listen-port:8443 \
  --set use-ssl:true \
  --set "http-servlet-extension:Hello World Servlet" \
  --set "http-operation-log-publisher:HTTP Common Access Logger" \
  --set "http-operation-log-publisher:HTTP Detailed Access Logger" \
  --set "key-manager-provider:JKS" \
  --set "trust-manager-provider:JKS"
```

4. To monitor the connection handler, use the **ldapsearch** tool.

**Note:**

By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE`.

Example:

```
$ bin/ldapsearch --baseDN "cn=monitor" \
```

```
"(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

## HTTP correlation IDs

Correlation IDs make it easier to track log messages across a software system request that passes through multiple subsystems.

Scattered and intermingled log messages create challenges for tracing the request flow on distributed systems. A correlation ID can be assigned to a request and added to all associated operations as the request is processed. A correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP or HTTPS Connection Handler.

When an HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID might also be passed to the LDAP subsystem.

The correlation ID appears with associated requests in LDAP logs in the `correlationID` key for the following REST APIs:

- SCIM 1
- Delegated admin
- Consent
- Directory

The correlation ID is used as the default client request ID value in intermediate client request controls used by the following REST APIs:

- SCIM 2
- Consent
- Directory

Values related to the intermediate client request control appear in the LDAP logs in the `via` key and are forwarded to downstream LDAP servers when received by PingDirectoryProxy Server. The correlation ID header is also added to requests forwarded by the PingDataGovernance gateway.

For Server SDK extensions that have access to the current `HttpServletRequest`, the current correlation ID can be retrieved as a string through the `HttpServletRequest` `com.pingidentity.pingdata.correlation_id` attribute, as shown.

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

## Configuring HTTP correlation ID support

About this task

Correlation ID support is enabled by default for each HTTP Connection Handler.

Steps

- To enable or disable correlation ID support for the HTTPS Connection Handler, use the `set-connection-handler-prop` option with `dsconfig`.

Example:

This example shows how to enable correlation ID support.

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
```

```
--set use-correlation-id-header:true
```

#### Example:

This example shows how to disable correlation ID support.

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set use-correlation-id-header:false
```

- To customize the response header name for the correlation ID, use the `set-connection-handler-prop` option with **dsconfig**.

#### Note:

The server generates a correlation ID for every HTTP request and sends it in the response through the **Correlation-Id** response header.

#### Example:

This example changes the **correlation-id-response-header** property value to `X-Request-Id`.

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set correlation-id-response-header:X-Request-Id
```

- To designate the names of one or more HTTP request headers that contain an existing correlation ID value, use the `set-connection-handler-prop` option with **dsconfig**.

#### Note:

This enables the server to integrate with a larger system consisting of every servers using correlation IDs.

By default, the server generates a new, unique correlation ID for each HTTP request and ignores any correlation ID that might be set on the request.

#### Example:

```
$ dsconfig set-connection-handler-prop --handler-name "HTTPS Connection
Handler" \
  --set correlation-id-request-header:X-Request-Id \
  --set correlation-id-request-header:X-Correlation-Id \
  --set correlation-id-request-header:Correlation-Id \
  --set correlation-id-request-header:X-Amzn-Trace-Id
```

### HTTP correlation ID example

In this example, a request to the directory REST API is made and the correlation ID enables finding HTTP-specific log messages that also have LDAP-specific log messages. The response to the API call includes a **Correlation-Id** header with the value `ee919049-6710-4594-9c66-28b4ada4b127`.

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
Accept: */*
Accept-Encoding: gzip, deflate
Authorization: Bearer ...
Connection: keep-alive
Host: localhost:1443
User-Agent: HTTPie/0.9.9
```

```

HTTP/1.1 200 OK
Content-Length: 266
Content-Type: application/hal+json
Correlation-Id: ee919049-6710-4594-9c66-28b4ada4b127
Date: Fri, 02 Nov 2018 15:16:50 GMT
Request-Id: 369

{
  "_dn": "uid=user.86,ou=People,dc=example,dc=com",
  "_links": {
    "schemas": [
      {
        "href": "https://localhost:1443/directory/v1/schemas/
inetOrgPerson"
      }
    ],
    "self": {
      "href": "https://localhost:1443/directory/v1/
uid=user.86,ou=People,dc=example,dc=com"
    }
  },
  "mail": [
    "user.86@example.com"
  ]
}

```

The correlation ID can be used to search the HTTP trace log for matching log records, as in the following example.

```

$ grep 'correlationID="ee919049-6710-4594-9c66-28b4ada4b127"'

## Configuring proxy transformations

The PingDirectory Server provides proxy transformations to alter the contents of client requests as they are sent from the client to the LDAP external server. Proxy transformations can also be used to alter the responses sent back from the server to the client, including altering or omitting search result entries. The Directory Proxy Server provides the following types of data transformations:

- **Attribute mapping.** This transformation rewrites client requests so that references to one attribute type may be replaced with an alternate attribute type. The Directory Proxy Server can perform extensive replacements, including attribute names used in DNs and attribute names encoded in the values of a number of different controls and extended operations. For example, a client requests a `userid` attribute, which is replaced with `uid` before being forwarded on to the backend server. This mapping applies in reverse for the response returned to the client.
- **Default value.** This transformation instructs the Directory Proxy Server to include a static attribute value in search results being sent back to the client, in ADD requests being forwarded to an external server, or both. For example, a value of "marketing" for `businessCategory` could be returned for all search results under the base DN `ou=marketing,dc=example,dc=com`.

- **DN mapping.** This transformation rewrites client requests so that references to entries below a specified DN will be mapped to appear below another DN. For example, references to entries below `o=example.com` could be rewritten so that they are below `dc=example,dc=com` instead. The mapping applies in reverse for the response returned to the client.
- **Groovy scripted.** This custom transformation is written in Groovy and does not need to be compiled, though they use the Server SDK. These scripts make it possible to alter requests and responses in ways not available using the transformations provided with the Directory Proxy Server.
- **Suppress attribute.** This proxy transformation allows you to exclude a specified attribute from search result entries. It also provides the ability to reject add, compare, modify, modify DN, or search requests if they attempt to reference the target attribute.
- **Suppress entry.** This proxy transformation allows you to exclude any entries that match a specified filter from a set of search results. Search requests are transformed so that the original filter will be ANDed with a NOT filter containing the exclude filter. For example, if the suppression filter is `"(objectClass=secretEntry)"`, then a search request with a filter of `"(uid=john.doe)"` will be transformed so that it has a filter of `"(&(uid=john.doe)(!(objectClass=secretEntry)))"`.
- **Simple to external bind.** This proxy transformation may be used to intercept a simple bind request and instead process the bind as a SASL EXTERNAL bind. If the SASL EXTERNAL bind fails, then the original simple bind request may or may not be processed, depending on how you configure the server.
- **Third-party scripted.** This custom transformation is created using the Server SDK, making it possible to alter requests and responses in ways not available using the transformations provided with the Directory Proxy Server.

### Configuring proxy transformations using dsconfig

Create and configure a proxy transformation.

About this task

To create and configure a proxy transformation:

#### Steps

1. Run the `dsconfig` tool.

Example:

```
$ bin/dsconfig
```

2. When prompted, enter the connection parameters to the server.

Connection parameters can include:

- Host name
- Connection method
- Port
- Bind distinguished name (DN)
- Bind DN password

3. In the Directory Proxy Server main menu, enter the selection for `Proxy transformations`.
4. In the `Proxy Transformation` menu, enter the selection for `Create a new proxy transformation`.
5. Select the type of proxy transformation you want to create. Enter a name for the new transformation.

Example:

This example creates an attribute mapping transformation.

```
>>>> Enter a name for the Attribute Mapping Proxy Transformation that
you
```

```
want to create: userid-to-uid
```

6. To choose if the proxy transformation is enabled by default or not, select `true` or `false`.

Example:

```
Select a value for the 'enabled' property:
```

```
1) true
2) false

?) help
c) cancel
q) quit
```

```
Enter choice [c]: 1
```

7. Enter the name of the client attribute that you want to remap to a target attribute.

**Note:**

This attribute must not be equal to the target attribute.

Example:

```
Enter a value for the 'source-attribute' property: userid
```

8. Enter the name of the target attribute to which the client attribute should be mapped.

Example:

```
Enter a value for the 'target-attribute' property: uid
```

Result: The properties of your new proxy transformation are displayed.

9. Optional: To make any modifications, enter the selection for the desired property.  
10. To finish the creation of the proxy transformation, enter `f`.

Example:

```
Enter choice [b]: f
```

### Next steps

The transformation must be assigned to a request processor. For information on creating and configuring request processors, see [Configuring request processors](#) on page 1270.

## Configuring request processors

A request processor is responsible for handling client requests by passing the request through a load-balancing algorithm or one or more subordinate request processors. The request processor is also the Directory Proxy Server component that performs proxy transformations. You can create one of the following types of request processors:

- **Proxying request processor.** This request processor is responsible for passing allowed operations through a load balancing algorithm. Proxy transformations can be applied to requests and responses that are processed. Multiple servers may be configured to provide high availability and load balancing, and various transformations may be applied to the requests and responses that are processed.
- **Entry-balancing request processor.** This request processor is used to distribute entries under a common parent entry among multiple backend sets. A backend set is a collection of replicated directory servers that contain identical portions of the data. This request processor uses multiple,

subordinate proxying request processors to process operations and maintains in-memory indexes to speed the processing of specific search and modify operations.

- **Failover request processor.** This request processor performs ordered failover between subordinate proxying processors, sometimes with different behavior for different types of operations.

## Configuring request processors using dsconfig

About this task

To create and configure a request processor:

### Steps

1. Run the `dsconfig` tool.

Example:

```
$ bin/dsconfig
```

2. When prompted, enter the connection parameters to the server.

Connection parameters can include:

- Host name
- Connection method
- Port
- Bind distinguished name (DN)
- Bind DN password

3. In the Directory Proxy Server main menu, enter the selection for `Request Processor configuration`.
4. Enter the selection for `Create a new request processor`.
5. Select an existing request processor to use as a template for creating a new one or enter `n` to create one from scratch.
6. Select an existing load balancing algorithm or create a new one.

Result:

The following example shows the configuration of a new proxying request processor after the selection of the load balancing algorithm.

| Property                    | Value(s)                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1) description              | -                                                                                                                                                                                                                                                                                                                                                                                                              |
| 2) enabled                  | true                                                                                                                                                                                                                                                                                                                                                                                                           |
| 3) allowed-operation        | abandon, add, bind, compare, delete, extended, modify, modify-dn, search                                                                                                                                                                                                                                                                                                                                       |

```

8) supported-control-oid -
?) help
f) finish - create the new Proxying Request Processor
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit

```

7. Review the configuration properties of the new request processor. To finish, enter `f`.

**Note:**

To use the request processor, you must associate it with a subtree view.

## Passing LDAP controls with the proxying request processor

### About this task

If your deployment does not use entry balancing and requires the use of LDAP controls not defined in the request processor's `supported-control` property, configure the Directory Proxy Server to forward these controls correctly.

### Steps

- Configure the `supported-control-oid` property to define the request OID of the LDAP control.  
Result: The Directory Proxy Server updates the root DSA-specific entry (DSE) `supportedControl` attribute with the values entered for the `supported-control-oid` property.

## Configuring server affinity

### About this task

The Directory Server supports the ability to forward a sequence of requests to the same external server if specific conditions are met. This feature, called server affinity, is applied by the load balancing algorithms. The following server affinity methods are available in the Directory Proxy Server:

- **Client Connection.** Requests from the same Directory Proxy Server client connection are consistently routed to the same external server.
- **Client IP.** Directory Proxy Server client requests coming from the same client IP address are routed to the same external server.
- **Bind DN.** Requests from all client connections authenticated as the same bind DN are routed to the same external server.

For each algorithm, you can specify the set of operations for which an affinity will be established, as well as the set of operations for which affinity will be used. Affinity assignments have a time-out value so that they are in effect for some period of time after the last operation that may cause the affinity to be set or updated.

In this example, we create a bind DN server affinity provider for any client requesting write operations to have subsequent requests, whether read or write, forwarded to the same external server. The affinity period will last for 30 seconds after the last write request.

### Steps

1. Use the `dsconfig` tool to configure server affinity. Specify the host name, connection method, port number, and bind DN as described in previous procedures.

Example:

```
$ bin/dsconfig
```

2. In the Directory Proxy Server main menu, enter the number associated with server affinity provider configuration
3. On the Server Affinity menu, enter the number corresponding to creating a new server affinity provider.
4. Enter a name for your new server affinity provider.

Example:

```
>>>> Enter a name for the Bind DN Server Affinity Provider
that you want to create: Affinity for Writing Applications
```

5. Indicate whether you want the server affinity provider to be enabled for use by the Directory Proxy Server. In this example, enter 1 to enable to the server affinity provider.
6. Next, configure the properties of the server affinity provider. For example, you can customize the types of operations for which affinity may be set and the types of operations for which affinity may be used, as well as the length of time for which the affinity should persist. This example illustrates the properties of the bind DN server affinity provider.

Example:

```
>>>> >>>> Configure the properties of the Bind DN Server Affinity Provider
```

| Property                                                           | Value(s)                                              |
|--------------------------------------------------------------------|-------------------------------------------------------|
| 1) description                                                     | -                                                     |
| 2) enable                                                          | true                                                  |
| 3) affinity-duration                                               | 30 s                                                  |
| 4) set-affinity-operation                                          | add, delete, modify, modify-dn                        |
| 5) use-affinity-operation                                          | add, bind, compare, delete, modify, modify-dn, search |
| ?) help                                                            |                                                       |
| f) finish - create the new Bind DN Server Affinity Provider        |                                                       |
| d) display the equivalent dsconfig arguments to create this object |                                                       |
| b) back                                                            |                                                       |
| q) quit                                                            |                                                       |

```
Enter choice [b]:
```

7. Review the properties of the server affinity provider. If you are satisfied, enter `f` to finish. Once defined, the affinity provider can now be assigned to a load balancing algorithm.

## Configuring subtree views

### About this task

You provide clients access to a specific portion of the DIT creating a subtree view and assigning it to a client connection policy. You can configure subtree views from the command line or using the Administrative Console.

When you create a subtree view, you provide the following information to configure its properties:

- Subtree view name
- Base DN managed by the subtree view
- Request processor used by the subtree view to route requests. If one does not exist already, you will create a new one.

### Steps

1. Use `dsconfig` to configure a subtree view.
2. In the Directory Proxy Server main menu, enter the number associated with subtree view configuration
3. In the Subtree View menu, enter the number corresponding to creating a new subtree view.

4. Enter a name for the subtree view.
5. Enter the base DN of the subtree managed by this subtree view.

Example:

```
Enter a value for the 'base-dn' property:dc=example,dc=com
```

6. Select a request processor for this subtree view to route requests or make the appropriate selection to create a new one.

Example:

```
Select a Request Processor for the 'request-processor' property:
```

```
1) dc_example_dc_com-req-processor
2) Create a new Request Processor
```

```
?) help
c) cancel
q) quit
```

```
Enter choice [c]: 1
```

7. Review the properties of the subtree view. If you are satisfied, enter `f` to finish.

Example:

```
>>>> Configure the properties of the Subtree View
>>>> via creating 'example.com' Subtree View
```

|    | Property                                                        | Value(s)                        |
|----|-----------------------------------------------------------------|---------------------------------|
| 1) | description                                                     | -                               |
| 2) | base-dn                                                         | "dc=example,dc=com"             |
| 3) | request-processor                                               | dc_example_dc_com-req-processor |
| ?) | help                                                            |                                 |
| f) | finish - create the new Subtree View                            |                                 |
| d) | display the equivalent dsconfig arguments to create this object |                                 |
| b) | back                                                            |                                 |
| q) | quit                                                            |                                 |

Result: Once configured, you can assign one or more subtree views to any client connection policies.

## Client connection policy configuration

Client connection policies help distinguish what portions of the DIT the client can access.

They enforce restrictions on what clients can do in the server. A client connection policy specifies criteria for membership based on information about the client connection, including client address, protocol, communication security, and authentication state and identity. The client connection policy, however, does not control membership based on the type of request being made.

Every client connection is associated with exactly one client connection policy at any given time, which is assigned to the client when the connection is established. The choice of which client connection policy to use is reevaluated when the client attempts a bind to change its authentication state or uses the StartTLS extended operation to convert an insecure connection to a secure one. Any changes you make to the client connection policy do not apply to existing connections. The changes only apply to new connections.

Client connections are always unauthenticated when they are first established. If you plan to configure a policy based on authentication, you must define at least one client connection policy with criteria that match unauthenticated connections.

When a client has been assigned to a policy, you can determine what operations they can perform. For example, your policy might allow only SASL bind operations. Client connection policies are associated

with one or more subtree views, which determine the portions of the DIT a particular client can access. For example, you might configure a policy that prevents users connecting over the extranet from accessing configuration information. The client connection policy is evaluated in addition to access control, so even a root user connecting over the extranet would not have access to the configuration information.

### About the client connection policy

Client connection policies are based on two factors.

#### Connection criteria

The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can be used in other instances when the server needs to perform matching based on connection-level properties, such as filtered logging. A single connection can match multiple connection criteria definitions.

#### Evaluation order index

If multiple client connection policies are defined in the server, then each of them must have a unique value for the `evaluation-order-index` property. The client connection policies are evaluated in order of ascending evaluation order index. If a client connection does not match the criteria for any defined client connection policy, then that connection will be terminated.

If the connection policy matches a connection, then the connection is assigned to that policy and no further evaluation occurs. If, after evaluating all of the defined client connection policies, no match is found, the connection is terminated.

### When a client connection policy is assigned

A client connection policy can be associated with a client connection at the following times.

- When the connection is initially established. This association occurs exactly once for each client connection.
- After completing processing for a StartTLS operation. This association occurs once at most for a client connection because StartTLS cannot be used more than once on a particular connection. You can not stop using StartTLS while keeping the connection active.
- After completing processing for a bind operation. This association occurs zero or more times for a client connection because the bind request can be processed many times on a given connection.

StartTLS and bind requests are subject to whatever constraints are defined for the client connection policy that is associated with the client connection at the time that the request is received. When they have completed, then subsequent operations are subject to the constraints of the new client connection policy assigned to that client connection. This policy might not be the same client connection policy that was associated with the connection before the operation was processed. That is, any policy changes do not apply to existing connections and only apply when the client reconnects.

All other types of operations are subject to whatever constraints are defined for the client connection policy used by the client connection at the time that the request is received. The client connection policy assigned to a connection never changes as a result of processing any operation other than a bind or StartTLS. The server does not re-evaluate the client connection policy for the connection in the course of processing an operation. For example, the client connection policy is never re-evaluated for a search operation.

### Restricting the type of search filter used by clients

You can restrict the types of search filters that a given client might be allowed to use to prevent the use of potentially expensive filters, like range or substring searches.

You can use the `allowed-filter-type` property to provide a list of filter types that can be included in the search requests from clients associated with the client connection policy. This setting is only used if search is included in the set of allowed operation types. This restriction only applies to searches with a scope other than `baseObject`, such as searches with a scope of `singleLevel`, `wholeSubtree`, or `subordinateSubtree`.

You can use the `minimum-substring-length` property to specify the minimum number of non-wildcard characters in a substring filter. Any attempt to use a substring search with an element containing fewer than this number of bytes is rejected. For example, you can configure the server to reject filters like `"(cn=a*)"` and `"(cn=ab*)"`, but to allow `"(cn=abcde*)"`. This property setting is only used if `search` is included in the set of allowed operation types and at least one of `sub-initial`, `sub-any`, or `sub-final` is included in the set of allowed filter types.

There are two primary benefits to enforcing a minimum substring length:

- Allowing short substrings can require the server to perform more expensive processing. The search requires more server effort to assemble a candidate entry list for short substrings because the server has to examine more index keys.
- Allowing short substrings makes it easier for a client to put together a series of requests to retrieve all the data from the server, a process known as "trawling". If a malicious user wants to obtain all the data from the server, then it is easier to issue 26 requests like `"(cn=a*)"`, `"(cn=b*)"`, `"(cn=c*)"`, ..., `"(cn=z*)"` than if the user is required to do something like `"(cn=aaaaa*)"`, `"(cn=aaaab*)"`, `"(cn=aaaac*)"`, ..., `"(cn=zzzzz*)"`.

### Defining Request Criteria

The client connection policy provides several properties that allow you to define the kinds of requests that it can issue.

`required-operation-request-criteria`

This property causes the server to reject any requests that do not match the referenced request criteria.

`prohibited-operation-request-criteria`

This property causes the server to reject any request that matches the referenced request criteria.

### Setting Resource Limits

A client connection policy can specify resource limits, helping to ensure that no single client monopolizes server resources.

The resource limits are applied in addition to any global configuration resource limits. A client connection policy can't grant additional resources beyond what is set in the global configuration. If a client connection exceeds either a globally-defined limit or a policy limit, it is terminated.

#### Note:

The Directory Proxy Server's global configuration can enforce limits on the number of concurrent connections that can be established in the following ways:

- Limit the total number of concurrent connections to the server.
- Limit the total number of concurrent connections from the same IP address.
- Limit the total number of concurrent connections authenticated as the same bind distinguished name (DN).

### Defining the operation rate

Configure the maximum operation rate for individual client connections and collectively for all connections associated with a client connection policy.

If the operation rate limit is exceeded, the Directory Server can either reject the operation or terminate the connection. You can define multiple rate limit values, making it possible to fine tune limits for both a long term average operation rate and short term operation bursts. For example, you can define a limit of one thousand operations per second and one million operations per day, which works out to an average of fewer than twelve operations per second, but with bursts of up to one thousand operations per second.

Specify rate limit strings as a maximum count, followed by a slash and a duration. The count portion must contain an integer and can be followed by the following multipliers:

- k (to indicate that the integer should be interpreted as thousands)
- m (to indicate that the integer should be interpreted as millions)
- g (to indicate that the integer should be interpreted as billions)

The duration portion must contain a time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w) and can be preceded by an integer to specify a quantity for that unit.

For example, the following are valid rate limit strings:

- 1/s (no more than one operation over a one-second interval)
- 10K/5h (no more than ten thousand operations over a five-hour interval)
- 5m/2d (no more than five million operations over a two-day interval)

You can provide time units in many different formats. For example, a unit of seconds can be signified using s, sec, sect, second, and seconds.

### Client connection policy deployment example

In this example scenario, we assume the following:

1. Two external LDAP clients are allowed to bind to the Directory Server.
2. Client 1 should be allowed to open only one connection to the server.
3. Client 2 should be allowed to open up to five connections to the server.

For more information on this client connection policy deployment example, see the following topics:

- [Define the connection policies](#) on page 497
- [How the policy is evaluated](#) on page 497
- [Configuring a client connection policy using the console](#) on page 498
- [Configuring a client connection policy using dsconfig](#) on page 499
- [Restricting server access based on client IP address](#) on page 500

### Define the connection policies

Set a per-client connection policy limit on the number of connections that can be associated with a particular client connection policy

Define at least two client connection policies, one for each of the two clients. Each policy must have different connection criteria for selecting the policy with which a given client connection should be associated.

Because the criteria is based on authentication, you must create a third client connection policy that applies to unauthenticated clients because client connections are always unauthenticated as soon as they are established and before they have sent a bind request. Clients are not required to send a bind request as their first operation.

Define the following three client connection policies:

- Client 1 Connection Policy, which only allows client 1, with an evaluation order index of 1
- Client 2 Connection Policy, which only allows client 2, with an evaluation order index of 2
- Unauthenticated Connection Policy, which allows unauthenticated clients, with an evaluation order index of 3

Define simple connection criteria for the Client 1 Connection Policy and the Client 2 Connection Policy with the following properties:

- The `user-auth-type` must not include none so that it only applies to authenticated client connections.

- The `included-user-base-dn` should match the bind DN for the target user. This distinguished name (DN) can be full DN for the target user, or it can be the base DN for a branch that contains a number of users that you want treated in the same way.

**Tip:**

To create more generic criteria that match more than one user, you could list the DNs of each of the users explicitly in the `included-user-base-dn` property. If there is a group that contains all of the pertinent users, then you could instead use the `[all|any|not-all|not-any]-included-user-group-dn` property to apply to all members of that group. If the entries for all of the users match a particular filter, then you could use the `[all|any|not-all|not-any]-included-user-filter` property to match them.

### How the policy is evaluated

Whenever a connection is established, the server associates the connection with exactly one client connection policy.

The server does this by iterating over all of the defined client connection policies in ascending order of the evaluation order index. Policies with a lower evaluation order index value are examined before those with a higher evaluation order index value. The first policy that the server finds whose criteria match the client connection is associated with that connection. If no client connection policy is found with criteria matching the connection, then the connection is terminated.

So, in this example, when a new connection is established, the server first checks the connection criteria associated with the Client 1 Connection Policy because it has the lowest evaluation order index value. If it finds that the criteria do not match the new connection, the server then checks the connection criteria associated with the Client 2 Connection Policy because it has the second lowest evaluation order index. If these criteria do not match, the server finally checks the connection criteria associated with the Unauthenticated Connection Policy because it has the third lowest evaluation order index. It finds a match, so the client connection is associated with the Unauthenticated Connection Policy.

After the client performs a bind operation to authenticate to the server, then the client connection policies are re-evaluated. If Client 2 performs the bind, then the Client 1 Connection Policy does not match, but the Client 2 Connection Policy does, so the connection is re-associated with that client connection policy. Whenever a connection is associated with a client connection policy, the server checks to see if the maximum number of client connections have already been associated with that policy. If so, then the newly-associated connection is terminated.

For example, Client 1 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. Client 1 then sends a bind request. The determination of whether the bind operation is allowed is made based on the constraints defined in the Unauthenticated Connection Policy because it is the client connection policy already assigned to the client connection. When the bind has completed, the server re-evaluates the client connection policy against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to the Client 1 Connection Policy.

Next, Client 2 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. When Client 2 sends a bind request, the operation is allowed based on the constraints defined in the Unauthenticated Connection Policy. When the bind is complete, the client connection is evaluated against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria do not match, so the Client 2 connection is evaluated against the connection criteria associated with Client 2 Connection Policy because it has the next lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to Client 2 Connection Policy.

Client 1 sends a search request. The Client 1 Connection Policy is used to determine whether the search operation should be allowed because this is the client connection policy assigned to the client connection for Client 1. The connection is not re-evaluated before or after processing the search operation.

## Configuring a client connection policy using dsconfig

Creates and configure a new client connection policy using `dsconfig`.

About this task

To create and configure a client connection policy:

### Steps

1. Run the `dsconfig` tool.

Example:

```
$ bin/dsconfig
```

2. Enter the connection parameters to the server.

Connection parameters can include:

- Host name
- Connection method
- Port
- bind distinguished name (DN)
- Bind DN password

3. In the Directory Proxy Server main menu, enter the selection for Client connection policy configuration. To create a new client connection policy, enter 2.

Example:

```
>>>> Client connection policy menu
What would you like to do?
  1) List existing client connection policies
  2) Create a new client connection policy
  3) View and edit an existing client connection policy
  4) Delete an existing client connection policy
  b) back
  q) quit
Enter choice [b]: 2
```

4. To create a new client connection policy from scratch, enter n.

Example:

```
>>>> Select an existing Client Connection Policy to use as a
template for the new Client Connection Policy configuration or
'n' to create one from scratch:
  1) default
  n) new Client Connection Policy created from scratch
  c) cancel
  q) quit
```

5. Enter a name for the new client connection policy.

Example:

```
Enter the 'policy-id' for the Client Connection Policy that you
```

```
want to create: new_policy
```

- To set up the policy to be enabled by default or not, select `true` or `false`.

Example:

```
Select a value for the 'enabled' property:
```

```
1) true
2) false

?) help
c) cancel
q) quit
```

```
Enter choice [c]: 1
```

- Enter a value for the `evaluation-order-index` property.

**Note:**

Client connection policies with a lower index are evaluated before those with a higher index.

Example:

```
Enter a value for the 'evaluation-order-index' property: 2
```

Result: The properties of your new client connection policy are displayed.

- Optional: To make any further modifications, enter the number corresponding to the property.
- To finish the creation of the client connection policy, enter `f`.

**Note:**

Any changes that you make to the client connection policy don't apply to existing connections. They only apply to new connections.

## Configuring globally unique attributes

PingDirectoryProxy Server supports a globally unique attributes feature that ensures uniqueness for values defined for a set of attributes within a subtree view.

You can configure the attributes when the server checks for attribute conflicts, either prior to any `add`, `modify`, or `modifyDN` change request (pre-commit) or after the successful completion of a change request (post-commit).

### About the Globally Unique Attribute plugin

The Directory Proxy Server supports a globally unique attribute plugin that prevents any value within a defined set of attributes to appear more than once in any entry for one or more subtree views.

Administrators can also configure whether conflict validation should be checked before an `add`, `modify`, or `modifyDN` request to one or more backend servers or after the change has successfully completed.

For example, if the `pre-commit-validation` property is enabled, the Globally Unique Attribute Plugin performs one or more searches to determine whether any entries conflict with the change, such as `add`, `modify`, or `modifyDN`. If a conflict is detected, the change request is rejected. If the `post-commit-validation` property is enabled, the server performs one or more searches after the change has been processed to determine if a conflict was created in multiple servers at the same time. If a conflict is detected in this manner, an administrative alert is generated to notify administrators of the problem so that they can take any manual corrective action.

The Globally Unique Attribute plugin attempts to detect and prevent unique attribute conflicts for changes processed through this Directory Proxy Server, but it cannot detect conflicts introduced by changes applied by clients communicating directly with backend servers.

You should enable the plugin for all backend servers with the same configuration so that conflicts can be detected within individual backend server instances. However, the Unique Attribute plugin alone might not be sufficient for cases in which the content is split across multiple sets of servers, such as in an entry-balanced environment or in proxy configurations with different branches on different servers.

The LDAP SDK uniqueness request control can be used for enforcing uniqueness on a per-request basis. See the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control. See the ASN.1 specification to implement support for it in other APIs.

#### Note:

Consider the following points about pre-commit validation versus post-commit validation:

- Pre-commit validation is the only mechanism that can try to prevent conflicts. It increases the processing time for **add**, **modify**, or **modifyDN** operations because the necessary searches to look for conflicts happen before the update request is forwarded to any backend servers.
- Post-commit validation only sends administrative alerts about conflicts that already exist in the data. It can't prevent conflicts, but can allow you to deal with them in a timely manner. It also operates during the post-response phase, so it does not affect the processing time for the associated write operation.

In most cases, pre-commit validation should be sufficient to prevent conflicts. However, you should periodically run the **identify-unique-attribute-conflicts** tool to find any conflicts that might have arisen.

#### Note:

If you want to mitigate any risks due to conflicts being generated by concurrent operations in different servers, then using both **pre-commit-validation** and **post-commit-validation** properties provides the best combination of preventing most conflicts in advance, and detecting and alerting about conflicts that arise from concurrent writes.

## Configuring the Globally Unique Attribute plugin

About this task

The following example shows how to configure the Globally Unique Attribute plugin. The example defines an attribute set consisting of the `telephoneNumber` and `mobile` attributes within the `test-view` subtree view.

The `multiple-attribute-behavior` property determines the scope of how attributes might differ among entries and is the same property for the Directory Server plugin. The property is set to `unique-across-all-attributes-including-in-same-entry`, which indicates that the `telephone` and `mobile` attributes must be unique throughout the subtree view, even within an entry.

The `pre-commit-validation` property ensures that the Globally Unique Attribute Plugin performs one or more searches to determine whether any entries conflict with the change, such as **add**, **modify**, or **modifyDN**. If a conflict is detected, the change request is rejected.

#### Note:

You should index all configured attributes for equality in all backend servers.

## Steps

- To create the Globally Unique Attribute plugin, run **dsconfig** with the `create-plugin` option.

Example:

```
$ bin/dsconfig create-plugin \
  --plugin-name "Globally-Unique telephone and mobile" \
  --type globally-unique-attribute \
  --set enabled:true \
  --set type:telephoneNumber \
  --set type:mobile \
  --set subtree-view:test-view \
  --set multiple-attribute-behavior:unique-across-all-attributes-
including-in-same-entry \
  --set pre-commit-validation:all-available-backend-servers
```

## Configuring the Global Referential Integrity plugin

PingDirectoryProxy Server supports a global referential integrity plugin mechanism that maintains distinguished name (DN) references from a specified set of attributes to entries that exist in the server, such as between the members values of a static group and the corresponding user entries.

The plugin intercepts `delete` and `modifyDN` operations and updates any references to the target entry. For a `delete` operation, any references to the target entry are removed. For `modifyDN` operations, any references to the target entry are updated to reflect the new DN of the entry.

The plugin is similar to the Directory Server Referential Integrity plugin but does not have an asynchronous mode. When enabled on the Directory Server, the client response is delayed until the referential integrity processing is complete.

For Directory Server deployments not using entry balancing and using Directory Server external servers, use the Referential Integrity plugin on the Directory Server.

### Note:

An equality index must be defined on all attributes referenced within the Global Referential Integrity plugin across all external servers.

## Sample Global Referential Integrity plugin

### Steps

- To configure the Global Referential Integrity plugin, run **dsconfig** with the `create-plugin` option.

### Note:

Any attributes for which referential integrity should be maintained should have values that are DNs and should be indexed for equality in all backend servers.

Example:

In this example, the plugin ensures that the `member`, `uniqueMember`, and `manager` attributes maintain their DN references in the defined subtree views.

```
$ bin/dsconfig create-plugin \
  --plugin-name "Global Referential Integrity" \
  --type global-referential-integrity \
  --set "enabled:true" \
  --set "attribute-type:member" \
```

```
--set "attribute-type:uniqueMember" \
--set "attribute-type:manager" \
--set "subtree-view:employee-view" \
--set "subtree-view:groups-view"
```

## Configuring an Active Directory Server back-end

To configure an Active Directory server backend, run a `dsconfig` script.

The following settings are required for an Active Directory server:

- `verify-credentials-method:bind-on-existing-connections` and `authorization-method:rebind`

### Note:

Active Directory does not support `proxy-as`. Existing connections must be reused.

- `set max-connection-age:5m` and `health-check-pooled-connections:true`

### Note:

Active Directory drops idle connections after 15 minutes. The proxy must refresh the connection pool in a shorter interval.

## Example

The following example `dsconfig` script configures two Active Directory servers, AD-SRV1 and AD-SRV2.

```
dsconfig set-ldap-health-check-prop --check-name "Consume Admin Alerts" \
--reset use-for-all-servers

dsconfig set-trust-manager-provider-prop \
--provider-name "Blind Trust" \
--set enabled:true

dsconfig create-external-server --server-name AD-SRV1 --type active-
directory \
--set server-host-name:example.server \
--set server-port:636 \
--set bind-dn:cn=ProxyUser,dc=dom-ad2,dc=local \
--set password:password --set connection-security:ssl \
--set key-manager-provider:Null --set trust-manager-provider:"Blind Trust"
\
--set authorization-method:rebind \
--set verify-credentials-method:bind-on-existing-connections \
--set max-connection-age:5m \
--set health-check-pooled-connections:true

dsconfig create-external-server --server-name AD-SRV2 --type active-
directory \
--set server-host-name:example.server \
--set server-port:636 \
--set bind-dn:cn=ProxyUser,dc=dom-ad2,dc=local \
--set password:password \
--set connection-security:ssl \
--set key-manager-provider:Null \
--set trust-manager-provider:"Blind Trust" \
--set authorization-method:rebind \
--set verify-credentials-method:bind-on-existing-connections \
--set max-connection-age:5m \
```

```

--set health-check-pooled-connections:true

dsconfig create-load-balancing-algorithm --algorithm-name AD-LBA \
--type fewest-operations \
--set enabled:true \
--set backend-server:AD-SRV1 \
--set backend-server:AD-SRV2 \
--set use-location:false

dsconfig create-request-processor --processor-name AD-Proxy --type proxying \
--set load-balancing-algorithm:AD-LBA

dsconfig create-subtree-view --view-name AD-View \
--set base-dn:dc=dom-ad2,dc=local \
--set request-processor:AD-Proxy

dsconfig set-client-connection-policy-prop --policy-name default \
--set subtree-view:AD-View

```

## Setting up SSO to PingDirectory from PingOne

To set up single sign-on (SSO) access from the administrative console home page to PingDirectory, configure PingOne and test the sign-on experience.

Before you begin

Ensure that you have:

- A PingDirectory server that accepts LDAPS connections  
This server will host the admin console that is being configured for SSO.
- A PingOne account

For more information, see [Getting Started with PingOne](#).

### Tip:

You can use groups to organize user identities, as explained in [Groups](#). You can also set access to applications, as explained in [Application access control](#).

About this task

During this setup:

- Step 2 sets up a matching user between PingOne and the PingDirectory environments that allows the server's All Admin Users identity mapper to map the PingOne ID token to a Directory Server LDAP user.
- Steps 3-8 set up the OpenID Connect (OIDC) client as described in [Single sign-on with the PingDirectoryServer administrative console](#) on page 539.
- Steps 9-11 configure both the administrative console's configuration requirements (except for the `ldap.server` property) and the PingDirectory server's configuration requirements.

### Note:

These configuration properties are outlined in more detail in [Single sign-on with the PingDirectoryServer administrative console](#) on page 539.

To set up SSO to the PingDirectory administrative console from PingOne:

## Steps

1. From the admin console home page, add PingOne and PingDirectory:  
Choose from:

- To add a new environment for PingOne SSO and PingDirectory:
  - a. On the PingOne console home page, click **Add Environment**.
  - b. Select **Customer solution**, and then click **Next**.
  - c. Click **Next**.
  - d. Enter an **Environment Name** and **Description**, then in the labeled lists, select an **Environment Type**, **Region**, and **License**.
  - e. Click **Finish**.

PingOne SSO, PingOne Risk, PingOne Verify, and PingOne MFA are automatically deployed.

- f. On the PingOne console home page, in the **Your Environments** list, select your new environment, and then click the **+** icon.
- g. Click **Add** next to **PingDirectory**.

### Note:

Services that have been already added have a green **check mark** icon next to the service name instead of **+ Add**.

- h. Click **Finish**.
- To add PingOne SSO and PingDirectory to an existing environment:
    - a. On the PingOne console home page, in the **Your Environments** list, select the environment, and then click the **+** icon.
    - b. Click **Add** next to **PingOne SSO** and **PingDirectory**.

### Note:

Services that have been already added have a green **check mark** icon next to the service name instead of **+ Add**.

- c. Click **Finish**.
- a. Click **Add Admin UI Link**, and in the **Enter Admin URL** field, enter `https://<hostname>:<port>/console/login`, replacing the bracketed variables with the PingDirectory server's hostname and HTTP port.

### Tip:

You can specify the LDAP server to bind to using the query parameters `ldap-hostname` and `ldaps-port` when the administrative console is configured for SSO. By binding to the LDAP server, you can use a single console instance to administer multiple PingDirectory servers. An

LDAPS scheme is always assumed because an encrypted connection is always required for SSO. Using these parameters, you can specify the URL as follows.

```
https://<hostname>:<port>/console?ldap-hostname=<my-ldap-host>&ldaps-port=<my-ldaps-port>
```

- b. Click **Save**.
2. To configure the matching administrator accounts for PingOne and the PingDirectory server, go to the PingOne dashboard for the environment that will be used with the PingDirectory server and repeat the following steps for each PingOne user for whom you want to enable SSO:
  - a. On the admin console home page, select the appropriate environment and click the **PingOne** icon.
  - b. In PingOne, go to **Identities**.
  - c. Select the administrative user you want to configure and click the **Expand** icon.
  - d. Run the following **dsconfig** command and replace the bracketed fields with the values of the administrative user.

```
~/<pd_install>/dsconfig create-root-dn-user --user-name <Username> \
  --set first-name:<Given Name> \
  --set last-name:<Family Name>
```

3. Register the admin console with PingOne.
  - a. Go to [Add an application - Web application](#) and follow the instructions in the **Add an OIDC application** subsection.
  - b. Enter the application properties, as shown in this table.

| Property          | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Name  | PingDirectory Administrative Console                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description       | Application for the PingDirectory Administrative Console                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Redirect URLs     | https://<hostname>:<port>/console/oidc/cb<br><br><div style="border: 1px solid #ccc; padding: 5px;">  <b>Note:</b><br/>           Replace the bracketed values in <b>Redirect URLs</b> with your PingDirectory server's hostname and HTTP port. To find the port, run the <b>status</b> command from the <code>bin</code> directory.           <pre>0.0.0.0:11443 : HTTPS      : Enabled  :   HTTPS Connection Handler</pre> </div> |
| Attribute Mapping | 'Username' = 'sub'                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

 **Note:**

No OIDC scopes are required for PingOne to grant access to the PingDirectory console.

4. Select the newly-created **PingDirectory Administrative Console** application in the **Applications** list, and go to the **Configuration** tab.

- To edit the listed configuration properties, click the **Pencil** icon.

Edit the configuration properties using the values in this table.

| Property                                    | Value                                           |
|---------------------------------------------|-------------------------------------------------|
| <b>Response Type</b>                        | Select the <b>Code</b> check box.               |
| <b>Grant Type</b>                           | Select the <b>Authorization Code</b> check box. |
| <b>Token Endpoint Authentication Method</b> | Click <b>Client Secret Basic</b> .              |

**Note:**

For more information about updating the properties of your new application, see [Edit an application - OIDC](#) in the *PingOne Administration Guide*.

- Click **Save**.
- Click the toggle to enable user access to the application.
- On the **Configuration** tab, record the values for these application properties to use in step 10:
  - Issuer**
  - Client ID**
  - Client Secret**
- Create a copy of the `PingDirectory/config/sample-dsconfig-batch-files/enable-pingone-admin-console-sso.dsconfig` file, leaving the source file as-is.
- Open the copy of the file and replace the bracketed values with the values from step 8.

```
# Create an ID token validator suitable for verifying ID tokens generated
# by the PingOne service. The "All Admin Users" identity mapper will be
# used
# to match users that authenticate with PingOne to either root DN users
# or
# topology admin users defined in the server configuration.
dsconfig create-id-token-validator \
--validator-name "PingOne ID Token Validator" \
--type ping-one \
--set enabled:true \
--set "identity-mapper:All Admin Users" \
--set evaluation-order-index:1 \
--set issuer-url:[PING_ONE_APPLICATION_ISSUER_URL]

[...]

# Configure the Administrative Console with your application's client
# credentials and issuer URI.
dsconfig set-web-application-extension-prop \
--extension-name Console \
--set sso-enabled:true \
--set oidc-client-id:[PING_ONE_APPLICATION_CLIENT_ID] \
--set oidc-client-secret:[PING_ONE_APPLICATION_CLIENT_SECRET] \
--set oidc-issuer-url:[PING_ONE_APPLICATION_ISSUER_URL]
```

- Run the file using the following command.

```
dsconfig --batch-file \
  enable-pingone-admin-console-sso-copy.dsconfig \
  --no-prompt
```

12. Select the link to the PingDirectory server from the PingOne solutions home page.

Result:

A PingOne sign-on page opens.

13. Sign on using the administrative user credentials.

Result:

The PingDirectory Server administrative console home page opens.

## Managing Access Control

---

The PingDirectory Server provides a fine-grained access control model to ensure that users can access the information they need, but are prevented from accessing information that they shouldn't be allowed to see.

The access control model also includes a privilege subsystem that provides even greater flexibility and protection in many key areas.

This section presents the access control model and how it applies to the Directory Server and includes the following topics:

- [Overview of access control](#) on page 718
- [Access token validators](#) on page 730
- [Working with targets](#) on page 737
- [Examples of common access control rules](#) on page 742
- [Validating ACIs before migrating data](#) on page 744
- [Migrating ACIs from Oracle to PingDirectory Server](#) on page 746
- [Working with privileges](#) on page 749
- [Working with proxied authorization](#) on page 754
- [Working with parameterized ACIs](#) on page 763
- [\\$attr.attrName macro](#) on page 764

### Overview of access control

The access control model uses access control instructions (ACIs) to determine what a user or a group of users can do with a set of entries, down to the attribute level.

The ACIs are stored in the `aci` operational attribute. The operational attribute can appear on any entry and affects the entry or any subentries within that branch of the directory information tree (DIT).

Access control instructions specify four items:

#### Resources

Resources are the targeted items or objects that specifies the set of entries and operations to which the access control instruction applies. For example, you can specify access to certain attributes, such as the `cn` or `userPassword` password.

#### Name

Name is the descriptive label for each ACI. Typically, you have multiple ACIs for a given branch of your DIT. The access control name helps describe its purpose. For example, you can configure an ACI labeled "ACI to grant full access to administrators."

#### Clients

Clients are the users or entities to which you grant or deny access. You can specify individual users or groups of users using an LDAP URL. For example, you can specify a group of administrators using the LDAP URL: `groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com."`

## Rights

Rights are permissions granted to users or client applications. You can grant or deny access to certain branches or operations. For example, you can grant `read` or `write` permission to a `telephoneNumber` attribute.

### Key access control features

The PingDirectory Server provides important access control features that provide added security for the Directory Server's entries.

#### Improved validation and security

The Directory Server provides an access control model with strong validation to help ensure that invalid access control instructions (ACIs) are not allowed into the server.

The Directory Server ensures that all access control rules (ACRs) added over LDAP are valid and can be fully parsed. The Directory Server rejects any operation that attempts to store one or more invalid ACIs. It also validates ACIs contained in data imported from an LDIF file. The Directory Server rejects any entry containing a malformed `aci` value.

As an additional level of security, the Directory Server examines and validates all ACIs stored in the data whenever a backend is brought online. If the server finds any malformed ACIs in the backend, it generates an administrative alert to notify administrators of the problem and places itself in lockdown mode. While in lockdown mode, the server only allows requests from users who have the `lockdown-mode` privilege. This action allows administrators to correct the malformed ACI while ensuring that no sensitive data is inadvertently exposed because of an ACI not being enforced. When the problem has been corrected, the administrator can use the `leave-lockdown-mode` tool or restart the server to allow it to resume normal operation.

### Global ACIs

Global ACIs are a set of ACIs that apply to entries anywhere in the server or scoped to only apply to a specific set of entries.

Global ACIs work in conjunction with ACRs stored in user data and provide a convenient way to define ACIs that span disparate portions of the directory information tree (DIT).

In the PingDirectory Server, global ACIs are defined within the server configuration, in the `global-aci` property of the configuration object for the access control handler. To view and manage global ACIs, use configuration tools like `dsconfig` and the administrative console.

The global ACIs available by default in the PingDirectory Server include:

- Allow anyone, including unauthenticated users, to access key attributes of the root DSA-specific entry (DSE), including:
  - `namingContexts`
  - `subschemaSubentry`
  - `supportedAuthPasswordSchemes`
  - `supportedControl`
  - `supportedExtension`
  - `supportedFeatures`
  - `supportedLDAPVersion`
  - `supportedSASLMechanisms`
  - `vendorName`
  - `vendorVersion`

- Allow anyone, including unauthenticated users, to access key attributes of the subschema subentry, including:
  - `attributeTypes`
  - `dITContentRules`
  - `dITStructureRules`
  - `ldapSyntaxes`
  - `matchingRules`
  - `matchingRuleUse`
  - `nameForms`
  - `objectClasses`
- Allow anyone, including unauthenticated users, to include the following controls in requests made to the server:
  - Authorization identity request
  - Manage DSA IT
  - Password policy
  - Real attributes only
  - Virtual attributes only
- Allow anyone, including unauthenticated users, to request the following extended operations:
  - Get symmetric key
  - Password modify request
  - Password policy state
  - StartTLS
  - Who Am I?

### Access controls for public or private backends

Depending on their intended purpose, the PingDirectory Server classifies backends as either public or private.

A backend is private if one of the following applies:

- Its content is generated by the Directory Server itself, such as the root DSE, monitor, and backup backends.
- It is used in the operation of the server, such as the configuration, schema, task, and trust store backends.
- Its content is maintained by the server, such as the LDAP changelog backend.

A public backend is intended to hold user-defined content, such as user accounts, groups, application data, and device data.

The PingDirectory Server access control model also supports the distinction between public backends and private backends. Many private backends do not allow writes of any kind from clients, and some of the private backends that do allow writes only allow changes to a specific set of attributes. As a result, you should define any ACI intended to permit or restrict access to information in private backends as global ACIs, rather than attempting to add those instructions to the data for that private backend.

### General format of the access control rules

Access control instructions (ACIs) are represented as strings that are applied to one or more entries within the directory information tree (DIT).

Typically, an ACI is placed on a subtree, such as `dc=example,dc=com`, and applies to that base entry and all entries below it in the tree. The Directory Server iterates through the DIT to compile the access control rules into an internally-used list of denied and allowed targets and their permissible operations. When a client application, such as `ldapsearch`, enters a request, the Directory Server checks that the user who binds with the server has the necessary access rights to the requested search targets. ACIs are cumulatively applied so that a user who has an ACI at an entry can also have other access rights available

if ACIs are defined higher in the DIT and are applicable to the user. In most environments, ACIs are defined at the root of a main branch or a subtree, and not on individual entries unless absolutely required.

## ACI

An access control rule has the following basic syntax.

```
aci : (targets) (version 3.0; aci "name";
      permissions
      bind rules
      ;)
```

## Access Control Components

| Access Control Component | Description                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| targets                  | Specifies the set of entries and attributes to which an access control rule applies. Use the following syntax: (target keyword =    != expression)                    |
| name                     | Specifies the name of the ACI                                                                                                                                         |
| permissions              | Specifies the type of operations to which an access control rule might apply. Use the following syntax: allow  deny (permission)                                      |
| bind rules               | Specifies the criteria that indicate whether an access control rule should apply to a given requester. Use the following syntax: bind rule keyword =   != expression; |
|                          |  <b>Note:</b><br>The bind rule syntax requires that it be terminated with a ; .    |

## Summary of access control keywords

This section provides an overview of the supported keywords in the PingDirectory Server access control implementation.

### Targets

A target expression specifies the set of entries and attributes to which an access control rule applies.

A target expression has three components:

#### Keyword

The keyword specifies the type of target element.

#### Expression

The expression specifies the items that are targeted by the access control rule.

## Operator

The operator is either equal, =, or not-equal, !=.

### Note:

You cannot use the != operator with the `targetattrfilters` and `targetscope` keywords.

For specific examples of each target keyword, see [Working with Targets](#).

```
(keyword [=|!=]expression)
```

You can use the following keywords in the target portion of ACIs:

### Summary of Access Control Target Keywords

| Target Keyword                 | Description                                                                                                                                                                  | Wildcards |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| <code>extop</code>             | Specifies the OIDs for any extended operations to which the access control rule should apply.                                                                                | No        |
| <code>target</code>            | Specifies the set of entries, identified using LDAP URLs, to which the access control rule applies.                                                                          | Yes       |
| <code>targetattrfilters</code> | Identifies specific attribute values based on filters that can be added to or removed from entries to which the access control rule applies.                                 | Yes       |
| <code>targetattr</code>        | Specifies the set of attributes to which the access control rule should apply.                                                                                               | Yes       |
| <code>targetcontrol</code>     | Specifies the OIDs for any request controls to which the access control rule should apply.                                                                                   | No        |
| <code>targetfilter</code>      | Specifies one or more search filters that can be used to indicate the set of entries to which the access control should apply.                                               | Yes       |
| <code>targetscope</code>       | Specifies the scope of entries, relative to the defined target entries or the entry containing the ACI if there is no target, to which the access control rule should apply. | No        |

### Permissions

Permissions indicate the types of operations to which an access control rule could apply.

You can specify if the user or group of users are allowed or not allowed to carry out a specific operation. For example, you can grant read access to targeted entries using the `allow (read)` permission. You can also deny access to the target entries and attributes using the `deny (read)` permission. You can list multiple permissions as required in the ACI.

```
allow (permission1
.../
```

```
permission2
,...permissionN)
```

```
deny (permission1
     ...,
     permission2
     ,...permissionN)
```

You can use the following keywords in the permissions portion of ACIs.

| Keyword   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| add       | Indicates that the access control applies to <code>add</code> operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| compare   | Indicates that the access control applies to <code>compare</code> operations and to search operations with a base-level scope that targets a single entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| delete    | Indicates that the access control applies to <code>delete</code> operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| export    | Indicates that the access control applies only to <code>modify DN</code> operations in which an entry is moved below a different parent by specifying a new superior distinguished name (DN) in the <code>modify DN</code> request. The requestor must have the <code>export</code> permission for operations against the entry's original DN. The requestor must have the <code>import</code> permission for operations against the entry's new superior DN.<br><br>For <code>modify DN</code> operations that alter the relative distinguished name (RDN) of an entry but keeps it below the same parent, such as renaming the entry, only the <code>write</code> permission is required. This is true regardless of whether the entry being renamed is a leaf entry or has subordinate entries. |
| import    | See the description for the <code>export</code> permission.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| proxy     | Indicates that the access control rule applies to operations that attempt to use an alternate authorization identity, such as operations that include a proxied authorization request control, an intermediate client request control with an alternate authorization identity, or a client that has authenticated with a Simple Authentication and Security Layer (SASL) mechanism that allows an alternate authorization identity to be specified.                                                                                                                                                                                                                                                                                                                                               |
| read      | Indicates that the access control rule applies to search result entries returned by the server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| search    | Indicates that the access control rule applies to <code>search</code> operations with a non-base scope.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| selfwrite | Indicates that the access control rule applies to operations in which a user attempts to add or remove their own DN to the values for an attribute, such as users adding or removing themselves from groups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| write     | Indicates that the access control rule applies to <code>modify</code> and <code>modify DN</code> operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| all       | An aggregate permission that includes all other permissions except <code>import</code> , <code>export</code> , and <code>proxy</code> . This is equivalent to providing a permission of <code>add</code> , <code>compare</code> , <code>delete</code> , <code>read</code> , <code>search</code> , <code>selfwrite</code> , and <code>write</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Bind rules**

The bind rules indicate whether an access control rule should apply to a given requester.

The syntax for the target keyword has three components:

**Keyword**

The keyword specifies the type of target element.

**Expression**

The expression specifies the items that are targeted by the access control rule.

**Operator**

The operator is either equal, =, or not-equal, !=.

You must use the semicolon delimiter symbol, ;, after the end of the final bind rule.

```
keyword [=||!= ] expression;
```

For added access control precision, you can combine multiple bind rules using the Boolean operations AND, OR, and NOT. The standard Boolean rules for evaluation apply:

- Innermost to outer parentheses first
- Left to right expressions
- NOT before AND or OR

For example, an access control instruction (ACI) with the following bind rule targets all users who are not `uid=admin,dc=example,dc=com` and use simple authentication.

```
(userdn!="ldap:///uid=admin,dc=example,dc=com" and authmethod="simple");
```

The following bind rule targets users that are `uid=admin,dc=example,dc=com` and authenticate using Simple Authentication and Security Layer (SASL) EXTERNAL or access the server from a loopback interface.

```
(userdn="ldap:///uid=admin,dc=example,dc=com and (authmethod="SSL" or ip="127.0.0.1"));
```

You can use the following keywords in the bind rule portion of ACIs.

| Bind Rule Keyword | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| authmethod        | <p>Indicates that the requester's authentication method is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.</p> <p>Use the syntax <code>authmethod = <i>method</i></code> where <i>method</i> is one of the following representations:</p> <ul style="list-style-type: none"> <li>▪ <code>none</code></li> <li>▪ <code>simple</code> Indicates that the client is authenticated to the server using a bind DN and password.</li> <li>▪ <code>ssl</code> Indicates that the client is authenticated with an SSL/TLS certificate (for example, via SASL EXTERNAL), and not just over a secure connection to the server.</li> <li>▪ <code>sasl {<i>sasl_mechanism</i>}</code>. Indicates that the client is authenticated to the server using a specified SASL mechanism.</li> </ul> <p>The following example allows users who authenticate with an SSL/TLS certificate (for example, using SASL EXTERNAL) to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (userdn="ldap:///self" and authmethod="ssl");)</pre> |
| dayofweek         | <p>Indicates that the day of the week is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.</p> <p>You can separate multiple day of week values by commas. Use the following syntax.</p> <pre>dayofweek = <i>day1</i>, <i>day2</i>, ...</pre> <p><i>day</i> is one of the following:</p> <ul style="list-style-type: none"> <li>▪ <code>sun</code></li> <li>▪ <code>mon</code></li> <li>▪ <code>tues</code></li> <li>▪ <code>wed</code></li> <li>▪ <code>thu</code></li> <li>▪ <code>fri</code></li> <li>▪ <code>sat</code></li> </ul> <p>The following example allows users who authenticate on weekdays with an SSL/TLS certificate, such as SASL EXTERNAL, to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (dayofweek!="sun,sat" and userdn="ldap:/// self" and authmethod="ssl");)</pre>                                                                                                                                                                                                                   |

| Bind Rule Keyword | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dns               | <p>Indicates that the requester's DNS-resolvable host name is taken into account when determining whether the access control rule should apply to an operation. You can use wildcards in this expression.</p> <p>You can separate multiple DNS patterns by commas. ## Access token validators

Access token validators verify the tokens that HTTP client applications submit when they request access to protected resources and associate each token with an identity stored in the directory server.

To authenticate to PingDirectory Server's HTTP services, clients use OAuth 2 bearer token authentication to present an access token in the HTTP Authorization request header.

To process the incoming access tokens, PingDirectory Server uses access token validators, which determine whether to accept an access token and translate it into a set of properties, called claims, which PingDirectory Server's HTTP services use to make access control decisions.

Most access tokens identify a user as its subject using the `sub` claim. Access token validators can retrieve the token subject's attributes from the directory using an identity mapper, which correlates the access token subject to an LDAP entry.

Access token validators are used by the following services:

- Directory REST API
- SCIM 2
- Delegated Admin
- Consent API

You can configure PingDirectory Server to accept access tokens provided by LDAP clients using the OAUTHBEARER Simple Authentication and Security Layer (SASL) authentication method.

## About access token validator processing

You can configure any number of access token validators for PingDirectory Server.

Each access token validator has an evaluation order index, which is an integer that determines the processing priority when multiple access token validators are configured. Lower values are processed before higher values.

### Note:

Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by PingDirectory Server.

## Processing steps

1. If an incoming HTTP request contains an access token, the token is sent to the access token validator with the lowest evaluation order index.
2. The access token validator validates the access token. Validation logic varies by access token validator type, but the validator generally verifies the following information:
  - A trusted source issued the token.
  - The token is not expired.
3. If the access token contains a subject, the access token validator uses its identity mapper to find a matching LDAP entry.
4. If the access token validator is unable to validate the access token, it passes the token to the access token validator with the next lowest evaluation order index, and the previous two steps are repeated.
5. HTTP request processing continues, and the policy request is sent to the HTTP service, such as the Directory REST API, for further evaluation.
6. Using either the access token claims parsed by the access token validator or the LDAP entry found by the identity mapper, the HTTP service determines whether the request should be accepted and which access control rules should be applied. This access control behavior varies by each HTTP service.

## Access token validator types

PingDirectory Server works with a variety of access token validators.

### Configuring a sample PingFederate access token validator

To verify the access tokens that a PingFederate authorization server issues, the PingFederate access token validator uses HTTP to submit the tokens to PingFederate Server's token introspection endpoint.

## Before you begin

Before using a PingFederate access token validator, create a client that represents the access token validator in the PingFederate configuration. This client must use the Access Token Validation grant type.

## About this task

This step allows the authorization server to determine whether a token is valid.

### Note:

Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by PingDirectory Server.

Because this step requires an outgoing HTTP request to the authorization server, the PingFederate access token validator might perform slower than other access token validator types. The validation result is guaranteed to be current, which is an important consideration if the authorization server permits the revocation of access tokens.

## Steps

1. In PingFederate, create a client with the following properties:
  - Client ID: Ping Identity
  - Client authentication: Client Secret
  - Allowed grant types: Access Token Validation
2. Take note of the client secret and use the PingDirectory Server's `dsconfig` command to create an access token validator, as shown.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com
# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031
# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "PingFederate Access Token Validator" \
  --type ping-federate \
  --set enabled:true \
  --set "authorization-server:PingFederate External Server" \
  --set client-id:PingDataGovernance \
  --set "client-secret:<client secret>" \
  --set evaluation-order-index:2000 \
  --set "identity-mapper:User ID Identity Mapper"
```

3. Replace `<client secret>` with the client secret value generated by the PingFederate client.

### JWT access token validator

The JWT access token validator verifies access tokens that are encoded in JSON Web Token (JWT) format, which can be signed in JSON web signature (JWS) format or signed and encrypted in JSON web encryption (JWE) format.

The JWT access token validator inspects the JWT token without presenting it to an authorization server for validation. Because the JWT access token validator does not make a token introspection request for every access token that it processes, it performs faster than the PingFederate access token validator. The access token is self-validated, so the JWT access token validator cannot determine whether the token has been revoked.

### Supported JWS/JWE features

For signed tokens, the JWT access token validator supports the following JWT web algorithm (JWA) types:

- RS256
- RS384
- RS512
- ES256
- ES384
- ES512

For encrypted tokens, the JWT access token validator supports the following key-encryption algorithms:

- RSA-OAEP

- ECDH-ES
- ECDH-ES+A128KW
- ECDH-ES+A192KW
- ECDH-ES+A256KW

For encrypted tokens, the JWT access token validator supports the following content-encryption algorithms:

- A128CBC-HS256
- A192CBC-HS384
- A256CBC-HS512

The JWT access token validator configuration defines three allow lists for the JWS/JWE signing and encryption algorithms that it accepts. Customize these allow lists to reflect only the signing and encryption algorithms used by your access token issuer and no others. This minimizes the access token validator's security threat surface.

Configure these allow lists using the following configuration properties:

`allowed-signing-algorithm`

Specifies the signing algorithms that the access token validator accepts.

`allowed-key-encryption-algorithm`

Specifies the key-encryption algorithms that the access token validator accepts.

`allowed-content-encryption-algorithm`

Specifies the content-encryption algorithms that the access token validator accepts.

#### *Handling signed tokens*

The token issuer must cryptographically sign all access tokens that the JSON web token (JWT) access token validator handles. The JWT access token validator validates a token's signature using a public signing key provided by the issuer.

#### Steps

- Configure the JWT access token validator with the issuer's public signing key:  
Choose from:
  - Store the public key as a trusted certificate in PingDirectory Server's local configuration using the `trusted-certificate` property.
  - Provide the issuer's JSON Web Key Set (JWKS) endpoint using the `jwtks-endpoint-path` property.

#### **Note:**

The JWT access token validator then retrieves the issuer's public keys when it initializes. This method ensures that the JWT access token validator uses updated copies of the issuer's public keys.

**Example:** Use a locally configured trusted certificate

The following example configures a JWT access token validator to use a locally stored public signing certificate to validate access token signatures. The signing certificate is assumed to have been obtained out-of-band and must be a PEM-encoded X.509v3 certificate.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
```

```

--type exact-match \
--set enabled:true \
--set match-attribute:uid \
--set match-base-dn:ou=people,dc=example,dc=com

# Add the public signing certificate to the server configuration
dsconfig create-trusted-certificate \
  --certificate-name "JWT Signing Certificate" \
  --set "certificate</path/to/signing-certificate.pem"

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "JWT Access Token Validator" \
  --type jwt \
  --set enabled:true \
  --set evaluation-order-index:1000 \
  --set allowed-signing-algorithm:RS256 \
  --set "trusted-certificate:JWT Signing Certificate"
  --set "identity-mapper:User ID Identity Mapper"

```

#### Example: Use the issuer's JWKS endpoint

The following example configures a JWT access token validator to retrieve public keys from a PingFederate authorization server's JWKS endpoint.

```

# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "JWT Access Token Validator" \
  --type jwt \
  --set enabled:true \
  --set evaluation-order-index:1000 \
  --set allowed-signing-algorithm:RS256 \
  --set "authorization-server:PingFederate External Server" \
  --set jwks-endpoint-path:/ext/oauth/jwks
  --set "identity-mapper:User ID Identity Mapper"

```

#### *Handling encrypted tokens*

Configure the JSON web token (JWT) access token validator to accept encrypted access tokens. You must configure the access token validator with a private and public key pair and provide the public key to the token issuer.

#### Steps

1. Create an encryption key pair.
2. Create the JWT access token validator.

- Export the public encryption key from Server and provide it to your token issuer.

Choose from:

- To copy the public key to a file, run **dsconfig**.
- Copy the value of the key pair's `certificate-chain` property in the administrative console.

**Note:**

Without this public encryption key, the issuer cannot encrypt tokens that can be decrypted by the JWT access token validator.

### Example

The following example configures a JWT access token validator to handle access tokens signed and encrypted using elliptic curve algorithms.

For RSA signing and encryption algorithms, the configuration is similar, but you choose different values for the `allowed-signing-algorithm` and `allowed-encryption-algorithm` properties.

- Create an encryption key pair.

```
# Create an encryption key pair
dsconfig create-key-pair \
  --pair-name "JWT Elliptic Curve Encryption Key Pair" \
  --set key-algorithm:EC_256
```

- Create the JWT access token validator.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "JWT Access Token Validator" \
  --type jwt \
  --set enabled:true \
  --set evaluation-order-index:1000 \
  --set allowed-signing-algorithm:ES256 \
  --set "authorization-server:PingFederate External Server" \
  --set jwks-endpoint-path:/ext/oauth/jwks \
  --set "encryption-key-pair:JWT Elliptic Curve Encryption Key Pair" \
  --set allowed-key-encryption-algorithm:ECDH_ES
  --set "identity-mapper:User ID Identity Mapper"
```

- Export the public encryption key from PingDataGovernance Server and provide it to your token issuer.

The following command copies the key to a file.

```
dsconfig get-key-pair-prop \
  --pair-name "JWT Elliptic Curve Encryption Key Pair" \
  --property certificate-chain \
```

```
--no-prompt \  
--script-friendly > jwt-public-encryption-key.pem
```

### Mock access token validator

A mock access token validator is a special access token validator type for development or testing purposes.

A mock access token validator accepts arbitrary tokens without validating whether a trusted source issued them. This allows you to make bearer token-authenticated requests without first setting up an authorization server.

Mock access tokens are formatted as plain-text JSON objects using standard JSON web token (JWT) claims.

Always provide the boolean `active` claim when creating a mock token. If this value is `true`, the token is accepted. If this value is `false`, the token is rejected.

If the `sub` claim is provided, a token owner lookup populates the `TokenOwner` policy request attribute as with the other access token validator types.

The following example cURL command shows a mock access token in an HTTP request.

```
curl -k -X GET https://localhost:8443/scim/v2/Me -H 'Authorization:  
Bearer {"active": true, "sub":"user.3", "scope":"email profile",  
"client":"client1"}'
```

#### Important:

Never use mock access token validators in a production environment because they do not verify whether a trusted source issued an access token.

### Example

#### Sample configuration

The configuration for a mock access token validator resembles the configuration for a JWT access token validator. However, the JSON web signature (JWS) signatures require no configuration because mock tokens are not authenticated.

```
# Create an identity mapper that expects the token subject to be a uid  
dsconfig create-identity-mapper \  
  --type exact-match \  
  --set enabled:true \  
  --set match-attribute:uid \  
  --set match-base-dn:ou=people,dc=example,dc=com  
  
# Create the Access Token Validator  
dsconfig create-access-token-validator \  
  --validator-name "Mock Access Token Validator" \  
  --type mock --set enabled:true \  
  --set evaluation-order-index:9999  
  --set "identity-mapper:User ID Identity Mapper"
```

### Third-party access token validator

To create custom access token validators, use the Server SDK.

## Working with targets

The following section presents a detailed look and examples of the target access control instruction (ACI) keywords:

- `target`
- `targetattr`
- `targetfilter`
- `targattrfilters`
- `targetscope`
- `targetcontrol`
- `extop`

### target

The `target` keyword indicates that the ACI should apply to one or more entries at or below the specified distinguished name (DN).

The target DN must be equal or subordinate to the DN of the entry in which the ACI is placed. For example, if you place the ACI at the root of `ou=People,dc=example,dc=com`, you can target the DN, `uid=user.1,ou=People,dc=example,dc=com`, within your ACI rule. The DN must meet the string representation specification of distinguished names, outlined in RFC 4514, and requires that special characters be properly escaped.

The `target` clause has the following format, where *DN* is the distinguished name of the entry or branch:

```
(target = ldap:///<DN>)
```

For example, to target a specific entry, use a clause like the following.

```
(target = ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

#### Note:

In most cases, you should avoid specifying a target DN. Instead, define the ACI in that entry and omit the `target` element altogether.

For example, although you can have `(target="ldap:///uid=john.doe,ou=People,dc=example,dc=com)` in any of the `dc=example,dc=com` or `ou=People` entries, you should define it in the `uid=john.doe` entry and not explicitly include the `target` element.

The expression allows for the not equal operator (`!=`) to indicate that all entries within the scope of the given branch that do not match the expression be targeted for the ACI. The following expression targets all entries within the subtree that do not match `uid=john.doe`.

```
(target != ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

The `target` keyword also supports the use of asterisk (`*`) characters as wildcards to match elements within the distinguished name.

- The following target expression matches all entries that contain and begin with `john.d`.

```
(target = ldap:///uid=john.d*,ou=People,dc=example,dc=com)
```

Entries such as `john.doe,ou=People,dc=example,dc=com` and `john.davies,ou=People,dc=example,dc=com` would match the target expression.

- The following target expression matches all entries whose DN begins with `john.d` and matches the `ou` attribute.

```
(target = ldap:///uid=john.d*,ou=*,dc=example,dc=com)
```

Entries such as `john.doe,ou=People,dc=example,dc=com` and `john.davies,ou=asia-branch,dc=example,dc=com` would match the target expression.

Another example of a complete ACI targets the entries in the `ou=People,dc=example,dc=com` branch and the entries below it and grants the users the privilege to modify all of their user attributes within their own entries.

```
aci: (target="ldap:///ou=People,dc=example,dc=com")
(targetattr="*")
(version 3.0; acl "Allow all the ou=People branch to modify their own
entries";
allow (write) userdn="ldap:///self";)
```

### targetattr

The `targetattr` keyword targets the attributes for which the access control instruction should apply.

There are four general forms that it can take in the PingDirectory Server:

```
(targetattr="*")
```

Indicates that the access control rule applies to all user attributes. Operational attributes are not automatically included in this set.

```
(targetattr="+")
```

Indicates that the access control rule applies to all operational attributes. User attributes are not automatically included in this set.

```
(targetattr="<attr1>||<attr2>||<attr3>||...||<attrN>")
```

Indicates that the access control rule applies only to the named set of attributes.

```
(targetattr!="attr1||attr2||attr3||...||attrN")
```

Indicates that the access control rule applies to all user attributes except the named set of attributes. It does not apply to any operational attributes.

The targeted attributes can be classified as user attributes and operational attributes. User attributes define the actual data for that entry while operational attributes provide additional metadata about the entry that can be used for informational purposes, such as when the entry was created, last modified and by whom. Metadata can also include attributes specifying which password policy applies to the user, or overridden default constraints like size limit, time limit, or look-through limit for that user.

The PingDirectory Server distinguishes between these two types of attributes in its access control implementation. The Directory Server does not automatically grant any access at all to operational attributes. For example, the following clause applies only to user attributes and not to operational attributes.

```
(targetattr="*")
```

You can also target multiple attributes in the entry. The following clause targets the common name (`cn`), surname (`sn`) and state (`st`) attribute.

```
(targetattr="cn||sn||st")
```

You can use the `+` symbol to indicate that the rule should apply to all operational attributes.

```
(targetattr="+")
```

To include all user and all operational attributes, use both symbols.

```
(targetattr="*||+")
```

If you need to target a specific operational attribute rather than all operational attributes, include it in the values of the `targetattr` clause.

```
(targetattr="ds-rlim-size-limit")
```

If you want to target all user attributes and a specific operational attribute, use them in the `targetattr` clause.

```
(targetattr="*||ds-rlim-size-limit")
```

The following sample ACIs are placed on the `dc=example,dc=com` tree. The first ACI allows any user anonymous read access to all entries except the `userPassword` attribute. The second ACI allows users to update their own contact information. The third ACI allows the `uid=admin` user full access privileges to all user attributes in the `dc=example,dc=com` subtree.

```
aci: (targetattr!="userPassword") (version 3.0; acl "Allow anonymous
  read access for anyone"; allow (read,search,compare) userdn="ldap:///
  anyone");
aci: (targetattr="telephonenumber||street||homePhone||l||st")
  (version 3.0; acl "Allow users to update their own contact info";
  allow (write) userdn="ldap:///self");
aci: (targetattr="*") (version 3.0; acl "Grant full access for the admin
  user";
  allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

When assigning access to user and operational attributes, it is easy to inadvertently create an access control instruction that grants far more capabilities to a user than originally intended. The following example shows the implications of the Directory Server not distinguishing between these attributes.

```
aci: (targetattr!="uid||employeeNumber")
  (version 3.0; acl "Allow users to update their own entries";
  allow (write) userdn="ldap:///self");
```

This instruction is intended to allow a user to update any attribute in his or her own entry with the exception of `uid` and `employeeNumber`. This ACI is a common rule and seems harmless, but has serious consequences for a Directory Server that does not distinguish between user attributes and operational attributes. It allows users to update operational attributes in their own entries, and could be used for a number of malicious purposes, including:

- A user could alter password policy state attributes to become exempt from password policy restrictions.
- A user could alter resource limit attributes and bypass size limit, time limit, and look-through-limit constraints.
- A user could add access control rules to his or her own entry, which could allow them to make their entry completely invisible to all other users, including administrators granted full rights by access

control rules, but excluding users with the `bypass-acl` privilege allows them to edit any other attributes in their own entry, including those excluded by rules like `uid` and `employeeNumber` in the previous example, or add, modify, or delete any entries below his or her own entry.

Because the PingDirectory Server does not automatically include operational attributes in the target attribute list, these types of ACIs do not present a security risk for it. Users cannot add ACIs to any entries unless they have the `modify-acl` privilege.

Another danger in using the `(targetattr!="x")` pattern is that two ACIs within the same scope could have two different `targetattr` policies that cancel each other out. For example, if one ACI has `(targetattr!="cn|sn")` and a second ACI has `(targetattr!="userPassword")`, then the net effect is `(targetattr="*")`, because the first ACI inherently allows `userPassword` and the second allows `cn` and `sn`.

### targetfilter

The `targetfilter` keyword targets all attributes that match results returned from a filter.

The `targetfilter` clause has the following syntax.

```
(targetfilter = <ldap_filter>)
```

For example, the following clause targets all entries that contain the `ou=engineering` attribute.

```
(targetfilter = "(ou=engineering)")
```

You can only specify a single filter, but that filter can contain multiple elements combined with the `OR` operator. The following clause targets all entries that contain `ou=engineering`, `ou=accounting`, and `ou=marketing`.

```
(targetfilter = "(|(ou=engineering)(ou=accounting)(ou=marketing)")
```

The following example allows the user, `uid=eng-mgr`, to modify the `departmentNumber`, `cn`, and `sn` attributes for all entries that match the filter `ou=engineering`.

```
aci:(targetfilter="(ou=engineering)")
(targetattr="departmentNumber|cn|sn")
(version 3.0; acl "example"; allow (write)
 userdn="ldap:///uid=eng-mgr,dc=example,dc=com";)
```

### targattrfilters

The `targattrfilters` keyword targets specific attribute values that match a filtered search criteria.

This keyword allows you to set up an ACI that grants or denies permissions on an attribute value if that value meets the filter criteria. The `targattrfilters` keyword applies to individual values of an attribute, not to the whole attribute. The keyword also allows the use of wildcards in the filters.

The keyword clause has the following format.

```
(target = "add=attr1:Filter1 && attr2:Filter2... && attrn:FilterN,
del=attr1:Filter1 && attr2:Filter2 ... && attrN:FilterN" )
```

Where:

`add`

Represents the operation of adding an attribute value to the entry.

`del`

Represents the operation of removing an attribute value from the entry.

`<attr1>, <attr2> ... <attrN>`

Represents the targeted attributes.

`<filter1>, <filter2> ... <filterN>`

Represents filters that identify matching attribute values.

The following conditions determine when the attribute must satisfy the filter:

- When adding or deleting an entry containing an attribute targeted a `targattrfilters` element, each value of that attribute must satisfy the corresponding filter.
- When modifying an entry, if the operation adds one or more values for an attribute targeted by a `targattrfilters` element, each value must satisfy the corresponding filter. If the operation deletes one or more values for a targeted attribute, each value must satisfy the corresponding filter.
- When replacing the set of values for an attribute targeted by a `targattrfilters` element, each value removed must satisfy the delete filters and each value added must satisfy the add filters.

The following example allows any user who is part of the `cn=directory server admins` group to add the `soft-delete-read` privilege.

```
aci: (targattrfilter="add=ds-privilege-name:(ds-privilege-name=soft-delete-read) ")
  (version 3.0; acl "Allow members of the directory server admins group to grant the
  soft-delete-read privilege"; allow (write)
  groupdn="ldap:///cn=directory server admins,ou=group,dc=example,dc=com";)
```

### targetscope

Use the `targetscope` keyword to restrict the scope of an access control rule (ACR).

ACIs use a subtree scope by default, meaning they are applied to the target entry and all entries below it, either as defined by the target clause of the ACI or the entry in which the ACI is defined if it does not include a target. However, you can add the `targetscope` element into an ACR to restrict the set of entries to which it applies.

The following `targetscope` keyword values are allowed:

`base`

Indicates that the ACR applies only to the target entry and not to any of its subordinates.

`onelevel`

Indicates that the ACR applies only to entries that are immediate children of the target entry and not to the target entry itself nor to any subordinates of the immediate children of the target entry.

`subtree`

Indicates that the ACR applies to the target entry and all of its subordinates. This is the default behavior if no `targetscope` is specified.

`subordinate`

Indicates that the ACR applies to all entries below the target entry but not the target entry itself.

The following ACI targets all users to view the operational attributes present in the root DSA-specific entry (DSE):

- `supportedControl`
- `supportedExtension`
- `supportedFeatures`
- `supportedSASLMechanisms`
- `vendorName`

- `vendorVersion`

In the following example, `targetscope` is set to `base` to limit users to view only those attributes in the root DSE.

```
aci: (target="ldap:///") (targetscope="base")
    (targetattr="supportedControl||supportedExtension||
    supportedFeatures||supportedSASLMechanisms||vendorName||vendorVersion")
    (version 3.0; acl "Allow users to view Root DSE Operational Attributes";
    allow (read,search,compare) userdn="ldap:///anyone")
```

### targetcontrol

Use the `targetcontrol` keyword to indicate whether a given request control can be used by users targeted in the ACI.

You can provide multiple OIDs by separating them with two pipe characters, optionally surrounded by spaces. When specifying control OIDs, wildcards are not allowed.

The following ACI example shows the controls required to allow an administrator to use and manage the soft delete feature. The soft delete request control allows the user to soft-delete an entry, so that it could be undeleted at a later time. The hard delete request control allows the user to permanently remove an entry or soft-deleted entry. The undelete request control allows the user to undelete a currently soft-deleted entry. The soft-deleted entry access request control allows the user to search for any soft-deleted entries in the server.

```
aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.22||
    1.3.6.1.4.1.30221.2.5.23||1.3.6.1.4.1.30221.2.5.24")
    (version 3.0; acl "Allow admins to use the Soft Delete Request Control,
    Hard Delete Request Control, Undelete Request Control, and
    Soft-deleted entry access request control";
    allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

### extOp

Use the `extop` keyword to indicate whether a given extended request operation can be used.

You can provide multiple OIDs by separating them with two pipe characters, optionally surrounded by spaces. When specifying extended request OIDs, wildcards are not allowed.

The following ACI example allows the `uid=user-mgr` to use the password modify request, `OID=1.3.6.1.4.1.4203.1.11.1`, and the `StartTLS`, `OID=1.3.6.1.4.1.1466.20037`, which are extended request OIDs.

```
aci: (extop="1.3.6.1.4.1.4203.1.11.1 || 1.3.6.1.4.1.1466.20037")
    (version 3.0; acl "Allows the mgr to use the Password Modify Request and
    StartTLS;
    allow(read) userdn="ldap:///uid=user-mgr,ou=people,dc=example,dc=com";)
```

## Examples of common access control rules

This section demonstrates access controls that are commonly used in your environment.

To modify access control definitions in the server, a user must have the `modify-acl` privilege.

### Administrator access

The following access control instructions (ACIs) grant members of the `cn=admins,ou=groups,dc=example,dc=com` group the following permissions:

- Add, modify, and delete entries
- Reset passwords

- Read operational attributes, such as `isMemberOf` and password policy state

```
aci: (targetattr="+") (version 3.0; acl "Administrators can read, search or
  compare operational attributes";
allow (read,search,compare) groupdn="ldap:///
cn=admins,ou=groups,dc=example,dc=com");
aci: (targetattr="*") (version 3.0; acl "Administrators can add, modify and
  delete entries";
allow (all) groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com");
```

### Anonymous and authenticated access

The following ACIs allow anonymous read, search, and compare on select attributes of `inetOrgPerson` entries while authenticated users can access several more. An authenticated user inherits the privileges of the anonymous ACI and can also change `userPassword`.

```
aci: (targetattr="objectclass || uid || cn || mail || sn || givenName")
(targetfilter="(objectClass=inetorgperson)")
(version 3.0; acl "Anyone can access names and email addresses of entries
  representing people";
allow (read,search,compare) userdn="ldap:///anyone");
aci: (targetattr="departmentNumber || manager || isMemberOf")
(targetfilter="(objectClass=inetorgperson)")
(version 3.0; acl "Authenticated users can access these fields for entries
  representing people";
allow (read,search,compare) userdn="ldap:///all");
aci: (targetattr="userPassword") (version 3.0; acl "Authenticated users can
  change password";
allow (write) userdn="ldap:///all");
```

To prevent anonymous access to the Directory Server, set the global configuration property `reject-unauthenticated-requests` to `true`.

### Delegated access to a manager

The following ACI allows an employee's manager to edit the value of the employee's `telephoneNumber` attribute. This ACI uses the `userattr` keyword with a bind type of `USERDN`, which indicates that the target entry's manager attribute must have a value equal to the distinguished name (DN) of the authenticated user.

```
aci: (targetattr="telephoneNumber")
(version 3.0; acl "A manager can update telephone numbers of her direct
  reports";
allow (read,search,compare,write) userattr="manager#USERDN");
```

### Proxy authorization

The following ACI allows the application `cn=OnBehalf,ou=applications,dc=example,dc=com` to use the proxied authorization V2 control to request that operations be performed using an alternate authorization identity.

```
aci: (version 3.0;acl "Application OnBehalf can proxy as another entry";
allow (proxy) userdn="ldap:///
cn=OnBehalf,ou=applications,dc=example,dc=com");
```

#### Note:

The application user must have the `proxied-auth` privilege.

## Validating ACIs before migrating data

Identify any access control instruction (ACI) syntax problems before migrating data.

Many directory servers allow for a less restrictive application of their access control instructions so that they accept invalid ACIs. For example, if an Oracle directory server encounters an access control rule that it can't parse, it ignores the rule without providing a warning, and the server might not offer the intended access protection. The PingDirectory Server rejects any ACIs that it can't interpret, which ensures that data access is limited as intended. However, this can cause problems when migrating data with existing access control rules to a PingDirectory Server.

To validate an ACI, the PingDirectory Server provides a `validate-aci` tool in the `bin` directory on UNIX or Linux systems or in the `bat` directory on Windows systems.

The `validate-aci` tool identifies any ACI syntax problems before you migrate data. The tool can examine access control rules contained in either an LDIF file or an LDAP directory and write its result in LDIF with comments providing information about any problems that were identified.

Each entry in the output contains a single ACI. If an entry in the input contains multiple ACIs, then it can be present multiple times in the output, each time with a different ACI value. The entries contained in the output contains only ACI values. All other attributes are ignored.

### Validating ACIs from a file

Use the `validate-aci` tool to process data contained in an LDIF file.

About this task

#### Note:

The `validate-aci` tool ignores all attributes except `aci` and ignores all entries that do not contain the `aci` attribute. You can use any existing LDIF file that contains access control rules.

### Steps

1. Run the `validate-aci` tool and specify the input file and output file.

Choose from:

- UNIX or Linux: `bin/validate-aci`
- Windows: `bat\validate-aci`

If the output file already exists, the existing file contents are re-written. If no output file is specified, the results are written to standard output.

Example:

```
$ bin/validate-aci --ldifFile test-aci.ldif --outputFile validated-aci.ldif
```

Result:

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

## 2. Open the output file and review the results.

Example:

For example, the `validated-acis.ldif` file generated in the previous step reads as follows.

```
# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr!="userPassword")
    (version 3.0; acl "Allow anonymous read access for anyone";
      allow (read,search,compare) userdn="ldap:///anyone");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
    (version 3.0; acl "Allow users to update their own entries";
      allow (write) userdn="ldap:///self");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
    (version 3.0; acl "Grant full access for the admin user";
      allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

Example:

If the input file has any malformed access control instructions (ACIs), then the generated output file will show what was incorrectly entered. For example, if `userPassword` in the `test-acis.ldif` file does not have quotation marks around it, the output file reports an error. The following command uses the `--onlyReportErrors` option to write any error messages to the output file only if a malformed ACI syntax is encountered.

```
$ bin/validate-acis --ldifFile test-acis.ldif --outputFile validated-
acis.ldif \
  --onlyReportErrors
```

Result:

```
# Processing complete
# Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 1
# Other processing errors encountered: 0
```

The output file shows the following message.

```
# The following access control rule is malformed or contains an
  unsupported
# syntax: The provided string '(targetattr!=userPassword)(version 3.0;
  acl
# "Allow anonymous read access for anyone"; allow (read,search,compare)
# userdn="ldap:///anyone");' could not be parsed as a valid Access
  Control
# Instruction (ACI) because it failed general ACI syntax evaluation
dn: dc=example,dc=com
aci: (targetattr!=userPassword)
    (version 3.0; acl "Allow anonymous read access for anyone";
      allow (read,search,compare) userdn="ldap:///anyone");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
```

```
(version 3.0; acl "Allow users to update their own entries";
  allow (write) userdn="ldap:///self");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

### Validating ACIs in another Directory Server

Use the `validate-acis` tool to examine access control instructions (ACIs) in data that exists in another Directory Server that you are planning to migrate to the PingDirectory Server.

About this task

The tool helps to determine whether the Ping Identity Server accepts those ACIs.

Steps

- Run the `validate-acis` tool.  
Choose from:
  - UNIX or Linux: `bin/validate-acis`
  - Windows: `bat\validate-acis`

Provide arguments that specify:

- The address and port of the target Directory Server
- Credentials to use to bind
- The base DN of the subtree containing the ACIs to validate

Example:

```
$ bin/validate-acis
```

Result:

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

## Migrating ACIs from Oracle to PingDirectory Server

This section describes the most important differences in access control evaluation between Oracle and the PingDirectory Server.

### Support for macro ACIs

Oracle supports macro access control instructions (ACIs), making it possible to define a single ACI that you can use to apply the same access restrictions to multiple branches in the same basic structure.

Macro ACIs are infrequently used and can cause severe performance degradation, so the PingDirectory Server does not support them. However, you can achieve the same result by creating the same ACIs in each branch.

### Support for the roleDN bind rule

Oracle roles are a proprietary, non-standard grouping mechanism that provide little value over standard grouping mechanisms.

The PingDirectory Server does not support DSEE roles and does not support the use of the `roleDN` ACI bind rule. However, you can achieve the same behavior by converting the DSEE roles to standard groups and using the `groupDN` ACI bind rule.

### Targeting operational attributes

The Oracle access control model doesn't differentiate between user attributes and operational attributes.

In the Oracle access control model, using `targetattr="*"` automatically targets both user and operational attributes. Using an exclusion list like `targetattr!="userPassword"` automatically targets all operational attributes in addition to all user attributes except `userPassword`. This presents several significant security holes in which users are unintentionally given access to operational attributes. In some cases, it can allow users to exempt themselves from password policy restrictions.

The PingDirectory Server treats operational attributes differently from user attributes and never automatically includes operational attributes. For example, `targetattr="*"` targets all user attributes but no operational attributes, and `targetattr!="userPassword"` targets all user attributes except `userPassword`, but no operational attributes.

You can target specific operational attributes by including the names in the list, such as `targetattr="creatorsName|modifiersName"`. You can target all operational attributes by using the "+" character. For example, `targetattr="+"` targets all operational attributes but no user attributes and `targetattr="*|+"` targets all user and operational attributes.

#### Example

The following example searches for all immediate children of `ou=People,dc=example,dc=com`. The attributes returned are restricted to `sn`, `givenName`, and all operational attributes.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --baseDN ou=People,dc=example,dc=com --searchScope one
  '(objectclass=*)' \
  sn givenName "+"
```

#### Example

You can use compound filters to search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree. The following example limits the returned entry amount to 200 and the server will spend no more than 5 seconds processing the request.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --baseDN ou=People,dc=example,dc=com --searchScope sub --sizeLimit 200
  \
  --timeLimit 5 "(&(sn<=Doe) (employeeNumber<=1000))" ds-entry-unique-id \
  entryUUID
```

### Returning all user and operational attributes in a schema search

Specify "\*" in a search attribute list to represent all user attributes. Specifying "+" retrieves all operational attributes.

#### About this task

The following standards are used in PingDirectory as part of the LDAP specification.

| Standard                 | Overview                                                         |
|--------------------------|------------------------------------------------------------------|
| <a href="#">RFC 3673</a> | Describes the use of "+" to represent all operational attributes |
| <a href="#">RFC 4511</a> | Describes the use of "*" to represent all user attributes        |

### Steps

- To search the `cn=schema` entry and return all user and operational attributes, run `ldapsearch`.

Example:

```
bin/ldapsearch --baseDN cn=schema --searchScope base "(objectclass=*)" "*" "+"
```

### Exclude attributes

PingDirectory accepts syntax, in addition to the [RFC 3673](#), [RFC 4511](#), and [RFC 4529](#) standards, that allows you to exclude attributes from search results.

### About this task

To exclude an attribute from the search results in PingDirectory:

### Steps

- Prefix the attribute name with either "^" or "!"

Example:

The following example returns organizational units (OUs) that are part of the object class `group` in Colorado with the exception of OUs in Denver.

```
(&(objectClass=group) (&(ou:dn:=Colorado) (!(ou:dn:=Denver))))
```

Example:

The following example returns all users that aren't device.

```
(&(objectClass=user) (!(objectClass=device)))
```

#### Note:

To exclude all attributes associated with an object class, prefix the object class name with either "^@" or "!@".

### Specification of global ACIs

Both DSEE and PingDirectory Server support global ACIs, which you can use to define ACIs that apply throughout the server.

In servers with multiple naming contexts, this feature allows you to define a rule once as a global ACI rather than maintaining an identical rule in each naming context.

In DSEE, global ACIs are created by modifying the root DSA-specific entry (DSE) to add values of the `aci` attribute. In the PingDirectory Server, you manage global ACIs with `dsconfig` referenced in the `global-aci` property of the access control handler.

## Defining ACIs for non-user content

In DSEE, you can write to the following backends to define ACIs:

- Configuration
- Monitor
- Changelog
- Tasks

In the PingDirectory Server, you should define access control for private backends as global ACIs, such as the following backends:

- Configuration
- Monitor
- Schema
- Changelog
- Tasks
- Encryption settings
- Backups
- Alerts

## Limiting access to controls and extended operations

DSEE provides limited support for restricting access to controls and extended operations.

To the extent that you can control access to controls and extended operations with access control instructions (ACIs), DSEE defines entries with a distinguished name (DN), such as `oid={oid},cn=features,cn=config`, where `{oid}` is the OID of the associated control or extended operation. For example, the following DSEE entry defines ACIs for the persistent search control.

```
oid=2.16.840.1.113730.3.4.3,cn=features,cn=config
```

In the PingDirectory Server, you can use the `targetcontrol` keyword to define ACIs that grant or deny access to controls. You can use the `extop` keyword to define ACIs that grant or deny access to extended operation requests.

## Tolerance for malformed ACI values

If the server is running with less than the intended set of access control instructions (ACIs), it might prevent access to data that should be allowed or grant access to data that should be restricted. In DSEE, if the server encounters a malformed access control rule (ACR), it ignores the rule. This can cause the server to run with less than the intended set of ACIs. To guard against this, the PingDirectory Server is more strict about the ACRs that it accepts.

When performing an LDIF import, the PingDirectory Server rejects any entry containing a malformed or unsupported ACR. The PingDirectory Server also rejects any `add` or `modify` request that attempts to create an invalid ACI.

In the unlikely event that a malformed ACI is accepted into the data, the server immediately places itself in lockdown mode. In lockdown mode, the server terminates connections and rejects requests from users without the `lockdown-mode` privilege. Lockdown mode allows an administrator to correct the problem without risking exposure to user data.

### Note:

To review any rejected ACIs, run the `import-ldif` tool with the `--rejectFile` option.

### About the privilege subsystem

In DSEE, only the root user is exempt from access control evaluation.

While administrators can create access control instructions (ACIs) that give normal users full access to any content, they can also create ACIs that would make a portion of the data inaccessible to those users. Additionally, some tasks can only be accomplished by the root user and the capabilities assigned to the root user can't be restricted.

The PingDirectory Server uses a privilege subsystem to control the capabilities available to various users. Non-root users can be granted limited access to certain administrative capabilities, and restrictions can be enforced on root users. Additionally, certain risky actions require that the requester have certain privileges in addition to the sufficient access control rights to process the operation.

These risky actions include:

- Interacting with the server configuration
- Changing another user's password
- Impersonating another user
- Shutting down and restarting the server

### Identifying unsupported ACIs

To determine whether access control instructions (ACIs) are suitable for use, the PingDirectory Server provides a `validate-acis` tool that you can use to examine content in an LDIF file or data in another directory server, such as a DSEE instance.

When migrating data from a DSEE deployment into a PingDirectory Server instance, use the `validate-acis` tool to determine whether ACIs contained in the data are acceptable. If any problems exist, update the data to redefine the ACIs so they are suitable for use in the PingDirectory Server.

For more information, see [Validating ACIs Before Migrating Data](#).

## Working with privileges

In addition to the access control implementation, the PingDirectory Server includes a privilege subsystem that you can use to control what users are allowed to do.

The privilege subsystem works in conjunction with the access control subsystem to only allow privileged operations that are permitted by the access control configuration. The user must also have all of the necessary privileges.

You can use privileges to grant normal users the ability to perform certain tasks that, in most other directories, would only be allowed for the root user. The capabilities given to root users in the PingDirectory Server are all granted through privileges, so you can create a normal user account with the ability to perform the same actions as root users.

Administrators can also remove privileges from root users so that they are unable to perform certain types of operations. To restrict root users to only the tasks that they must perform, define multiple root users in the server with different sets of privileges.

### Available privileges

The following privileges are defined in the PingDirectory Server.

#### Summary of Privileges

| Privilege                        | Description                                                                                                                                |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>audit-data-security</code> | This privilege is required to initiate a data security audit on the server, which is invoked by the <code>audit-data-security</code> tool. |

| Privilege                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>backend-backup</code>    | This privilege is required to initiate an online backup through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>backend-restore</code>   | This privilege is required to initiate an online restore through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>bypass-acl</code>        | <p>This privilege allows a user to bypass access control evaluation. For a user with this privilege, any access control determination made by the server immediately returns that the operation is allowed.</p> <p> <b>Note:</b></p> <p>This does not bypass privilege evaluation, so the user must have the appropriate set of additional privileges to be able to perform any privileged operation. For example, a user with the <code>bypass-acl</code> privilege but without the <code>config-read</code> privilege is not allowed to access the server configuration.</p> |
| <code>bypass-pw-policy</code>  | This privilege allows a user entry to bypass password policy evaluation. This privilege is intended for cases where external synchronization might require passwords that violate the password validation rules. The privilege is also evaluated for bind operations, meaning password restrictions are also bypassed when binding as a user who has this privilege.                                                                                                                                                                                                                                                                                            |
| <code>bypass-read-acl</code>   | This privilege allows the associated user to bypass access control checks performed by the server for bind, search, and compare operations. Access control evaluation may still be enforced for other types of operations.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>config-read</code>       | This privilege is required for a user to access the server configuration. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to see.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>config-write</code>      | This privilege is required for a user to alter the server configuration. The user must also have the <code>config-read</code> privilege. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to alter.                                                                                                                                                                                                                                                                                                                                                                           |
| <code>disconnect-client</code> | This privilege is required for a user to request that an existing client connection be terminated. The connection is terminated through the disconnect client task. The server's access control configuration must also allow the user to add the corresponding entry to the tasks backend.                                                                                                                                                                                                                                                                                                                                                                     |
| <code>jmx-notify</code>        | This privilege is required for a user to subscribe to Java Management Extensions (JMX) notifications generated by the Directory Server. The user is also required to have the <code>jmx-read</code> privilege.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>jmx-read</code>          | This privilege is required for a user to access any information provided by the Directory Server through the JMX.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Privilege        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| jmx-write        | <p>This privilege is required for a user to update any information exposed by the Directory Server through the JMX. The user is also required to have the <code>jmx-read</code> privilege.</p> <p> <b>Note:</b><br/>Currently, all of the information exposed by the server over JMX is read-only.</p>                                                                                                            |
| ldif-export      | This privilege is required to initiate an online LDIF export through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, you can set up a global access control instruction (ACI) that allows access to members of an Administrators group.                                                                                                                         |
| ldif-import      | This privilege is required to initiate an online LDIF import through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, configure the global ACI as described in the previous description of the <code>ldif-export</code> privilege.                                                                                                                               |
| lockdown-mode    | This privilege allows the associated user to request that the server enter or leave lockdown mode, or to perform operations while the server is in lockdown mode.                                                                                                                                                                                                                                                                                                                                  |
| modify-acl       | This privilege is required for a user to add, modify, or remove access control rules defined in the server. The server's access control configuration must also allow the user to make the corresponding change to the <code>aci</code> operational attribute.                                                                                                                                                                                                                                     |
| password-reset   | This privilege is required for one user to be allowed to change another user's password. This privilege is not required for a user to be allowed to change his or her own password. The user must also have the access control instruction privilege to write the <code>userPassword</code> attribute to the target entry.                                                                                                                                                                         |
| privilege-change | This privilege is required for a user to change the set of privileges assigned to a user, including the set of privileges, which are automatically granted to root users. The server's access control configuration must also allow the user to make the corresponding change to the <code>ds-privilege-name</code> operational attribute.                                                                                                                                                         |
| proxied-auth     | This privilege is required for a user to request that an operation be performed with an alternate authorization identity. This privilege applies to operations that include the proxied authorization v1 or v2 control operations that include the intermediate client request control with a value set for the client identity field, or for Simple Authentication and Security Layer (SASL) bind requests that can include an authorization identity different from the authentication identity. |
| server-restart   | This privilege is required to initiate a server restart through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.                                                                                                                                                                                                                                                                                       |

| Privilege                     | Description                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>server-shutdown</code>  | This privilege is required to initiate a server shutdown through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.                                                                                                                                                               |
| <code>soft-delete-read</code> | This privilege is required for a user to access a soft-deleted-entry.                                                                                                                                                                                                                                                                                                       |
| <code>stream-values</code>    | This privilege is required for a user to perform a stream values extended operation, which obtains all entry distinguished names (DNs) and all values for one or more attributes for a specified portion of the directory information tree (DIT).                                                                                                                           |
| <code>unindexed-search</code> | This privilege is required for a user to be able to perform a search operation in which a reasonable set of candidate entries cannot be determined using the defined index and instead, a significant portion of the database needs to be traversed to identify matching entries. The server's access control configuration must also allow the user to request the search. |
| <code>update-schema</code>    | This privilege is required for a user to modify the server schema. The server's access control configuration must allow the user to update the operational attributes that contain the schema elements.                                                                                                                                                                     |

### Privileges automatically granted to root users

The special abilities that root users have are granted through privileges.

You can assign privileges to root users in two ways:

- By default, root users can be granted a specified set of privileges.

#### Note:

You can create root users which are not automatically granted these privileges by including the `ds-cfg-inherit-default-root-privileges` attribute with a value of `FALSE` in the entries for those root users.

- You can grant additional privileges to individual root users and remove some automatically-granted privileges from individual root users.

The `default-root-privilege-name` property of the root distinguished name (DN) configuration object controls the set of privileges that are automatically granted to root users. By default, these privileges include:

- `audit-data-security`
- `backend-backup`
- `backend-restore`
- `bypass-acl`
- `config-read`
- `config-write`
- `disconnect-client`
- `ldif-export`
- `lockdown-mode`
- `manage-topology`
- `metrics-read`
- `modify-acl`
- `password-reset`

- permit-get-password-policy-state-issues
- privilege-change
- server-restart
- server-shutdown
- soft-delete-read
- stream-values
- unindexed-search
- update-schema

The privileges not granted to root users by default include:

- bypass-pw-policy
- bypass-read-acl
- jmx-read
- jmx-write
- jmx-notify
- permit-externally-processed-authentication
- permit-proxied-mschapv2-details
- proxied-auth

You can change the set of default root privileges to add or remove values as necessary. This requires the `config-read`, `config-write`, and `privilege-change` privileges, and either the `bypass-acl` privilege or sufficient permission granted by the access control configuration to change the server's configuration.

### Assigning additional privileges for administrators

#### Steps

- To allow access to the Tasks backend, set up a global access control instruction (ACI) using `dsconfig` that allows access to members of an Administrators group.

Example:

```
$ dsconfig set-access-control-handler-prop \
  --add 'global-aci:(target="ldap:///cn=tasks") (targetattr="*|+")(
    version 3.0; acl "Access to the tasks backend for
    administrators";
    allow (all) groupdn="ldap:///
    cn=admin,ou=groups,dc=example,dc=com";) '
```

### Assigning privileges to normal users and individual root users

You can grant privileges to normal users on an individual basis.

Add the `ds-privilege-name` operational attribute to the user's entry with the names of the desired privileges. For example, the following change grants the `proxied-auth` privilege to the `uid=proxy,dc=example,dc=com` account.

```
dn: uid=proxy,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: proxied-auth
```

The user making this change must have the `privilege-change` privilege, and the server's access control configuration must also allow the requester to write to the `ds-privilege-name` attribute in the target user's entry.

You can use the same method to grant root users privileges that aren't included in the set of default root privileges. You can also remove default root privileges from root users by prefixing the name of the

privilege to remove with a minus sign. For example, the following change grants a root user the `jmx-read` privilege in addition to the set of default root privileges and removes the `server-restart` and `server-shutdown` privileges.

```
dn: cn=Sync Root User,cn=Root DNs,cn=config
changetype: modify
add: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: -server-restart
ds-privilege-name: -server-shutdown
```

#### Note:

Because root user entries exist in the configuration, this update requires the `config-read` and `config-write` privileges in addition to the `privilege-change` privilege.

### Disabling privileges

Although the privilege subsystem in the PingDirectory Server is a powerful feature, it might break some applications if they expect to perform an operation requiring a privilege that they do not have.

In the majority of these cases, you can assign the necessary privilege manually to the account used by that application. However, if this workaround isn't sufficient, or if you need to remove a particular privilege, such as allowing anyone to access information through Java Management Extensions (JMX) without requiring the `jmx-read` privilege, then you can disable privileges on an individual basis.

The `disabled-privilege` property in the global configuration object controls the set of disabled privileges. By default, no privileges are disabled. If a privilege is disabled, then the server behaves as if all users have that privilege.

## Deploying a Standard Directory Proxy Server

---

You can deploy Directory Proxy Server in a variety of ways depending on the needs of your enterprise.

This section describes and illustrates a standard deployment scenario and includes the following topics:

- [Introduction](#) on page 1325
- [Automatic server discovery](#) on page 1326
- [Creating a standard multi-location deployment](#) on page 1338
- [Expanding the deployment](#) on page 1346
- [Merging two data sets using proxy transformations](#) on page 1352

### Introduction

Derived from the words development and operations, the term DevOps refers to the practices that a company follows to ensure the production of high-quality products while also minimizing the amount of time between the commitment of a system change and the implementation of that change in a production environment.

Most companies practice one of the following service models:

#### Pets

With the pets service model, servers are built and managed manually and are treated as unique and indispensable. Examples include mainframes, database systems, and load balancers.

#### Cattle

With the cattle service model, arrays of multiple replaceable servers are built with automated tools. During a failure event, an array automatically restarts failed services and replicates data. Examples include web server arrays, search clusters, and multi-master datastores.

Historically, servers have been treated like pets. The failure of one or multiple servers was often viewed as an emergency, and extensive resources were usually required to repair the damage. In the new DevOps paradigm, servers are recognized as dispensable and treated like cattle. When a server fails, the infrastructure replaces it immediately, configuring the replacement server identically to the failed one. Because no human intervention is required to fix them, the servers are considered self-healing.

To help treat your servers more like cattle than pets, PingDirectoryProxy Server supports server profiles and features like topology-management tools. For example, the `manage-profile setup` represents a single command that performs all the steps from the pet service model on a `server-profile` directory, a well-defined directory structure with all the necessary server configuration bits. Similarly, the `manage-profile replace-profile` command performs similar steps with a single command invocation after a server is updated to a new version.

The scripts in the `server-profile` directory are declarative of the environment. What you define in the `server-profile` directory is what you get on the servers. No one needs to identify a server's current configuration and compute the differences that must be applied to attain the appropriate end state.

Before server profiles, this problem was difficult to address, especially where no history was available. In such scenarios, an administrator might have needed to obtain the current configuration from the servers, to manually compute the difference between the current and desired configuration, and to apply the configuration changes, hoping that nobody had changed the configuration during the process.

Server profiles eliminate this procedural approach to applying configuration changes, and they simplify the steps associated with determining what's deployed in an environment. For more information on server profiles, see [Server profiles](#) on page 1038.

Another principle that relates closely to DevOps is infrastructure as code (IaC), the concept of managing your operations in the same manner as your application and other code for general release with proper versioning, continuous integration, quality control, and release cycles. Customers who deploy PingDirectoryProxy Servers as pets today can take advantage of current DevOps and IaC principles to turn them into cattle.

## Automatic server discovery

Version 8.3 supports the use of information in the topology registry to automatically discover the backend Directory Server instances to which requests might be forwarded.

This is an alternative to explicitly configuring the PingDirectoryProxy Server with the backend servers that should be used. This option is only available if all of the backend servers are Directory Server instances and only if the following are true:

- The PingDirectoryProxy Server must be a member of the same topology as the Directory Server instances to which requests will be forwarded.
- The PingDirectoryProxy Server must be configured with an LDAP external server template that provides the settings to use when communicating with dynamically discovered backend Directory Server instances.
- The PingDirectoryProxy Server's load-balancing algorithms must be configured to use the desired LDAP external server template.
- The topology registry entries for each Directory Server instance must be updated to indicate which of the PingDirectoryProxy Server's load-balancing algorithms can forward requests to the server.

### Note:

When using automatic server discovery, you don't need to run the `prepare-external-server` command. Servers do not need a service account and associated ACIs before discovery since the inter-

server bind process is used to initiate communication. The server is identified using information contained in the topology registry and is given appropriate privileges during the inter-server bind process.

### Joining a PingDirectoryProxy Server to an existing PingDirectory Server topology

PingDirectory Server 8.0.0.0 supports the addition of PingDirectoryProxy Server instances to the same topology as Directory Server instances.

You can do this when the PingDirectoryProxy Server instance is initially configured using either the setup utility (in either interactive or non-interactive mode) or the `manage-profile setup` command. You can do this later using the `manage-topology add-server` command.

### Joining a topology with interactive setup

If you run `setup` without any arguments, it starts in interactive mode and prompts you for all of the necessary information. After you accept the license, the next prompt asks if you want to add the server to an existing PingDirectoryProxy Server topology.

If you have at least one PingDirectoryProxy Server instance that is already in the desired topology, you can enter `yes` at this prompt and it walks you through the process of creating a new instance that is a copy of the existing instance (with all of the same configuration). You are then asked for the information needed to connect and authenticate to the existing PingDirectoryProxy Server instance, as shown in the following example.

```
Do you accept the terms of this license agreement? Enter 'yes' to accept,
'no' to reject, or press ENTER to display the next page of the agreement []:
yes

Would you like to add this server to an existing Directory Proxy Server
topology? (yes / no) [no]: yes

Enter the host name of the peer Directory Proxy Server from which you would
like to copy configuration settings. [proxy2.example.com]:
proxy1.example.com

Enter the LDAP port of the peer Directory Proxy Server [389]: 636

How would you like to connect to the peer Directory Proxy Server?

1) None
2) SSL
3) StartTLS

Enter option [1]: 2

Enter the manager account DN for the peer Directory Proxy Server
[cn=Directory
Manager]: cn=Directory Manager

Enter the password for cn=Directory Manager:
The server presented the following certificate chain:

Do you wish to trust this certificate? Enter 'y' or 'n': y

Initializing ..... Done
Reading Peer Configuration ..... Done
Connecting to 'proxyl' ..... Done

```

However, cloning an existing installation isn't possible when setting up the first PingDirectoryProxy Server instance.

In this case, if you enter `no` at the prompt to join an existing PingDirectoryProxy Server topology, `setup` asks if you want to join a Directory Server topology instead. If you enter `yes`, the process is basically the same as joining an existing PingDirectory Server topology, and you are prompted for the information needed to connect and authenticate to a Directory Server instance in the topology. The primary difference is that you have to define the PingDirectoryProxy Server configuration yourself, as shown in the following example.

```

Do you accept the terms of this license agreement? Enter 'yes' to accept,
'no' to reject, or press ENTER to display the next page of the agreement []:
yes

Would you like to add this server to an existing Directory Proxy Server
topology? (yes / no) [no]: no

Would you like to add this server to an existing PingDirectory server
topology
to enable automatic backend server discovery? (yes / no) [no]: yes

Enter the host name of a PingDirectory server instance in the topology to
join. [proxyl.example.com]: dsl.example.com

Enter the LDAP port of a PingDirectory server instance in the topology to
join
[389]: 636

How would you like to secure communication with the PingDirectory server

1) None
2) SSL
3) StartTLS

Enter option [1]: 2

Enter the DN used to bind to a PingDirectory server instance in the topology
to join [cn=Directory Manager]: cn=Directory Manager

Enter the password for cn=Directory Manager:
Testing connection to the existing PingDirectory server topology
The server presented the following certificate chain:

## Joining a topology with non-interactive setup

### About this task

Interactive mode is a convenient method to get the server up and running when you're just getting started, but the installation process for production deployments is generally scripted. For this process, non-interactive mode is a better choice and setup offers several useful arguments.

To join a topology with non-interactive setup:

### Steps

- Run **setup**:  
Choose from:

- Use the following arguments to join an existing Directory Server topology:

**--existingDSTopologyHostName** *{address}*

The address of a Directory Server instance in the topology to be joined.

**--existingDSTopologyPort** *{port}*

The port for communication with the Directory Server to retrieve information about the topology.

**--existingDSTopologyUseSSL**

Indicates that the communication with the Directory Server to retrieve information about the topology should be encrypted with SSL.

**--existingDSTopologyUseStartTLS**

Indicates that the communication with the Directory Server to retrieve information about the topology should be encrypted with the StartTLS extended operation.

**--existingDSTopologyUseNoSecurity**

Indicates that the communication with the Directory Server to retrieve information about the topology should be not be encrypted.

**--existingDSTopologyUseJavaTruststore** *{path}*

The path to a JKS trust store that has the information needed to trust the certificate presented by the Directory Server when using SSL or StartTLS.

**--existingDSTopologyUsePkcs12Truststore** *{path}*

The path to a PKCS #12 trust store that has the information needed to trust the certificate presented by the Directory Server when using SSL or StartTLS.

**--existingDSTopologyTrustStorePassword** *{password}*

The password needed to access the contents of the JKS or PKCS #12 trust store. A password is typically required when using a PKCS #12 trust store but is optional when using a JKS trust store.

**--existingDSTopologyTrustStorePasswordFile** *{path}*

The path to a file containing the password needed to access the contents of the JKS or PKCS #12 trust store.

**--existingDSTopologyBindDN** *{path}*

The DN of the account to use to authenticate to the Directory Server. This account must have full read and write access to the configuration and to manage the topology.

**--existingDSTopologyBindPassword** *{password}*

The password for the account to use to authenticate to the Directory Server.

**--existingDSTopologyBindPasswordFile** *{path}*

The path to a file containing the password to use to authenticate to the Directory Server.

For example, you can use a command similar to the following to set up a PingDirectoryProxy Server instance in the same topology as a Directory Server instance.

```
$ ./setup --acceptLicense \  
  --licenseKeyFile PingDirectory.lic \  
  --maxHeapSize 2g \  
  --localHostName proxy1.example.com \  
  --skipHostnameCheck \  
  --instanceName proxy1 \  
  --location Austin \  
  --rootUserDN "cn=Directory Manager" \  
  --rootUserPasswordFile directory-manager-password.txt \  
  --ldapPort 389 \  
  --ldapsPort 636 \  
  --httpsPort 443 \  
  --enableStartTLS \  
  --useJavaKeyStore config/keystore \  
  --keyStorePasswordFile config/keystore.pin \  
  --certNickname server-cert \  
  --useJavaTrustStore config/truststore \  
  --trustStorePasswordFile config/truststore.pin \  
  --encryptDataWithPassphraseFromFile encryption-passphrase.txt \  
  --existingDSTopologyHostName ds1.example.com \  
  --existingDSTopologyPort 636 \  
  --existingDSTopologyBindDN "cn=Directory Manager" \  
  --existingDSTopologyBindPasswordFile directory-manager-  
password.txt \  
  --existingDSTopologyUseSSL \  
  --existingDSTopologyUseJavaTrustStore config/truststore \  
  --no-prompt
```

- Use the following arguments to clone the configuration of an existing PingDirectoryProxy Server instance, including joining the same topology as the existing instance:

**--peerHostName** *{address}*

The address of a PingDirectoryProxy Server instance whose configuration should be cloned and whose topology should be joined.

**--peerPort** *{port}*

The port communication with the PingDirectoryProxy Server to retrieve the configuration and topology information.

**--peerUseSSL**

Indicates that communication with the PingDirectoryProxy Server to retrieve configuration and topology information should be encrypted with SSL.

**--peerUseStartTLS**

Indicates that communication with the PingDirectoryProxy Server to retrieve configuration and topology information should be encrypted with the StartTLS extended operation.

**--peerUseNoSecurity**

Indicates that communication with the PingDirectoryProxy Server to retrieve configuration and topology information should not be encrypted.

 **Note:**

When using SSL or StartTLS to encrypt the communication, you also need to use one of the `--useJavaTruststore` or `--usePkcs12Truststore` arguments to specify the path to a trust store with the information needed to trust the certificate that is presented by the PingDirectoryProxy Server.

The following is an example of a sample command to set up a new PingDirectoryProxy Server as a clone of an existing PingDirectoryProxy Server instance.

```
$ ./setup --acceptLicense \  
  --licenseKeyFile PingDirectory.lic \  
  --maxHeapSize 2g \  
  --localHostName proxy2.example.com \  
  --skipHostnameCheck \  
  --instanceName proxy2 \  
  --location Austin \  
  --rootUserDN "cn=Directory Manager" \  
  --rootUserPasswordFile directory-manager-password.txt \  
  --ldapPort 389 \  
  --ldapsPort 636 \  
  --httpsPort 443 \  
  --enableStartTLS \  
  --useJavaKeyStore config/keystore \  
  --keyStorePasswordFile config/keystore.pin \  
  --certNickname server-cert \  
  --useJavaTrustStore config/truststore \  
  --trustStorePasswordFile config/truststore.pin \  
  --encryptDataWithPassphraseFromFile encryption-passphrase.txt \  
  --peerHostName proxy1.example.com \  
  --peerPort 636 \  
  --peerUseSSL \  
  --no-prompt
```

### Joining a topology with manage-profile setup

#### About this task

You can use the `manage-profile` tool to set up an instance of the server from information contained in a server profile. This tool invokes `setup` and performs other tasks, such as applying configuration changes, installing schema and extensions, and adding files to the server root.

## Steps

1. Place an appropriate set of arguments in the `setup-arguments.txt` file in the root directory of the profile, along with all of the other arguments that should be used when invoking `setup`.

Because `manage-profile setup` uses the `setup` tool in non-interactive mode, you should use the arguments listed in the previous section, including:

- `--existingDSTopologyHostName {address}`
- `--existingDSTopologyPort {port}`
- `--existingDSTopologyUseSSL`
- `--existingDSTopologyUseStartTLS`
- `--existingDSTopologyUseNoSecurity`
- `--existingDSTopologyUseJavaTruststore {path}`
- `--existingDSTopologyUsePkcs12Truststore {path}`
- `--existingDSTopologyTrustStorePassword {password}`
- `--existingDSTopologyTrustStorePasswordFile {path}`
- `--existingDSTopologyBindDN {path}`
- `--existingDSTopologyBindPassword {password}`
- `--existingDSTopologyBindPasswordFile {path}`

### Note:

Unlike the `setup` utility, `manage-profile setup` does not support cloning an existing PingDirectoryProxy Server instance, so the `--peerHostName`, `--peerPort`, and other related arguments cannot be included in the `setup-arguments.txt` file.

2. Run `manage-profile setup`.
3. If you have already set up an instance of the server, run `manage-profile generate-profile` to generate a profile from the information contained in that instance.

If the server was added to the topology during the setup process, the generated profile includes an appropriate set of arguments for joining the same topology.

## Joining a topology with `manage-topology add-server`

### Steps

- Use the `manage-topology add-server` command to add a PingDirectoryProxy Server instance to a topology after it has been installed.

You can only do this if the PingDirectoryProxy Server instance is not already part of any other topology, since it is not possible to join two topologies together. This tool supports all of the normal arguments for connecting and authenticating to the local server instance, including the following:

- `--hostname {address}`
- `--port {port}`
- `--useSSL`
- `--useStartTLS`
- `--trustStorePath {path}`
- `--trustStorePassword {password}`
- `--trustStorePasswordFile {path}`
- `--bindDN {dn}`
- `--bindPassword {password}`
- `--bindPasswordFile {path}`

The `manage-topology add-server` command also allows the following arguments to provide information about a server in the topology to be joined:

`--remoteServerHostname {address}`

The address of a server in the topology to be joined.

`--remoteServerPort {port}`

The port for communication with the remote server.

`--remoteServerConnectionSecurity {noSecurity|useSSL|useStartTLS}`

The type of security to use when communicating with the remote server. This value must be one of `useSSL`, to indicate that the communication should be encrypted with SSL, `useStartTLS`, to indicate that the communication should be encrypted with the StartTLS extended operation, or `noSecurity` to indicate that the communication should not be encrypted.

`--remoteServerBindDN {dn}`

The DN of the account to use to authenticate to the remote server.

`--remoteServerBindPassword {password}`

The password for the account to use to authenticate to the remote server.

`--remoteServerBindPasswordFile {path}`

The path to a file containing the password for the account to use to authenticate to the remote server.

### Example:

Use a command similar to the following to add a PingDirectoryProxy Server to an existing Directory Server topology.

```
$ bin/manage-topology add-server \
  --hostname proxyl.example.com \
  --port 636 \
  --useSSL \
  --trustStorePath config/truststore \
  --bindDN "cn=Directory Manager" \
```

```
--bindPasswordFile directory-manager-password.txt \
--remoteServerHostname ds1.example.com \
--remoteServerPort 636 \
--remoteServerConnectionSecurity useSSL \
--remoteServerBindDN "cn=Directory Manager" \
--remoteServerBindPasswordFile directory-manager-password.txt
```

### Creating an LDAP external server template

An LDAP external server template is a configuration object that can be used to provide a load-balancing algorithm with many of the settings that it should use when communicating with a backend server that has been discovered from the topology registry.

An LDAP external server template configuration object has most of the same properties as an LDAP external server configuration object but omits those related to information that it obtains from the topology registry. The omitted properties include:

- `server-host-name`
- `server-port`
- `location`
- `connection-security`

Additionally, the `health-check-state` property is not available for LDAP external server templates because it primarily applies to individual servers rather than all of the servers associated with a load-balancing algorithm.

Because the only LDAP servers which can be in the topology registry are Directory Servers, most of the remaining properties in LDAP external server templates have the same default values as the corresponding properties in the Directory Server external server type. However, there are exceptions, including the following:

- The `authentication-method` property has a default value of `inter-server` in LDAP external server templates while it has a default value of `simple` in Directory Server external servers. The `inter-server` authentication type indicates that the PingDirectoryProxy Server should authenticate to the Directory Server with a proprietary authentication method that uses inter-server certificates stored in the topology registry.

#### Note:

This option is only supported if all of the Directory Server instances are 8.0.0.0 or later.

- The `key-manager-provider` property has a default value of `Null` in LDAP external server templates, while it has no default value in Directory Server external servers. When using the inter-server authentication type, the topology registry is used to obtain the inter-server certificates, so no additional key manager provider is required.
- The `trust-manager-provider` property has a default value of `JVM-Default` in LDAP external server templates while it has no default value in Directory Server external servers. When using the inter-server authentication type, the topology registry is used to obtain information about the listener certificates that the servers are expected to present.

In many cases the PingDirectoryProxy Server's default settings for an LDAP external server template are acceptable for most properties. However, you might want to add custom health checks that are invoked against servers created from the template. The PingDirectoryProxy Server automatically checks to see whether the server reports any degraded or unavailable alert types, and also verifies that the backend server's root DSA-specific entry (DSE) is accessible in a timely manner, but you might want to add additional health checks including the following:

- A search health check that verifies that the base entry from the associated subtree view can be retrieved in a timely manner.

- A replication backlog health check that verifies that replication is working and that none of the servers is too far out of sync.

The following example demonstrates the process for creating these health checks and then creating an LDAP external server template that uses them.

```
# Create a health check to verify that the dc=example,dc=com entry can be
# retrieved in a timely manner.
dsconfig create-ldap-health-check \
  --check-name dc_example_dc_com-retrieve-base-entry \
  --type search \
  --set enabled:true \
  --set base-dn:dc=example,dc=com \
  --set allow-no-entries-returned:false \
  --set allow-multiple-entries-returned:false

# Create a health check to verify that replication is working without a
# significant backlog.
dsconfig create-ldap-health-check \
  --check-name dc_example_dc_com-replication-backlog \
  --type replication-backlog \
  --set enabled:true \
  --set base-dn:dc=example,dc=com

# Create an LDAP external server template with the above
dsconfig create-ldap-external-server-template \
  --template-name dc_example_dc_com \
  --set health-check:dc_example_dc_com-retrieve-base-entry \
  --set health-check:dc_example_dc_com-replication-backlog
```

### Defining the load-balancing algorithm configuration

In versions earlier than 8.0.0.0, each load-balancing algorithm had to be explicitly configured with a set of backend servers. This is still supported and might be the preferred configuration in some cases.

For example, explicitly configured algorithms are required if any backend server is not a Directory Server or if it is a Directory Server version earlier than 8.0.0.0. It might also be preferable if you want to have more direct control over the configuration that the PingDirectoryProxy Server uses for each backend server.

Beginning with 8.0.0.0, it is possible to configure the fewest operations and failover load-balancing algorithms so that they can automatically discover the appropriate set of backend servers from information in the topology registry. To do this, the load-balancing algorithm should be configured with a value for the `ldap-external-server-template` property rather than with one or more values for the `backend-server` property.

For example, the following configuration change can be used to create a fewest operations load-balancing algorithm that uses an LDAP external server template named `dc_example_dc_com`.

```
dsconfig create-load-balancing-algorithm \
  --algorithm-name fewest-operations-load-balancer \
  --type fewest-operations \
  --set enabled:true \
  --set ldap-external-server-template:dc_example_dc_com
```

You can use a similar change to create an instance of a failover load-balancing algorithm that automatically discovers its backend servers, as in the following example.

```
dsconfig create-load-balancing-algorithm \
  --algorithm-name failover-load-balancer \
  --type failover \
  --set enabled:true \
  --set ldap-external-server-template:dc_example_dc_com
```

**Note:**

With the failover load-balancing algorithm, the backend servers are ordered lexicographically by instance name. This ensures that all PingDirectoryProxy Server instances have a consistent ordering, but it is not as easy to control the ordering when automatically discovering backend servers as when they are explicitly configured. This is acceptable in many cases because the primary use of failover load-balancing is often to avoid replication and unique attribute conflicts for write operations, and potentially to avoid read-after-write issues. However, if you want to direct all traffic to a specific instance as long as it is available, then it might be better to explicitly configure the set of backend servers rather than use automatic discovery.

Although you can use just the fewest operations load-balancing algorithm or the failover load-balancing algorithm, you should use both of these together with failover load-balancing for writes and fewest operations for reads. When combined with the Directory Server's default use of assured replication (for all add, delete, and modify DN operations, as well as for modify operations that target passwords or password-related attributes) this provides an excellent balance that minimizes the chance for replication and unique attribute conflicts, minimizes the chance for read-after-write issues that result from propagation delay, and maximizes performance and minimizes response time for read operations. You can do this by using criteria-based load balancing, which involves the following:

- Creating a failover load-balancing algorithm instance for write operations
- Creating a fewest operations load-balancing algorithm instance for read operations
- Creating a criteria-based load-balancing algorithm instance that uses failover load-balancing for write operations
- Configuring the proxying request processor to use the above criteria-based load balancing algorithm for writes and the fewest operations load-balancing algorithm for everything else

The following is an example of this configuration.

```
# Create a health check to verify that the dc=example,dc=com entry can be
# retrieved in a timely manner.
dsconfig create-ldap-health-check \
  --check-name dc_example_dc_com-retrieve-base-entry \
  --type search \
  --set enabled:true \
  --set base-dn:dc=example,dc=com \
  --set allow-no-entries-returned:false \
  --set allow-multiple-entries-returned:false

# Create a health check to verify that replication is working without a
# significant backlog.
dsconfig create-ldap-health-check \
  --check-name dc_example_dc_com-replication-backlog \
  --type replication-backlog \
  --set enabled:true \
  --set base-dn:dc=example,dc=com

# Create an LDAP external server template with the above
dsconfig create-ldap-external-server-template \
  --template-name dc_example_dc_com \
  --set health-check:dc_example_dc_com-retrieve-base-entry \
  --set health-check:dc_example_dc_com-replication-backlog

# Create a fewest operations failover load-balancing algorithm instance that
# uses the default LDAP external server template for backend servers that it
# discovers from the topology registry.
dsconfig create-load-balancing-algorithm \
  --algorithm-name dc_example_dc_com-fewest-operations \
  --type fewest-operations \
  --set enabled:true \
```

```

--set ldap-external-server-template:dc_example_dc_com

# Create a failover load-balancing algorithm instance that also uses the
# default LDAP external server template for backend servers that it
# discovers from the topology registry.
dsconfig create-load-balancing-algorithm \
  --algorithm-name dc_example_dc_com-failover \
  --type failover \
  --set enabled:true \
  --set ldap-external-server-template:dc_example_dc_com

# Create a criteria-based load-balancing algorithm instance that will use
# failover load-balancing for writes.
dsconfig create-criteria-based-load-balancing-algorithm \
  --algorithm-name failover-for-writes \
  --set load-balancing-algorithm:dc_example_dc_com-failover \
  --set "request-criteria:Write Requests"

# Create a proxying request processor instance that uses criteria-based load
# balancing to ensure that writes use a failover strategy, and the remaining
# read operations use a default fewest operations strategy.
dsconfig create-request-processor \
  --processor-name dc_example_dc_com \
  --type proxying \
  --set load-balancing-algorithm:dc_example_dc_com-fewest-operations \
  --set criteria-based-load-balancing-algorithm:failover-for-writes

# Create a subtree view to ensure that operations below "dc=example,dc=com"
# will use the above proxying request processor.
dsconfig create-subtree-view \
  --view-name dc_example_dc_com \
  --set "base-dn:dc=example,dc=com" \
  --set request-processor:dc_example_dc_com

# Update the default client connection policy to include the above subtree
# view.
dsconfig set-client-connection-policy-prop \
  --policy-name default \
  --add subtree-view:dc_example_dc_com

```

### Associating PingDirectory Server instances with the appropriate load-balancing algorithms

When Directory Server is configured with an LDAP external server template, either the fewest operations algorithm or the failover load-balancing algorithm uses the topology registry to determine which Directory Server instances should be accessible through the server.

To accomplish this, the load-balancing algorithm searches for `directory-server-instance` objects with a `load-balancing-algorithm-name` property that matches the name of the load-balancing algorithm. For example, in the following sample configuration, the load-balancing algorithms are named `dc_example_dc_com-fewest-operations` and `dc_example_dc_com-failover`, so if you want a Directory Server instance to be accessible through those load-balancing algorithms, add those values to the `load-balancing-algorithm-name` property in the topology registry's entry for that instance. You can do this with a configuration change similar to the following.

```

dsconfig set-server-instance-prop \
  --instance-name dsl.example.com:636 \
  --add load-balancing-algorithm-name:dc_example_dc_com-fewest-operations
\
  --add load-balancing-algorithm-name:dc_example_dc_com-failover

```

The PingDirectoryProxy Server automatically detects and reacts to applicable changes in the topology registry. This includes the following:

### Adding a new Directory Server instance to the topology

If this instance has any `load-balancing-algorithm-name` values that match the names of any load-balancing algorithms that are configured for automatic backend server discovery, the new instance is immediately eligible to process client requests as soon as the instance satisfies all of the configured health checks.

### Removing an existing Directory Server instance

If this instance was associated with any load-balancing algorithms, then it is no longer eligible to receive requests through these load-balancing algorithms.

### Modifying an existing Directory Server instance to add one or more values to the `load-balancing-algorithm-name` property

If any of the new values matches the name of any of the configured load-balancing algorithms, the instance is immediately eligible to process client requests.

### Modifying an existing Directory Server instance to remove one or more values from the `load-balancing-algorithm-name` property

If any of the removed values matches the name of any of the configured load-balancing algorithms, then the instance is no longer eligible to receive requests through these load-balancing algorithms.

## Automatic backend server discovery with entry balancing

Entry balancing allows directory data to be split across multiple mutually exclusive sets of backend servers.

This can provide better scalability by allowing a data set to be fully cached even if it is too large to fit in the memory of any single system. It can also provide better write performance by spreading entries into multiple independent replication sets.

Entry balancing breaks the data into backend sets. Each backend set has its own proxying request processor, which has its own load-balancing configuration which might optionally include criteria-based load balancing. Each of these load-balancing algorithms can be configured to use automatic backend set discovery in exactly the same way as in a non-entry-balanced configuration. The backend sets must be explicitly configured, but the servers within each set can be automatically determined from the information in the topology registry.

## Creating a standard multi-location deployment

In this example deployment, PingDirectory Server will be deployed in the data centers of two geographic locations, east and west. All LDAP external servers in this deployment are PingDirectory Servers.

The directory servers in the eastern city are assigned to the location named east, and the directory servers in the western city are assigned to the location named west.

### Note:

Password policies should be kept synchronized across all PingDirectory Server and Directory Proxy Server instances. See the PingDirectory Server Administration Guide for details about configuring password policies.

This example refers to four PingDirectory Server instances in two locations with replication of the `dc=example,dc=com` base distinguished name (DN) enabled:

- `ds-east-01.example.com`
- `ds-east-02.example.com`
- `ds-west-01.example.com`
- `ds-west-01.example.com`

You will configure four Directory Proxy Server instances:

- proxy-east-01.example.com
- proxy-east-02.example.com
- proxy-west-01.example.com
- proxy-west-02.example.com

### Overview of the deployment steps

This deployment scenario involves the following procedure:

- Install the first Directory Server in the east location using the `setup` or `setup.bat` file included in the `.zip` installation file.
- Use the **create-initial-proxy-config** tool to provide a proxy user bind DN and password, define locations for each of our data centers, and configure the LDAP external servers in these data centers.
- Test that external server communications after initial setup is complete and test a simulated external server failure.
- Install the second proxy server in the east location using the `setup` or `setup.bat` file included in the zip installation file and copy the configuration of the first Directory Proxy Server using the configuration cloning feature.
- Install two Directory Proxy Server instances in the west location, which includes using the `setup` file and manually setting the location to west using the **dsconfig** command and then copying the configuration of the Directory Proxy Server using the configuration cloning feature.

After you have configured and tested the proxy server, tour the configuration of each of the proxy server components. You can modify these properties later as needed using the **dsconfig** tool.

### Installing the first Directory Proxy Server

Install the first Directory Proxy Server from the `.zip` installation file.

#### About this task

To begin with, we have the PingDirectory Server installation `.zip` file. In this example, we plan to use SSL security, so we also have a key store certificate database and a `.pin` file that contains the private key password for the key store. The key store files are only necessary when using SSL or StartTLS.

In this deployment scenario, the key store database is assumed to be a Java KeyStore (JKS), which can be created by the `keytool` program.

The PingDirectory directory contains the following.

```
root@proxy-east-01: ls
ExampleKeystore.jks  ExampleTruststore.jks ExampleKeystore.pin
PingDirectory-8.1.0.0-with-je.zip
```

The `ExampleKeystore.jks` key store file contains the private key entry for the `proxy-east-01.example.com` server certificate with the alias `server-cert`. The server certificate, certificate authority (CA), and intermediate signing certificates are all contained in the `ExampleTruststore.jks` file. The password for `ExampleKeystore.jks` is defined in clear text in the corresponding `.pin` file, though the name of the file need not match as it does in this example. The private key password in this example is the same as the password defined for the `ExampleKeystore.jks` key store.

#### Steps

1. Extract the compressed archive file into the PingDirectory directory and move to this directory.

Example:

```
root@proxy-east-01: unzip -q PingDirectory-<version>-with-je.zip
root@proxy-east-01: cd PingDirectory
```

2. Copy the key store and `.pin` files into the `config` directory.

Example:

```
root@proxy-east01: cp ../Keystore* config/
root@proxy-east01: cp ../Truststore* config/
```

3. Install the first proxy server by running the `setup` tool on `proxy-east-01.example.com`.

Example:

```
root@proxy-east01: ./setup --no-prompt --acceptLicense \
--ldapPort 389 --rootUserPassword pass \
--aggressiveJVMTuning --maxHeapSize 1g \
--enableStartTLS --ldapsPort 636 \
--useJavaKeystore config/ExampleKeystore.jks \
--keyStorePasswordFile config/ExampleKeystore.pin \
--certNickname server-cert \
--useJavaTrustStore config/ExampleTruststore.jks
```

Result:

New key store password files are created in `config/keystore.pin`. The original file, `config/ExampleKeystore.pin`, is no longer needed. If you are not using SSL or StartTLS, then the SSL arguments are not necessary.

```
root@proxy-east01: ./setup --no-prompt --acceptLicense \
--ldapPort 389 --rootUserPassword pass \
--aggressiveJVMTuning --maxHeapSize 1g
```

Next steps

After installing the Directory Server, you can configure it using the `create-initial-proxy-config` tool as presented in [Configuring the first Directory Proxy Server](#).

### Configuring the first Directory Proxy Server

After the Directory Server has been installed, it can be automatically configured using the `create-initial-proxy-config` tool.

About this task

The tool `create-initial-proxy-config` can only be used once for this initial configuration, after which you must use `dsconfig` to make any changes to your proxy server configuration.

Configuring the Directory Server with the `create-initial-proxy-config` tool involves the following steps:

- Providing a Directory Server base distinguished name (DN) and password.
- Defining locations for each of our data centers, east and west.
- Configuring the LDAP external server in the east location.
- Configuring the LDAP external servers in the west location.
- Applying the changes to the Directory Server.

Steps

1. After completing setup, run the `create-initial-proxy-config` tool.

Example:

```
root@proxy-east01: bin/create-initial-proxy-config
```

2. Provide the bind DN and password that the Directory Proxy Server will use to authenticate to the backend PingDirectory Server instances.

The `create-initial-proxy-config` tool requires that the same bind DN and password be used to authenticate to all of the backend servers. All Directory Proxy Server instances have identical proxy user accounts and passwords. If necessary, the proxy user account password can be defined differently for each external server using `dsconfig` after the `create-initial-proxy-config` tool has been executed.

3. Specify the type of external server communication security that will be used to communicate with the PingDirectory Server instances.

For this example, enter the option for `None`.

4. Specify the base DN of the PingDirectory Server instances that the Directory Proxy Server will access.

For this example, use `dc=example,dc=com`.

5. Enter any other base DN of the PingDirectory Server instances that will be accessed through the proxy server.

Because you are only using one proxy base DN, press Enter to finish.

### Defining locations

Define the first location, `east`, to accommodate the servers in the deployment located on the East Coast of the United States.

About this task

Continuing from the same `create-initial-proxy-config` session:

Steps

1. Enter a location name for the Directory Proxy Server. Press Enter.  
In this example, enter `east`.
2. Define a location named `west` for the servers in our deployment located on the West Coast. Press Enter.
3. Select the location that contains the Directory Proxy Server itself.

The Directory Proxy Server is located in the `east`.

### Configuring the external servers in the east and west locations

After the locations have been defined, identify the directory servers.

Start by defining one of the servers in the east location.

#### Configuring the external servers in the east location

Steps

1. Define one of the servers in the east location by entering the host name and port of the server.

Example:

For this example, enter `ds-east-01.example.com:389`.

```
>>>> External Servers
```

```
External Servers identify directory server instances including
host, port, and authentication information.
```

```
Enter the host and port (host:port) of the first directory server
in 'east'
```

```
b) back
q) quit
```

```
Enter a host:port or choose a menu item [localhost:389]: ds-
east-01.example.com:389
```

2. Enter the option to prepare the server and all subsequent servers.

Preparing the servers involves testing the connections to these servers and sets up the `cn=Proxy User` account on the Directory Proxy Server.

3. Enter the DN of the account with which to manage the `cn=Proxy User`, `cn=Root DNs`, `cn=config` account.

For this example, use the default, `cn=Directory Manager`.

4. Repeat the previous steps to prepare the other server in the east location, `ds-east-02.example.com`.
5. Press Enter to complete preparing the servers.

### Configuring the external servers in the west location

#### About this task

The same process used for the east location is used to define the LDAP external servers for the west location.

#### Steps

1. Define the first external server, `ds-west-01.example.com`.
2. Define the second server in the west location, `ds-west-02.example.com`.
3. Press Enter.

### Apply the configuration to the Directory Proxy Server

Review the configuration summary.

#### About this task

After confirming that the changes are correct, press Enter to write the configuration.

#### Steps

1. Review the configuration and then apply the changes to the Directory Proxy Server. Press Enter to write the configuration to the server.

During the configuration process, the `create-initial-proxy-config` tool writes the configuration settings to a `dsconfig` batch file, which are applied to the Directory Proxy Server. The batch file can be reused to configure other servers. On the final step, the `create-initial-proxy-config` tool presents a configuration summary.

2. On the final confirmation prompt, press Enter to apply the changes to the proxy server, and then enter the LDAP connection parameters to the server.

After the changes have been applied, the `create-initial-proxy-config` tool cannot be used to configure this proxy server again.

## Configuring additional Directory Proxy Server instances

Install and configure additional Directory Proxy Server using the **setup** tool.

### About this task

Install and configure the second Directory Proxy Server by running the **setup** tool on `proxy-east-02.example.com`.

### Steps

1. Copy the key store and `.pin` files into the `config` directory for the `proxy-east-02.example.com` server.

Example:

```
root@proxy-east-02: cp ../Keystore* config/
root@proxy-east-02: cp ../Truststore* config/
```

2. Install the second Directory Proxy Server by running the **setup** tool on `proxy-east-02.example.com`.

Example:

```
root@proxy-east-02: ./setup --no-prompt \
--listenAddress proxy-east-02.example.com \
--ldapPort 389 --enableStartTLS --ldapsPort 636 \
--useJavaKeystore config/ExampleKeystore.jks \
--keyStorePasswordFile config/ExampleKeystore.pin \
--certNickName server-cert \
--useJavaTrustStore config/ExampleTruststore.jks \
--rootUserPassword pass --acceptLicense \
--aggressiveJVMTuning --maxHeapSize 1g \
--localHostName proxy-east-02.example.com \
--peerHostName proxy-east-01.example.com \
--peerPort 389 --location east
```

3. Configure the third Directory Proxy Server, `proxy-west-01.example.com` in the same way as shown in steps 1 - 2.

Example:

```
root@proxy-west-01: cp ../Keystore* config/
root@proxy-west-01: cp ../Truststore* config/
```

4. Run the **setup** tool on `proxy-west-01.example.com`.

Example:

```
root@proxy-west-01: ./setup --no-prompt \
--listenAddress proxy-west-01.example.com \
--ldapPort 389 --enableStartTLS --ldapsPort 636 \
--useJavaKeystore config/ExampleKeystore.jks \
--keyStorePasswordFile config/ExampleKeystore.pin \
--certNickName server-cert \
--useJavaTrustStore config/ExampleTruststore.jks \
--rootUserPassword pass --acceptLicense \
--aggressiveJVMTuning --maxHeapSize 1g \
--localHostName proxy-west-01.example.com \
--peerHostName proxy-east-01.example.com \
--peerPort 389 --location west
```

5. Repeat steps 1 - 4 to install the last Directory Proxy Server.

## Result

All proxies have the same Admin Data backend and have the `all-servers` group defined as their configuration-server-group in the Directory Proxy Server Global Configuration object. When making a change to a Directory Proxy Server using the `dsconfig` command-line tool or the Administrative Console, you have the choice to apply the changes locally only or to all proxies in the `all-servers` group.

### Testing external server communications after initial setup

After setting up the basic deployment scenario, the communication between the proxies and the LDAP external servers can be tested using a feature in the proxy server in combination with an LDAP search.

#### About this task

After initial setup, the Directory Server exposes a special search base distinguished name (DN) for testing external server connectivity, called the `backend server pass-through subtree view`. While disabled by default, you can enable this feature using `dsconfig` in the Client Connection Policy menu.

#### Steps

1. Run `dsconfig` to set the `include-backend-server-passthrough-subtree-views` property to `TRUE`.

Example:

```
root@proxy-east-01: dsconfig set-client-connection-policy-prop \
--policy-name default \
--set include-backend-server-passthrough-subtree-views:true
```

Result:

When set to `TRUE`, an LDAP search against the Directory Proxy Server with the base DN `dc=example,dc=com,ds-backend-server=ds-east-02.example.com:389` instructs the Directory Proxy Server to perform the search against the `ds-east-02.example.com:389` external server with the base DN set to `dc=example,dc=com`. The value of `ds-backend-server` should be the name of the configuration object representing the external server. Depending on your naming scheme, this name might not be a `host:port` combination.

2. Run `ldapsearch` to fetch the `dc=example,dc=com` entry from the `ds-east-01.example.com` server.

Perform this search on each external server to determine if external server communication has been configured correctly on the Directory Proxy Server.

Example:

```
root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=Directory Manager" \
--bindPassword password \
--baseDN "dc=example,dc=com,ds-backend-server=ds-east-01.example.com:389" \
--searchScope base --useStartTLS "(objectclass=*)" "
```

3. Use this special subtree view to track the operations performed on each external server to help determine load balancing requirements.

This LDAP search can be run with the base DN values for the `ds-east-01` and `ds-east-02` servers to track the distribution of search and bind requests over time. These statistics are reset to zero when the server restarts.

Example:

The following example searches an external server's monitor entry to display operation statistics.

```
root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=directory manager" \
--bindPassword password \
--baseDN "cn=monitor,ds-backend-server=ds-east-02.example.com:389" \
--searchScope sub --useStartTLS "(cn=ldap*statistics)"

dn: cn=LDAP Connection Handler 192.168.1.203 port 389
Statistics,cn=monitor,ds-backend-server=ds-east-02.example.com:389

objectClass: top
objectClass: ds-monitor-entry

## Testing a simulated external server failure

After you have tested connectivity, run a simulated failure of a load-balanced external server to verify that the Directory Proxy Server redirects LDAP requests appropriately.

### About this task

In this procedure, stop the `ds-east-01.example.com:389` server instance and test searches through `proxy-east-01.example.com`.

### Steps

1. Perform several searches against the Directory Proxy Server. Verify activity in each of the servers in the east location, `ds-east-01` and `ds-east-02`, by looking at the access logs.

Because you used the default load balancing algorithm of fewest operations, it's likely that all of the searches go to only one of the proxies.

Example:

The following simple search can be repeated as needed.

```
root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=Directory Manager" \
--bindPassword password --baseDN "dc=example,dc=com" \
--searchScope base --useStartTLS "(objectclass=*)"
```

2. Stop the Directory Server instance on `ds-east-01.example.com` using the **stop-server** command and immediately retry the searches in step 1.

#### Note:

There should be no errors or noticeable delay in processing the search.

Example:

```
root@ds-east-01: bin/stop-server

root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=Directory Manager" \
--bindPassword password --baseDN "dc=example,dc=com" \
--searchScope base --useStartTLS "(objectclass=*)"
```

3. Restart the Directory Proxy Server instance on `ds-east-01.example.com`.
4. Check the access log to confirm that the Directory Proxy Server started to include the `ds-east-01` server in load-balancing within 30 seconds.

The default time is 30 seconds, but you can change this default.

## Expanding the deployment

In the following example deployment, the PingDirectory Server is deployed in a third, centrally-located data center.

The directory servers in the central city is assigned to a new location named `central`. The proxies use StartTLS to communicate with the directory servers in the central region.

#### Note:

Other than the ability to add to the Directory Proxy Server's trust store, the **prepare-external-server** tool does not alter the Directory Proxy Server configuration in any way.

The Directory Proxy Server itself, installed on `proxy-east-01.example.com`, remains in the east location. This example reconfigures load balancing between the six directory servers in these locations:

- `ds-east-01.example.com`
- `ds-east-02.example.com`
- `ds-west-01.example.com`
- `ds-west-02.example.com`
- `ds-central-01.example.com`
- `ds-central-02.example.com`

### Overview of deployment steps

This deployment scenario takes the following steps:

1. Prepare the new external servers using the `prepare-external-server` tool.
2. Use the `dsconfig` tool to configure the new LDAP external servers in the central data center and reconfigure the load-balancing algorithm to take these servers into account.
3. Test external server communications after the servers have been configured and test a simulated external server failure.

### Preparing two new external servers using the `prepare-external-server` tool

Prepare the external directory servers, `ds-central-01` and `ds-central-02`, by creating the proxy user account and the supporting access rules.

#### About this task

Connect to the `ds-central-01` PingDirectory Server using StartTLS. Because you are using StartTLS, you must capture the `ds-central-01` server's certificate and put it in the trust store on your Directory Proxy Server instance.

The `prepare-external-server` tool is located in the `bin` or `bat` directory of the server root directory, PingDirectory. In this example, run the tool on the `ds-east-01` instance of the Directory Proxy Server.

#### Steps

1. Run the `prepare-external-server` tool to prepare the two new servers.

Example:

On the first attempted bind to the server, the tool reports a `failed to bind` message because it can't bind to the `cn=Proxy User` entry because it hasn't been created yet. The tool sets up the `cn=Proxy User` entry so that the Directory Proxy Server can access it and tests the communication settings to the server.

```
root@proxy-east-01: ./prepare-external-server \
--hostname ds-central-01.example.com --port 389 \
--baseDN dc=example,dc=com \
--proxyBindPassword password \
--useStartTLS \
--proxyTrustStorePath ../config/ExampleTruststore.jks

Failed to bind as 'cn=Proxy User'

Would you like to create or modify root user 'cn=Proxy User' so that it
is
available for this Directory Proxy Server? (yes / no)[yes]:

Enter the DN of an account on ds-central-01:389 with which to create or
manage the 'cn=Proxy User'
account [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':
```

```
Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User' privileges ....Done
```

2. Repeat the process on the other new server in the central location, `ds-central-02`.

#### Note:

For entry-balancing deployments, the global base distinguished name (DN) is required when using `prepare-external-server`.

## Adding the new PingDirectory Servers to the Directory Proxy Server

After preparing the external PingDirectory Servers to communicate with the Directory Server, add the two servers in the central location to the proxy server instance.

### About this task

Because you ran the `prepare-external-server` tool, the two servers have the `cn=Proxy User` entry configured.

### Steps

- Run the `dsconfig` tool.

Example:

```
root@proxy-east-01:~/dsconfig
>>>> Specify LDAP connection parameters

Directory Proxy Server host name or IP address [localhost]:

How do you want to connect to the Directory Proxy Server at
localhost?

    1)  LDAP
    2)  LDAP with SSL
    3)  LDAP with StartTLS

Enter choice [1]: 1

Directory Proxy Server at localhost port number [389]:
Administrator user bind DN [cn=Directory Manager]:
Password for user 'cn=Directory Manager':
```

## Adding new locations

Add a new central location to which the new PingDirectory Servers will be added.

### About this task

The following steps show how to add the new servers to a new location using `dsconfig` interactive.

### Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.

Example:

```
$ bin/dsconfig
```

2. In the main menu, enter the number corresponding to **Location**.

3. In the `Location` menu, enter the number corresponding to creating a new location.
4. Enter the option to create a new location from scratch.
5. Configure the `preferred-failover-location` property of the new location so that this location fails over first to the east location and then to the west location if all of the servers in the central location become unavailable.
6. Add the east and west locations as values of the property, specifying them in the order that they will be used for failover.
7. Confirm that these are the correct values and finish configuring the location.

### Editing the existing locations

Edit the existing east and west locations to include the new central location in their failover logic.

#### About this task

The new failover logic is based on geographic distance so that the east location will first fail over to the central and then the west location.

The following example procedure uses `dsconfig` interactive mode to edit the east location.

#### Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. In the Directory Proxy Server console configuration menu, enter the number corresponding to Location.
3. In the `Location` menu, enter the number corresponding to viewing and editing an existing location. Then, enter the number corresponding to the Location to be changed.
4. Remove the west location from the `preferred-failover-location` property.  
You will add the west location later.
5. Add a new value to the `preferred-failover-location` property.
6. Select the values of the new failover locations for the east.
7. Confirm the new configuration information and save the changes.
8. Repeat steps 2-7 to reconfigure the failover logic for the west location to include the new central location.
9. List the locations to confirm that the new location was added correctly.

### Adding new health checks for the central servers

Add new health checks for the two new servers.

#### Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. Select the number corresponding to creating a new health check.
3. Enter the option to use an existing health check as a template.
4. Enter the number corresponding to the `ds-east-01` health check to use it as a template for the new health check.
5. Name the new health check using the same naming strategy established for the other servers in the deployment.

Example:

As this health check is for the `ds-central-01` server, the name takes the following format.

```
>>>> Enter a name for the Search LDAP Health Check that you want to
create:
```

```
ds-central-01.example.com:389_dc_example_dc_com-search-health-check
```

6. Review the configuration properties and then enter `f` to finish configuring the new health check and save changes.
7. Repeat steps 2-6 to create another new health check for the `ds-central-02` server.

### Adding new external servers

Add new external servers using `dsconfig`.

About this task

Add new external servers by selecting `External Server` from the main menu.

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. In the `External Server` menu, enter the number corresponding to `Create a new External Server`.
3. Base the configuration of the new external server on the existing configuration of the `ds-east-01` server. Enter `t` to use an existing external server as a template.
4. Enter the number to base the configuration of the new server on the configuration of the `ds-east-01` server.
5. Enter a name for the new `ds-central-01` server that complies with the naming strategy.

Example:

```
>>>> Enter a name for the Ping Identity DS External Server that you
want to create: ds-central-01.example.com:389
```

6. Enter the value of the `server-host-name` property.
7. Review and modify the configuration properties of the external server.
8. In the `External Server` menu, change the `server-host-name` property to reflect the name of the `ds-central-01` server.
9. In the `External Server` menu, change the `location` property to reflect the central location.
10. Change the `health-check` property to reflect the new health check created for the `ds-central-01` server in the previous section.
11. On the `'health-check'` Property menu, enter the number to remove one or more values.
12. Add the health-check created in the previous section.
13. Select the health check associated with the `ds-central-01` server.
14. Press `Enter` to use the value associated with `ds-central-01` health check.
15. Review the configuration of the new external server and enter `f` to create the server.
16. Repeat steps 1-15 to add the new `ds-central-02` external server.

### Modifying the load-balancing algorithm

Modify the existing load-balancing algorithm to include the newly created servers.

About this task

To modify the existing load-balancing algorithm to include the newly created servers, select `Load-Balancing Algorithm` from the main menu.

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. Select the option for `Load-Balancing Algorithm`.

3. On the `Load-Balancing Algorithm` menu, enter the number corresponding to view and edit an existing `Load-Balancing Algorithm`.
4. Add the `ds-central-01` and `ds-central-02` servers to the `backend-server` configuration property.
5. On the `backend-server property` menu, enter the number corresponding to adding one or more values.
6. Select the external servers to add.

For this example, select `ds-central-01.example.com` and `ds-central-02.example.com`.

7. Review the changes made to the load-balancing algorithm's configuration properties, and enter `f` to save changes.

Result:

The change is saved and applied to the Directory Proxy Server. The load-balancing algorithm is referenced in the `load-balancing-algorithm` property of the request processor used by this Directory Proxy Server.

8. To view this property, go to the main menu and select the `Request Processor` option.
9. In the `Request Processor` menu, enter the number corresponding to view and edit an existing request processor.
10. Select the request process used by the Directory Proxy Server, and review the configuration properties.

Result:

This request processor is used by the subtree view serviced by the Directory Proxy Server, which is in turn referenced by the client connection policy.

**Note:**

The changes made in this procedure are already in effect. The Directory Proxy Server does not have to be restarted.

## Testing external server communication

### About this task

After adding and configuring the new external servers, test the communication between the Directory Proxy Server and the LDAP external servers using the `include-backend-server-passthrough-subtree-views` property of the Directory Proxy Server in combination with an LDAP search. For more information about this option, see [Testing External Server Communications](#) on page 190.

### Steps

- Run the `ldapsearch` command to test communications on the `ds-central-01` serverTask.

Example:

```
root@proxy-east-01: bin/ldapsearch --port 389 --bindDN "cn=directory
manager" \
--bindPassword password \
--baseDN "dc=example,dc=com,ds-backend-server=ds-
central-01.example.com:389" \
--searchScope base "(objectclass=*)"
```

You can repeat this search on the `ds-central-02` server, to confirm that the server returns the entry as expected.

## Testing a simulated external server failure

After you have tested connectivity, run a simulated failure of a load-balanced external server to verify that the Directory Proxy Server redirects LDAP requests appropriately.

About this task

To run a simulated external server failure:

### Steps

1. Stop the `ds-east-01.example.com:389` and `ds-east-02.example.com:389` server instances and test searches through `proxy-east-01.example.com`.
2. Perform several searches against the Directory Proxy Server and verify activity in each of the servers in the east location, `ds-east-01` and `ds-east-02`, by looking at the access logs.

Example:

The following simple search can be repeated as needed.

```
root@proxy-east-01: bin/ldapsearch --bindDN "cn=Directory Manager" \
--bindPassword password --baseDN "dc=example,dc=com" \
--searchScope base --useStartTLS "(objectclass=*)"
```

3. Stop the Directory Server instance on `ds-east-01.example.com` and `ds-east-02.example.com` using the **stop-server** command and immediately retry the searches in step 2.

There should be no errors or noticeable delay in processing the search.

Example:

```
root@proxy-east-01: bin/stop-server

root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=Directory Manager" --bindPassword password \
--baseDN "dc=example,dc=com" --searchScope base --useStartTLS \
"(objectclass=*)"
```

4. Check the access log to confirm that requests made to these servers are routed to the central servers because these servers are the first failover location in the failover list for the `ds-east-01` and `ds-east-02` servers.
5. Restart the Directory Server instance on `ds-east-01.example.com` and `ds-east-02.example.com`.
6. Check their access logs to ensure that traffic is redirected back from the failover servers.

## Merging two data sets using proxy transformations

In the following example, the Example.com company acquires Sample Corporation.

During the merger, Example.com migrates data from Sample Corporation's `o=sample` rooted directory, converting Sample Corporation's `sampleAccount` auxiliary object class usage to Example.com's `exampleAccount` object class for entries rooted under `dc=example,dc=com`.

Knowing that it can take considerable time for Sample Corporation's directory clients to become aware of the new directory information tree (DIT) and schema, proxy data transformations are created to give the Sample Corporation's clients as consistent a view of the data as possible during the migratory period. These transformations allow the clients to search and modify entries under `o=sample` using the Sample Corporation schema.

## Overview of the attribute and DN mapping

To achieve the merger of the two data sets, create proxy transformations that map the Sample Corporation's source attributes to Example.com target attributes.

The Example.com schema already defines an attribute to contain the relative distinguished name (RDN) of user entries, called `uid`. However, Example.com chooses to create two new attributes within its `exampleAccount` object class to accommodate two attributes in the Sample Corporation schema for representing the region and the distinguished name (DN) of linked accounts.

During the merger, Example.com decides to re-parent the Sample Corporation's customer entries, which are defined under two different subtrees, `ou=east,o=sample` and `ou=west,o=sample`, placing them under Example.com's `ou=people,dc=example,dc=com` subtree. Associated proxy transformations are described in the DN Mappings table below. In this process, Example.com collapses the Sample Corporation tree, moving entries from the east and west region under a single DN, `dc=example,dc=com`. The DN proxy transformations assume that all the Sample Corporation users have been co-located under this single Example.com subtree.

| Sample Attribute                  | Example.com Attribute               | Description                          |
|-----------------------------------|-------------------------------------|--------------------------------------|
| <code>sampleID</code>             | <code>uid</code>                    | RDN of user entries                  |
| <code>sampleRegion</code>         | <code>exSampleRegion</code>         | String value representing the region |
| <code>sampleLinkedAccounts</code> | <code>exSampleLinkedAccounts</code> | DN value                             |

Legacy Sample LDAP applications searching for entries in either the Sample Corporation base DN `ou=east,o=sample` or `ou=west,o=sample` will be successfully serviced, though there will be one or more differences in the user entries seen by the Sample Corporation legacy applications.

Because the Example.com Directory Server has no knowledge of the Sample Corporation user's former `ou=east` or `ou=west` association, search results for client searching under `o=sample` will return a DN that might differ from the original search base. For instance, a search for `sampleID=abc123` under `ou=west,o=sample` might return the user entry for `abc123` with the DN of `sampleID=abc123,ou=east,o=sample`.

The following table illustrates the mapping DNs.

| Sample DN                     | Example.com DN                 |
|-------------------------------|--------------------------------|
| <code>ou=east,o=sample</code> | <code>dc=example,dc=com</code> |
| <code>ou=west,o=sample</code> | <code>dc=example,dc=com</code> |
| <code>o=sample</code>         | <code>dc=example,dc=com</code> |

## About mapping multiple source DNs to the same target DN

Some complications exist when defining multiple distinguished names (DN) mappings that are used for the same request processor and the same source or target DN or that have source or target DNs that are hierarchically related.

The client request might not include enough information to disambiguate and determine the proper rule to follow.

Several solutions exist to avoid problems of disambiguation. If the client does not need to be able to see all mappings at the same time, then a new client connection policy can be created to use connection criteria that select the set of mappings applied to the client based on information such as the IP address or bind DN. Each client connection policy would have separated subtree views with separate proxying request processors that reference the appropriate transformation for that client.

Alternatively, if it is unnecessary to search under the `o=sample` base DN, then you can create separate subtree views in the same client connection policy. For example, you would create one subtree view for `ou=east, o=sample` and one for `ou=west, o=sample`. Each subtree view is then associated with its own proxying request processor, one for `ou=east` requests and one for `ou=west` requests.

### Example of a migrated sample customer entry

The following is an example of a Sample Corporation customer entry that has been migrated to the Example.com database.

The user entry is defined in Example.com Directory Server's database as follows.

#### Note:

This view is how the entry appears to search requests under the `dc=example, dc=com` base distinguished name (DN).

```
dn: uid=scase,ou=People,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: exampleAccount
objectClass: top
description: A customer account migrated from Sample merger
uid: scase
exAccountNumber: 234098
exSampleRegion: east
exSampleLinkedAccounts: uid=jcase,ou=people,dc=example,dc=com
userPassword: password
givenName: Sterling
cn: Sterling Case
sn: Case
telephoneNumber: +1 804 094 3356
street: 00468 Second Street
l: Arlington
mail: sterlingcase@maildomain.com st: VA
```

The following example shows what the Directory Proxy Server returns to LDAP clients who have requested the entry when searching under the `o=sample` base DN.

#### Note:

The DN returned includes `ou=east` even though this branch doesn't exist in the Example.com directory information tree (DIT). It also returns the attribute names as they are defined in the Sample Corporation schema.

```
dn: sampleID=scase,ou=east,o=sample
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: exampleAccount
objectClass: top
description: A customer account migrated from Sample merger
uid: scase
exAccountNumber: 234098
exSampleRegion: east
exSampleLinkedAccounts: sampleID=jcase,ou=people,dc=example,dc=com
userPassword: password
givenName: Sterling
cn: Sterling Case
```

```
sn: Case
telephoneNumber: +1 804 094 3356
street: 00468 Second Street
l: Arlington
mail: sterlingcase@maildomain.com st: VA
```

### Overview of deployment steps

This deployment scenario takes the following steps:

- Install any necessary schema on the Directory Proxy Server.
- Create three attribute mapping proxy transformations and three distinguished name (DN) mapping proxy transformations.
- Create a new proxying request processor using the existing `dc_example_dc_com` request processor as a template.
- Assign the six proxy transformations to the new proxying request processor.
- Create a new subtree view for `o=sample` that references the new proxying request processor.
- Add the new subtree view to the existing client connection policy.
- Test the configuration by performing some searches on the Sample Corporation directory information tree (DIT).

### About the schema

The Directory Proxy Server inherits user-defined schema from all external servers by comparing `cn=schema` on these servers at Directory Proxy Server startup and at five minute intervals.

In the following example, the Example.com company acquires Sample Corporation. The Example.com schema does not need to be added manually to the Directory Proxy Server's `config/schema` directory. We assume that the schema for Sample Corporation's entries has been defined on the external servers with the example.com directory information tree (DIT), requiring no direct schema management on the Directory Proxy Server. The following schema definitions are assumed to exist on the external Directory Server.

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( 1.3.6.1.4.1.32473.2.1.1
  NAME 'exAccountNumber'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  SINGLE-VALUE )
attributeTypes: ( 1.3.6.1.4.1.32473.1.1.3
  NAME 'sampleLinkedAccounts'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.12 )
attributeTypes: ( 1.3.6.1.4.1.32473.1.1.2
  NAME 'sampleRegion'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  SINGLE-VALUE )
attributeTypes: ( 1.3.6.1.4.1.32473.1.1.1
  NAME 'sampleID'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  SINGLE-VALUE )
attributeTypes: ( 1.3.6.1.4.1.32473.2.1.3
  NAME 'exSampleLinkedAccounts'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.12 )
attributeTypes: ( 1.3.6.1.4.1.32473.2.1.2
  NAME 'exSampleRegion'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  SINGLE-VALUE )
objectClasses: ( 1.3.6.1.4.1.32473.2.2.1
  NAME 'exampleAccount'
```

```
SUP top
AUXILIARY
MAY ( exAccountNumber $
      exSampleRegion $
      exSampleLinkedAccounts $
      sampleID $
      sampleRegion $
      sampleLinkedAccounts ) )
```

The schema file defines some example.com schema, such as `exAccountNumber` and `exSampleRegion`, and some Sample Corporation schema, such as `sampleRegion` and `sampleID`.

### Creating proxy transformations

In this deployment scenario, you create three attribute mapping proxy transformations and three distinguished name (DN) mapping proxy transformations.

#### About this task

To create attribute and distinguished name (DN) mapping proxy transformations, you can use the `dsconfig` tool, which is located in the `bin` or `bat` directory of the server root directory, PingDirectory.

#### Steps

1. In the main server root directory, PingDirectory, run the `start-server` command.
2. Run `dsconfig` in interactive mode and enter the LDAP connection parameters.
3. In the Configuration main menu, enter the number corresponding to your desired Proxy Transformation.

### Creating the Attribute Mapping Proxy Transformations

Create the attribute mapping proxy transformations using `dsconfig` interactive.

For this example, assume you are continuing from the previous `dsconfig` session in [Creating proxy transformations](#) on page 1356. In [Creating the DN mapping proxy transformations](#) on page 1356, this transformation maps `ou=east,o=sample` in the Sample Corporation schema `dc=example,dc=com` in the Example.com schema.

### Creating the DN mapping proxy transformations

Create the distinguished name (DN) mapping proxy transformations.

#### Steps

1. In the Proxy Transformation menu, enter the number corresponding to Create a new Proxy Transformation.
2. Enter the option to create a new Proxy Transformation.
3. Enter the option for DN Mapping Proxy Transformation.
4. Enter a name for the DN Mapping Proxy Transformation.

This transformation maps `ou=east,o=sample` in the Sample Corporation schema `dc=example,dc=com` in the Example.com schema.

5. To enable the transformation by default, select `True`.
6. Specify the source DN as it appears in client requests.

Example:

```
>>>> Configuring the 'source-dn' property
```

```
Specifies the source DN that may appear in client
requests which should be remapped to the target DN.
Note that the source DN must not be equal to the target DN.
```

Syntax: DN

Enter a value for the 'source-dn' property:  
ou=east,o=sample

7. Specify the target DN, where requests for the source DN should be routed.

Example:

```
>>>> Configuring the 'target-dn' property
```

Specifies the DN to which the source DN should be mapped.  
Note that the target DN must not be equal to the source  
DN.

Syntax: DN

Enter a value for the 'target-dn' property: dc=example,dc=com

8. To create the new DN mapping proxy transformation, enter `f`.
9. Repeat the previous steps to create a new DN mapping proxy transformation that maps `ou=west,o=sample` in the Sample Corporation schema to `dc=example,dc=com` in the `Example.com` schema, and name it `sample_west-to-example`.
10. Create a DN mapping proxy transformation for the base DN of the Sample Corporation database.

### Creating a request processor to manage the proxy transformations

Create a new proxying request processor that includes your new attribute and distinguished name (DN) mapping proxy transformations.

About this task

Use the existing `dc_example_dc_com` request processor as a template.

Steps

1. In the Configuration main menu, enter the number corresponding to Request Processor.
2. On the Request Processor menu, enter the number corresponding to Create a new Request Processor.
3. Select the option to use the current request processor as a template.
4. Enter a name for the new proxying request processor, such as `o_sample-req-processor`.
5. Review the properties and enter the number corresponding to the Transformation property.

#### Note:

The load-balancing algorithm is the same as for the previous request processor, but you must change the transformation property.

6. Enter the number corresponding to the proxy transformations that were previously created.

7. Select the attribute mapping proxy transformations, then select the DN mapping proxy transformations.

**Note:**

The order of the selection is important because you have related DNs. Begin with the DNs that are lower in the tree, and finish with the base DN transformation.

**Example:**

```
Select the Proxy Transformations you wish to add:

  1) sample-to-example          5) sampleLinkedAccounts-to-
  2) sample_east-to-example    6) exSampleLinkedAccounts
  3) sample_west-to-example    7) sampleRegion-to-
  4) sampleID-to-uid          8) exSampleRegion
                                7) Create a new Proxy
                                Transformation
                                8) Add all Proxy Transformations

  ?) help
  b) back
  q) quit

Enter one or more choices separated by commas [b]: 4,5,6,2,3,1
```

8. Confirm that the proxy transformations are listed in the correct order and press Enter to accept and use the values.
9. To save your changes, enter f.

### Creating subtree views

#### About this task

Configure subtree views for the Directory Proxy Server.

#### Steps

1. In the Configuration main menu, enter the number corresponding to Subtree View.
2. In the Subtree View menu, enter the number corresponding to Create a new Subtree View.
3. Enter the option to create the new subtree view from an existing subtree.
4. Select the dc\_example\_dc\_com-view subtree view.
5. Enter a descriptive name for the subtree view configuration.
6. Configure the base distinguished name (DN) property of the Sample Corporation data set.
7. Enter the request processor created in [Creating a request processor to manage the proxy transformations](#) on page 1357.
8. To save the changes, press f.

**Example:**

```
>>>> Configure the properties of the Subtree View

Property          Value(s)
-----
  1) description   -
  2) base-dn       "o=sample"
  3) request-processor o_sample-req-processor

  ?) help
```

```
f) finish - create the new Subtree View
d) display the equivalent dsconfig arguments to create this
   object
b) back
q) quit
```

### Editing the client connection policy

Edit the client connection policy.

About this task

To add the new `o=sample` subtree view:

Steps

1. In the Configuration main menu, enter the number corresponding to Client Connection Policy.
2. In the Client Connection menu, enter the number corresponding to Create a new Client Connection.
3. In the configuration properties, select the `subtree-view` property and enter the number corresponding to "Add one or more values" to add the new subtree view created for the previous example.
4. Select the subtree view that you created in [Creating subtree views](#) on page 1358.

Example:

```
Select the Subtree Views you wish to add:
```

```
1) o_sample-view
2) Create a new Subtree View
```

5. Review the subtree views now referenced by the property and press **Enter** to use these values.
6. Review the configuration properties of the client connection policy and enter `f` to save changes.

### Testing proxy transformations

You can test the proxy transformation service by imitating example client requests to search and modify users.

About this task

After setting up the deployment scenario, the Directory Proxy Server will respond to requests to the `dc=example,dc=com` and `o=sample` base distinguished names (DNs).

Steps

1. To view a Sample Corporation entry, run `ldapsearch`.

Example:

The following example fetches the user with `sampleID=scase` under the `ou=east,o=sample` base DN.

```
root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
--bindPassword password --baseDN "ou=east,o=sample" "(sampleID=scase) "
```

Result:

```
dn: sampleID=scase,ou=People,ou=east,o=sample
objectClass: person
objectClass: organizationalPerson
```

```

objectClass: inetOrgPerson
objectClass: exampleAccount
objectClass: top
description: A customer account migrated from Sample merger
sampleID: scase
userPassword: {SSHA}A5O4RrQHWXc2Ii3btD4exGdP0TVW9VL3CR3ZXAX==
exAccountNumber: 234098
givenName: Sterling
cn: Sterling Case
sn: Case
telephoneNumber: +1 804 094 3356
street: 00468 Second Street
mail: sterlingcase@maildomain.com
l: Arlington
st: VA
sampleRegion: east
sampleLinkedAccounts: sampleID=jcase,ou=People,ou=east,o=sample

```

2. Modify the `sampleRegion` value by changing it to `west`.

**Example:**

To modify the value, create an `ldapmodify` input file, called `scase-mod.ldif`, with the following contents.

```

dn: sampleID=scase,ou=People,ou=east,o=sample
changetype: modify
replace: sampleRegion
sampleRegion: west

```

3. Use the file as an argument in the `ldapmodify` command.

**Example:**

```

root@proxy-east-01: bin/ldapmodify --bindDN "cn=Directory Manager" \
--bindPassword password --filename scase-mod.ldif

```

**Result:**

```

Processing MODIFY request for sampleID=scase,ou=People, ou=east,o=sample
MODIFY operation successful for DN sampleID=scase,ou=People,
ou=east,o=sample

```

4. Search for the `scase` `sampleRegion` value under `o=sample`

**Example:**

```

root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
--bindPassword password --baseDN "o=sample" "(sampleID=scase)" \
sampleRegion

```

**Result:**

```

dn: sampleID=scase,ou=People,ou=east,o=sample
sampleRegion: west

```

5. To search for `scase`, use `uid` instead of `sampleID`, under the `dc=example,dc=com` base DN.

**Example:**

You can see the Example.com schema version of the entry in the following sample.

```

root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \

```

```
--bindPassword password --baseDN "dc=example,dc=com" "(uid=scase) "
```

**Result:**

```
dn: uid=scase,ou=People,dc=example,dc=com
objectClass: person
objectClass: exampleAccount
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
description: A customer account migrated from Sample merger
uid: scase
userPassword: {SSHA}A5O4RrQHWXc2Ii3btD4exGdP0TVW9VL3CR3ZXAX==
exAccountNumber: 234098
givenName: Sterling
cn: Sterling Case
sn: Case
telephoneNumber: +1 804 094 3356
street: 00468 Second Street
mail: sterlingcase@maildomain.com
l: Arlington
st: VA
exSampleRegion: west
exSampleLinkedAccounts: uid=jcase,ou=People,dc=example,dc=com
```

## Deploying an Entry-Balancing Directory Proxy Server

---

Depending upon the needs of your enterprise, you can deploy PingDirectory Server in a variety of ways.

This section describes and illustrates an entry-balancing deployment scenario that involves:

- [Deploying an entry-balancing proxy configuration](#) on page 1361
- [Rebalancing your entries](#) on page 1373
- [Managing the global indexes in entry-balancing configurations](#) on page 1376
- [Working with alternate authorization identities](#) on page 1383

### Deploying an entry-balancing proxy configuration

Entry-balancing is a Directory Proxy Server configuration that allows the entries within a portion of the directory information tree (DIT) to reside on multiple external servers.

This configuration is useful when the DIT contains many millions of entries, which can be difficult to bring completely into memory for optimal performance. Entry-balancing allows entries under a balancing point base distinguished name (DN) to be divided among any number of separate directory servers, making Directory Proxy Server responsible for intelligently routing requests based on the division.

In this example scenario, the entries in the DIT outside of the balancing point are replicated across all external servers known to Directory Proxy Server. You must properly configure replication on the external directory servers before proceeding through this example. The directory servers are expected to contain two replication domains: the global domain, `dc=example,dc=com`, and the balancing point, `ou=people,dc=example,dc=com`.

In this deployment scenario, an `austin-proxy1` instance of Directory Proxy Server communicates with four external directory servers. Directory Proxy Server is configured to use entry balancing for the `ou=people,dc=example,dc=com` base DN with two sets of user entries split beneath it. The first set of user entries is defined in the replicated pair of external servers, `austin-set1.example.com` and `newyork-set1.example.com`.

The second set of entries is defined in `austin-set2.example.com` and `newyork-set2.example.com`. The entries in the `dc=example,dc=com` DIT outside of the balancing point base DN are replicated among the four external servers.

The following `dsreplication status` output from the PingDirectory Server external servers describes the replication configuration that exists before creating the Directory Proxy Server configuration.

```
--- Replication Status for dc=example,dc=com: Enabled ---

Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
-----:-----:-----:-----:-----:-----

austin-set1.example.com:389 : 10003 : 0 : N/A : 722087263
austin-set2.example.com:389 : 10003 : 0 : N/A : 722087263
newyork-set1.example.com:389 : 10003 : 0 : N/A : 722087263
newyork-set2.example.com:389 : 10003 : 0 : N/A : 722087263

--- Replication Status for ou=people,dc=example,dc=com (Set: dataset1):
Enabled ---

Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
-----:-----:-----:-----:-----:-----

austin-set1.example.com:389 : 100001 : 0 : N/A : 178892712
newyork-set1.example.com:389 : 100001 : 0 : N/A : 178892712

--- Replication Status for ou=people,dc=example,dc=com (Set: dataset2):
Enabled ---

Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
-----:-----:-----:-----:-----:-----

austin-set2.example.com:389 : 100001 : 0 : N/A : 1057593890
newyork-set2.example.com:389 : 100001 : 0 : N/A : 1057593890
```

### Determining how to balance your data

If a single Directory Server instance can hold all of your data, then you should store your data on a single server and replicate for high availability to simplify your deployment.

If a single server can't hold all of your data, then you can spread it across multiple servers in these ways:

- If the data is already broken up by hierarchy and all of the clients understand how to access it that way, the number of top-level branches is small and a single Directory Server instance can hold all of the information within one or more branches. Configure the Directory Proxy Server with multiple base distinguished names (DNs) and use simple load-balancing rather than entry balancing to simplify your deployment.
- If simply breaking up the data using the existing hierarchy is not an option, for example if a large number of top-level branches must be configured, then consider using entry balancing. The contents of any single branch still must fit on a given server, because only entries that are immediate subordinates of the entry-balancing base DN might be spread across multiple servers. Any entries that are further subordinates must be placed in the same directory server instance as their parent.
- If one or more branches are so large that any single Directory Server instance can't hold all of the data, you need to use entry balancing within that branch to divide the entries among two or more sets of Directory Servers. You might also need to change the way that the data is arranged in the server so that it uses as flat a directory information tree (DIT) as possible, which is easier to use in an entry-balancing deployment.

In an entry-balancing deployment, there can be data that is common to all external directory servers outside the balancing point. This data is referred to as the global domain. The Directory Proxy Server entry-balancing configuration will contain at least two subtree views and associated request processors,

one for the global domain and one for the entry-balancing domain. In our examples, the global domain is `dc=example,dc=com`, and the entry-balancing domain is `ou=people, dc=example,dc=com`.

#### Note:

The entry-balancing base DN, `ou=people,dc=example,dc=com`, is also the balancing point.

### Entry balancing and ACIs

In an entry-balancing deployment, access control instructions (ACIs) are still configured in the backend Directory Server data.

When defining access controls in an entry-balancing deployment, you must ensure that the data used by the access control rule is available for evaluation on all data sets.

If you use groups for access control and a group contains users from different data sets, then that group must exist on each data set. For a single ACI to apply to entries in all data sets, it must be specified above the entry-balancing point. For example, if an ACI allows access to modify users that are part of group 1, then two things must exist on both data sets:

- Group 1 must exist in the `ou=groups` branch of both data sets.
- The ACI referencing group 1 must exist in the `ou=people` branch or above. The `ou=people` branch entry itself is part of the common data.

The Directory Proxy Server ensures that any changes to entries within the scope of the entry-balancing request processor, but outside the balancing point, are applied to all backend server sets. Any ACI stored at the entry-balancing point is kept in sync if changes are made through the Directory Proxy Server.

### Overview of deployment steps

This deployment scenario takes the following steps:

- Install the Directory Proxy Server on `austin-proxy1`.
- Use the `create-initial-proxy-config` tool to provide our initial setup for entry balancing.  
The initial setup includes defining multiple subtree views and global indexes in support of entry balancing.
- Change the placement algorithm of the `austin-proxy-01` server to use an entry-count placement algorithm.

This algorithm is used to select the backend set to which to forward an add request. It looks at the number of entries in the backend sets and forwards the add request to the backend with either the fewest or the most entries, depending on the configuration. You can also configure the placement algorithm to make the decision based on the on-disk database size rather than the number of entries.

### Installing the Directory Proxy Server

Start by configuring the Directory Proxy Server.

About this task

The four external servers, `austin-set1.example.com`, `newyork-set1.example.com`, `austin-set2.example.com`, and `newyork-set2.example.com`, are running.

Steps

- Run the `setup` program in non-interactive mode.

Example:

```
root@austin-proxy1: ./setup --acceptLicense \  
--listenAddress austin-proxy1.example.com \  
--ldapPort 389 --rootUserDN "cn=Directory Manager" \  

```

```
--rootUserPassword pass --entryBalancing \  
--aggressiveJVMtuning --maxHeapSize 2g --no-prompt \  
--instanceName ds1 --location Austin
```

### Configuring the entry-balancing Directory Proxy Server

After the Directory Proxy Server has been installed, it can be automatically configured using the **create-initial-proxy-config** tool.

#### About this task

This tool can only be used once for this initial configuration after which you will have to use **dsconfig** to make any changes to the Directory Proxy Server configuration.

#### Steps

1. Run the **create-initial-proxy-config** tool.

Example:

```
root@austin-proxy1: ./bin/create-initial-proxy-config
```

2. If the topology meets the requirements, press Enter to continue.

Example:

```
Some assumptions are made about the topology to keep  
this tool simple:
```

- 1) all servers will be accessible via a single user account
- 2) all servers support the same communication security type
- 3) all servers are PingDirectory Servers

```
If your topology does not have these characteristics you can  
use this tool to define a basic configuration and then use the  
'dsconfig' tool or the Administrative Console to fine tune the  
configuration.
```

```
Would you like to continue? (yes / no) [yes]:
```

3. Provide the external server access credentials.

All of the proxies have identical proxy user accounts and passwords.

Example:

```
Enter the DN of the proxy user account [cn=Proxy User,cn=Root  
DNs,cn=config]:
```

```
Enter the password for 'cn=Proxy User,cn=Root DNs,cn=config':  
Confirm the password for 'cn=Proxy User,cn=Root DNs,cn=config':
```

4. Specify the type of security that the Directory Proxy Server will use to communicate with Directory Servers.
5. Enter a base distinguished name (DN) of the Directory Server instances that will be accessed by the Directory Proxy Server.
6. Define the balancing point as a separate base DN, which is entry balanced.

Example:

```
Enter another base DN of the directory server instances that  
will be accessed through the Directory Proxy Server:
```

```
1)Remove dc=example,dc=com
```

```
b)back
```

```
q)quit
```

```
Enter a DN or choose a menu item [Press ENTER when finished
entering base DNs]: ou=people,dc=example,dc=com
```

```
Are entries within 'ou=people,dc=example,dc=com' split across
multiple servers so that each server stores only a subset of
the entries (i.e. is this base DN 'entry balanced')? (yes / no)
[no]: yes
```

7. Because the data in `ou=people,dc=example,dc=com` will be split across two backend sets, enter 2 to specify that the data will be balanced across two sets of servers.

Example:

```
Across how many sets of servers is the data balanced?
```

```
c) cancel creating ou=people,dc=example,dc=com
```

```
q) quit
```

```
Enter a number greater than one or choose a menu item: 2
```

8. Because the balancing point is the same as the base DN, `ou=people,dc=example,dc=com`, use it as the entry balancing base.

Example:

```
>>>> Entry Balancing Base
```

```
The entry balancing base DN specifies the entry below which the
data is balanced. Entries not below this entry must be duplicated
in all the server sets. If all the entries in the base DN are
distributed the entry balancing base DN is the same as the base DN.
```

```
c) cancel creating ou=people,dc=example,dc=com
```

```
b) back
```

```
q) quit
```

```
Enter the entry balancing base DN or choose a menu item
[ou=people,dc=example,dc=com]: ou=people,dc=example,dc=com
```

9. To improve the performance for equality search filters referencing the `uid` attribute, create a `uid` global index. Enter `yes` to add a new attribute to the global index.
10. Specify the `uid` attribute.

Example:

```
Enter attributes that you would like to add to the global index:
```

```
c)cancel creating ou=people,dc=example,dc=com
```

```
b)back
```

```
q)quit
```

```
Enter an attribute name or choose a menu item [Press ENTER when
finished entering index attributes]: uid
```

11. To optimize Directory Proxy Server performance from the moment it starts accepting connections, enter the number corresponding to `Yes`, and all subsequent attributes.
12. Press Enter to finish specifying index attributes.

13. Press Enter to enable relative distinguished name (RDN) index priming.

Example:

```
Would you like to enable RDN index priming for
'ou=people,dc=example,dc=com'? (yes / no) [yes]:
```

14. Press Enter to finish specifying base DNs.

Example:

```
Enter another base DN of the directory server instances that
will be accessed through the Directory Proxy Server:
```

- 1) Remove dc=example,dc=com
- 2) Remove ou=people,dc=example,dc=com (distributed)

- b) back
- q) quit

```
Enter a DN or choose a menu item [Press ENTER when finished
entering base DNs]:
```

15. The external servers are spread among two locations, New York and Austin. Define **austin** as the location of this Directory Proxy Server instance.

Example:

```
A good rule of thumb when naming locations is to use the
name of your data centers or the cities containing them.
```

- b) back
- q) quit

```
Enter a location name or choose a menu item: austin
```

- 1) Remove austin

- b) back
- q) quit

16. Define the newyork location.

Example:

```
Enter another location name or choose a menu item [Press ENTER
when finished entering locations]: newyork
```

- 1) Remove austin
- 2) Remove newyork

- b) back
- q) quit

```
Enter another location name or choose a menu item [Press ENTER
when finished entering locations]:
```

17. Select the austin location for this Directory Proxy Server instance.

Example:

```
Choose the location for this Directory Proxy Server
```

- 1) austin
- 2) newyork

```
b) back
q) quit
```

```
Enter choice [1]:
```

18. Specify the LDAP external server instances associated with this location.

Example:

```
Enter the host and port (host:port) of the first directory server
in 'austin'
```

```
b) back
q) quit
```

```
Enter a host:port or choose a menu item [localhost:389]:
austin-set1.example.com:389
```

19. Specify that the `austin-set1` server can handle requests from the global domain and from set 1 restricted domain.

Example:

```
Assign server austin-set1.example.com:389 to handle requests for
one or more of the defined sets of data:
```

```
1) dc=example,dc=com
2) ou=people,dc=example,dc=com; Server Set 1
3) ou=people,dc=example,dc=com; Server Set 2
```

```
Enter one or more choices separated by commas: 1,2
```

20. Enter the number corresponding to Yes, and all subsequent servers to prepare the server for access by the Directory Proxy Server.

Example:

```
Would you like to prepare austin-set1.example.com:389 for access
by the Directory Proxy Server?
```

```
1) Yes
2) No
3) Yes, and all subsequent servers
4) No, and all subsequent servers
```

```
Enter choice [3]:
```

21. Select the entry-balanced data set that the `austin-set1` server replicates with other servers.

Example:

```
You may choose a single entry-balanced data set with which
austin-set1.example.com:389 will replicate data with other servers
```

```
1) ou=people,dc=example,dc=com; Server Set 1
2) None, data will not be replicated
```

```
Enter choice: 1
```

```
Testing connection to austin-set1.example.com:389 ..... Done
Testing 'cn=Proxy User,cn=Root DNs,cn=config' access ....Denied
```

22. Modify the root user for use by the Directory Proxy Server, specifying the directory manager password for the initial creation of the proxy user.

Example:

```
Would you like to create or modify root user 'cn=Proxy User,
cn=Root DNs,cn=config' so that it is available for this
Directory Proxy Server? (yes / no) [yes]:

Enter the DN of an account on austin-set1.example.com:389
with which to create or manage the 'cn=Proxy User,cn=Root DNs,
cn=config' account and configuration [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':
Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User,cn=Root DNs,cn=config'privileges...Done
Setting replication set name .....
```

23. Because the replication set name has already been configured, you do not need to use the name created automatically by the Directory Proxy Server.

Example:

```
This server is currently configured for replication set 'dataset1'.
Would you like to reconfigure this server for replication set
'set-1'? (yes / no) [no]:

Setting replication set name .....
```

```
Done
Verifying backend 'dc=example,dc=com' .....
```

```
Done
Verifying backend 'ou=people,dc=example,dc=com' .....
```

```
Done
Testing 'cn=Proxy User' privileges .....
```

```
Done
Verifying backend 'dc=example,dc=com' .....
```

```
Done
```

24. Define the other Austin and New York servers using the same procedure in steps 17-24.

Example:

```
Enter another server in 'austin'

    1) Remove austin-set1.example.com:389
    b) back
    q) quit

Enter a host:port or choose a menu item [Press ENTER when
finished entering servers]: austin-set2.example.com:389

Assign server austin-set2.example.com:389 to handle requests
for one or more of the defined sets of data

    1) dc=example,dc=com
    2) ou=people,dc=example,dc=com; Server Set 1
    3) ou=people,dc=example,dc=com; Server Set 2

Enter one or more choices separated by commas: 1,3

You may choose a single entry-balanced data set with which
austin-set2.example.com:389 will replicate data with other
servers

    1) ou=people,dc=example,dc=com; Server Set 2
    2) None, data will not be replicated

Enter choice: 1

Testing connection to austin-set2.example.com:389 ....Done
```

```

Testing 'cn=Proxy User,cn=Root DNs,cn=config' access ... Denied

Would you like to create or modify root user 'cn=Proxy User,
cn=Root DNs,cn=config' so that it is available for this
Directory Proxy Server? (yes / no) [yes]:

Would you like to use the previously entered manager credentials
to access all prepared servers? (yes / no) [yes]:

Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User,cn=Root DNs,cn=config' privileges...Done
Setting replication set name .....

This server is currently configured for replication set 'dataset2'.

Would you like to reconfigure this server for replication set 'set-2'?
(yes / no) [no]:

### Configuring the placement algorithm using a batch file

Configure the placement algorithm using a batch file.

#### About this task

You want to place new entries added through the proxy using LDAP `ADD` operations into the least used dataset. Do this using an entry-count placement algorithm. To change the placement algorithm from round-robin to entry-count, first create and enable an entry-count placement algorithm configuration object, and then disable the existing round-robin placement algorithm. The batch file, `dsconfig.post-setup`, contains the `dsconfig` commands required to create the entry-count placement algorithm and disable the old round-robin algorithm.

The batch file contains comments to explain each `dsconfig` command.

#### Note:

In this example, line wrapping is used for clarity. The `dsconfig` command requires that the full command be provided on a single line.

The batch file itself looks like the following.

```
root@austin-proxy1:more ../dsconfig.post-setup

# This dsconfig operation creates the entry-count placement
# algorithm with the default behavior of adding entries to the
# smallest backend dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name entry-count --type entry-counter --set enabled:true

# Note that once the entry-count placement algorithm is created
# and enabled, we can disable the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then disable the
# original round-robin algorithm created during the setup
# procedure.

dsconfig set-placement-algorithm-prop
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin --set enabled:false

# At this point, LDAP ADD operations will be forwarded to an external
# server representing the dataset with the least number of entries.
```

## Steps

- Run the **dsconfig** command using the batch file.

Example:

```
root@austin-proxy1: bin/dsconfig --no-prompt \
--bindDN "cn=directory manager" --bindPassword password \
--port 389 --batch-file ../dsconfig.post-setup
```

Result:

After the batch file has executed, a new entry-count placement algorithm, called `entry-count`, has been created and the old round-robin placement algorithm, `round-robin`, has been disabled.

```
Batch file '../dsconfig.post-setup' contains 2 commands

Executing: create-placement-algorithm --no-prompt
--bindDN "cn=directory manager" --bindPassword pass
--port 1389
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name entry-count --type entry-counter --set enabled:true

Executing: delete-placement-algorithm --no-prompt
--bindDN "cn=directory manager" --bindPassword pass
--port 1389
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin --set enabled:false
```

## Rebalancing your entries

If your deployment distributes entries using an entry counter placement algorithm or third party algorithm, you might need to redistribute your entries.

If you have an environment that distributes entries across three backends using an entry counter placement algorithm, this algorithm distributes entries to the backend that has the most space. If the

backends all reach their maximum capacity and you decide to add a new backend to the deployment, you must move the entries from the full backends and distribute them evenly across all the backends, including the new backend.

You might also want to deliberately rebalance your entries to meet the needs of your organization, such as by direct entry balancing based on attributes on the entries themselves. You can write a custom algorithm that looks at the value of an attribute that is being modified on the entry. Based on the attribute, you can then put this entry somewhere specific. You might use this feature if you want to have certain entries closer geographically to the client application using them. The geographical information could be included in the entry. Rebalancing would be used to move these entries to the server in the correct geographical location.

You can redistribute entry-balanced entries in two ways:

#### Using dynamic rebalancing

With dynamic rebalancing, as existing entries get modified, they get moved. You configure dynamic rebalancing in the entry counter placement algorithm.

#### Using the `move-subtree` tool

This tool can be used to move either small subtrees through a transactional method or to move large subtrees, potentially taking them offline for a short period.

This section describes each of these methods of entry rebalancing in more detail.

### About dynamic rebalancing

During dynamic rebalancing, entries get moved as they are modified. You configure dynamic rebalancing in the entry counter placement algorithm or a third-party placement algorithm that supports rebalancing.

This algorithm keeps a count of the number of entries or the size of the backend set. Configure dynamic rebalancing using the following parameters:

#### **`rebalancing-enabled`**

Determines whether entry rebalancing is enabled. When rebalancing is enabled, the placement algorithm is consulted after `modify` and `add` operations to determine whether the target entry should be moved to a different backend set.

#### **`rebalancing-scope`**

Indicates which modified entries are candidates for rebalancing. A value of `top-level` indicates that only entries immediately below the entry-balancing base can be rebalanced. A value of `any` indicates that entries at any level below the entry-balancing base might be rebalanced.

#### **`rebalancing-minimum-percentage`**

Specifies the minimum threshold for entries to be migrated from one backend set to a preferred backend set with a smaller size. Entries are not migrated unless the percentage difference between the value of the current backend set and the value of the preferred backend set exceeds this threshold. This parameter prevents unnecessarily migrating entries back and forth between backend sets of similar sizes.

#### **`rebalancing-subtree-size-limit`**

Specifies the maximum size of a subtree that can be rebalanced.

#### **`poll-interval`**

Specifies how long to wait between polling the size of the backends to determine how to rebalance and works in conjunction with the `rebalancing-minimum-percentage` property.

#### **`placement-criteria`**

Determines which approach to use to select a destination backend for rebalancing. Possible values are:

- entry-count
- backend-size
- custom

The following figure illustrates an entry-balancing base DN and three subtrees, A, B, and C. If the rebalancing scope is set to `any`, any child entries under the base DN can be rebalanced. For example, if a change is made to entry A1, the entire subtree A might be rebalanced, depending upon how you have configured rebalancing. If the rebalancing scope is set to `top-level`, rebalancing is only triggered when entries at the top level, such as A, are modified. Changes made to subentries, such as A1 or A2, do not trigger rebalancing. Rebalancing is also triggered upon the addition of entries such as A1, A2, provided the scope is `any`.

If you are writing your own third-party algorithm, you program dynamic rebalancing using the `SelectRebalancingBackendSet` method on the placement algorithm. For more information, see the [Server SDK documentation](#).

### Configuring dynamic rebalancing

Configure dynamic rebalancing on an existing entry balancing configuration.

#### Steps

1. If the current placement algorithm does not support rebalancing, create an entry counter placement algorithm.

Example:

You can either do this using `dsconfig` in interactive mode or using the `dsconfig` command line as in this example.

```
$ dsconfig create-placement-algorithm \
  --processor-name dc_example_dc_com-eb-req-processor \
  --algorithm-name rebalancing --type entry-counter \
  --set enabled:true --set rebalancing-enabled:true
```

2. Remove any placement algorithm previously configured on this entry-balancing request processor.
3. Throttle how many entries are being moved by the proxy so that the backend servers do not have too heavy a load by setting the `rebalancing-queue-maximum-size` property of the request processor created in the previous step.

Example:

By default, the value is 1000. If the load is too high, reduce this value

```
$ dsconfig set-request-processor-prop \
  --processor-name dc_example_dc_com-eb-req-processor \
  --set rebalancing-queue-maximum-size:50
```

4. Verify that the access logs are configured to display the subtrees being moved by dynamic rebalancing.

The access logs provide a good way to monitor progress. If the write load on the backend servers is high and you see lots of rebalancing activity in the access log, lower the queue size to lower the rebalancing activity.

Example:

This example configures the access log to display entry rebalancing processing information.

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set log-entry-rebalancing-requests:true
```

### About the move-subtree tool

The **move-subtree** tool allows you to specify subtrees for rebalancing.

You specify the source server, the target server, and one or more base distinguished names (DNs) identifying the subtrees you want to move. You can move small subtrees using the transactional method or move large subtrees, which does not use this method.

Instead, the large subtree is not fully accessible during the move, so clients might get an `insufficient access rights` error if they try to access the subtree. As entries are moved, clients can read but not write to them. When the transfer is complete, the entries are fully available to client requests.

This tool accepts a file containing a list of the base DN of the subtrees you want to move.

#### Note:

The **move-subtree** tool requires users to have access to the extended operations and controls needed to run the tool. Make sure to apply the following ACIs to your data.

```
aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.5 ||
  1.3.6.1.4.1.30221.2.5.24 || 1.3.6.1.4.1.30221.2.5.13")
  (version 3.0; acl "Allow admin to submit move-subtree controls";
  allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
aci: (extop="1.3.6.1.4.1.30221.2.6.19")
  (version 3.0; acl "Allow admin to request move-subtree extended
  operation"; allow (read) userdn="ldap:///
  uid=admin,dc=example,dc=com";)
```

### About the subtree-accessibility tool

The **subtree-accessibility** tool helps you determine if a subtree has restricted access and helps you fix any problems.

If, during rebalancing, the Directory Server issues an alert that a subtree has been unavailable for too long, then you can use this tool to evaluate the problem.

For example, if the **move-subtree** tool is interrupted by a host machine going down unexpectedly, the subtree can't be successfully moved. You can use the **subtree-accessibility** tool to evaluate and correct any problems with the subtrees and then re-run the **move-subtree** tool.

## Managing the global indexes in entry-balancing configurations

In an entry-balancing configuration, the Directory Proxy Server maintains the default relative distinguished name (RDN) index as well as one or more in-memory global attribute indexes.

The global indexes allow the Directory Proxy Server to select the correct backend server set for incoming operations, which avoids broadcasting operations to all backend sets.

The indexes can be preloaded from peer proxies or the backend directory servers when the server starts up and are updated by certain operations that come through the Directory Proxy Server. For example, when a new entry is added, the distinguished name (DN) of the new entry is added to the DN index of the Directory Proxy Server performing the operation. The indexes are also fault-tolerant and can adapt to changes made in the backend servers without going through the Directory Proxy Server. For example, operations are processed directly through the backend server.

This section describes:

- When to create a global attribute index
- How to reload the global index
- How to monitor the global index growth
- How to prime the global index from a peer at start-up

### Creating a global attribute index

Create a global attribute index for Directory Proxy Server to use as a optional index.

About this task

The relative distinguished name (RDN) index is referenced whenever a `modify`, `delete`, or base search is requested. The RDN index is needed when the LDAP request contains the complete distinguished name (DN) of the targeted entry. If the entry-balancing request processor is not configured to prime the RDZ index at startup, then the index is populated over time as LDAP requests are processed.

A global attribute index is an optional index and is referenced when the Directory Proxy Server is handling a search request with an equality filter involving an attribute, such as the `telephoneNumber` attribute with the `telephoneNumber=+11234567890` filter.

Because the Directory Proxy Server doesn't know what the data within the subtree view looks like or how it is searched, it can't create or recommend default global attribute index definitions. The creation of a global attribute index is based on the range of equality-filtered search requests processed by the Directory Proxy Server. The Directory Server must also have an equality or ordering index type for the associated attribute Local database (DB) Index.

The common candidates for global attribute indexing are the uniquely-valued equality-indexed attributes on the external servers, such as `uid`, `mail` and `telephoneNumber`. These attributes don't require unique values for use as global attribute indexes by the entry-balancing request processor.

Steps

- Create a global attribute index using the `dsconfig` tool with the `create-global-attribute-index` option.

Example:

In this example, a Directory Server deployment expects to process frequent searches of the form `(&(mail=user@example.com)(objectclass=person))`. The `mail` attribute is indexed for equality searches on each of the external servers behind the Directory Proxy Server. Because the filter is constructed with an equality match and `&` clause, you can use a global attribute index on the `mail` attribute to avoid forwarding the search request to each entry balanced dataset.

```
$ bin/dsconfig create-global-attribute-index \
  --processor-name ou_people_dc_example_dc_com-eb-req-processor \
  --index-name mail --set prime-index:true \
```

Result

The index begins populating as search requests are made to the Directory Proxy Server that involve the `mail` attribute.

**Tip:**

You can use the `reload-index` tool to fully populate the index for optimal performance as described in [Reloading the global indexes](#) on page 1378.

**Reloading the global indexes**

The Directory Proxy Server `reload-index` tool allows you to manually reload the Directory Proxy Server global indexes.

Use the `reload-index` tool to reload all configured indexes in the global index, including the relative distinguished name (RDN) index and all attribute indexes or to reload only the indexes you specify.

You might need to reload the index when:

- The Directory Proxy Server fails to successfully load its global indexes on startup.
- Changes are made to the set of indexed attributes.
- Significant changes are made to the content in backend servers.
- The integrity of the index is in question.

The `reload-index` tool schedules an operation to run within the Directory Proxy Server's process. You must supply the LDAP connection information so that the tool can communicate with the server through its task interface. You can schedule tasks to run immediately or at a later time. After the tasks are scheduled, manage them using the `manage-tasks` tool.

**Reloading all of the indexes**

About this task

Reload all the indexes within the scope of the base distinguished name (DN) `dc=example,dc=com`. The task is performed as `cn=Directory Manager` on port 389 of the localhost server.

**Attention:**

The existing index contents are erased before reloading.

Steps

- To reload all of the indexes within the scope of the `dc=example,dc=com` base DN, run the `reload-index` tool.

Example:

```
$ bin/reload-index --task --bindPassword password --baseDN
"dc=example,dc=com"
```

**Reloading the RDN and UID index**

About this task

To reload the RDN and unique identifier (UID) index in the background so that the existing contents of these indexes can continue to be used:

Steps

- Run the `reload-index` tool with the `--index rdn` and `--index uid` options.

Example:

```
$ bin/reload-index --task --bindPassword password \
```

```
--baseDN "dc=example,dc=com" --index rdn --index uid --background
```

## Priming the backend server using the `--fromDS` option

About this task

You can force the Directory Proxy Server to prime from the backend directory server using the `--fromDS` option, which overrides the configuration of the `prime-index-source` property.

### Tip:

You can do this on a one-off basis if the global index appears to be growing too large.

To prime the backend server:

### Steps

- Run the `reload-index` tool with the `--fromDS` option.

Example:

```
$ bin/reload-index --bindPassword password --baseDN "dc=example,dc=com"
--fromDS
```

## Monitoring the size of the global indexes

Monitor the size of the global indexes over LDAP and reload the indexes to prevent a build up of stale entries in the global indexes.

About this task

The proxies don't communicate changes to the indexes with one another, which can result in stale entries building up over time in the global indexes. In this situation, the Directory Proxy Server continues to operate normally because the global indexes are used only as a hint for where to find entries.

The rate of this growth is typically slow because in most environments the key attributes change infrequently. In addition, the global indexes are compact. However, if the global indexes start to fill up the allocated memory, you might need to flush and reload them.

If the global indexes become full, the Directory Proxy Server continues to operate normally, but it needs to start evicting entries from the indexes. Evicting the entries leads to more broadcast searches and reduces the overall performance of the Directory Proxy Server.

### Steps

- To monitor the size of the global indexes over LDAP, use the `ldapsearch` with the `global-index-current-memory-percent` option.

Example:

```
$ bin/ldapsearch -b "cn=monitor" -D "uid=admin,dc=example,dc=com" -w
password \
"(objectClass=ds-entry-balancing-request-processor-monitor-entry) " \
global-index-current-memory-percent
```

- To reload the indexes so they no longer hold stale information, run the `reload-index` command with the `--fromDS` option.

This option ensures that data is loaded from backend directory servers.

#### Tip:

You should reload the indexes during off-peak hours because it might impact the performance while the reload is in progress.

### Sizing the global indexes

Use the Directory Proxy Server `global-index-size` tool to help you estimate the memory size of your global indexes.

#### About this task

You can estimate the size of more than one index in a single invocation by providing multiple sets of options.

The `global-index-size` tool creates its estimate using the following information:

#### Number of keys in the index

For example, for the built-in relative distinguished name (RDN) index, the number of keys is the total number of entries in the Directory Server that are immediately below the balancing point. Entries more than one level below the balancing point and entries that are not subordinate to the balancing point aren't contained in the RDN index. For attribute indexes, the number of keys is the number of unique values for that attribute in the entry-balanced portion of the data.

#### Average size of each key, in bytes

For attributes indexes, the key is the attribute value. For the built-in RDN index, the key is the RDN directly below the balancing base distinguished name (DN). For example, for the DN `uid=user.0,dc=example,dc=com` under the balancing base DN of `dc=example,dc=com`, the key size is 10 bytes (the number of bytes in the RDN `uid=user.0`).

#### Estimated number of keys

This value corresponds to the maximum number of keys you expect in your Directory Server. The number of keys is provided in the `index-size` configuration property of the `global-attribute-index` object when you configure an attribute index. For the built-in RDN index, the configured number of keys is provided in the `rdn-index-size` property. If you do not provide a value, the tool assumes that the configured number of keys is the same as the actual number of keys.

#### Steps

- To estimate the size of two separate indexes, run the `global-index-size` tool.

Example: In this example, the two indexes both have 10,000,000 keys but with differing average key sizes. The configured number of keys is assumed to be equal to the actual number of keys.

```
$ bin/global-index-size --numKeys 10000000 \
  --averageKeySize 11 --numKeys 10000000 \
  --averageKeySize 15
```

| Num Keys | : Cfg. Num Keys | : Avg. Key Size | : Est. Memory Size |
|----------|-----------------|-----------------|--------------------|
| 10000000 | : 10000000      | : 11            | : 159 mb           |
| 10000000 | : 10000000      | : 15            | : 197 mb           |

### Priming the global indexes on startup

The Directory Proxy Server can prime the global indexes at startup from the backend directory server or from a peer proxy server, preferably one that resides on the same LAN or subnet.

When priming occurs locally, you can avoid WAN bandwidth consumption and reduce the processing load on the directory servers in the topology. You can specify the data sources for the index priming and the order in which priming occurs from these sources. Use the `prime-index-source` property to specify the sources of data, either `ds`, `file` or some combination of the two.

The order you specify is the order in which priming is attempted from these sources. Priming is most efficient if the source server is on the same local network as the Directory Proxy Server.

For example, if you specify `prime-index-source:file,ds`, priming is performed from the `global-index` data file created from the previous run of the directory servers. If the entire global index has been primed previously from a startup or reloaded-index directory servers source, the contents of the global index are written to disk periodically with the `file,ds` configuration.

### Configuring all indexes at startup

#### Steps

- To prime all indexes at startup, run the `dsconfig` tool.

Example:

The following example configures the entry-balancing request processor so that it primes the global index from the persisted file, if present, or from an external directory servers source, if necessary.

```
$ bin/dsconfig set-request-processor-prop \
  --processor-name dc_example_dc_com-eb-req-processor \
  --set prime-all-indexes:true --set prime-index-source:file \
  --set prime-index-source:ds
```

### Configuring the global indexes manually

#### About this task

If you don't want to configure priming during setup, you can configure the index priming manually.

To do this, create an external server, create a global attribute index, and change the entry-balancing request processor to load indexes from the external server.

#### Steps

1. To create an external server of the PingDirectory Server type to represent a peer of the Directory Proxy Server, use the `dsconfig` tool with the `create-external-server` subcommand.

Example:

```
$ bin/dsconfig create-external-server \
  --server-name intra-proxy-host.example.com:3389 \
  --type PingDirectory-server \
  --set server-host-name:intra-proxy-host \
  --set server-port:338 \
  --set "bind-dn:cn=Directory Manager" \
  --set "password:secret123"
```

2. Create a global attribute index on the `uid` attribute.

Example:

```
$ bin/dsconfig create-global-attribute-index \
  --processor-name dc_example+dc+com-eb-req-processor \
```

```
--index-name uid \
```

3. To load the indexes at startup from the peer Directory Proxy Server, change the entry-balancing request processor using `dsconfig set-request-processor-prop`.

### Persisting the global index from a file

#### About this task

PingDirectory Server supports periodically persisting the global index to a file and priming the global index from the persisted file when the server is restarted.

You can configure an Entry Balancing Request Processor to periodically persist the global index to disk so that when the Entry Balancing Request Processor is reinitialized on startup it can prime the values from disk instead of putting load on the remote servers. Reading the index from disk eliminates the load on backend Directory Server instances if many PingDirectory Server instances are starting at the same time.

You can configure an entry-balancing request processor to persist the global index to disk by including `file` as one of the prime index sources with the `prime-index-source` property. The `persist-global-index-frequency` property controls the frequency at which the file is written.

The global index must be primed before it is persisted. It can be primed initially using a peer PingDirectory Server or from a backend Directory Server.

When new global attribute indexes are added on a running PingDirectory Server, the global index can be primed with those attribute indexes by running the `rebuild-index` tool. The `rebuild-index` tool uses a remote server for priming the global index, even if `file` is configured as a source.

On subsequent restarts of the PingDirectory Server, the global index is primed from the persisted file instead of going over the network to a remote server, which allows it to be primed much faster than if it is using a remote priming source. During server startup, the global index priming works by using each configured `prime-index-source` property in the specified order until it is fully primed to take advantage of what is available locally before contacting one or more remote servers.

#### Steps

- To prime all indexes at startup from a file, run the `dsconfig` tool.

Example:

```
dsconfig -n set-request-processor-prop \
  --processor-name entry-balancing \
  --set prime-index-source:file \
  --set prime-index-source:ds \
  --set persist-global-index-frequency:10s \
  --set persist-global-index-directory:/servers/proxy-1/index-files \
  --set prime-all-indexes:true
```

### Priming or reloading the global indexes from Sun Directory servers

When priming or reloading a global index based on a Sun Directory Server environment, the Sun servers might become overwhelmed and unresponsive because of their method of streaming data.

#### About this task

To reduce the impact of priming and reloading on these servers, use the `prime-search-entry-per-second` property and the `--searchEntryPerSecond` property of the `reload-index` command. These properties control the rate at which the Directory Proxy Server accepts search result entries from the backend directory servers.

The `index-priming-idle-listener-timeout` property specifies the amount of time an extended operation response listener can be idle while the global index priming is in progress. For example, if the

global index is priming and a backend server stops returning results but doesn't disconnect, this timeout can be used to force a retry of the operation.

### Tip:

To find the optimum rate, start low and specify a few thousand search entries per second. Then increase as necessary.

To reduce the impact on server performance:

### Steps

- To reduce the impact of priming on servers, use the `prime-search-entry-per-second` property.
- To reduce the impact of reloading these indexes, use the `--searchEntryPerSecond` property of the `reload-index` command.
- To specify the amount of time an extended operation response listener can be idle while the global index priming is in progress, use the `index-priming-idle-listener-timeout`.

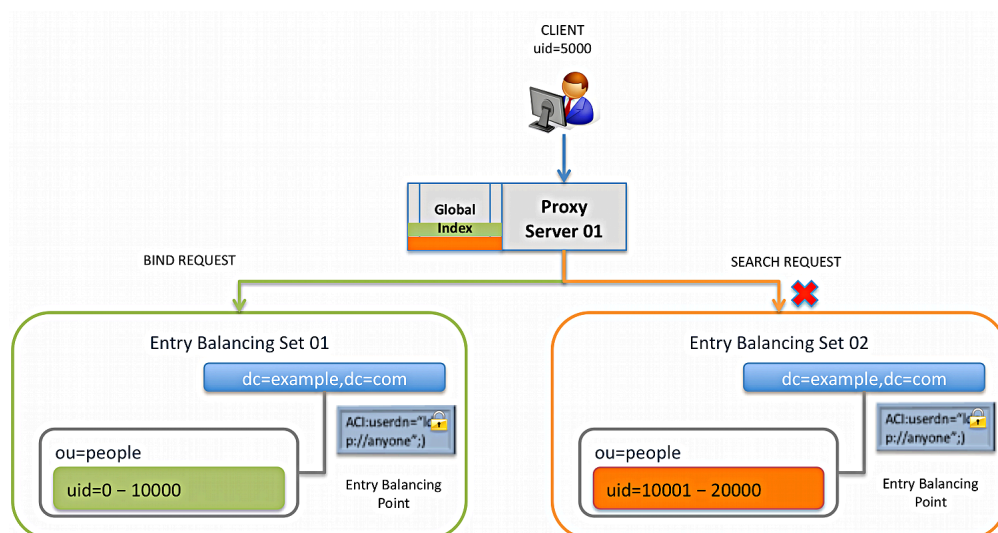

## Working with alternate authorization identities

The following sections cover the procedures to configure the alternate authorization identities for the Directory Proxy Server.

Access control rules in an entry-balanced deployment are configured in the Directory Server backend servers and require access to the entry contents of the user issuing the request.

This can introduce a potential issue when clients to the Directory Proxy Server authenticate as users whose entries are among the entry-balanced sets. If the server processing a request doesn't contain the issuing user's entry, the access control can't be evaluated. One solution to this problem is to make use of an alternate authorization identity for the user, which references an entry that exists in all Directory Server's in all backend sets and has an equivalent set of access control rights as the authenticated user.

For the following example, assume a deployment has two entry-balancing sets: `set-01` and `set-02`. `Set-01` has entries in the `uid=0-10000` range, while `set-02` has entries for `uid=10001-20000`.

### Entry-Balancing Issue with Clients Not Present in the Underlying Data Set

#### Processing steps

1. The client with `uid=5000` binds to the Directory Proxy Server, which sends a `BIND` request to entry-balancing set-01.

2. The client sends a `SEARCH` request with filter `(uid=15000)`.
3. The Directory Proxy Server determines that `uid=15000` lives on entry-balancing set-02.
4. The Directory Proxy Server determines that the entry for the authenticated user with `uid=5000` doesn't exist in set-02 and that the access control handler has to reject the `SEARCH` request issued by an unknown user.
5. The Directory Proxy Server observes that the Directory Server processing a request doesn't contain the entry of the user issuing the request and decides to use an alternate authorization identity.

### About alternate authorization identities

Alternate authorization identities allow for the proper evaluation of access control rules for users whose entries aren't present within an entry-balanced dataset.

Whenever the Directory Proxy Server forwards a request to the backend set containing the user's entry, it forwards the request with an authorization identity that reflects the user's actual identity because the user is known to servers in that set. However, when forwarding a request to a backend set that doesn't contain the user's entry, the Directory Proxy Server uses an alternate authorization identity that reflects the generic user with the same set of rights as the actual user issuing the request.

Alternate authorization identities allow for the proper evaluation of access control rules for users whose entries are not present within an entry-balanced dataset.

There are only a few different generic classes of users from an access control perspective. These can be placed in a portion of the directory information tree (DIT) that isn't below the entry-balancing base distinguished name (DN) and is replicated to all servers in the topology.

Whenever a user authenticates to the Directory Proxy Server, the server can keep track of which backend set holds that user's entry and determine whether an alternate authorization identity is required. The server can determine which of these generic accounts best describes the rights that the user should have.

For the following example, assume that you have three classes of users: full administrators, password administrators, and normal users. Assume that you create the following entries in the topology and assign them the appropriate access rights:

- `uid=normal user,dc=example,dc=com`
- `uid=server-admin,dc=example,dc=com`
- `uid=password-admin,dc=example,dc=com`

### Alternate Authorization Identity Solves Access Control Issues in Entry-Balancing Deployments

## Processing steps

1. The client with `uid=5000` binds to the Directory Proxy Server, which sends a `BIND` request to entry-balancing set-01.
2. The client sends a `SEARCH` request for `uid=15000`.
3. The Directory Proxy Server determines that `uid=15000` lives on entry-balancing set-02.
4. The Directory Proxy Server then determines that the client `uid=5000` doesn't have an entry on entry-balancing set-02.
5. The Directory Proxy Server uses an alternate authorization identity that reflects the generic user, `uid=normal user`, which has the same set of rights as the client `uid=5000` issuing the request.
6. The access control is accepted and the `SEARCH` request returns a response for `uid=5000`.
7. When an alternate authorization identity is invoked, `authzID='dn:uid=normal user,dc=example,dc=com'` records in the server log, which indicates the use of the alternate authorization identity.

For example, if the `user.15000` is in a different backend set from `user.5000`, the log shows the following response.

```
% bin/ldapsearch -D "uid=user.5000,ou=people,dc=example,dc=com" -w
password \
  -b uid=user15000,ou=people,dc=example,dc=com "(objectclass=*)"

[18/Aug/2013:11:54:35 -0500] SEARCH REQUEST conn=153 op=1 msgID=2
via="app='Directory-Proxy address='127.0.0.1'
authzID='dn:uid=normal user,dc=example,dc=com' sessionID='conn=2'
requestID='op=1'"
  base="uid=user.15000,ou=people,dc=example,dc=com"scope=2
filter="(objectclass=*)" attrs="ALL"

[18/Aug/2013:11:54:35 -0500] SEARCH REQUEST conn=153 op=1 msgID=2
resultCode=0 etime=2.038
entriesReturned=1 authzDN="uid=normal-user,dc=example,dc=com"
```

## Configuring alternate authorization identities

Alternate authorization identities are specified by the `authz-attribute` property of the entry-balancing request processor configuration object.

### About this task

By default, the `authz-attribute` property has the default value of `ds-authz-map-to-dn`, which is an attribute reserved for this purpose.

If a user entry has a value for `ds-authz-map-to-dn`, whether it's explicitly contained in the entry or only present with a virtual attribute, that value is used to specify the alternate authorization identity for the user. Otherwise, the default authorization identity, as indicated with the `authz-dn` configuration property, is used to determine the alternate authorization identity.

## Steps

1. Set the `authz-dn` property of the entry-balancing request processor configuration using the `dsconfig` tool.

### Note:

If any user among the balanced entries doesn't have an alternate authorization identity defined, the Directory Proxy Server uses the value of the `authz-dn` property of the entry-balancing request processor configuration.

### Example:

```
$ bin/dsconfig set-request-processor-prop \
  --processor-name dc_example_dc_com-eb-req-processor \
  --set "authz-dn:uid=normal user,dc=example,dc=com"
```

2. Create an auxiliary object class containing `ds-authz-map-to-dn` as an allowed attribute.
3. Add the auxiliary object class value to all user entries of interest.
4. Add the following attribute value to a `server-admin` user.

### Example:

```
ds-authz-map-to-dn: uid=server-admin,dc=example,dc=com
```

## Managing Entry-Balancing Replication

Replication in the PingDirectory Server synchronizes directory data between all servers in the topology.

However, in a deployment using the entry-balancing feature, directory data under the entry-balancing point is split into multiple data sets. Each data set is replicated to ensure high availability between a subset of the servers in the topology.

Other directory data, such as the schema or data above the entry-balancing point, is replicated between all servers in the topology.

This section about replication in an entry-balancing environment contains the following:

- [Overview of replication in an entry-balancing environment](#) on page 1386
- [Replication prerequisites in an entry-balancing deployment](#) on page 1387
- [About the `--restricted` argument of the `dsreplication` command-line Tool](#) on page 1388
- [Checking the status of replication in an entry-balancing deployment](#) on page 1389
- [Example of configuring entry-balancing replication](#) on page 1389

### Overview of replication in an entry-balancing environment

In an entry-balanced deployment some data is replicated everywhere, such as the schema, the server registry, and other shared data, and some data is replicated only on certain servers.

A replication domain contains all of the servers in a replicated topology and shares a schema. The replication domain is associated with the base distinguished name (DN) and must be a base DN of a backend.

By default, replication propagates updates to all replication servers in the topology. However, updates to data under the entry-balancing point must be replicated only among server instances in the same data set. Replication requires that in these deployments the Directory Server is configured with a `replication-set-name` global configuration property and two backends. One backend has a base DN that is replicated globally, such as `dc=example,dc=com`, and the second backend has a base DN associated with the entry-balancing point, such as `ou=people,dc=example,dc=com`.

The following illustration demonstrates the global and restricted backends in a directory information tree (DIT).

### Global and Restricted backends

If a data set name is not defined when you set up the Directory Proxy Server, one is provided by default. The proper configuration of an entry-balancing environment requires coordination between the Directory Server and the Directory Proxy Server. After you enable replication, you can designate the replication domain as the domain participating in entry balancing.

For more details about replication, managing the replication topology, and working with multiple backends, see the [PingDirectory Server Administration Guide](#).

## Replication prerequisites in an entry-balancing deployment

Before you can enable replication in an entry-balancing deployment, you must have the following set up in your server topology.

### Multiple local DB backends

When you set up the Directory Server instances, you need two backends, a global backend for globally replicated data, such as `userRoot`, and a backend for the balancing point base distinguished name (DN), such as `dataSet`.

Both backends must be enabled for replication and initialized separately.

### Replication set name

Every Directory Server in your replicated topology must have a replication set name. This replication set name coordinates the Directory Proxy Server and the Directory Server.

The restricted domain is only replicated within instances using the same replication set name.

### Multiple Directory Proxy Server subtree views

The entry-balanced proxy configuration relies on multiple subtree views, one for the globally replicated base DN and one for the entry-balancing point base DN. The globally replicated base DN has a proxying request processor associated with it. The restricted base DN has an entry-balancing request processor associated with it.

#### Note:

Configure the subtree views after running your setup using the `create-initial-proxy-config` tool.

## About the `--restricted` argument of the `dsreplication` command-line Tool

The `dsreplication` tool with the `--restricted` argument specifies a base distinguished name (DN) when multiple domains are enabled in an entry balanced environment.

When enabling replication for a server that takes part in an entry-balanced environment, the multiple domains involved are enabled at the same time. There is a global domain and a restricted domain. The restricted domain represents the entry-balancing point. Each base DN is defined in a separate local database (DB) backend. Use the `dsreplication` command-line interface (CLI) tool with the `--restricted` argument to specify which base DN is considered an entry-balancing point.

### Using the `--restricted` argument of the `dsreplication` command-line tool

About this task

To enable replication between two servers with entry balancing:

Steps

- Choose one of the following ways to run the `dsreplication` command:  
Choose from:

- Run `dsreplication` in non-interactive mode.

See the following example.

```
$ bin/dsreplication enable --host1 host1.example.com \
--port1 1389 --bindDN1 "cn=Directory Manager" \
--bindPassword1 secret --replicationPort1 8989 \
--host2 host2.example.com --port2 2389 \
--bindDN2 "cn=Directory Manager" --bindPassword2 secret \
--replicationPort2 8989 --baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--restricted ou=people,dc=example,dc=com
```

- Run `dsreplication` using the interactive command line.
  1. Enter `dsreplication` and the LDAP connection parameters.
  2. Specify that an entry balancing is being used.
  3. Specify the base distinguished name (DN) of the entry-balancing point.

See the following example.

```
You must choose at least one base DN to be replicated.
Replicate base DN dc=example,dc=com? (yes / no) [yes]: yes
Replicate base DN ou=people,dc=example,dc=com? (yes / no) [yes]: yes

Do you plan to configure entry balancing using the Directory Proxy
Server? (yes / no) [no]: yes

Is dc=example,dc=com an entry-balancing point? (yes / no) [no]: no
Is ou=people,dc=example,dc=com an entry-balancing point? (yes / no)
[no]: yes
```

## Checking the status of replication in an entry-balancing deployment

You can use the `dsreplication` status tool to check the status of an entry-balancing deployment.

About this task

In this example, the `ou=people,dc=example,dc=com` subtree is entry-balanced.

The data is split into two sets, `set1` and `set2`. The servers `host1` and `host2` are in replication set `set1` and servers `host3` and `host4` are in replication set `set2`.

Steps

- To get a status of replication in the entry-balancing deployment, run the `dsreplication` command.

Example:

### Note:

By default, all of the sets are displayed. To view only a specific replication set, use the `--setName` option.

Example:

```
$ bin/dsreplication status --hostname host1.example.com \
--port 1389 --adminUID admin --adminPassword secret
```

```

--- Replication Status for dc=example,dc=com: Enabled ---
Server      : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security
-----:-----:-----:-----:-----:-----:-----
austin1.example.com:1389 : 1000      : 0           : N/A           : 8989 : Enabled
austin2.example.com:2389 : 1000      : 0           : N/A           : 8989 : Enabled
newyork1.example.com:3389 : 1000      : 0           : N/A           : 8989 : Enabled
newyork2.example.com:4389 : 1000      : 0           : N/A           : 8989 : Enabled

-- Replication Status for ou=people,dc= example,dc=com (Set: set1): Enabled --
Server      : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security
-----:-----:-----:-----:-----:-----:-----
austin1.example.com:1389 : 1000000   : 0           : N/A           : 8989 : Enabled
austin2.example.com:2389 : 1000000   : 0           : N/A           : 8989 : Enabled

---Replication Status for ou=people,dc= example,dc=com (Set: set2): Enabled ---
Server      : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security
-----:-----:-----:-----:-----:-----:-----
newyork1.example.com:3389 : 1000000   : 0           : N/A           : 8989 : Enabled
newyork2.example.com:4389 : 1000000   : 0           : N/A           : 8989 : Enabled

```

Result:

## Example of configuring entry-balancing replication

This section covers how to set up a four-server replication topology that uses entry balancing to distribute entries across the servers and provides a start-to-finish example to walk you through this process.

### Assumptions

The example assumes the following conditions:

- None of the servers have participated in any previous replication topology. This is supported for one or multiple entry balancing domains.

- This example uses the LDAP (389) and replication (8989) ports. It configures the following hosts:
  - austin1.example.com
  - newyork1.example.com
  - austin2.example.com
  - newyork2.example.com
- The global domain is `dc=example,dc=com`, which is replicated across all servers.
- The data below the entry-balancing point of `ou=people,dc=example,dc=com` is distributed across two data sets, `dataSet1` and `dataSet2`.
- Each data set is replicated between two directory servers. Each of these servers is associated with one of two locations, Austin or New York.

### Configuration summary

To configure replication in an entry-balanced deployment:

1. Install two directory servers in an Austin location and two directory servers in a New York location.
2. Create a new backend, called `dataset`, to store the entry-balancing data set.
3. Define entry-balancing set names `dataSet1` and `dataSet2` for assignment to the `replication-set-name` Global Configuration Property of the Directory Server instances.
4. Import the data representing the global domain, stored in `userRoot`, into a server. Choose a server for each of the entry-balancing data sets, both stored in the backend named `dataset`.
5. Enable replication and initialize remaining servers.
6. Configure the proxies.
7. Check the status of replication.

### Installing the Directory Server

About this task

Install the Directory Server four server instances, two in the Austin location and two in the New York location:

- austin1.example.com
- newyork1.example.com
- austin2.example.com
- newyork2.example.com

Steps

1. Install the first Austin server, `austin1`.

Example:

```
root@austin1# ./setup --cli --baseDN dc=example,dc=com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --no-prompt --acceptLicense \
--instanceName ds1 --location Austin
```

2. Install the second Austin server, `austin2`.

Example:

```
root@austin2 # ./setup --cli --baseDN dc=example,dc=com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --no-prompt --acceptLicense \
--instanceName ds2 --location Austin
```

3. Install the first New York server, `newyork1`.

Example:

```
root@newyork1# ./setup --cli --baseDN dc=example,dc=com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --no-prompt --acceptLicense \
--instanceName ds3 --location NewYork
```

4. Install the second New York server, `newyork2`.

Example:

```
root@newyork# ./setup --cli --baseDN dc=example,dc=com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --no-prompt --acceptLicense \
--instanceName ds4 --location NewYork
```

## Creating the database backends and defining the replication set name

About this task

To store the entry-balancing data set, create a new backend.

Steps

1. On each server, create a dataset backend named `dataset`.

Example:

```
./bin/dsconfig --no-prompt create-backend \
--backend-name dataset --type local-db --set enabled:true \
--set base-dn:ou=people,dc=example,dc=com
```

2. Set the `replication-set-name` for `austin1.example.com` and `newyork1.example.com` to `dataset1`.

Example:

```
./bin/dsconfig --no-prompt \
set-global-configuration-prop \
--set replication-set-name:dataset1
```

3. Set the `replication-set-name` for `austin2.example.com` and `newyork1.example.com` to `dataset2`.

Example:

```
./bin/dsconfig --no-prompt \
set-global-configuration-prop \
--set replication-set-name:dataset2
```

## Creating and setting the locations

About this task

Create and set the locations of the Austin and New York server instances.

Steps

1. On the Austin servers, create two instance locations, `newyork` and `austin`.

Example:

```
./bin/dsconfig --no-prompt create-location --location-name austin
```

```
./bin/dsconfig --no-prompt create-location --location-name newyork \
--set preferred-failover-location:austin
```

2. Set the location of the Austin server instances to austin.

Example:

```
./bin/dsconfig --no-prompt set-location-prop --location-name austin \
--add preferred-failover-location:newyork

./bin/dsconfig --no-prompt set-global-configuration-prop \
--set location:austin
```

3. On the New York servers, create two instance locations, newyork and austin.

Example:

```
./bin/dsconfig --no-prompt create-location \
--location-name austin

./bin/dsconfig --no-prompt create-location \
--location-name newyork \
--set preferred-failover-location:austin
```

4. Set the location of on the New York server instances to newyork.

Example:

```
./bin/dsconfig --no-prompt set-location-prop \
--location-name austin \
--add preferred-failover-location:newyork

./bin/dsconfig --no-prompt set-global-configuration-prop \
--set location:newyork
```

### Importing the entries

Import the `userRoot` data based on data defined in the `userRoot.ldif` file into one server.

About this task

Choose a server for each of the entry-balancing data sets, both stored in the dataset backend.

#### Note:

The `userRoot.ldif` file doesn't contain entries at or within the entry-balancing point, `ou=people,dc=example,dc=com`.

### Steps

1. Import the `userRoot` data using the `import-ldif` command.

Example:

```
root@austin1# ./bin/import-ldif --backendID userRoot \
--ldifFile /data/userRoot.ldif \
--includeBranch dc=example,dc=com \
--rejectFile /data/austin1-import-rejects \
--port 389
--hostname austin1.example.com
```

2. Import the `dataSet1` data that is assigned the `replication-set-name` on one server into the dataset backend.

Example:

```
root@austin1# ./bin/import-ldif --backendID dataset \
--ldifFile /data/dataset1.ldif \
--includeBranch ou=people,dc=example,dc=com \
--rejectFile /data/austin1-dataset-import-rejects \
--hostname austin1.example.com --port 389
```

3. Import the `dataSet2` data that is assigned the `replication-set-name` on one server into the dataset backend.

Example:

```
root@austin2# ./bin/import-ldif --backendID dataset \
--ldifFile /data/dataset2.ldif \
--includeBranch ou=people,dc=example,dc=com \
--rejectFile /data/austin2-dataset-import-rejects \
--hostname austin2.example.com --port 389
```

### Enabling replication in an entry-balancing deployment

Enable replication between the servers and initialize the remaining servers without data.

About this task

#### Note:

In this example, the `--restricted` domain is specified in the `dsreplication` command.

To enable replication on the servers in the topology:

### Steps

1. Run `dsreplication enable`.

Example:

```
root@austin1# ./bin/dsreplication enable \
--host1 austin1.example.com \
--port1 389 --bindDN1 "cn=directory manager" \
--bindPassword1 pass --host2 austin2.example.com \
--port2 389 --bindDN2 "cn=directory manager" \
--bindPassword2 pass \
--replicationPort1 8989 \
--replicationPort2 8989 \
--baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--restricted ou=people,dc=example,dc=com \
--adminUID admin --adminPassword pass --trustAll \
--no-prompt
```

#### Note:

Running the `dsreplication enable` command for the first time creates the administrator account.

2. Enable replication between `austin1` and `newyork1`.

Example:

This procedure automatically also enables replication between `austin2` and `newyork1`.

```
root@austin1# ./bin/dsreplication enable \
--host1 austin1.example.com \
--port1 389 --bindDN1 "cn=directory manager" \
--bindPassword1 pass --host2 newyork1.example.com \
--port2 389 --bindDN2 "cn=directory manager" \
--bindPassword2 pass \
--replicationPort1 8989 \
--replicationPort2 8989 \
--baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--restricted ou=people,dc=example,dc=com \
--adminUID admin --adminPassword pass --trustAll \
--no-prompt
```

3. Enable replication between `austin1` and `newyork2`.

Example:

```
root@austin1# ./bin/dsreplication enable \
--host1 austin1.example.com \
--port1 389 --bindDN1 "cn=directory manager" \
--bindPassword1 pass --host2 newyork2.example.com \
--port2 389 --bindDN2 "cn=directory manager" \
--bindPassword2 pass \
--replicationPort1 8989 \
--replicationPort2 8989 \
--baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--restricted ou=people,dc=example,dc=com \
--adminUID admin --adminPassword pass --trustAll \
--no-prompt
```

Result: The entry-balancing replication setup is complete.

4. Initialize the remaining servers without data.
  - a. Initialize the global domain, **dc=example, dc=com** on `austin2`, `newyork1`, and `newyork2` servers.

Example:

```
root@austin1# ./bin/dsreplication initialize \
--hostSource austin1.example.com --portSource 389 \
--hostDestination austin2.example.com \
--portDestination 389 --adminUID admin \
--adminPassword password \
--baseDN dc=example,dc=com \
--no-prompt
```

- b. Initialize the entry-balancing domain, **ou=people, dc=example, dc=com**, from `austin1` to `newyork2`.

Example:

```
root@austin1# ./bin/dsreplication initialize \
--hostSource austin1.example.com --portSource 389 \
--hostDestination newyork1.example.com \
--portDestination 389 --adminUID admin \
--adminPassword password \
--baseDN dc=example,dc=com \
```

```
--baseDN ou=people,dc=example,dc=com \  
--no-prompt
```

- c. Initialize the entry-balancing domain, `ou=people,dc=example,dc=com`, from `austin2` to `newyork2`.

Example:

```
root@austin2# ./bin/dsreplication initialize \  
--hostSource austin2.example.com --portSource 389 \  
--hostDestination newyork2.example.com \  
--portDestination 389 --adminUID admin \  
--adminPassword password \  
--baseDN dc=example,dc=com \  
--baseDN ou=people,dc=example,dc=com \  
--no-prompt
```

**Note:**

After `austin2` is initialized with the global domain, you can combine steps 4b and 4c by initializing both domains with one invocation.

### Checking the status of replication

After you have configured replication, check the status of the replication topology using the `dsreplication status` command.

#### Steps

- To check the replication topology status, run the `dsreplication status` command.

Example:

```
root@austin1# ./bin/dsreplication status \  
--adminPassword pass --no-prompt --port 389
```

## Managing the Directory Proxy Server

---

After you have configured PingDirectory Server, you can manage the day-to-day operations of your deployment using the monitoring and logging features.

### Managing logs

Directory Server provides several different log publisher types that provide information about how the server is processing.

#### About the default logs

You can view all logs in the `PingDirectory/logs` directory. The following logs are documented in detail:

- Error Log
- server.out Log
- Debug Log
- Config Audit Log and the Configuration Archive
- Access Log
- Setup Log
- Tool Log
- LDAP SDK Debug Log

## Error log

By default, this log file is available at `logs/errors` below the server install root and it provides information about warnings, errors, and other significant events that occur within the server. A number of messages are written to this file on startup and shutdown, but while the server is running there is normally little information written to it. In the event that a problem does occur, however, the server writes information about that problem to this file.

The following is an example of a message that might be written to the error log:

```
[11/Apr/2011:10:31:53.783 -0500] category=CORE severity=NOTICE msgID=458887
msg="The Directory Server has started successfully"
```

The category field provides information about the area of the server from which the message was generated. Available categories include:

ACCESS\_CONTROL, ADMIN, ADMIN\_TOOL, BACKEND, CONFIG, CORE, DSCONFIG, EXTENSIONS, PROTOCOL, SCHEMA, JEB, SYNC, LOG, PLUGIN, PROXY, QUICKSETUP, REPLICATION, RUNTIME\_INFORMATION, TASK, THIRD\_PARTY, TOOLS, USER\_DEFINED, UTIL, VERSION.

The severity field provides information about how severe the server considers the problem to be. Available severities include:

- **DEBUG** – Used for messages that provide verbose debugging information and do not indicate any kind of problem. Note that this severity level is rarely used for error logging, as the Directory Server provides a separate debug logging facility as described below.
- **INFORMATION** – Used for informational messages that can be useful from time to time but are not normally something that administrators need to see.
- **MILD\_WARNING** – Used for problems that the server detects, which can indicate something unusual occurred, but the warning does not prevent the server from completing the task it was working on. These warnings are not normally something that should be of concern to administrators.
- **MILD\_ERROR** – Used for problems detected by the server that prevented it from completing some processing normally but that are not considered to be a significant problem requiring administrative action. Administrator
- **NOTICE** – Used for information messages about significant events that occur within the server and are considered important enough to warrant making available to administrators under normal conditions.
- **SEVERE\_WARNING** – Used for problems that the server detects that might lead to bigger problems in the future and should be addressed by administrators.
- **SEVERE\_ERROR** – Used for significant problems that have prevented the server from successfully completing processing and are considered important.
- **FATAL\_ERROR** – Used for critical problems that arise which might leave the server unable to continue processing operations normally.

The messages written to the error log may be filtered based on their severities in two ways. First, the error log publisher has a `default-severity` property, which may be used to specify the severity of messages logged regardless of their category. By default, this includes the NOTICE, SEVERE\_WARNING, SEVERE\_ERROR, and FATAL\_ERROR severities.

You can override these severities on a per-category basis using the `override-severity` property. If this property is used, then each value should consist of a category name followed by an equal sign and a comma-delimited set of severities that should be logged for messages in that category. For example, the following override severity would enable logging at all severity levels in the PROTOCOL category:

```
protocol=debug,information,mild-warning,mild-error,notice,severe-
warning,severe-error,fatal-error
```

AdmNote that for the purposes of this configuration property, any underscores in category or severity names should be replaced with dashes. Also, severities are not inherently hierarchical, so enabling the DEBUG severity for a category will not automatically enable logging at the INFORMATION, MILD\_WARNING, or MILD\_ERROR severities.

The error log configuration may be altered on the fly using tools like `dsconfig`, the Administrative Console, or the LDIF connection handler, and changes will take effect immediately. You can configure multiple error logs that are active in the server at the same time, writing to different log files with different configurations. For example, a new error logger may be activated with a different set of default severities to debug a short-term problem, and then that logger may be removed once the problem is resolved, so that the normal error log does not contain any of the more verbose information.

### server.out log

The `server.out` file holds any information written to standard output or standard error while the server is running. Normally, it includes a number of messages written at startup and shutdown, as well as information about any administrative alerts generated while the server is running. In most cases, this information is also written to the error log. The `server.out` file can also contain output generated by the JVM. For example, if garbage collection debugging is enabled, or if a stack trace is requested via "kill -QUIT" as described in a later section, then output is written to this file.

### Debug log

The debug log provides a means of obtaining information that can be used for troubleshooting problems but is not necessary or desirable to have available while the server is functioning normally. As a result, the debug log is disabled by default, but it can be enabled and configured at any time.

Some of the most notable configuration properties for the debug log publisher include:

- **enabled** – Indicates whether debug logging is enabled. By default, it is disabled.
- **log-file** – Specifies the path to the file to be written. By default, debug messages are written to the `logs/debug` file.
- **default-debug-level** – Specifies the minimum log level for debug messages that should be written. The default value is "error," which only provides information about errors that occur during processing (for example, exception stack traces). Other supported debug levels include warning, info, and verbose. Note that unlike error log severities, the debug log levels are hierarchical. Configuring a specified debug level enables any debugging at any higher levels. For example, configuring the info debug level automatically enables the warning and error levels.
- **default-debug-category** – Specifies the categories for debug messages that should be written. Some of the most useful categories include caught (provides information and stack traces for any exceptions caught during processing), database-access (provides information about operations performed in the underlying database), protocol (provides information about ASN.1 and LDAP communication performed by the server), and data (provides information about raw data read from or written to clients).

As with the error and access logs, multiple debug loggers can be active in the server at any time with different configurations and log files to help isolate information that might be relevant to a particular problem.

#### Note:

Enabling one or more debug loggers can have a significant impact on server performance. We recommend that debug loggers be enabled only when necessary, and then be scoped so that only pertinent debug information is recorded.

Debug targets can be used to further pare down the set of messages generated. For example, you can specify that the debug logs be generated only within a specific class or package. If you need to enable the debug logger, you should work with your authorized support provider to best configure the debug target and interpret the output.

## Audit log

The audit log is a specialized version of the access log used for troubleshooting problems that could occur in the course of processing.

The audit log records all changes to directory data in LDIF format so that administrators can quickly diagnose the changes an application made to the data or replay the changes to another server for testing purposes.

The audit log does not record authentication attempts but can be used in conjunction with the access log to troubleshoot security-related issues.

The audit log is disabled by default because it reduces the server's write performance.

By default, if you enable the audit log on Directory Server, the `userPassword` and `authPassword` attribute values are obscured. Each value of an obscured attribute is replaced in the audit log with a string of the form `"***** OBSCURED VALUE *****"`. You can unobscure these attributes by deleting them from the `obscure-attribute` property.

## Config audit log and the configuration archive

The configuration audit log provides a record of any changes made to the server configuration while the server is online. This information is written to the `logs/config-audit.log` file and provides information about the configuration change in the form that may be used to perform the operation in a non-interactive manner with the `dsconfig` command. Other information written for each change includes:

- Time that the configuration change was made.
- Connection ID and operation ID for the corresponding change, which can be used to correlate it with information in the access log.
- DN of the user requesting the configuration change and the method by which that user authenticated to the server.
- Source and destination addresses of the client connection.
- Command that can be used to undo the change and revert to the previous configuration for the associated configuration object.

In addition to information about the individual changes that are made to the configuration, the Directory Server maintains complete copies of all previous configurations. These configurations are provided in the `config/archived-configs` directory and are gzip-compressed copies of the `config/config.ldif` file in use before the configuration change was made. The file names contain timestamps that indicate when that configuration was first used.

## Access and audit log

The access log provides information about operations processed within the server. The default access log file is written to `logs/access`, but multiple access loggers can be active at the same time, each writing to different log files and using different configurations.

By default, a single access log message is generated, which combines the elements of request, forward, and result messages. If an error is encountered while attempting to process the request, then one or more forward-failed messages may also be generated.

```
[01/Jun/2011:11:10:19.692 -0500] CONNECT conn=49 from="127.0.0.1"
to="127.0.0.1"
  protocol="LDAP+TLS" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.764 -0500] BIND RESULT conn=49 op=0 msgID=1 version="3"
  dn="cn=Directory Manager" authType="SIMPLE" resultCode=0 etime=0.401
  authDN="cn=Directory Manager,cn=Root DNs,cn=config"
  clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.769 -0500] SEARCH RESULT conn=49 op=1 msgID=2
  base="ou=People,dc=example,dc=com" scope=2 filter="(uid=1)" attrs="ALL"
  resultCode=0 etime=0.549 entriesReturned=1
[01/Jun/2011:11:10:19.788 -0500] DISCONNECT conn=49 reason="Client Unbind"
```

Each log message includes a timestamp indicating when it was written, followed by the operation type, the connection ID (which is used for all operations processed on the same client connection), the operation ID (which can be used to correlate the request and response log messages for the operation), and the message ID used in LDAP messages for this operation.

The remaining content for access log messages varies based on the type of operation being processed, and whether it is a request or a result message. Request messages generally include the most pertinent information from the request, but generally omit information that is sensitive or not useful.

Result messages include a `resultCode` element that indicates whether the operation was successful or if failed and an `etime` element that indicates the length of time in milliseconds that the server spent processing the operation. Other elements that might be present include the following:

- **origin=replication** – Operation that was processed as a result of data synchronization (for example, replication) rather than a request received directly from a client.
- **message** – Text that was included in the `diagnosticMessage` field of the response sent to the client.
- **additionalInfo** – Additional information about the operation that was not included in the response sent back to the client.
- **authDN – DN** of the user that authenticated to the server (typically only included in bind result messages).
- **authzDN – DN** of an alternate authorization identify used when processing the operation (for example, if the proxied authorization control was included in the request).
- **authFailureID** – Unique identifier associated with the authentication failure reason (only included in non-successful bind result messages).
- **authFailureReason** – Information about the reason that a bind operation failed that might be useful to administrators but was not included in the response to the client for security reasons.
- **responseOID** – OID included in an extended response returned to the client.
- **entriesReturned** – Number of matching entries returned to the client for a search operation.
- **unindexed=true** – Indicates that the associated search operation could not be sufficiently processed using server indexes and a significant traversal through the database was required.

Note that this is not an exhaustive list, and elements that are not listed here may also be present in access log messages. The LDAP SDK for Java provides an API for parsing access log messages and provides access to all elements that they may contain.

The Directory Server provides a second access log implementation called the *audit log*, which is used to provide detailed information about write operations (add, delete, modify, and modify DN) processed within the server. If the audit log is enabled, the entire content of the change is written to the audit log file (which defaults to `logs/audit`) in LDIF form.

The PingDirectory Server also provides a very rich classification system that can be used to filter the content for access log files. This can be helpful when debugging problems with client applications, because it can restrict log information to operations processed only by a particular application (for example, based on IP address and/or authentication DN), only failed operations, or only operations taking a long time to complete, etc.

### Setup log

The `setup` tool writes a log file providing information about the processing that it performs. By default, this log file is written to `logs/setup.log` although a different name may be used if a file with that name already exists, because the `setup` tool has already been run. The full path to the setup log file is provided when the `setup` tool has completed.

### Tool log

Many of the administrative tools provided with the Directory Server (for example, `import-ldif`, `export-ldif`, `backup`, `restore`, etc.) can take a significant length of time to complete write information to standard output or standard error or both while the tool is running. They also write additional output to files

in the `logs/tools` directory (for example, `logs/tools/import-ldif.log`). The information written to these log files can be useful for diagnosing problems encountered while they were running. When running via the server tasks interface, log messages generated while the task is running may alternately be written to the server error log file.

### LDAP SDK debug log

This log can be used to help examine the communication between the Directory Server and the Directory Proxy Server. It contains information about exceptions that occur during processing, problems establishing and terminating network connections, and problems that occur during the reading and writing of LDAP messages and LDIF entries. You can configure the types of debugging that should be enabled, the debug level that should be used, and whether debug messages should include stack traces. As for other file-based loggers, you can also specify the rotation and retention policies.

## Types of log publishers

PingDirectory Server provides different types of loggers that get processing information about the server.

There are three primary types of loggers:

### Access loggers

Provide information about operations processed within the server. They can be used for understanding the operations performed by clients, debugging problems with directory-enabled applications, and collecting usage information for performance and capacity planning purposes.

### Error loggers

Provide information about warnings, errors, or significant events that occur within the server.

### Debug loggers

Provide detailed information about processing performed by the server, including any exceptions caught during processing, detailed information about data read from or written to clients, and accesses to the underlying database.

By default, the following log publishers are enabled on the system:

- File-based access logger
- File-based error logger
- Failed-operations access logger

The following log publishers are available for PingDirectory Server but are disabled by default:

- File-based debug logger
- File-based audit logger
- Expensive operations access logger
- Successful searches with no entries returned access logger

## Creating new log publishers

The PingDirectory Server provides customization options to help you create your own log publishers with the `dsconfig` command.

When you create a new log publisher, you must also configure the log retention and rotation policies for each new publisher.

For more information, see [Configuring Log Rotation](#) and [Configuring Log Retention](#).

## Creating a new log publisher

### Steps

1. Use the `dsconfig` command in non-interactive mode to create and configure the new log publisher.

Example:

This example shows how to create a logger that only logs disconnect operations.

```
$ bin/dsconfig create-log-publisher \
  --type file-based-access --publisher-name "Disconnect Logger" \
  --set enabled:true \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set log-connects:false \
  --set log-requests:false --set log-results:false \
  --set log-file:logs/disconnect.log
```

#### Note:

To configure compression on the logger, add the `--set compression-mechanism: gzip` option to the previous command.

Because compression cannot be disabled or turned off after configured for the logger, plan carefully to determine your logging requirements, including log rotation and retention with regards to compressed logs.

2. View log publishers with the following command.

```
$ bin/dsconfig list-log-publishers
```

## Creating a log publisher using dsconfig interactive command-line mode

### Steps

1. In the command line, enter `bin/dsconfig`.
2. Authenticate to the server by following the prompts.
3. In the main menu, select the option to configure the log publisher.
4. In the `Log Publisher` menu, select the option to create a new log publisher.
5. Select the Log Publisher type.  
For this example, select **File-Based Access Log Publisher**.
6. Enter a name for the log publisher.
7. Enable it.
8. Enter the path to the log file, relative to the Directory Server root.  
For this example, `logs/disconnect.log`.
9. Select the rotation policy to use for this log publisher.
10. Select the retention policy to use for this log publisher.
11. In the `Log Publisher Properties` menu, select the option for `log-connects:false`, `log-disconnects:true`, `log-requests:false`, and `log-results:false`.
12. Enter `f` to apply the changes.

## About log compression

The Directory Server supports the ability to compress log files as they are written.

This feature can significantly increase the amount of data that can be stored in a given amount of space so that log information can be kept for a longer period of time.

Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled at the time the logger is created. Compression cannot be turned on or off when the logger is configured. Because of problems in trying to append to an existing compressed file, if the server encounters an existing log file at startup, it rotates that file and begin a new one rather than attempting to append to the previous file.

Compression is performed using the standard gzip algorithm, so compressed log files can be accessed using readily available tools. The `summarize-access-log` tool can also work directly on compressed log files rather than requiring them to be uncompressed first.

However, because it can be useful to have a small amount of uncompressed log data available for troubleshooting purposes, administrators using compressed logging might want to have a second logger defined that does not use compression and has rotation and retention policies that minimizes the amount of space consumed by those logs while still making them useful for diagnostic purposes without the need to uncompress the files before examining them.

Configure compression by setting the `compression-mechanism` property to have the value of `gzip` when creating a new logger.

## About log signing

The Directory Server supports the ability to cryptographically sign a log to ensure that it has not been modified in any way.

For example, financial institutions require audit logs for all transactions to check for correctness. Tamper-proof files are needed to ensure that these transactions can be properly validated and ensure that they have not been modified by any third-party entity or internally by unscrupulous employees.

Use the `dsconfig` tool to enable the `sign-log` property on a log publisher to turn on cryptographic signing.

When enabling signing for a logger that already exists and was enabled without signing, the first log file is not completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled are considered completely valid. For the same reason, if a log file is still open for writing, then signature validation does not indicate that the log is completely valid because the log doesn't include the necessary end signed content indicator at the end of the file.

To validate log file signatures, use the `validate-file-signature` tool provided in the `bin` directory of the server or the `bat` directory for Windows systems.

After you have enabled this property, you must disable and then re-enable the log publisher for the changes to take effect.

## About encrypting log files

The Directory Server lets you encrypt log files as they are written.

The `encrypt-log` configuration property controls whether encryption is enabled for the logger. Enabling encryption causes the log file to have an `.encrypted` extension. If both encryption and compression are enabled, the extension is `.gz.encrypted`. Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption cannot be turned on or off after the logger is configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This reduces

the overall size of the log file. The `encrypt-file` tool or custom code, using the LDAP SDK's `com.unboundid.util.PassphraseEncryptedInputStream`, is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the `encryption-settings create` command. By default, the encryption is performed with the server's preferred encryption settings definition.

To explicitly specify which definition should be used for the encryption, set the `encryption-settings-definition-id` property with the ID of that definition. You should set the encryption settings definition to be created from a passphrase so that the file can be decrypted by providing that passphrase even if the original encryption settings definition is no longer available. You can also create a randomly generated encryption settings definition, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data might remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it cannot write an incomplete block of data until the file is closed. This is not an issue for any log file that is not being actively written.

To examine the contents of a log file that is being actively written, use the `rotate-log` tool to force the file to be rotated before attempting to examine it.

## Configuring log signing

Configure log signing.

### Steps

1. To enable log signing for a log publisher, use `dsconfig`.

Example:

In this example, the `sign-log` property is set on the File-based Audit Log Publisher.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
  --set sign-log:true
```

2. Disable and then re-enable the log publisher for the change to take effect.

Example:

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
  --set enabled:false
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
  --set enabled:true
```

## Validating a signed file

The Directory Server provides a tool, `validate-file-signature`, that checks if a file has not been tampered with in any way.

### Steps

- Run the `validate-file-signature` tool to check if a signed file has been tampered with.

Example:

For this example, assume that the `sign-log` property was enabled for the File-Based Audit Log Publisher.

```
$ bin/validate-file-signature --file logs/audit
```

Result:

```
All signature information in file 'logs/audit' is valid
```

#### Note:

If any validation errors occur, you will see a message similar to the one as follows.

```
One or more signature validation errors were encountered
while validating the contents of file 'logs/audit':
```

- \* The end of the input stream was encountered without encountering the end of an active signature block. The contents of this signed block cannot be trusted because the signature cannot be verified

## Configuring log file encryption

Configure log file encryption.

### Steps

- To enable encryption for a log publisher, use `dsconfig`.

Example:

In this example, the File-based Access Log Publisher "Encrypted Access" is created, compression is set, and rotation and retention policies are set.

```
$ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted
Access" \
  --type file-based-access \
  --set enabled:true \
  --set compression-mechanism:gzip \
  --set encryption-settings-definition-
id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
  --set encrypt-log:true \
  --set log-file:logs/encrypted-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "retention-policy:Size Limit Retention Policy"
```

## 2. Decrypt and decompress the file.

Example:

```
$ bin/encrypt-file --decrypt \
  --decompress-input \
  --input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
  --output-file decrypted-access
Initializing the server's encryption framework...Done
Writing decrypted data to file '/ds/Data-Sync/decrypted-access' using a
key generated from encryption settings definition
'332c846ef0dcd1d5187c1592e4c74cad33fc1e5fc20b726cd301cdd2b3ffbc2b'
Successfully wrote 123,456,789 bytes of decrypted data
```

## Configuring log rotation

The Directory Server allows you to configure the log rotation policy for the server.

About this task

When any rotation limit is reached, the Directory Server rotates the current log and starts a new log.

If you create a new log publisher, you must configure at least one log rotation policy.

You can select the following properties:

Time Limit Rotation Policy

Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every 7 days.

Fixed Time Rotation Policy

Rotates the logs every day at a specified time (based on 24-hour time). The default time is 2359.

Size Limit Rotation Policy

Rotates the logs when the file reaches the maximum size for each log. The default size limit is 100 MB.

Never Rotate Policy

Used in a rare event that does not require log rotation.

Steps

- Use `dsconfig` to modify the log rotation policy for the access logger.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

## Configuring log rotation listeners

The Directory Server provides two log file rotation listener, the copy log file rotation listener and the summarize log file rotation listener, which you can enable with a log publisher.

About this task

Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file is subject to deletion by a log file retention policy, but the copy is not automatically removed.

The summarize log file rotation listener invokes the `summarize-access-log` tool on a recently-rotated log file and writes its output to a file in a specified location. This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the `summarize-access-log` tool, including the `file-based-access` and `operation-timing-access` logger types.

## Steps

- Use the following command to create a new copy log file rotation listener.

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Copy on Rotate" \
  --type copy \
  --set enabled:true \
  --set copy-to-directory:/path/to/archive/directory \
  --set compress-on-copy:true
```

### Note:

The path specified by the `copy-to-directory` property must exist, and the file system containing that directory must have enough space to hold all of the log files that are written there. The server automatically monitors free disk space on the target file system and generates administrative alerts if the amount of free space gets too low.

- Use the following command to create a new summarize log file rotation listener.

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Summarize on Rotate" \
  --type summarize \
  --set enabled:true \
  --set output-directory:/path/to/summary/directory
```

### Note:

The summary output files have the same name as the rotated log file, with an extension of `.summary`. If the `output-directory` property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.

As with the copy log file rotation listener, summary files are not automatically deleted. Although files are generally small in comparison to the log files themselves, make sure that enough space is available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

## Configuring log retention

The Directory Server allows you to configure the log retention policy for each log on the server.

### About this task

When a retention limit is reached, the Directory Server removes the oldest archived log before creating a new log. Log retention is only effective if you have a log rotation policy in place.

If you create a new log publisher, you must configure at least one log retention policy.

### File Count Retention Policy

Sets the number of log files you want the Directory Server to retain. The default file count is 10 logs. If the file count is set to 1, then the log continues to grow indefinitely without being rotated.

### Free Disk Space Retention Policy

Sets the minimum amount of free disk space. The default free disk space is 500 MBytes.

### Size Limit Retention Policy

Sets the maximum size of the combined archived logs. The default size limit is 500 MBytes.

### Time Limit Retention Policy

Sets the maximum length of time that rotated log files should be retained.

### Custom Retention Policy

Create a new retention policy that meets your Directory Server's requirements. This requires developing custom code to implement the desired log retention policy

### Never Delete Retention Policy

Used in a rare event that does not require log deletion.

## Steps

- Use `dsconfig` to modify the log retention policy for the access logger.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

## Setting resource limits

You can set resource limits for the Directory Server using several global configuration properties as well as setting resource limits on specific client connection policies.

If you configure both global and client connection policy resource limits, the first limit reached is always honored. For example, if the server-wide maximum concurrent connections limit is reached, then all subsequent connections are rejected until existing connections are closed regardless of whether a client connection policy limit has been reached.

### Setting global resource limits

You can specify the following types of global resource limits:

`maximum-concurrent-connections`

Specify the maximum number of client connections that can be established at any given time.

If the server already has the maximum number of connections established, then any new connection attempts from any clients are rejected until an existing connection is closed.

The default value of zero indicates that no limit is enforced.

`maximum-concurrent-connections-per-ip-address`

Specify the maximum number of client connections that can be established at any give time from the same client system.

If the server already has the maximum number of connections established from a given client, then any new connection attempts from that client are rejected until an existing connection from that

client is closed. The server continues to accept connections from other clients that have not yet reached this limit.

The default value of zero indicates that no limit is enforced.

`maximum-concurrent-connections-per-bind-dn`

Specify the maximum number of client connections that can be established at any given time while authenticated as a particular user.

This property applies after the connection is established because the bind operation to authenticate the user happens after the connection is established rather than during the course of establishing the connection itself.

If a given user reaches the maximum number of connections, then any new attempt to authenticate as that user causes the connection performing the bind to be terminated.

**Note:**

This limit applies only to authenticated connections and isn't enforced for clients that haven't authenticated or for clients that have authenticated as the anonymous user.

The default value of zero indicates that no limit is enforced.

Any changes to the `maximum-concurrent-connections` and `maximum-concurrent-connections-per-ip-address` properties take effect only for new connections established after the change is made. Any change to the `maximum-concurrent-connections-per-bind-dn` property applies only to connections, including existing connections, that perform authentication after the change is made.

Existing connections are allowed to remain established even if that would cause the new limit to be exceeded.

### Setting client connection policy resource limits

Configure resource limits in a client connection policy using the following properties of the client connection policy:

`maximum-concurrent-connections`

This property specifies the maximum number of client connections that can be associated with a specific client connection policy at any given time. After this limit has been reached, any further attempts to associate a connection with this client connection policy result in the termination of the connection.

`maximum-connection-duration`

This property specifies the maximum length of time that a connection associated with a particular client connection policy can persist. After this period, the connection is terminated.

`maximum-idle-connection-duration`

This property specifies the maximum time that a connection associated with a particular client connection policy can persist after the completion of the last operation processed on that connection. Any new operation requested on the connection resets the timer. Connections that are idle for longer than the specified time are terminated.

`maximum-operation-count-per-connection`

This property specifies the maximum number of operations that can be requested by any client connection associated with this client connection policy. Attempts to process more than this number of operations on the connection will terminate the connection.

`maximum-concurrent-operations-per-connection`

This property specifies the maximum number of concurrent operations for any connection. This property can be used to prevent a single client connection from monopolizing server processing resources by sending a large number of concurrent asynchronous requests.

`maximum-connection-operation-rate`

This property specifies the maximum rate at which a client associated with a specific client connection policy can issue requests to the Directory Proxy Server. If a client attempts to request operations at a rate higher than this limit, then the server behaves as described by the `connection-operation-rate-exceeded-behavior` property.

`connection-operation-rate-exceeded-behavior`

This property describes how the server should behave if a client connection attempts to exceed a rate defined in the `maximum-connection-operation-rate` property.

`maximum-policy-operation-rate`

This property specifies the maximum rate at which all clients associated with a particular client connection policy can issue requests to the Directory Proxy Server. If this limit is exceeded, then the server responds as specified in the `policy-operation-rate-exceeded-behavior` property.

`policy-operation-rate-exceeded-behavior`

This property specifies the behavior of the Directory Proxy Server if a client connection attempts to exceed the rate defined in the `maximum-policy-operation-rate` property.

## Monitoring the Directory Proxy Server

While the Directory Proxy Server is running, it generates a significant amount of information available through monitor entries.

This section contains information about the following:

- Monitoring server status using the `status` tool
- About the monitor entries
- Using the monitoring interfaces
- Monitoring with Java Management Extensions (JMX)

### Monitoring system data using the PingDataMetrics Server

The PingDataMetrics Server provides collection and storage of performance data from your server topology. You can use the System Utilization Monitor with the PingDataMetrics Server to collect information about the host system CPU, disk, and network utilization on any platform except Linux. If you are not using the PingDataMetrics Server, you do not need to use the system utilization monitor. When data is being collected, it periodically forks the process and executes commands.

For more information about using the System Utilization Monitor, refer to the data collection chapter of the PingDataMetrics Server documentation.

### Monitoring the server using the `status` tool

PingDirectory Server provides a `status` tool that provides basic server status information, including version, connection handlers, a table of LDAP external servers, and the percent of the global index being used.

#### Steps

1. To view the current state of the server, run the `status` tool.

```
$ bin/status
```

## 2. Enter the LDAP connection parameters.

```
>>>> Specify LDAP connection parameters
Administrator user bind DN [cn=Directory Manager]:
Password for user 'cn=Directory Manager':
```

**Result:**

```

      --- Server Status ---

### About the monitor entries

While the Directory Server is running, it generates a significant amount of information available through monitor entries. Monitor entries are available over LDAP in the `cn=monitor` subtree. The types of monitor entries that are available include:

- **General Monitor Entry (cn=monitor)** – Provides a basic set of general information about the server.
- **Active Operations Monitor Entry (cn=Active Operations,cn=monitor)** – Provides information about all operations currently in progress in the server.
- **Backend Monitor Entries (cn={id} Backend,cn=monitor)** – Provides information about the backend, including the number of entries, the base DN(s), and whether it is private.
- **Client Connections Monitor Entry (cn=Client Connections,cn=monitor)** – Provides information about all connections currently established to the server.
- **Connection Handler Monitor Entry (cn={name},cn=monitor)** – Provides information about the configuration of each connection handler and the client connections established to it.
- **Database Environment Monitor Entries (cn={id} Database Environment,cn=monitor)** – Provides statistics and other data from the Oracle Berkeley DB Java Edition database environment used by the associated backend.
- **Disk Space Usage Monitor Entry (cn=Disk Space Usage,cn=monitor)** – Provides information about the amount of usable disk space available to server components.
- **JVM Memory Usage Monitor Entry (cn=JVM Memory Usage,cn=monitor)** – Provides information about garbage collection activity, the amount of memory available to the server, and the amount of memory consumed by various server components.
- **JVM Stack Trace Monitor Entry (cn=JVM Stack Trace,cn=monitor)** – Provides a stack trace of all threads in the JVM.
- **LDAP Statistics Monitor Entries (cn={name} Statistics,cn=monitor)** – Provides information about the number of each type of operation requested and bytes transferred over the connection handler.
- **Processing Time Histogram Monitor Entry (cn=Processing Time Histogram,cn=monitor)** – Provides information about the number of percent of operations that completed in various response time categories.
- **SSL Context Monitor Entry (cn=SSL Context,cn=monitor)** – Provides information about the available and supported SSL Cipher Suites and Protocols on the server.

- **System Information Monitor Entry (cn=System Information,cn=monitor)** – Provides information about the underlying JVM and system.
- **Version Monitor Entry (cn=Version,cn=monitor)** – Provides information about the Directory Server version.
- **Work Queue Monitor Entry (cn=Work Queue,cn=monitor)** – Provides information about the state of the Directory Server work queue, including the number of operations waiting on worker threads and the number of operations that have been rejected because the queue became full.

## Working with alarms, alerts, and gauges

Alarms, alerts, and gauges alert administrators to changes in server conditions that might require attention.

### Alarms

An alarm represents a stateful condition of the server or a resource that might indicate a problem, such as low disk space or external server unavailability.

Alarms have severity, name, and message. Alarms will always have a Condition property, and can have a Specific Problem or Resource property. If surfaced through SNMP, a Probable Cause property and Alarm Type property are also listed. You can configure alarms to generate alerts when the alarm's severity changes.

You can configure the Alarm Manager, which governs the actions performed when an alarm state is entered, through the `dsconfig` tool and Administrative Console. A complete list of system alerts, alarms, and their severity is available in `<server-root>/docs/admin-alerts-list.csv`.

Directory Server complies with the International Telecommunication Union CCITT Recommendation X.733 (1992) standard for generating and clearing alarms. If configured, entering or exiting an alarm state might result in one or more alerts.

An alarm state is exited when the condition no longer applies. An `alarm_cleared` alert type is generated by the system when an alarm's severity changes from a non-normal severity to any other severity. An `alarm_cleared` alert will correlate to a previous alarm when the Condition and Resource properties are the same. The Condition corresponds to the Summary column in the `admin-alerts-list.csv` file.

Like the Alerts Backend, which stores information in `cn=alerts`, the Alarm Backend stores information within the `cn=alarms` backend. Unlike alerts, alarm thresholds have a state over time that can change in severity and be cleared when a monitored value returns to normal. You can view alarms with the `status` tool. As with other alert types, you can configure alert handlers can to manage the alerts generated by alarms.

### Alerts

There are two alert types supported by the server: standard and alarm-specific.

The server constantly monitors for conditions that might need administrator attention, such as low disk space. For this condition, the standard alert is `low-disk-space-warning`, and the alarm-specific alert is `alarm-warning`.

You can configure the server to generate alarm-specific alerts as well as standard alerts. By default, standard alerts are generated for conditions internally monitored by the server. However, gauges can only generate alarm-alerts.

### Gauges

A gauge defines a set of threshold values with a specified severity that, when crossed, cause the server to enter or exit an alarm state.

Numeric gauges monitor continuous values like CPU load or free disk space. Indicator gauges monitor enumerated set of values such as 'server unavailable' or 'server unavailable'. Gauges generate alarms when the gauge's severity changes due to changes in the monitored value.

Directory Server installs a set of gauges that are specific to the product and that can be cloned or configured through the `dsconfig` tool. You can tailor existing gauges to fit each environment by adjusting the update interval and threshold values. Configuration of system gauges determines the criteria by which alarms are triggered.

Use the Stats Logger to view historical information about the value and severity of all system gauges. For more information, see [Profiling server performance using the Stats Logger](#) on page 963.

## Testing alarms and alerts

### Steps

1. Use `dsconfig` to configure a gauge and set the `override-severity` property to critical.

The following example configures the CPU Usage (Percent) gauge.

Example:

```
$ dsconfig set-gauge-prop \
  --gauge-name "CPU Usage (Percent)" \
  --set override-severity:critical
```

2. Run the `status` tool to verify that an alarm was generated with corresponding alerts.

The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts and alarms.

Example:

The sample output has been shortened to show just the alarms and alerts information.

```
$ bin/status

          --- Administrative Alerts ---

### Indeterminate alarms

Directory Server raises indeterminate alarms for a server condition for which a severity cannot be determined.

In most cases these alarms are benign and do not issue alerts, nor do they appear in the output of the **status** tool or Administrative Console by default.

These alarms are usually caused by an enabled gauge that is intended to measure an aspect of the server that is not currently enabled. For example, gauges intended to monitor metrics related to replication might produce indeterminate alarms if a directory server is not currently replicating data. The gauge can be disabled if needed.

For more information about indeterminate alarms, view the gauge's associated monitor entry. There might be messages that can help determine the issue.

The following is sample output from the **status** tool run with the `-alarmSeverity=indeterminate` option.

```

--- Alarms ---
Severity      : Severity Start : Condition      : Resource      : Details
:             : Time             :                :               :

        this severity Tue Aug 26 15:42:40 CDT 2014
error-message: No entries were found under cn=monitor having object
              class ds-replica-monitor-entry
...

```

## Administrative alert handlers

The PingDirectory Server provides mechanisms to send alert notifications to administrators when significant problems or events occur during processing, such as problems during server startup or shutdown. The Directory Server provides a number of alert handler implementations, including:

- **Error Log Alert Handler.** Sends administrative alerts to the configured server error logger(s).
- **Exec Alert Handler.** Executes a specified command on the local system if an administrative alert matching the criteria for this alert handler is generated by the Directory Server. Information about the administrative alert will be made available to the executed application as arguments provided by the command.
- **Groovy Scripted Alert Handler.** Provides alert handler implementations defined in a dynamically-loaded Groovy script that implements the `ScriptedAlertHandler` class defined in the Server SDK.
- **JMX Alert Handler.** Sends administrative alerts to clients using the Java Management Extensions (JMX) protocol. Ping Identity uses JMX for monitoring entries and requires that the JMX connection handler be enabled.
- **SMTP Alert Handler.** Sends administrative alerts to clients via email using the Simple Mail Transfer Protocol (SMTP). The server requires that one or more SMTP servers be defined in the global configuration.
- **SNMP Alert Handler.** Sends administrative alerts to clients using the Simple Network Monitoring Protocol (SNMP). The server must have an SNMP agent capable of communicating via SNMP 2c.
- **SNMP Subagent Alert Handler.** Sends SNMP traps to a master agent in response to administrative alerts generated within the server.
- **Third Party Alert Handler.** Provides alert handler implementations created in third-party code using the Server SDK.

### Configuring the JMX connection handler and alert handler

You can configure the Java Management Extensions (JMX) connection handler and the alert handler using the `dsconfig` tool.

To allow users to receive JMX notifications, enable the `jmx-read` and `jmx-notify` privileges. By default, these privileges aren't granted to any users, including root users or global administrators.

For security reasons, you should create a separate user account that has only these privileges.

You can also configure the JMX connection handler and the alert handler using `dsconfig` in interactive command-line mode, which is visible in the `Standard object` menu.

### Configuring the JMX connection handler

About this task

To enable the JMX connection handler:

## Steps

1. Run **dsconfig**.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "JMX Connection Handler" \
  --set enabled:true \
  --set listen-port:1689
```

2. Add a new non-root user account with the `jmx-read` and `jmx-notify` privileges using the **ldapmodify** tool using an LDIF representation.

Example:

```
dn: cn=JMX User,cn=Root DNs,cn=config
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-cfg-root-dn-user
givenName: JMX
sn: User
cn: JMX User
userPassword: password
ds-cfg-inherit-default-root-privileges: false
ds-cfg-alternate-bind-dn: cn=JMX User
ds-privilege-name: jmx-read
ds-privilege-name: jmx-notify
```

## Configuring the JMX alert handler

### About this task

To configure the Java Management Extensions (JMX) alert handler:

### Steps

- Run **dsconfig**.

Example:

```
$ bin/dsconfig set-alert-handler-prop --handler-name "JMX Alert Handler" \
  --set enabled:true
```

## Configuring the SMTP alert handler

To create a new instance of an SMTP alert handler, use the **dsconfig** tool.

### About this task

By default, there is no configuration entry for an SMTP alert handler.

### Steps

- Use the **dsconfig** tool to configure the SMTP Alert Handler.

Example:

```
$ bin/dsconfig create-alert-handler \
  --handler-name "SMTP Alert Handler" \
```

```
--type smtp \
--set enabled:true \
--set "sender-address:alerts@example.com" \
--set "recipient-address:administrators@example.com" \
--set "message-subject:Directory Admin Alert \%\%alert-type\%\%" \
--set "message-body:Administrative alert:\n\%\%alert-message\%\%"
```

### Configuring the SNMP subagent alert handler

You can configure the SNMP subagent alert handler using the `dsconfig` tool, which is visible in the Standard object menu.

#### About this task

Before you begin, you need an SNMP subagent capable of communicating using SNMP2c. For more information about SNMP, see [Monitoring using SNMP](#) on page 955.

Directory Server also supports an SNMP alert handler, which is used in deployments that do not enable an SNMP subagent.

To configure the SNMP subagent alert handler:

#### Steps

- Run `dsconfig`.

Example:

In this example:

- The `server-host-name` is the address of the system running the SNMP subagent.
- The `server-port` is the port number on which the subagent is running.
- The `community-name` is the name of the SNMP community that is used for the traps.

```
$ bin/dsconfig set-alert-handler-prop \
--handler-name "SNMP Subagent Alert Handler" \
--set enabled:true \
--set server-host-name:host2 \
--set server-port:162 \
--set community-name:public
```

## Working with virtual attributes

PingDirectory Server provides dynamically-generated attributes called virtual attributes for local Directory Proxy Server data.

The proxy virtual attributes apply to a local proxy backend, such as `cn=config` or the Root DSA-specific entry (DSE).

If you want virtual attributes in entries for proxied requests, they must be configured in the backend servers. Alternately, attributes can be inserted into those entries using proxy transformations. For more information, see [Configuring proxy transformations](#) on page 1268.

For example, you can define a virtual attribute and assign it to the Root DSE using `create-virtual-attribute`.

```
$ bin/dsconfig create-virtual-attribute \
--name defineDescriptionOnRootDSE --type user-defined \
--set enabled:true --set attribute-type:description \
--set filter:objectclass=ds-root-dse --set value:PrimaryProxy
```

If you search the Root DSE using the following LDAP search, you see that the description attribute now has the value `PrimaryProxy`.

```
$ bin/ldapsearch --baseDN "" --searchScope base --bindDN "" \
  --bindPassword "" --port 5389 --hostname localhost \
  "objectclass=*" description

dn:
description:PrimaryProxy
```

## Managing Monitoring

PingDirectory Server provides a flexible monitoring framework that exposes its monitoring information under the `cn=monitor` entry.

It provides interfaces with:

- The PingDataMetrics Server
- The Administrative Console
- SNMP
- Java management extensions (JMX)
- LDAP

The Directory Server also provides a tool, the Periodic Stats Logger, to profile server performance.

### The monitor backend

Directory Server exposes its monitoring information under the `cn=monitor` entry.

Administrators can use various means to monitor the servers, including the PingDataMetrics Server, through SNMP, the Administrative Console, JConsole, LDAP command-line tools, and the Periodic Stats Logger.

#### Note:

To display server component activity and state, use the `bin/status` tool.

To see the list of all monitor entries, use `ldapsearch` as in the following example.

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --baseDN "cn=monitor" "(objectclass=*)" cn
```

The following table describes a subset of the monitor entries.

#### Directory Server Monitoring Components

| Component         | Description                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Active Operations | Provides information about the operations currently being processed by the Directory Server. Shows the number of operations, information on each operation, and the number of active persistent searches.                                                |
| Backends          | Provides general information about the state of a Directory Server backend, including the entry count. If the backend is a local database, there is a corresponding database environment monitor entry with information on cache usage and on-disk size. |

| Component                                | Description                                                                                                                                                                                                                                                                                   |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client Connections                       | Provides information about all client connections to the Directory Server. The client connection information contains a name followed by an equal sign and a quoted value, such as <code>connID="15"</code> , <code>connectTime="20100308223038Z"</code> and so forth.                        |
| Connection Handlers                      | Provides information about the available connection handlers on the Directory Server, which includes the LDAP and LDIF connection handlers. These handlers are used to accept client connections and to read requests and send responses to those clients.                                    |
| Disk Space Usage                         | Provides information about the disk space available to various components of the Directory Server.                                                                                                                                                                                            |
| General                                  | Provides general information about the state of the Directory Server, including product name, vendor name, server version, etc.                                                                                                                                                               |
| Index                                    | The monitor captures the number of keys preloaded, and counters for read/write/remove/open-cursor/read-for-search. These counters provide insight into how useful an index is for a given workload.                                                                                           |
| HTTP/HTTPS Connection Handler Statistics | Provides statistics about the interaction that the associated HTTP connection handler has had with its clients, including the number of connections accepted, average requests per connection, average connection duration, total bytes returned, and average processing time by status code. |
| JVM Stack Trace                          | Provides a stack trace of all threads processing within the Java virtual machine (JVM).                                                                                                                                                                                                       |
| LDAP Connection Handler Statistics       | Provides statistics about the interaction that the associated LDAP connection handler has had with its clients, including the number of connections established and closed, bytes read and written, LDAP messages read and written, operations initiated, completed, and abandoned, etc.      |
| Processing Time Histogram                | Categorizes operation processing times into a number of user-defined buckets of information, including the total number of operations processed, overall average response time in milliseconds (ms), number of processing times between 0ms and 1ms, and so forth.                            |
| System Information                       | Provides general information about the system and the JVM on which the Directory Server is running, including system host name, operation system, JVM architecture, Java home, Java version, and so forth.                                                                                    |
| Version                                  | Provides information about the Directory Server version, including build ID, version, revision number, etc.                                                                                                                                                                                   |

| Component  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Work Queue | <p>Provides information about the state of the Directory Server work queue, which holds requests until they can be processed by a worker thread, including the requests rejected, current work queue size, number of worker threads, and number of busy worker threads. The work queue configuration has a <code>monitor-queue-time</code> property set to <code>true</code> by default. This logs messages for new operations with a <code>qtime</code> attribute included in the log messages. Its value is expressed in milliseconds and represents the length of time that operations are held in the work queue.</p> <p>A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the <code>ldapsearch</code> command for example, use the <code>--useAdministrativeSession</code> option. The requester must have the <code>use-admin-session</code> privilege, which is included for root users. By default, eight threads are available for this purpose. This can be changed with the <code>num-administrative-session-worker-threads</code> property in the work queue configuration.</p> |

## Monitoring disk space usage

The disk space usage monitor provides information about the amount of usable disk space available for Directory Server components.

The disk space usage monitor evaluates the free space at locations registered through the `DiskSpaceConsumer` interface by various components of the server. Disk space monitoring excludes disk locations that do not have server components registered. However, other disk locations might still impact server performance, such as the operating system disk, if it becomes full. When relevant to the server, these locations include the server root, the location of the `/config` directory, the location of every log file, all Java Runtime Environment (JRE) backend directories, the location of the changelog, the location of the replication environment database, and the location of any server extension that registers itself with the `DiskSpaceConsumer` interface.

The disk space usage monitor provides the ability to generate administrative alerts and take additional action if the amount of usable space drops below the defined thresholds.

You can configure three thresholds for this monitor:

### Low space warning threshold

This threshold is defined as either a percentage or absolute amount of usable space. If the amount of usable space drops below this threshold, then the Directory Server generates an administrative alert but remains fully functional. It generates alerts at regular intervals that you configure (such as once a day) unless action is taken to increase the amount of usable space. The Directory Server generates additional alerts as the amount of usable space is further reduced, such as each time the amount of usable space drops below a value 10% closer to the low space error threshold. If an administrator frees up disk space or adds additional capacity, then the server should automatically recognize this and stop generating alerts.

### Low space error threshold

This threshold is also defined as either a percentage or absolute size. If the amount of usable space drops below this threshold, the server generates an alert notification and begins rejecting all operations requested by non-root users with `UNAVAILABLE` results. The server should continue to generate alerts during this time. When the server enters this mode, an administrator has to take some kind of action, such as, running a command to invoke a task or removing a signal file, before the server resumes normal operation. This threshold must be less than or equal to the low

space warning threshold. If they are equal, the server begins rejecting requests from non-root users immediately upon detecting low usable disk space.

#### Out of space error threshold

This threshold can also be defined as a percentage or absolute size. If the amount of usable space drops below this threshold, the PingDirectory Server generates a final administrative alert and shuts itself down. This threshold must be less than or equal to the low space error threshold. If they are equal, the server shuts itself down rather than rejecting requests from non-root users.

The server monitors disk space consumption during processing for the `export-ldif`, `rebuild-index`, and `backup` tools. Space is monitored every 10 seconds if usable space for all monitored paths is greater than 15 percent of the capacity of those volumes. If usable space for any path drops below 15 percent, or below 10GB free, the space check frequency is increased to every second. Warning messages are generated if available space falls below 10 percent, or below 5GB free. If usable space for any path drops below two percent, or 1GB free, the tool processing is aborted and files can be removed to free up space.

The default configuration uses the same values for the low space error threshold and out of space error threshold. This is to prevent having the server online but rejecting requests, which causes problems with applications trying to interact with the server. The low space warning threshold generates an alert before the problem becomes serious, well in advance of available disk space dropping to a point that it is critical.

The default values might not be suitable for all disk sizes, and should be adjusted to fit the deployment. Determining the best values should factor in the size of the disk, how big the database might become, how much space log files might consume, and how many backups are stored.

The threshold values can be specified either as absolute sizes or as percentages of the total available disk space. You must specify all values as absolute values or as percentages. A mix of absolute values and percentages cannot be used. The low space warning threshold must be greater than or equal to the low space error threshold, the low space error threshold must be greater than or equal to the out of space error threshold, and the out of space error threshold must be greater than or equal to zero.

If the out of space error threshold is set to zero, then the server does not attempt to automatically shut itself down if it detects that usable disk space has become critically low. If the amount of usable space reaches zero, then the database preserves its integrity but might enter a state in which it rejects all operations with an error and requires the server, or at least the affected backends, to be restarted. If the low space error threshold is also set to zero, then the server generates periodic warnings about low available disk space but remains fully functional for as long as possible. If all three threshold values are set to zero, then the server does not attempt to warn about or otherwise react to a lack of usable disk space.

## Monitoring with the PingDataMetrics Server

The PingDataMetrics Server is an invaluable tool for collecting, aggregating and exposing historical and instantaneous data from the various Ping Identity servers in a deployment.

The PingDataMetrics Server relies on a captive PostgreSQL datastore for the metrics that it collects from internal instrumentation across the instances, replicas, and data centers in your environment. The data is available through a Monitoring API that can be used to build custom dashboards and monitoring applications to monitor the overall health of your PingData Platform system. For more information, see the PingDataMetrics Server Administration Guide.

### Monitoring key performance indicators by application

PingDirectory Server can be configured to track many key performance metrics, such as throughput and response-time, by the client applications requesting them.

This feature is invaluable for measuring whether the Ping Identity identify infrastructure meets all of your service-level agreements (SLA) that have been defined for client applications.

When enabled, the per-application monitoring data:

- Can be accessed in the `cn=monitor` backend
- Can be accessed in the Periodic Stats Logger

- Can be made available for collection by the Metrics Server

For more information on using the Stats Logger, see [Profiling server performance using the Stats Logger](#) on page 963.

For details on configuring the server to expose metrics that interest you, see the Directory Server [Configuration section of the PingDataMetrics Server Administration Guide](#).

Tracked application information is exposed in the PingDataMetrics Server by metrics having the `application-name` dimension. For information on which metrics are available with the `application-name` dimension, see the documentation under `docs/metrics` of the PingDataMetrics Server.

### Configuring the external Servers

Before you install the PingDataMetrics Server, you must configure the servers you want to monitor:

- PingDirectory Server
- PingDirectoryProxy Server
- PingDataSync Server

The PingDataMetrics Server requires all servers to be 3.5.0 or later. See the administration guides for each product for installation instructions.

After you have installed Directory Server, use the `dsconfig` tool to make configuration changes for the PingDataMetrics Server. When using the `dsconfig` tool interactively, set the complexity level to `Advanced` so that you can make all the necessary configuration changes.

### Preparing the servers monitored by the PingDataMetrics Server

The Metrics Backend manages the storage of metrics and provides access to the stored blocks of metrics via LDAP. The Metrics Backend is configured to keep a maximum amount of metric history based on log retention policies.

The default retention policy uses the Default Size Limit Retention Policy, Free Disk Space Retention Policy, and the File Growth Limit Policy, limiting the total disk space used to 500 MB. This amount of disk typically contains more than 24 hours of metric history, which is ample. Directory Server keeps a metric history so that the PingDataMetrics Server can be down for a period and then catch up when it comes back online.

The following two commands create a Retention Policy that limits the number of files to 2000 and sets the Metrics Backend to flush data to a new file every 30 seconds.

```
$ bin/dsconfig create-log-retention-policy \
  --policy-name StatsCollectorRetentionPolicy \
  --type file-count --set number-of-files:2000

$ bin/dsconfig set-backend-prop \
  --backend-name metrics --set sample-flush-interval:30s \
  --set retention-policy:StatsCollectorRetentionPolicy
```

These commands configure the Metrics Backend to keep 16 hours of metric history, which consumes about 250 MB of disk, ensuring that captured metrics are available to the PingDataMetrics Server within 30 seconds of when the metric was captured. The value of the `sample-flush-interval` attribute determines the maximum delay between when a metric is captured and when it can be picked up by the PingDataMetrics Server.

You can set the flush interval between 15 seconds and 60 seconds, with longer values resulting in less processing load on the PingDataMetrics Server. However, this flush interval increases the latency between when the metric was captured and when it becomes visible in the Dashboard Application. If you change the `sample-flush-interval` attribute to 60 seconds in the example above, then the Directory Server keeps 2000 minutes of history. Because the number of metrics produced per unit of time can vary depending on the configuration, no exact formula can be used to compute how much storage is required for each hour of history. However, 20 MB per hour is a reasonable estimate.

## Configuring the Processing Time Histogram plugin

The Processing Time Histogram plugin is configured on each Directory Server and Directory Proxy Server as a set of histogram bucket ranges.

When the bucket ranges for a histogram change, the PingDataMetrics Server notices the change and marks samples differently. This process allows for histograms with the same set of bucket definitions to be properly aggregated and understood when returned in a query. If different servers have different bucket definitions, then a single metric query cannot return histogram data from the servers.

You should try to keep the Processing Time Histogram bucket definitions the same on all servers. Having different definitions restricts the ability of the PingDataMetrics Server API to aggregate histogram data across servers and makes the results of a query asking "What percentage of the search requests took less than 12 milliseconds?" harder to understand.

For each server in your topology, you must set the `separate-monitor-entry-per-tracked-application` property of the Processing Time Histogram plugin to true. This property must be set to expose per-application monitoring information under `cn=monitor`. When the `separate-monitor-entry-per-tracked-application` property is set to true, then the `per-application-ldap-stats` property must be set to `per-application-only` on the Stats Collector plugin and vice versa.

The following `dsconfig` command line sets the required properties of the Processing Time Histogram plugin.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Processing Time Histogram" \
  --set separate-monitor-entry-per-tracked-application:true
```

The following `dsconfig` command-line sets the `per-application-ldap-stats` property of the Stats Collector plugin to `per-application-only`.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Stats Collector" \
  --set per-application-ldap-stats:per-application-only
```

## Setting the connection criteria to collect SLA statistics by application

To collect data about your service level agreements (SLAs), configure connection criteria for each SLA that you want to track.

The connection criteria are used in many areas within the server. They are used by the client connection policies, and are used when the server needs to perform matching based on connection-level properties, such as filtered logging. For assistance using connection criteria, contact a Ping Identity support representative.

For example, if you are interested in collecting statistics on data that is accessed by clients authenticating as the Directory Manager, you should create connection criteria on the Directory Server that identifies any user authenticating as the Directory Manager. The connection criteria name corresponds to the `application-name` dimension value that clients specify when accessing the data through the API. When you define the connection criteria, change the `included-user-base-dn` property to include the Directory Manager's full LDIF entry.

The following `dsconfig` command line creates connection criteria for the Directory Manager.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Directory Manager" \
  --type simple \
  --set "included-user-base-dn:cn=Directory Manager,cn=Root DNs,cn=config"
```

## Updating the Global Configuration

You must create Global Configuration tracked applications for each application (connection criteria) you intend to track.

About this task

The `tracked-application` property allows individual applications to be identified in the server by connection criteria.

### Note:

The name of the tracked application is the same as the name you defined for the connection criteria.

## Steps

- To add connection criteria to the list of tracked applications, run `dsconfig` with the `set-global-configuration-prop` option.

Example:

This example adds the connection criteria you created in the example in [Setting the connection criteria to collect SLA statistics by application](#) on page 954 to the list of tracked applications.

```
$ bin/dsconfig set-global-configuration-prop \
  --set "tracked-application:Directory Manager"
```

### Note:

The value of the `tracked-application` field corresponds to the value of the `application-name` dimension value that clients specify when accessing the data through the API.

## Proxy considerations for tracked applications

In a proxy environment, the criteria should be defined in the Directory Proxy Server because Directory Proxy Server passes the application name through to the Directory Server in the intermediate client control.

If a client of Directory Proxy Server or Directory Server happens to use the intermediate client control, then the client name specified in the control is used as the application name regardless of the criteria listed in the `tracked-application` property.

## Monitoring using SNMP

PingDirectory Server supports real-time monitoring using SNMP. Directory Server provides an embedded SNMPv3 subagent plugin that, when enabled, sets up the server as a managed device and exchanges monitoring information with a master agent based on the AgentX protocol.

### SNMP implementation

In a typical SNMP deployment, many production environments use a network management system (NMS) for a unified monitoring and administrative view of all SNMP-enabled devices.

The NMS communicates with a master agent, whose main responsibility is to translate the SNMP protocol messages and multiplex any request messages to the subagent on each managed device, such as a Directory Server instance, Directory Proxy Server, Data Sync Server, or OS Subagent. The master agent also processes responses or traps from the agents. Many vendors provide commercial NMS systems. Consult with your NMS system for specific information.

PingDirectory Server contains an SNMP subagent plugin that connects to a Net-SNMP master agent over TCP. The main configuration properties of the plugin are the address and port of the master agent, which default to localhost and port 705, respectively. When the plugin is initialized, it creates an AgentX subagent

and a managed object server and then registers as a management information base (MIB) server with the Directory Server instance. After the plugin's startup method is called, it starts a session thread with the master agent. Whenever the connection is lost, the subagent automatically attempts to reconnect with the master agent. Directory Server's SNMP subagent plugin transmits only read-only values for polling or trap purposes. Set and inform operations are not supported. SNMP management applications cannot perform actions on the server on their own or through an NMS system.

### Example SNMP Deployment

#### Note:

PingDirectory Server was designed to interface with a Net-SNMP (5.3.2.2 or later) master agent implementation with AgentX over TCP. Many operating systems provide their own Net-SNMP module. However, Service Management Automation (SMA) disables some features present in the Net-SNMP package and only enables AgentX over UNIX Domain Sockets, which cannot be supported by Java. If your operating system has a native Net-SNMP master agent that only enables UNIX Domain Sockets, you should download and install a separate Net-SNMP binary from its website.

### Configuring SNMP

Because all server instances provide information for a common set of management information bases (MIBs), each server instance provides its information under a unique SNMPv3 context name equal to the server instance name.

#### About this task

The server instance name is defined in the Global Configuration and is constructed from the host name and the server LDAP port by default. Information must be requested using SNMPv3, specifying the context name that pertains to the desired server instance.

#### Note:

Directory Server supports SNMPv3, and only SNMPv3 can access the MIBs. For systems that implement SNMP v1 and v2c, Net-SNMP provides a proxy function to route requests in one version of SNMP to an agent using a different SNMP version.

## Steps

1. To enable Directory Server's SNMP plugin, use the `dsconfig` tool.

### Note:

The SNMPv3 context name is limited to 30 bytes maximum. Any context name longer than 30 characters returns an error message when you attempt to enable the plugin.

The default context server name is the server instance name and the LDAP port number, so take note of the length of the fully-qualified DNS host name.

- a. Specify the address and port of the SNMP master agent.
- b. On each Directory Server instance, enable the SNMP subagent.
- c. Enable the SNMP Subagent Alert Handler so that the sub-agent sends traps for administrative alerts generated by the server.

Example:

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" --set enabled:true
```

2. View the error log.

Result:

A message displays that the master agent is not connected because it is not yet online.

```
The SNMP sub-agent was unable to connect to the master
agent at localhost/705: Timeout
```

3. Edit the SNMP agent `snmpd.conf` configuration file and add the directive to run the agent as an AgentX master agent.

The file is often located in `/etc/snmp/snmpd.conf`.

Example:

```
master agentx agentXSocket tcp:localhost:705
```

### Note:

Using `localhost` means that only sub-agents running on the same host can connect to the master agent. This is necessary because there are no security mechanisms in the AgentX protocol.

4. Add the trap directive to send SNMPv2 traps to `localhost` with the community name, `public` (or whatever SNMP community has been configured for your environment) and the port.

Example:

```
trap2sink localhost public 162
```

5. To create a SNMPv3 user, add the following lines to the `/etc/snmp/snmpd.conf` file.

Example:

```
rwuser initial
createUser initial MD5 setup_passphrase DES
```

6. To create the SNMPv3 user, run **snmpusm**.

Example:

```
snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
localhost create snmpuser initial
```

7. Start the **snmpd** daemon.

Result:

A message displays in the Directory Server error log.

```
The SNMP subagent connected successfully to the master agent
at localhost:705. The SNMP context name is host.example.com:389
```

8. To see the alerts that are generated by Directory Server, set up a trap client.

- Create a config file in `/tmp/snmptrapd.conf`.
- Add the `authcommunity log`, execute `public` directive to the file.

 **Note:**

The directive specifies that the trap client can process traps using the public community string and can log and trigger executable actions.

9. Install the MIB definitions for the Net-SNMP client tools in the `/usr/share/snmp/mibs` directory.

Example:

```
$ cp resource/mib/* /usr/share/snmp/mibs
```

10. To run the trap client, run the **snmptrapd** command.

Example:

This example specifies that the command should not create a new process using `fork()` from the calling shell (`-f`), should not read any configuration files (`-C`) except the one specified with the `-c` option, should print to standard output (`-Lo`), and then specifies that debugging output should be turned on for the User-based Security Module (`-Dusm`). The path after the `-M` option is a directory that contains the MIBs shipped with our product (`server-root/resource/mib`).

```
$ snmptrapd -f -C -c /tmp/snmptrapd.conf -Lf /root/trap.log -Dusm \
-m all -M +/usr/share/snmp/mibs
```

11. To test the feature, run the Net-SNMP client tools.

You must use the following options:

- `-v <SNMP version>`
- `-u <user name>`
- `-l <security level>`
- `-n <context name (instance name)>`
- `-A <user password>`

Example:

In this example, the `-m all` option loads all MIBs in the default MIB directory in `/usr/share/snmp/mibs` so that MIB names can be used in place of numeric OIDs.

```
$ snmpget -v 3 -u snmpuser -A password -l authNoPriv -n
host.example.com:389 \
-m all localhost localDBBackendCount.0
```

```
$ snmpwalk -v 3 -u snmpuser -A password -l authNoPriv -n
  host.example.com:389 \
  -m all localhost systemStatus
```

## MIBS

Directory Server provides SMIV2-compliant management information base (MIB) definitions (RFC 2578, 2579, 2580) for distinct monitoring statistics. These MIB definition text files are in the server's `/resource/mib` directory.

Each MIB provides managed object tables for each specific SNMP management information as follows:

### LDAP Remote Server MIB

Provides information related to the health and status of the LDAP servers that the Directory Proxy Server connects to and statistics about the operations invoked by the Directory Proxy Server on those LDAP servers.

### LDAP Statistics MIB

Provides a collection of connection-oriented performance data that is based on a connection handler in the Directory Server.

A server typically contain only one connection handler and therefore supplies only one table entry.

### Local DB Backend MIB

Provides key metrics related to the state of the local database backends contained in the server.

### Processing Time MIB

Provides a collection of key performance data related to the processing time of operations broken down by several criteria but reported as a single aggregated data set.

### Replication MIB

Provides key metrics related to the current state of replication that can help diagnose how much outstanding work replication might have to do.

### System Status MIB

Provides a set of critical metrics for determining the status and health of the system in relation to its work load.

For information on the available monitoring statistics for each MIB available on Directory Server and the Directory Proxy Server, see the text files located in the server's `/resource/mib` directory.

Directory Server generates an extensive set of SNMP traps for event monitoring. The traps display the severity, description, name, OID, and summary. For information about the available alert types for event monitoring, see the `resource/mib/UNBOUNDID-ALERT-MIB.txt` file.

## Monitoring with the Administrative Console

Before you begin

Ensure that the Directory Server is running.

About this task

Ping Identity has an Administrative Console for administrators to configure directory server. The console also provides a status option that accesses the server's monitor content.

To view the **Monitor Dashboard**:

### Steps

1. In your browser, enter `http://<server-name>:8443/console`.
2. Enter the root user distinguished name (DN) and password. Click **Login**.
3. In the top level navigation menu, select **Status**.
4. On the **Status** page, click the **Monitors** tab.

### Result

The **Monitors** page opens, and you can monitor your server using the Administrative Console.

## Accessing the Processing Time Histogram

PingDirectory Server provides a processing time histogram that classifies operation response time into user-defined buckets.

### About this task

The histogram tracks the processing on a per-operation basis and as a percentage of the overall processing time for all operations. It also provides statistics for each operation type:

- add
- bind
- compare
- delete
- modify
- modifyDN
- search

### Steps

1. From the Administrative Console, go to **Configuration # Status # Monitors**.
2. Select **Processing Time Histogram**.

#### Note:

You can access other monitor entries in similar ways.

## Monitoring with JMX

PingDirectory Server supports monitoring the Java virtual machine (JVM) through a Java Management Extensions (JMX) management agent, which can be accessed using JConsole or any other kind of JMX client.

The JMX interface provides JVM performance and resource utilization information for applications running Java. In addition to the monitor information that Directory Server provides, you can monitor generic metrics exposed by the JVM, including:

- Memory pools
- Threads
- Loaded classes
- MBeans

You can also subscribe to receive JMX notifications for any administrative alerts that are generated within the server.

## Running JConsole

Run `jconsole` to monitor the memory usage and thread activity of a Java virtual machine.

Before you begin

Before you can run `jconsole`, you must:

- Configure and enable the [MISSING glossAcronymn or glossSurfaceform for gJMX] Connection Handler for the server using the `dsconfig` tool.

### Note:

For more information, see [Configuring the JMX connection handler and alert handler](#) on page 977.

- Invoke the `jconsole` executable by entering `jconsole` in your command-line interface or terminal.

### Note:

If `<JDK_HOME>` is not set in your path, you can access `jconsole` in the `bin` directory of the `<JDK_HOME>` path.

## Steps

1. To open the **Java Monitoring & Management Console**, run `jconsole`:

If SSL is configured on the JMX Connection Handler, you must specify the `PingDirectory.jar` file in the class path when running `jconsole` over SSL, as in the following example:

```
$ jconsole \
  -J-Djavax.net.ssl.trustStore=/path/to/certStores/truststore \
  -J-Djavax.net.ssl.trustStorePassword=secret \
  -J-Djava.class.path=$SERVER_ROOT/lib/PingDirectory.jar:/Library/Java/
  JavaVirtualMachines/jdk-version.jdk/Contents/Home/lib/jconsole.jar
```

You need to set the following properties in the above command:

- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePath` property with the full trust store path.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStoreType` property if the default type, [MISSING glossAcronymn or glossSurfaceform for gJKS], is not used.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePin` property with the trust store file password, if there is one.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePinFile` property with the file path containing the trust store password in plain text.

Do not use this property if the

`com.unboundid.directory.server.protocol.jmx.trustStorePin` property is used.

### Note:

When establishing a connection to `jconsole`, a window opens asking if you want to retry connecting insecurely. Click **Insecure connection**.

Although `jconsole` considers anything other than `SslRmiClientSocketFactory` to be insecure, choosing to retry insecurely will enable PingDirectory's secure client socket factory.

2. In the **Java Monitoring & Administrative Console** window, click **Local Process**, and then click the **PID** corresponding to the server.

3. Review the resource monitoring information.

### Monitoring the Directory Server using JConsole

Set up JConsole to monitor the Directory Server using a remote process.

#### Steps

1. Start the Directory Server.

Example:

```
$ bin/start-server
```

2. Enable the Java Management Extensions (JMX) Connection handler using `dsconfig` with the `set-connection-handler-prop` option.

#### Note:

The handler is disabled by default.

Include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "JMX Connection Handler" --set enabled:true
```

3. Assign privileges to a regular user account with the `ldapmodify` tool.

#### Warning:

Do not use a root user account, as using a root user account would be a security risk.

Example:

This example grants `jmx-read`, `jmx-write`, and `jmx-notify` privileges to the user.

```
$ bin/ldapmodify --hostname server1.example.com --port 1389 \
  --bindDN "cn=Directory Manager" --bindPassword secret
dn: uid=admin,dc=example,dc=com
changetype: modify
replace: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: jmx-write
ds-privilege-name: jmx-notify
```

4. In the **Java Monitoring & Administrative Console**, click **Remote Process**, and enter the following JMX URL using the host and port of your Directory Server.

```
service:jmx:rmi:///jndi/rmi://<host>:<port>/
com.unboundid.directory.server.protocols.jmx.client-unknown
```

5. In the **Username** and **Password** fields, enter the bind distinguished name (DN) and password for a user that has at least the `jmx-read` privilege.
6. Click **Connect**.
7. Click **com.unboundid.directory.server**, and expand the `rootDSE` node and the `cn-monitor` subnode.
8. Select a monitoring entry.

## Monitoring using the LDAP SDK

To retrieve monitor entries from the Directory Proxy Server and retrieve specific types of monitor entries, you can use the monitoring API.

For example, you can retrieve all monitor entries published by the Directory Server and print the information contained in each using the generic API for accessing monitor entry data as follows.

```
for (MonitorEntry e : MonitorManager.getMonitorEntries(connection))
{
    System.out.println("Monitor Name: " + e.getMonitorName());
    System.out.println("Monitor Type: " + e.getMonitorDisplayName());
    System.out.println("Monitor Data:");
    for (MonitorAttribute a : e.getMonitorAttributes().values())
    {
        for (Object value : a.getValues())
        {
            System.out.println(" " + a.getDisplayName() + ": " +
String.valueOf(value));
        }
    }
    System.out.println();
}
```

For more information about the LDAP SDK and the methods in this example, see the [LDAP SDK repository on GitHub](#).

## Monitoring over LDAP

PingDirectory Server exposes a majority of its information under the `cn=monitor` entry.

### Steps

- To access these entries over LDAP, use the `ldapsearch` tool.

Example:

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
--bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
--baseDN "cn=monitor" "(objectclass=*)" "
```

## Profiling server performance using the Stats Logger

Directory Server includes a built-in Stats Logger that is useful for profiling server performance for a given configuration.

At a specified interval, the Stats Logger can write server statistics to a JSON file or to a log file in a `.csv` file, which can be read by spreadsheet applications. The logger has a negligible impact on server performance unless the `log-interval` property is set to a value of less than 1 second. You can customize the statistics logged and their verbosity.

The Stats Logger can also be used to view historical information about server statistics, including:

- Replication
- LDAP operations
- Host information
- Gauges

To update the configuration of the existing Stats Logger Plugin, you can either:

- Set the advanced `gauge-info` property to `basic/extended` to include this information.
- Create a dedicated Periodic Stats Logger for information about statistics of interest.

For information about how to enable this logging and where to find the log file, see [Enabling the Stats Logger](#) on page 964.

## Enabling the Stats Logger

About this task

By default, Directory Server's built-in Stats Logger is disabled. To enable the Stats Logger:

Steps

1. Run `dsconfig` in interactive mode.

When you are prompted, enter the LDAP or LDAPS connection parameters.

Example:

```
$ bin/dsconfig
```

2. To change to the `Advanced Objects` menu, enter `o`.
3. On the main menu, enter the selection for `Plugins`.
4. On the `Plugin` menu, enter the selection for `View and edit an existing plugin`.
5. From the `Plugin` selection list, enter the selection for `Stats Logger`.
6. On the `Stats Logger Plugin` menu, enter the selection to set the `enabled` property to `TRUE`. To save and apply the configuration, enter `f`.

Result: The default logger logs information about the server every second to `<server-root>/logs/dsstats.csv`. If the server is idle, nothing is logged.

### Note:

To change the idle logging behavior, set the `suppress-if-idle` property to `FALSE`.

7. Run the Directory Server.

Example:

For example, if you are running in a test environment, you can run the `search-and-mod-rate` tool to apply some searches and modifications to the server.

### Tip:

To see an example command, run `search-and-mod-rate --help`.

8. View the Stats Logger output at `<server-root>/logs/dsstats.csv`.

You can open the file in a spreadsheet.

## Configuring multiple Periodic Stats Loggers

About this task

You can create multiple Periodic Stats Loggers to:

- Log different statistics
- View historical information about gauges
- To create a log at different intervals, such as logging cumulative operations statistics every hour

To create a new log, use the existing Stats Logger as a template to get reasonable settings, including rotation and retention policy.

## Steps

1. Run `dsconfig` in interactive mode.

When prompted, enter the LDAP or LDAPS connection parameters.

Example:

```
$ bin/dsconfig
```

2. To change to the `Advanced Objects` menu, enter `o`.
3. In the main menu, enter the selection for `Plugins`.
4. In the `Plugin management` menu, enter the selection for `Create a new plugin`.
5. To use an existing plugin as a template, in the `Create a New Periodic Stats Logger Plugin` menu, enter `t`.
6. Enter the number corresponding to the existing stats logger as a template.
7. Enter a descriptive name for the new stats logger.

For this example, enter `Stats Logger-10s`.

8. Enter the log file path to the file.

For this example, enter `logs/dsstats2.csv`.

9. In the menu, make any other changes to the logger. To save and apply the configuration, enter `f`.

Example:

For this example, change the `log-interval` to `10s`, and the `suppress-if-idle` to `FALSE`.

## Result

You should see two loggers, `dsstats.csv` and `dsstats2.csv`, in the `logs` directory.

### Adding custom logged statistics to a Periodic Stats Logger

Add custom statistics based on any attribute in any entry under `cn=monitor` with the Custom Logged Stats object.

This configuration object provides powerful controls for how monitor attributes are written to the log. For example, you can extract a value from a monitor attribute using a regular expression. New Custom Logged Stats are automatically included in the Periodic Stats Logger output.

In addition to allowing a straight pass-through of the values using the `raw` `statistic-type`, you can configure attributes to be treated as any of the following:

- A counter, where the interval includes the difference in the value since the last interval
- An average value held by the attribute during the specified interval
- A minimum value held by the attribute during the specified interval
- A maximum value held by the attribute during the specified interval

The value of an attribute can also be scaled by a fixed value or by the value of another monitor attribute.

#### Note:

Custom third-party server extensions written using the Server SDK can also expose interval statistics using a Periodic Stats Logger. The extension must first implement the SDK's `MonitorProvider` interface and register with the server. The monitor attributes produced by this custom `MonitorProvider` are then available to be referenced by a Custom Logged Stats object.

To illustrate how to configure a Custom Logged Statistics Logger, the following section reproduces the built-in `Consumer Total GB` column that displays in the output when the `included-resource-stat` property is set to `memory-utilization` on the Periodic Stats Logger.

The column is derived from the `total-bytes-used-by-memory-consumers` attribute of the `cn=JVM Memory Usage,cn=monitor` entry as follows.

```
dn: cn=JVM Memory Usage,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-memory-usage-monitor-entry
objectClass: extensibleObject
cn: JVM Memory Usage
...
total-bytes-used-by-memory-consumers: 3250017037
```

## Configuring a custom logged statistic using dsconfig interactive

### Steps

1. Run `dsconfig` and, when prompted, enter the LDAP or LDAPS connection parameters.

Example:

```
$ bin/dsconfig
```

2. In the Directory Server Advanced Objects menu, enter the selection for Custom Logged Stats.
3. In the Custom Logged Stats menu, enter the selection for Create a new Custom Logged Stats.
4. Select the Stats Logger Plugin from the list if more than one is present on the system. If you only have one stats logger, press Enter to confirm that you want to use the existing plugin.
5. Enter a descriptive name for the Custom Logged Stats.  
For this example, enter `Memory Usage`.
6. From the `monitor-objectclass` property menu, enter the `objectclass` attribute to monitor.  
For this example, enter `ds-memory-usage-monitor-entry`.

#### Note:

To view the entry, run `ldapsearch` using the base distinguished name (DN) `cn=JVM Memory Usage,cn=monitor` entry.

7. Enter the attributes of the monitor entry that you want to log in the stats logger, and then press Enter again to continue.  
For this example, enter `total-bytes-used-by-memory-consumers`.
8. Specify the type of statistics for the monitored attribute to appear in the log file.  
For this example, enter the option for `raw statistics` as recorded by the logger.
9. In the Custom Logged Stats menu, review the configuration.
10. To set up a column name that lists the memory usage, enter the option to change the `column-name` property.
11. To add a specific label for the column name, enter the option to add a value, and then enter `Memory Consumer Total (GB)`. To continue, press Enter.
12. Confirm that you want to use the `column-name` value that you entered in the previous step. To use the value, press Enter.
13. To scale the `Memory Consumer Totals (GB)` by 1 gigabyte (GB), in the Custom Logged Stats menu, enter the option to change the `divide-value-by` property.

14. In the `divide-value-by` property menu, enter the option to change the value, and then enter `1073741824`.
- `1073741824` bytes is equivalent to 1 gigabyte.
15. In the Custom Logged Stats menu, review your configuration. To save and apply the settings, enter `f`.
- Example:

```
>>>> Configure the properties of the Custom Logged Stats
>>>> via creating 'Memory Usage' Custom Logged Stats

Property                                     Value(s)
-----
1) description                               -
2) enabled                                   true
3) monitor-objectclass                       ds-memory-usage-monitor-entry
4) include-filter                            -
5) attribute-to-log                          total-bytes-used-by-memory-consumers
6) column-name                               Memory Consumer Total (GB)
7) statistic-type                            raw
8) header-prefix                             -
9) header-prefix-attribute                   -
10) regex-pattern                            -
11) regex-replacement                        -
12) divide-value-by                           1073741824
13) divide-value-by-attribute                 -
14) decimal-format                           #.##
15) non-zero-implies-not-idle                false

?) help
f) finish - create the new Custom Logged Stats
a) hide advanced properties of the Custom Logged Stats
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit

Enter choice [b]:
```

Result: A message of `The Custom Logged Stats was created successfully` is returned.

After the Custom Logged Stats configuration change is completed, the new stats value should immediately show up in the Stats Logger output file.

### Configuring a custom stats logger using `dsconfig` non-interactive

About this task

The following task replicates the previous procedure using `dsconfig` in non-interactive mode.

To create a custom stats logger:

Steps

- Run the `dsconfig` non-interactive command with the `create-custom-logged-stats` option.

Example:

In this example, the command produces a column named `Memory Consumer Total (GB)` that contains the value of the `total-bytes-used-by-memory-consumers` attribute pulled from the entry with the `ds-memory-usage-monitor-entry` objectclass. This value is scaled by `1073741824` to get to a value represented in GBs.

```
$ bin/dsconfig create-custom-logged-stats --plugin-name "Stats Logger" \
```

```
--stats-name "Memory Usage" --type custom \
--set monitor-objectclass:ds-memory-usage-monitor-entry \
--set attribute-to-log:total-bytes-used-by-memory-consumers \
--set "column-name:Memory Consumer Total (GB)" --set statistic-type:raw \
--set divide-value-by:1073741824
```

## Enabling and configuring the StatsD monitoring endpoint

The Monitoring Endpoint configuration type provides the StatsD endpoint type that you can use to transfer metrics data in the StatsD format.

About this task

You can configure the Monitoring Endpoint using the `dsconfig` command or the Administrative Console.

Steps

- To create the StatsD monitoring Endpoint, use either of the following:  
Choose from:

- To use the command-line, run `dsconfig` with the `create-monitoring-endpoint` option.

This example configures a new StatsD Monitoring Endpoint to send UDP data to localhost port 8125 using `dsconfig`.

```
dsconfig create-monitoring-endpoint \
--type statsd \
--endpoint-name StatsDEndpoint \
--set enabled:true \
--set hostname:localhost \
--set server-port:8125 \
--set connection-type:unencrypted-udp
```

- To use the Administrative Console:
  1. From the Administrative Console, click **Show Advanced Configuration**.
  2. In the **Logging, Monitoring, and Notifications** section, click **Monitoring Endpoints**.
  3. Click **New Monitoring Endpoint**.

When you configure Monitoring Endpoint include:

- The endpoint's host name
- The endpoint's port
- A toggle to use TCP or UDP
- A toggle to use SSL if you use TCP

You can configure a StatsD Monitoring Endpoint with custom tags using the `additional-tags` property. This adds the defined tags to each metric message sent to the endpoint. Each tag should be created in a "key=value" format. Additional tags are appended to the end of the StatsD message. Here is a sample StatsD message with custom tags:

```
example.metric:123|g|#tag1:value1,tag2:value2
```

### Note:

You can send data to any number of monitoring endpoints.

## Sending Metrics to Splunk with StatsD

About this task

Using the StatsD Endpoint type, you can send metric data to a Splunk installation. In Splunk, you can use SSL to secure ports that are open for StatsD. You can configure open UDP or TCP ports in Splunk to accept only connections from a certain hostname or IP address.

### Note:

StatsD metrics are typically sent over UDP. Using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost.

To securely send UDP or TCP data to Splunk:

Steps

1. Send the data to a Splunk Universal Forwarder.
2. Request that the forwarder use SSL to communicate with the Splunk Indexer.

## DevOps and Infrastructure as Code

---

Derived from the words *development* and *operations*, the term *DevOps* refers to the practices that a company follows to ensure the production of high-quality products, while also minimizing the amount of time between the commitment of a system change and the implementation of that change in a production environment.

Most companies practice one of the following service models:

- **Pets** — With the *pets service model*, servers are built and managed manually, and are treated as unique and indispensable. Examples include mainframes, database systems, and load balancers.
- **Cattle** — With the *cattle service model*, arrays of multiple replaceable servers are built with automated tools. During a failure event, an array automatically restarts failed services and replicates data. Examples include web server arrays, search clusters, and multi-master datastores.

Historically, servers have been treated like pets. The failure of one or multiple servers was often viewed as an emergency, and extensive resources were usually required to repair the damage. In the new DevOps paradigm, servers are recognized as dispensable and treated like cattle. When a server fails, the infrastructure replaces it immediately, configuring the replacement server identically to the failed one. Because no human intervention is required to fix them, the servers are considered self-healing.

To help treat your servers more like cattle than pets, PingDirectory Server supports server profiles and features like topology-management tools. For example, the `manage-profile setup` represents a single command that performs all the steps from the pet service model on a `server-profile` directory, a well-defined directory structure with all the necessary server configuration bits. Similarly, the `manage-profile replace-profile` command performs similar steps with a single command invocation after a server is updated to a new version.

The scripts in the `server-profile` directory are declarative of the environment. Consequently, what you define in the `server-profile` directory is what you get on the servers. No one needs to identify a server's current configuration and compute the differences that must be applied to attain the appropriate end state. Prior to server profiles, this problem was difficult to address, especially where no history was available. In such scenarios, an administrator might have needed to obtain the current configuration from the servers, to manually compute the difference between the current and desired configuration, and to apply the configuration changes, hoping all the while that nobody had changed the configuration during the process. Server profiles eliminate this procedural approach to applying configuration changes, and they

simplify the steps associated with determining what is deployed in an environment. For more information on server profiles, see [Server profiles](#) on page 1038.

Another principle that relates closely to DevOps is infrastructure as code (IaC), the concept of managing your operations in the same manner as your application and other code for general release with proper versioning, continuous integration, quality control, and release cycles. Customers who deploy PingDirectory Servers as pets today can take advantage of current DevOps and IaC principles to turn them into cattle.

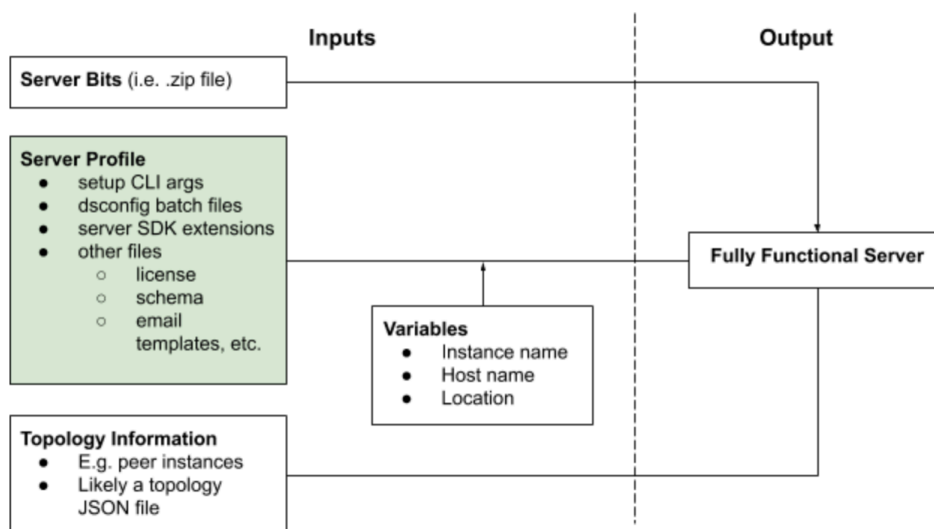

## Server profiles

Regardless of the service model that your company follows, *server profiles* help you achieve your goals. At a basic level, a server profile defines a format for the configuration of a server by combining the following files into a single concrete structure:

- **dsconfig**
- Setup arguments
- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDirectory Server and related products by using deployment automation frameworks. When products support this capability, the amount of scripting that is required across automation frameworks — like Docker, Kubernetes, and Ansible — is reduced considerably.

The following image shows the role that a server profile plays in building a fully functional running server.

As a declarative form of a full server configuration, a server profile provides the following advantages:

- Provides a more complete and easily comparable way to define an individual server's configuration. Changes between different servers are easier to understand, and incremental changes to a server's configuration are easier to track.
- Ensures that each server instance is configured identically to its peers.
- Can be applied directly to new as well as previously installed instances.
- Shares a common configuration across a deployment pipeline of development, test, and production environments without unnecessary duplication. For information about substituting variables that differ by environment, see [Variable substitution](#) on page 1040.
- Facilitates deployment automation by representing configuration as code.
- Reduces the number of additional configuration steps that are required to place a server into production.

- Makes the execution of various configuration changes more consistent and repeatable. The strategy of using a server profile to represent the final state of a server is less error-prone than recording a step-by-step process to attain that state.
- Can be managed easily in a version-control system.
- Simplifies the management of servers outside deployment automation frameworks.

A continuous deployment workflow can work with server profiles to make certain that changes to a server profile are moved automatically into production. In a stateful environment, the **manage-profile replace-profile** subcommand can be used to update existing servers. In a stateless environment, in which servers are considered immutable, **manage-profile setup** can be used to deploy new servers whenever a profile changes. With multiple environments, this deployment can be performed in a test environment before moving to production.

When working with zipped server SDK extensions and other files that might not be stored in a version-control system, the server profile can be modified to include these files prior to its use. For example, if the code for an extension is stored in a separate repository, it can be built and dropped into the server profile immediately before the **manage-profile** tool is run. This process is part of the deployment automation logic that uses the server profile, and it can be followed for any files that are needed by the server profile but whose versions are not controlled.

For more information about the **manage-profile** tool, see [About the manage-profile tool](#) on page 1042.

### Variable substitution

You can use the **manage-profile** tool to substitute different variables in server profiles.

The **manage-profile** tool uses the format `${VARIABLE}` to support the substitution of variables in profiles. This format can be escaped by using another `$`. For example, after substitution, `$$${VARIABLE}` becomes `${VARIABLE}`.

Variable values can be read from a profile variables file or from environment variable values. If both options are used, the values that are specified in the file overwrite any environment variables.

The following code provides an example of how you can set user-defined variables by using a variables file in the server profile.

```
HOSTNAME=testserver.example.com
PORT=389
```

The following table describes built-in variables that can also be referenced in the server profile. Use these variables in the format previously described.

| Built-in variable | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PING_SERVER_ROOT  | Evaluates to the absolute path of the server's root directory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PING_PROFILE_ROOT | Evaluates to the individual profile's root directory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                   |  <b>Note:</b><br>Use <b>PING_PROFILE_ROOT</b> only with files that are not needed after initial setup, such as password files in <code>setup-arguments.txt</code> . Do not use the <b>PING_PROFILE_ROOT</b> variable for files needed while the server is running. For files you need while the server is running, such as keystore and |

| Built-in variable | Description                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | truststore files, copy the files into the server root using the profile's <code>server-root/pre-setup</code> directory, and then refer to the files using with the <code>PING_SERVER_ROOT</code> variable. |

For more information about the tool's usage, run the command `bin/manage-profile --help`.

## Profile Structure

Use either of the following methods to create a server profile:

- Use the template named `server-profile-template.zip`, which is located in the `resource/` directory.
- Run the `manage-profile generate-profile` subcommand. The `manage-profile` tool references a file system directory structure rather than a ZIP file.

Files can be added to each directory as needed.

The following hierarchy represents the file structure of a basic server profile:

```
-server-profile/
|-- dsconfig/
|-- misc-files/
|-- server-root/
|   |-- post-setup/
|   |-- pre-setup/
|-- server-sdk-extensions/
|-- setup-arguments.txt
|-- variables-ignore.txt
```

### setup-arguments.txt

When creating a [profile](#), the first step is to add arguments to the `setup-arguments.txt` file, located in the `resources/server-profile-template.zip` archive.

When you run the `manage-profile setup` command, these arguments are passed to the server's setup tool. To view the arguments available in this file, run the server's `setup --help` command.

To provide the equivalent, non-interactive command-line interface (CLI) arguments after any prompts have been completed, run `setup` interactively. The `setup-arguments.txt` file in the server profile template contains an example set of arguments that can be changed.

`setup-arguments.txt` is the only required file in the profile.

### dsconfig/

`dsconfig` batch files can be added to the `dsconfig` directory. These files, each of which must include a `.dsconfig` extension, contain `dsconfig` commands to apply to server.

Because the `dsconfig` batch files are ordered lexicographically, `00-base.dsconfig` runs before `01-second.dsconfig`, and so on.

To produce a `dsconfig` batch file that reproduces the current configuration, run `bin/config-diff`.

### server-root/

Any server root files can be added to the `server-root` directory, including schema files, email template files, custom password dictionaries, and other files that must be present on the final server root. Add these files to the `server-root/pre-setup` or `server-root/post-setup` directory, depending on when they need to be copied to the server root. Most server root files are added to the `server-root/pre-setup` directory.

### server-sdk-extensions/

Add server SDK extension `.zip` files to the `server-sdk-extensions` directory. Include any configuration that is necessary for the extensions in the profile's `dsconfig` batch files.

### variables-ignore.txt

The `variables-ignore.txt` file is an optional component of the server profile. It is useful when adding bash scripts to the server root because such files often contain expressions that the `manage-profile` tool normally interprets as variables.

Add `variables-ignore.txt` to a profile's root directory to indicate the relative paths of any files that are not to have their variables substituted.

The following example shows the contents of a typical `variables-ignore.txt` file:

```
server-root/pre-setup/script-to-ignore.sh
server-root/post-setup/another-file-to-ignore.txt
```

### server-root/permissions.properties

The `permissions.properties` file, located in the `server-root` directory, is an optional file that specifies the permissions to apply to files that are copied to the server root. These permissions are represented in octal notation. By default, server root files maintain their permissions when copied.

The following example shows the contents of a typical `permissions.properties` file:

```
default=700
file-with-special-permissions.txt=600
new-subdirectory/file-with-special-permissions.txt=644
bin/example-script.sh=760
```

### misc-files/

Additional documentation and other files can be added to the `misc-files` directory, which the `manage-profile` tool does not use. Use the variable `PING_PROFILE_ROOT` to refer to files in this directory from other locations, such as `setup-arguments.txt`.

#### Note:

Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using with the `PING_SERVER_ROOT` variable.

For example, a password file named `password.txt` in the `misc-files` directory could be referenced with `${PING_PROFILE_ROOT}/misc-files/password.txt` in `setup-arguments.txt`. Use a reference like this example to supply the file for the `--rootUserPasswordFile` argument in `setup-arguments.txt`.

### About the manage-profile tool

The `manage-profile` tool is provided with the server to work with server profiles. It includes subcommands for creating, applying, and replacing server profiles, all of which significantly reduce the effort required by an administrator to configure a server appropriately.

The following sections describe these subcommands in more detail. For more information about the **manage-profile** tool, run **manage-profile --help**. For more information about each individual subcommand and its options, run **manage-profile <subcommand> --help**.

### **manage-profile generate-profile**

To create a server profile from a configured server, use the **generate-profile** subcommand. The generated profile contains the following information, which provides a base for completing a profile:

- Command-line arguments that were used to set up the server
- **dsconfig** commands necessary to configure the server
- Installed server SDK extensions
- Files that are added to the server root

To produce a complete profile, some parts of the generated profile might require modifications, such as adding password files that `setup-arguments.txt` uses. The **--instanceName** and **--localHostName** arguments in `setup-arguments.txt` are made variables by **generate-profile**, and must be provided values when other **manage-profile** subcommands use the generated profile.

### **manage-profile setup**

To apply a server profile to a fresh, unconfigured server, use the **setup** subcommand, which replaces the normal setup tool when using a server profile. Run **manage-profile setup** to complete the following tasks:

- Copies the pre-setup files to the server root
- Runs the setup tool
- Copies the post-setup files to the server root
- Installs any server SDK extensions
- Runs any dsconfig batch files
- Imports any LDIF files
- Starts the server

While **manage-profile setup** is running, a copy of the profile is created in a temporary directory that can be specified by using the **--tempProfileDirectory** argument. The command leaves the server in a complete and running state when finished, unless the **--doNotStart** argument is specified.

### **manage-profile replace-profile**

Run the **replace-profile** subcommand on a server that was originally set up with a server profile to replace its configuration with a new profile. The tool applies a specified server profile to an existing server while preserving its data, topology configuration, and replication configuration.

While **manage-profile replace-profile** is running, the existing server is stopped and moved to a temporary directory that the **--tempServerDirectory** argument can specify. A fresh, new server is subsequently installed and set up with the new profile. The final server is left running if it was running before the command was started, and remains stopped if it was stopped.

Run **manage-profile replace-profile** from a second unzipped server install package on the same host as the existing server, similar to the **update** tool. Use the **--serverRoot** argument to specify the root of the existing server that will have its profile replaced.

If files have been added or modified in the server root since the most recent **manage-profile setup** or **manage-profile replace-profile** was run, they are included in the final server with the replaced profile. Otherwise, files specifically added from the `server-root` directory of the previous server profile are absent from the final server with the replaced profile. If errors occur during the subcommand, such as the new profile having an invalid `setup-arguments.txt` file, the existing server returns to its original state from before **manage-profile replace-profile** was run.

**Note:**

The `manage-profile replace-profile` tool can update the server version when needed.

**Note:**

The `manage-profile replace-profile` tool can directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to `dsconfig`.

### Server Profiles in a Pets Service Model

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server. Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new pet server has been set up with a server profile, `manage-profile replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see [About the manage-profile tool](#) on page 1042.

## Troubleshooting PingDirectoryProxy Server

---

This section provides potential solutions for common problems that could occur when running PingDirectoryProxy.

It's primarily targeted at cases in which PingDirectoryProxy Server is running on Linux systems, but much of the information is useful when PingDirectoryProxy is running on other platforms.

### Garbage Collection Diagnostic Information

You can enable the JVM debugging options to track garbage collection data for your system. The options can impact JVM performance, but they provide valuable data to tune your server when troubleshooting garbage collection issues. While the `jstat` utility with the `-gc` option can be used to obtain some information about garbage collection activity, there are additional arguments that can be added to the JVM to use when running the server to provide additional detail.

```
-XX:+PrintGCDetails
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
-XX:+PrintGCDateStamps
```

To run the Directory Server with these options, edit the `config/java.properties` file and add them to the end of the line that begins with " `bin/start-server.java-args`". After the file has been saved, invoke the following command to make those new arguments take effect the next time the server is started:

```
$ bin/dsjavaproperties
```

## Working with the Troubleshooting Tools

Problems might arise with Directory Proxy Server, such as issues in the Directory Proxy Server or problems with the Java virtual machine (JVM), operating system, or hardware.

You must be able to diagnose problems quickly to determine the underlying cause and the best available solution.

### Working with the collect-support-data tool

The Directory Server provides a significant amount of information about its current state including any problems that it has encountered during processing. If a problem occurs, the first step is to run the `collect-support-data` tool in the `bin` directory. The tool aggregates all relevant support files into a zip file that administrators can send to your authorized support provider for analysis. The tool also runs data collector utilities, such as `jps`, `jstack`, and `jstat` plus other diagnostic tools, and bundles the results in the zip file.

The tool may only archive portions of certain log files to conserve space, so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

The data collected by the `collect-support-data` tool varies between systems. However, the tool always tries to get the same information across all systems for the target Directory Server. The data collected includes the configuration directory, summaries and snippets from the `logs` directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

### Available tool options

The `collect-support-data` tool has some important options that you should be aware of:

- **--noLdap**. Specifies that no effort should be made to collect any information over LDAP. This option should only be used if the server is completely unresponsive or will not start and only as a last resort.
- **--pid {pid}**. Specifies the ID of an additional process from which information is to be collected. This option is useful for troubleshooting external server tools and can be specified multiple times for each external server, respectively.
- **--sequential**. Use this option to diagnose “Out of Memory” errors. The tool collects data in parallel to minimize the collection time necessary for some analysis utilities. This option specifies that data collection should be run sequentially as opposed to in parallel. This action has the effect of reducing the initial memory footprint of this tool at a cost of taking longer to complete.
- **--reportCount {count}**. Specifies the number of reports generated for commands that supports sampling (for example, `vmstat`, `iostat`, or `mpstat`). A value of 0 (zero) indicates that no reports will be generated for these commands. If this option is not specified, it defaults to 10.
- **--reportInterval {interval}**. Specifies the number of seconds between reports for commands that support sampling (for example, `mpstat`). This option must have a value greater than 0 (zero). If this option is not specified, it default to 1.
- **--maxJstacks {number}**. Specifies the number of `jstack` samples to collect. If not specified, the default number of samples collected is 10.
- **--collectExpensiveData**. Specifies that data on expensive or long running processes be collected. These processes are not collected by default, because they will impact the performance of a running server.
- **--comment {comment}**. Provides the ability to submit any additional information about the collected data set. The comment will be added to the generated archive as a README file.
- **--includeBinaryFiles**. Specifies that binary files be included in the archive collection. By default, all binary files are automatically excluded in data collection.
- **--adminPassword {adminPassword}**. Specifies the global administrator password used to obtain `dsreplication status` information.
- **--adminPasswordFile {adminPasswordFile}**. Specifies the file containing the password of the global administrator used to obtain `dsreplication status` information.

- **--outputPath**. Specifies the path (and optionally, the name) for the support data archive file. If the path specifies a filename, the archive is written to that file. If the path specifies a directory, the file is written into that directory with a server-generated name.
- **--useRemoteServer**. Invokes the tool against a remote server instance and streams the output and resulting support data archive back to the client. This option can be especially useful when the server instance is running in a container because it might otherwise be difficult to invoke commands or access files in that container. See also: **--proxyToServerAddress** and **--proxyToServerPort**.
- **--proxyToServerAddress** and **--proxyToServerPort**. Use these options with **--useRemoteServer** to indicate that the support data archive should be retrieved from a server that is not directly accessible but can be accessed through a Directory Proxy Server.

## Running the collect-support-data tool

### Steps

1. Go to the server root directory.
2. Use the **collect-support-data** tool. Make sure to include the host, port number, bind DN, and bind password.

Example:

```
$ bin/collect-support-data --hostname 127.0.0.1 --port 389 \
  --bindDN "cn=Directory Manager" --bindPassword secret \
  --serverRoot /opt/PingDirectory --pid 1234
```

3. Email the zip file to your Authorized Support Provider.

## Directory Server troubleshooting tools

The PingDirectory Server provides a set of tools that can also be used to obtain information for diagnosing and solving problems.

### Server version information

If it becomes necessary to contact your authorized support provider, then it will be important to provide precise information about the version of the Directory Server software that is in use. If the server is running, then this information can be obtained from the "cn=Version,cn=monitor" entry. It can also be obtained using the command:

```
$ bin/status --fullVersion
```

This command outputs a number of important pieces of information, including:

- Major, minor, point and patch version numbers for the server.
- Source revision number from which the server was built.
- Build information including build ID with timestamp, OS, user, Java and JVM version for the build.
- Auxiliary software versions: Jetty, JZlib, SNMP4j (SNMP4J, Agent, Agentx), Groovy, LDAP SDK for Java, and the Server SDK.

### PingDirectory Server gauges

The PingDirectory Server provides a number of built-in gauges to monitor PingDirectory Server performance. These gauges are listed in the following table:

#### Directory Server Gauges

| Gauge Name                  | Enabled by default? | Description                                                                                                                           |
|-----------------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Authentication Failure Rate | false               | Rate of LDAP bind failures per second. A high rate of failures may indicate a misconfigured client application or a malicious attack. |

| Gauge Name                    | Enabled by default? | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Available File Descriptors    | true                | Monitors the number of file descriptors available to the server process. The server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. The number of file descriptors that the server will use can be configured by either using a <b>NUM_FILE_DESCRIPTOR</b> environment variable, or by creating a <code>config/num-file-descriptors</code> file with a single line such as <code>NUM_FILE_DESCRIPTOR=12345</code> . If these are not set, the default of 65535 is used. Running out of available file descriptors can lead to unpredictable behavior and severe system instability.                                                                                                                                                                                                                                     |
| Certificate Expiration (Days) | true                | Monitors the expiration dates of key server certificates. A server certificate expiring may cause server unavailability, degradation, or loss of key server functionality. Certificates nearing the end of their validity should be replaced as soon as possible. See the status tool, or Status in the Administrative Console, for more information about server certificates and how they are managed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CPU Usage (Percent)           | true                | Monitors server CPU use and provides an averaged percentage for the interval defined. The monitored resource is the host system's CPU, which does not include a resource identifier. If CPU use is high, check the server's current workload and other processes on this system and make any needed adjustments. Reducing the load on the system will lead to better response times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Data Set Availability         | true                | For each data set, indicates whether there is at least one backend server available to fulfill requests. The resource identifier for this gauge is the name of the load-balancing algorithm used to define the set of backend servers fulfilling requests for the data set. Use the <code>dsconfig list-load-balancing-algorithms</code> command to see a list of load balancing algorithms. A data set may be included or excluded from monitoring by specifying its load-balancing algorithm name in the include resource and exclude resource properties respectively. A data set's availability depends upon the availability of the backend servers available to fulfill the PingDirectory Server requests. The set of backend servers is defined by the set of servers configured in a data set's load-balancing algorithm. Make sure that backend servers are available to fulfill proxy requests. |

| Gauge Name                  | Enabled by default? | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data Set Local Availability | true                | For each data set, indicates whether there is at least one local backend server available to fulfill requests. The resource identifier for this gauge is the name of the load-balancing algorithm used to define the set of backend servers fulfilling requests for the data set. Use the <code>dsconfig list-load-balancing-algorithms</code> command to see a list of load balancing algorithms. A data set may be included or excluded from monitoring by specifying its load-balancing algorithm name in the <code>include resource</code> and <code>exclude resource</code> properties respectively. A data set's availability depends upon the availability of the backend servers available to fulfill the PingDirectory Server requests. The set of backend servers is defined by the set of servers configured in a data set's load-balancing algorithm. Locations are used to indicate the set of preferred backend servers that should be used to fulfill requests. You can denote that a backend server is local by setting its external server configuration object's location attribute to be the same as this Directory Proxy Server instance's location set in its global configuration. Make sure that backend servers are available to fulfill proxy requests. |
| Disk Busy (Percent)         | true                | Monitors the percentage of disk use time averaged over the specified update interval. This gauge requires that the Host System Monitor Provider be enabled and that any monitored disks be registered using the <code>disk-devices</code> property of that configuration object. The resource identifier for this gauge is the disk device name. Use the <code>iostat</code> command or a similar system utility to see a list of disk device names. A separate gauge monitor entry will be created for each monitored disk.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| HTTP Processing (Percent)   | true                | Monitors the percentage of time that request handler threads spend processing HTTP requests. This percentage represents the inverse of the server's ability to handle new requests without queueing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Gauge Name                                          | Enabled by default? | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JVM Memory Usage (Percent)                          | true                | Monitors the percentage of Java Virtual Machine memory that is in use. This value naturally fluctuates due to garbage collection, so the minimum value within an interval is reported since it is a better indication of overall memory growth. When the memory usage exceeds 90%, this should be reported to customer support since the server is either misconfigured or has a memory leak. As memory usage approaches 100%, the server is more and more likely to experience garbage collection pauses, which leave the server unresponsive for a long time. Restarting the server is likely the only remedy for this situation. Prior to restarting the server, please run <code>collect-support-data</code> and capture the output of <code>jmap -histo</code> to provide to customer support. The pid of the server can be found from <code>/logs/server.pid</code> . |
| LDAP Operation Average Response Time (Milliseconds) | false               | Monitors the average response time across all LDAP operations processed by this server since it was started. There is no resource identifier associated with this gauge. The monitored resource is overall response time of all LDAP operations processed by this server since it was started. High response times may be indicative of a number of factors including a disk-bound server, network latency, or misconfiguration. Enabling the Stats Logger plugin may help isolate problems. See the administration guide for more information on common problems and solutions.                                                                                                                                                                                                                                                                                            |
| LDAP Operations Failed (Percent)                    | false               | Monitors the percentage of all LDAP operations processed by this server that have failed since it was started. There is no resource identifier associated with this gauge. The monitored resource is the overall number of failed LDAP operations processed by this server since it was started. A high percentage of failed operations may indicate misconfiguration of a client or server in a topology.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| License Expiration (Days)                           | true                | Monitors the expiration date of the product license. An expired license will cause warnings to appear in the server's logs and in the status tool output. Request a license key through the Ping Identity licensing website <a href="https://www.pingidentity.com/en/account/request-license-key.html">https://www.pingidentity.com/en/account/request-license-key.html</a> or contact <a href="mailto:sales@pingidentity.com">sales@pingidentity.com</a> . Use the <code>dsconfig</code> tool to update the License configuration's license key property.                                                                                                                                                                                                                                                                                                                  |
| Memory Usage (Percent)                              | false               | Monitors the percentage of memory use averaged over the update interval defined. The monitored resource is the host system's memory use, which does not have a resource identifier. Some operating systems, including Linux, use the majority of memory for file system cache, which is freed as applications need it. If memory use is high, check the applications that are running on the server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Gauge Name                           | Enabled by default? | Description                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Strong Encryption Not Available      | true                | The JVM does not appear to support strong encryption algorithms, like 256-bit AES. The server will fall back to using weaker algorithms, like 128-bit AES. To enable support for strong encryption, update your JVM to a newer version that supports it by default, or install or enable the unlimited encryption strength jurisdiction policy files in your Java installation.                           |
| Work Queue Size (Number Of Requests) | true                | Number of requests in the server's work queue waiting to be processed, averaged over the update interval. There is no resource identifier associated with this gauge. The monitored resource is the server's work queue. If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available. |

### LDIF connection handler

The Directory Server provides an LDIF connection handler that provides a way to request operations that do not require any network communication with the server. This can be particularly helpful if a configuration problem or bug in the server has left a connection handler unusable, or if all worker threads are busy processing operations.

The LDIF connection handler is enabled by default and looks for LDIF files to be placed in the `config/auto-process-ldif` directory. This Directory Server does not exist by default, but if it is created and an LDIF file is placed in it that contains one or more changes to be processed, then those changes will be applied.

Any changes that can be made over LDAP can be applied through the LDIF connection handler. It is primarily intended for administrative operations like updating the server configuration or scheduling tasks, although other types of changes (including changes to data contained in the server) can be processed. As the LDIF file is processed, a new file is written with comments for each change providing information about the result of processing that change.

### Embedded profiler

If the Directory Server appears to be running slowly, then it is helpful to know what operations are being processed in the server. The JVM Stack Trace monitor entry can be used to obtain a point-in-time snapshot of what the server is doing, but in many cases, it might be useful to have information collected over a period of time.

The embedded profiler is configured so that it is always available but is not active by default so that it has no impact on the performance of the running server. Even when it is running, it has a relatively small impact on performance, but it is recommended that it remain inactive when it is not needed. It can be controlled using the `dsconfig` tool or the Administrative Console by managing the "Profiler" configuration object in the "Plugin" object type, available at the standard object level. The `profile-action` property for this configuration object can have one of the following values:

- **start** – Indicates that the embedded profiler should start capturing data in the background.
- **stop** – Indicates that the embedded profiler should stop capturing data and write the information that it has collected to a `logs/profile{timestamp}` file.
- **cancel** – Indicates that the embedded profiler should stop capturing data and discard any information that it has collected.

Any profiling data that has been captured can be examined using the `profiler-viewer` tool. This tool can operate in either a text-based mode, in which case it dumps a formatted text representation of the

profile data to standard output, or it can be used in a graphical mode that allows the information to be more easily understood.

### Invoking the profile viewer in text-based mode

#### Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option.  
Example:

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z
```

### Invoking the profile viewer in GUI mode

#### Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option. To invoke GUI mode, add the option `--useGUI`.

Example:

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z --useGUI
```

## Troubleshooting resources for Java applications

Because the PingDirectory Server is written entirely in Java, it is possible to use standard Java debugging and instrumentation tools when troubleshooting problems with the Directory Server. In many cases, obtaining the full benefit of these tools requires access to the Directory Server source code. These Java tools should be used under the advisement of your authorized support provider.

### Java troubleshooting tools

The Java Development Kit provides a number of very useful tools to obtain information about Java applications and diagnosing problems. These tools are not included with the Java Runtime Environment (JRE), so the full Java Development Environment (JDK) should always be installed and used to run the PingDirectory Server.

#### **jps**

The `jps` tool is a Java-specific version of the UNIX `ps` tool. It can be used to obtain a list of all Java processes currently running and their respective process identifiers. When invoked by a non-root user, it will list only Java processes running as that user. When invoked by a root user, then it lists all Java processes on the system.

This tool can be used to see if the Directory Server is running and if a process ID has been assigned to it. This process ID can be used in conjunction with other tools to perform further analysis.

This tool can be run without any arguments, but some of the more useful arguments that include:

- `-v` – Includes the arguments passed to the JVM for the processes that are listed.
- `-m` – Includes the arguments passed to the main method for the processes that are listed.
- `-l` – (lowercase L). Include the fully qualified name for the main class rather than only the base class name.

#### **jstack**

The `jstack` tool is used to obtain a stack trace of a running Java process, or optionally from a core file generated if the JVM happens to crash. A stack trace can be extremely valuable when trying to debug a problem, because it provides information about all threads running and exactly what each is doing at the point in time that the stack trace was obtained.

Stack traces are helpful when diagnosing problems in which the server appears to be hung or behaving slowly. Java stack traces are generally more helpful than native stack traces, because Java threads can

have user-friendly names (as do the threads used by the PingDirectory Server), and the frame of the stack trace may include the line number of the source file to which it corresponds. This is useful when diagnosing problems and often allows them to be identified and resolved quickly.

To obtain a stack trace from a running JVM, use the command:

```
jstack {processID}
```

where {processID} is the process ID of the target JVM as returned by the `jps` command. To obtain a stack trace from a core file from a Java process, use the command:

```
jstack {pathToJava} {pathToCore}
```

where {pathToJava} is the path to the java command from which the core file was created, and {pathToCore} is the path to the core file to examine. In either case, the stack trace is written to standard output and includes the names and call stacks for each of the threads that were active in the JVM.

In many cases, no additional options are necessary. The `-l` option can be added to obtain a long listing, which includes additional information about locks owned by the threads. The `-m` option can be used to include native frames in the stack trace.

### jmap

The `jmap` tool is used to obtain information about the memory consumed by the JVM. It is very similar to the native `pmmap` tool provided by many operating systems. As with the `jstack` tool, `jmap` can be invoked against a running Java process by providing the process ID, or against a core file, like:

```
jmap {processID}
jmap {pathToJava} {pathToCore}
```

Some of the additional arguments include:

- **-dump:live,format=b,file=filename** – Dump the live heap data to a file that can be examined by the `jhat` tool
- **-heap** – Provides a summary of the memory used in the Java heap, along with information about the garbage collection algorithm in use.
- **-histo:live** – Provides a count of the number of objects of each type contained in the heap. If the `:live` portion is included, then only live objects are included; otherwise, the count include objects that are no longer in use and are garbage collected.

### jhat

The `jhat` (Java Heap Analysis Tool) utility provides the ability to analyze the contents of the Java heap. It can be used to analyze a heap dump file, which is generated if the Directory Server encounters an out of memory error (as a result of the `-XX:+HeapDumpOnOutOfMemoryError` JVM option) or from the use of the `jmap` command with the `-dump` option.

The `jhat` tool acts as a web server that can be accessed by a browser in order to query the contents of the heap. Several predefined queries are available to help determine the types of objects consuming significant amounts of heap space, and it also provides a custom query language (OQL, the Object Query Language) for performing more advanced types of analysis.

The `jhat` tool can be launched with the path to the heap dump file, like:

```
jhat /path/to/heap.dump
```

This command causes the `jhat` web server to begin listening on port 7000. It can be accessed in a browser at `http://localhost:7000` (or `http://address:7000` from a remote system). An alternate port number can be specified using the `-port` option, like:

```
jhat -port 1234 /path/to/heap.dump
```

To issue custom OQL searches, access the web interface using the URL `http://localhost:7000/oql/` (the trailing slash must be provided). Additional information about the OQL syntax may be obtained in the web interface at `http://localhost:7000/oqlhelp/`.

### **jstat**

The `jstat` tool is used to obtain a variety of statistical information from the JVM, much like the `vmstat` utility that can be used to obtain CPU utilization information from the operating system. The general manner to invoke it is as follows:

```
jstat {type} {processID} {interval}
```

The `{interval}` option specifies the length of time in milliseconds between lines of output. The `{processID}` option specifies the process ID of the JVM used to run the Directory Server, which can be obtained by running `jps` as mentioned previously. The `{type}` option specifies the type of output that should be provided. Some of the most useful types include:

- **-class** – Provides information about class loading and unloading.
- **-compile** – Provides information about the activity of the JIT complex.
- **-printcompilation** – Provides information about JIT method compilation.
- **-gc** – Provides information about the activity of the garbage collector.
- **-gccapacity** – Provides information about memory region capacities.

### **Java diagnostic information**

In addition to the tools listed in the previous section, the JVM can provide additional diagnostic information in response to certain events.

#### **Garbage Collection Diagnostic Information**

You can enable the JVM debugging options to track garbage collection data for your system. The options can impact JVM performance, but they provide valuable data to tune your server when troubleshooting garbage collection issues. While the `jstat` utility with the `-gc` option can be used to obtain some information about garbage collection activity, there are additional arguments that can be added to the JVM to use when running the server to provide additional detail.

```
-XX:+PrintGCDetails
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
-XX:+PrintGCDateStamps
```

To run the Directory Server with these options, edit the `config/java.properties` file and add them to the end of the line that begins with " `bin/start-server.java-args`". After the file has been saved, invoke the following command to make those new arguments take effect the next time the server is started:

```
$ bin/dsjavaproperties
```

#### **JVM crash diagnostic information**

If the JVM itself should happen to crash for some reason, then it generates a fatal error log with information about the state of the JVM at the time of the crash. By default, this file is named `hs_err_pid{processID}.log` and is written into the base directory of the Directory Server installation. This file includes information on the underlying cause of the JVM crash, information about the threads running and Java heap at the time of the crash, the options provided to the JVM, environment variables that were set, and information about the underlying system.

#### **Troubleshooting resources in the operating system**

The underlying operating system also provides a significant amount of information that can help diagnose issues that impact the performance and the stability of the Directory Server. In some cases, problems with

the underlying system can be directly responsible for the issues seen with the Directory Server, and in others system, tools can help narrow down the cause of the problem.

### Identifying problems with the underlying system

If the underlying system itself is experiencing problems, it can adversely impact the function of applications running on it. To look for problems in the underlying system view the system log file (`/var/log/messages` on Linux). Information about faulted or degraded devices or other unusual system conditions are written there.

### Monitoring system data using the PingDataMetrics Server

The PingDataMetrics Server provides collection and storage of performance data from your server topology. You can use the System Utilization Monitor with the PingDataMetrics Server to collect information about the host system CPU, disk, and network utilization on any platform except Linux. If you are not using the PingDataMetrics Server, you do not need to use the system utilization monitor. When data is being collected, it periodically forks the process and executes commands.

For more information about using the System Utilization Monitor, refer to the data collection chapter of the PingDataMetrics Server documentation.

### Examining CPU utilization

Observing CPU utilization for the Directory Server process and the system as a whole provides clues as to the nature of the problem.

#### *System-Wide CPU utilization*

To investigate CPU consumption of the system as a whole, use the `vmstat` command with a time interval in seconds, like:

```
vmstat 5
```

The specific output of this command varies between different operating systems, but it includes the percentage of the time the CPU was spent executing user-space code (user time), the percentage of time spent executing kernel-space code (system time), and the percentage of time not executing any code (idle time).

If the CPUs are spending most of their time executing user-space code, the available processors are being well-utilized. If performance is poor or the server is unresponsive, it can indicate that the Directory Server is not optimally tuned. If there is a high system time, it can indicate that the system is performing excessive disk and/or network I/O, or in some cases, there can be some other system-wide problem like an interrupt storm. If the system is mostly idle but the Directory Server is performing poorly or is unresponsive, there can be a resource constraint elsewhere (for example, waiting on disk or memory access, or excessive lock contention), or the JVM can be performing other tasks like stop-the-world garbage collection that cannot be run heavily in parallel.

#### *Per-CPU utilization*

To investigate CPU consumption on a per-CPU basis, use the `mpstat` command with a time interval in seconds, like:

```
mpstat 5
```

On Linux systems, it might be necessary to add `"-P ALL"` to the command, like:

```
mpstat -P ALL 5
```

Among other things, this shows the percentage of time each CPU has spent in user time, system time, and idle time. If the overall CPU utilization is relatively low but `mpstat` reports that one CPU has a much higher utilization than the others, there might be a significant bottleneck within the server or the JVM might be performing certain types of garbage collection which cannot be run in parallel. On the other hand, if

CPU utilization is relatively even across all CPUs, there is likely no such bottleneck and the issue might be elsewhere.

#### *Per-process utilization*

To investigate CPU consumption on a per-process basis, use a command such as the `top`. Directory Server is consuming a significant amount of available CPU, it might be interfering with the ability of the Directory Server to run effectively.

#### **Examining disk utilization**

If the underlying system has a very high disk utilization, it can adversely impact Directory Server performance. It could delay the ability to read or write database files or write log files. It could also raise concerns for server stability if excessive disk I/O inhibits the ability of the cleaner threads to keep the database size under control.

The `iostat` tool may be used to obtain information about the disk activity on the system.

On Linux systems, `iostat` should be invoked with the `-x` argument, like:

```
iostat -x 5
```

A number of different types of information will be displayed, but to obtain an initial feel for how busy the underlying disks are, look at the `%util` column on Linux. This field shows the percentage of the time that the underlying disks are actively servicing I/O requests. A system with a high disk utilization likely exhibits poor Directory Server performance.

If the high disk utilization is on one or more disks that are used to provide swap space for the system, the system might not have enough free memory to process requests. As a result, it might have started swapping blocks of memory that have not been used recently to disk. This can cause very poor server performance. It is important to ensure that the server is configured appropriately to avoid this condition. If this problem occurs on a regular basis, then the server is likely configured to use too much memory. If swapping is not normally a problem but it does arise, then check to see if there are any other processes running, which are consuming a significant amount of memory, and check for other potential causes of significant memory consumption (for example, large files in a `tmpfs` file system).

#### **Examining process details**

There are a number of tools provided by the operating system that can help examine a process in detail.

#### *ps*

The standard `ps` tool can be used to provide a range of information about a particular process. For example, the command can be used to display the state of the process, the name of the user running the process, its process ID and parent process ID, the priority and nice value, resident and virtual memory sizes, the start time, the execution time, and the process name with arguments:

```
ps -fly -p {processID}
```

Note that for a process with a large number of arguments, the standard `ps` command displays only a limited set of the arguments based on available space in the terminal window.

#### *pstack*

The `pstack` command can be used to obtain a native stack trace of all threads in a process. While a native stack trace might not be as user-friendly as a Java stack trace obtained using `jstack`, it includes threads that are not available in a Java stack trace. For example, the command displays those threads used to perform garbage collection and other housekeeping tasks. The general usage for the `pstack` command is:

```
pstack {processID}
```

### *dbx / gdb*

A process debugger provides the ability to examine a process in detail. Like `psstack`, a debugger can obtain a stack trace for all threads in the process, but it also provides the ability to examine a process (or core file) in much greater detail, including observing the contents of memory at a specified address and the values of CPU registers in different frames of execution. The GNU debugger `gdb` is widely-used on Linux systems.

Note that using a debugger against a live process interrupts that process and suspends its execution until it detaches from the process. In addition, when running against a live process, a debugger has the ability to actually alter the contents of the memory associated with that process, which can have adverse effects. As a result, it is recommended that the use of a process debugger be restricted to core files and only used to examine live processes under the direction of your authorized support provider.

### *pfiles / lsof*

To examine the set of files that a process is using (including special types of files, like sockets), you can use a tool such as `lsof` on Linux systems, (

```
lsof -p {processID}
```

)

### Tracing process execution

If a process is unresponsive but is consuming a nontrivial amount of CPU time, or if a process is consuming significantly more CPU time than is expected, it might be useful to examine the activity of that process in more detail than can be obtained using a point-in-time snapshot. For example, if a process is performing a significant amount of disk reads and/or writes, it can be useful to see which files are being accessed. Similarly, if a process is consistently exiting abnormally, then beginning tracing for that process just before it exits can help provide additional information that cannot be captured in a core file (and if the process is exiting rather than being terminated for an illegal operation, then no core file may be available).

This can be accomplished using the `strace` tool on Linux (

```
strace -f -p {processID}
```

).

Consult the `strace` manual page for additional information.

### Problems with SSL communication

Enable TLS debugging in the server to troubleshoot SSL communication issues:

```
$ dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name
com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
  --set debug-level:verbose \
  --set include-throwable-cause:true
```

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true \
  --set default-debug-level:disabled
```

In the `java.properties` file, add `-Djavax.net.debug=ssl` to the `start-server` line, and run `bin/dsjavaproperties` to make the option take effect on a scheduled server restart.

### Examining network communication

Because the PingDirectory Server is a network-based application, it can be valuable to observe the network communication that it has with clients. The Directory Server itself can provide details about its

interaction with clients by enabling debugging for the protocol or data debug categories, but there may be a number of cases in which it is useful to view information at a much lower level. A network sniffer, like the `tcpdump` tool on Linux, can be used to accomplish this.

There are many options that can be used with these tools, and their corresponding manual pages will provide a more thorough explanation of their use. However, to perform basic tracing to show the full details of the packets received for communication on port 389 with remote host 1.2.3.4, the following command can be used on Linux:

```
tcpdump -i {interface} -n -XX -s 0 host 1.2.3.4 and port 389
```

It does not appear that the `tcpdump` tool provides support for LDAP parsing. However, it is possible to write capture data to a file rather than displaying information on the terminal (using "`-w {path}`" with `tcpdump`), so that information can be later analyzed with a graphical tool like Wireshark, which provides the ability to interpret LDAP communication on any port.

Note that enabling network tracing generally requires privileges that are not available to normal users and therefore may require root access.

### Common problems and potential solutions

This section describes a number of different types of problems that can occur and common potential causes for them.

#### General troubleshooting methodology

When a problem is detected, Ping Identity recommends using the following general methodology to isolate the problem:

1. Run the `bin/status` tool or look at the server status in the Administrative Console. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts.
2. Look in the server logs. In particular, view the following logs:
  - `logs/errors`
  - `logs/failed-ops`
  - `logs/expensive-ops`
3. Use system commands, such as `vmstat` and `iostat` to determine if the server is bottle-necked on a system resource like CPU or disk throughput.
4. For performance problem (especially intermittent ones like spikes in response time), enabling the `periodic-stats-logger` can help to isolate problems, because it stores important server performance information on a per-second basis. The `periodic-stats-logger` can save the information in a csv-formatted file that can be loaded into a spreadsheet. The information this logger makes available is very configurable. You can create multiple loggers for different types of information or a different frequency of logging (for example, hourly data in addition to per-second data). For more information, see "Profiling Server Performance Using the Periodic Stats Logger".
5. For replication problem, run `dsreplication status` and look at the `logs/replication` file.
6. For more advanced users, run the `collect-support-data` tool on the system, unzip the archive somewhere, and look through the collected information. This is often useful when administrators most familiar with the PingData Platform do not have direct access to the systems where the production servers are running. They can examine the `collect-support-data` archive on a different server. For more information, see Using the Collect Support Data Tool.

#### Important:

Run the `collect-support-data` tool whenever there is a problem whose cause is not easily identified, so that this information can be passed back to your authorized support provider before corrective action can be taken.

## The Server will not run setup

If the `setup` tool does not run properly, some of the most common reasons include the following:

### *A suitable Java environment is not available*

The PingDirectory Server requires that Java be installed on the system and made available to the server, and it must be installed prior to running `setup`. If the `setup` tool does not detect that a suitable Java environment is available, it will refuse to run.

To ensure that this does not happen, the `setup` tool should be invoked with an explicitly-defined value for the `JAVA_HOME` environment variable that specifies the path to the Java installation that should be used. For example:

```
env JAVA_HOME=/ds/java ./setup
```

If this still does not work for some reason, then it can be that the value specified in the provided `JAVA_HOME` environment variable can be overridden by another environment variable. If that occurs, try the following command, which should override any other environment variables that can be set:

```
env UNBOUNDID_JAVA_HOME="/ds/java" UNBOUNDID_JAVA_BIN="" ./setup
```

### *Unexpected arguments provided to the JVM*

If the `setup` script attempts to launch the `java` command with an invalid set of Java arguments, it might prevent the JVM from starting. By default, no special options are provided to the JVM when running `setup`, but this might not be the case if either the `JAVA_ARGS` or `UNBOUNDID_JAVA_ARGS` environment variable is set. If the `setup` tool displays an error message that indicates that the Java environment could not be started with the provided set of arguments, then invoke the following command before trying to re-run `setup`:

```
unset JAVA_ARGS UNBOUNDID_JAVA_ARGS
```

### *The Server has already been configured or used*

The `setup` tool is only intended to provide the initial configuration for the Directory Server. It refuses to run if it detects that the `setup` tool has already been run, or if an attempt has been made to start the Directory Server prior to running the `setup` tool. This protects an existing Directory Server installation from being inadvertently updated in a manner that could harm an existing configuration or data set.

If the Directory Server has been previously used and if you want to perform a fresh installation, it is recommended that you first remove the existing installation, create a new one and run `setup` in that new installation. However, if you are confident that there is nothing of value in the existing installation (for example, if a previous attempt to run `setup` failed to complete successfully for some reason but it will refuse to run again), the following steps can be used to allow the `setup` program to run:

- Remove the `config/config.ldif` file and replace it with the `config/update/config.ldif.{revision}` file containing the initial configuration.
- If there are any files or subdirectories below the `db` directory, then remove them.
- If a `config/java.properties` file exists, then remove it.
- If a `lib/setup-java-home` script (or file on Microsoft Windows) exists, then remove it.

## The Server will not start

If the Directory Server does not start, then there are a number of potential causes.

### *The Server or other administrative tool is already running*

Only a single instance of the Directory Server can run at any time from the same installation root. If an instance is already running, then subsequent attempts to start the server will fail. Similarly, some other administrative operations can also prevent the server from being started. In such cases, the attempt to start the server should fail with a message like:

```
The Directory Server could not acquire an exclusive lock on file
/ds/PingDirectory/locks/server.lock: The exclusive lock requested for file
/ds/PingDirectory/locks/ server.lock was not granted, which indicates
that another process already holds a shared or exclusive lock on that
file. This generally means that another instance of this server is already
running
```

If the Directory Server is not running (and is not in the process of starting up or shutting down) and there are no other tools running that could prevent the server from being started, and the server still believes that it is running, then it is possible that a previously-held lock was not properly released. In that case, you can try removing all of the files in the `locks` directory before attempting to start the server.

If you wish to have multiple instances running at the same time on the same system, then you should create a completely separate installation in another location on the file system.

#### *There is not enough memory available*

When the Directory Server is started, the JVM attempts to allocate all memory that it has been configured to use. If there is not enough free memory available on the system, then the Directory Server generates an error message that indicates that the server could not be started with the specified set of arguments. Note that it is possible that an invalid option was provided to the JVM (as described below), but if that same set of JVM arguments has already been used successfully to run the server, then it is more likely that the system does not have enough memory available.

There are a number of potential causes for this:

- If the amount of memory in the underlying system has changed (for example, system memory has been removed, or if the Directory Server is running in a zone or other type of virtualized container and a change has been made to the amount of memory that container will be allowed to use), then the Directory Server might need to be re-configured to use a smaller amount of memory than had been previously configured.
- Another process running on the system is consuming a significant amount of memory so that there is not enough free memory available to start the server. If this is the case, then either terminate the other process to make more memory available for the Directory Server, or reconfigure the Directory Server to reduce the amount of memory that it attempts to use.
- The Directory Server was just shut down and an attempt was made to immediately restart it. In some cases, if the server is configured to use a significant amount of memory, then it can take a few seconds for all of the memory that had been in use by the server, when it was previously running, to be released back to the operating system. In that case, run the `vmstat` command and wait until the amount of free memory stops growing before attempting to restart the server.
- If the system is configured with one or more memory-backed file systems, verify whether any large files might be consuming a significant amount of memory in any of those locations. If so, remove them or relocate them to a disk-based file system.
- For Linux systems only, if a mismatch exists between the huge pages setting for the JVM and the huge pages reserved in the operating system.

If nothing else works and there is still not enough free memory to allow the JVM to start, then as a last resort, try rebooting the system.

#### *An invalid Java Environment or JVM option was used*

If an attempt to start the Directory Server fails with an error message indicating that no valid Java environment could be found, or indicates that the Java environment could not be started with the configured set of options, then you should first ensure that enough memory is available on the system as described above. If there is a sufficient amount of memory available, then other causes for this error can include the following:

- The Java installation that was previously used to run the server no longer exists (for example, an updated Java environment was installed and the old installation was removed). In that case, update the `config/java.properties` file to reference to path to the new Java installation and run the `bin/dsjavaproperties` command to apply that change.

- The Java installation used to run the server has been updated and the server is trying to use the correct Java installation but one or more of the options that had worked with the previous Java version no longer work with the new version. In that case, it is recommended that the server be re-configured to use the previous Java version, so that it can be run while investigating which options should be used with the new installation.
- If an `UNBOUNDID_JAVA_HOME` or `UNBOUNDID_JAVA_BIN` environment variable is set, then its value may override the path to the Java installation used to run the server as defined in the `config/java.properties` file. Similarly, if an `UNBOUNDID_JAVA_ARGS` environment variable is set, then its value might override the arguments provided to the JVM. If this is the case, then explicitly unset the `UNBOUNDID_JAVA_HOME`, `UNBOUNDID_JAVA_BIN`, and `UNBOUNDID_JAVA_ARGS` environment variables before trying to start the server.

Note that any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration. If a problem with the previous Java configuration prevents the `bin/dsjavaproperties` tool from running properly, then it can be necessary to remove the `lib/set-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) and invoke the `bin/dsjavaproperties` tool with an explicitly-defined path to the Java environment, like:

```
env UNBOUNDID_JAVA_HOME=/ds/java bin/dsjavaproperties
```

*An invalid command-line option was provided*

There are a small number of arguments that are provided when running the `bin/start-server` command, but in most cases, none are required. If one or more command-line arguments were provided for the `bin/start-server` command and any of them is not recognized, then the server provides an error message indicating that an argument was not recognized and displays version information. In that case, correct or remove the invalid argument and try to start the server again.

*The Server has an invalid configuration*

If a change is made to the Directory Server configuration using an officially-supported tool like `dsconfig` or the Administrative Console, the server should validate that configuration change before applying it. However, it is possible that a configuration change can appear to be valid at the time that it is applied, but does not work as expected when the server is restarted. Alternately, a change in the underlying system can cause a previously-valid configuration to become invalid.

In most cases involving an invalid configuration, the Directory Server displays (and writes to the error log) a message that explains the problem, and this can be sufficient to identify the problem and understand what action needs to be taken to correct it. If for some reason the startup failure does not provide enough information to identify the problem with the configuration, then look in the `logs/config-audit.log` file to see what recent configuration changes have been made with the server online, or in the `config/archived-configs` directory to see if there might have been a recent configuration change resulting from a direct change to the configuration file itself that was not made through a supported configuration interface.

If the server does not start as a result of a recent invalid configuration change, then it can be possible to start the server using the configuration that was in place the last time that the server started successfully (for example, the "last known good" configuration). This can be achieved using the `--useLastKnownGoodConfig` option:

```
$ bin/start-server --useLastKnownGoodConfig
```

Note that if it has been a long time since the last time the server was started and a number of configuration changes have been made since that time, then the last known good configuration can be significantly out of date. In such cases, it can be preferable to manually repair the configuration.

If there is no last known good configuration, if the server no longer starts with the last known good configuration, or if the last known good configuration is significantly out of date, then manually update the configuration by editing the `config/config.ldif` file. In that case, you should make sure that the server is offline and that you have made a copy of the existing configuration before beginning. You might wish

to discuss the change with your authorized support representative before applying it to ensure that you understand the correct change that needs to be made.

#### Note:

In addition to manually-editing the config file, you can look at previous archived configurations to see if the most recent one works. You can also use the `ldif-diff` tool to compare the configurations in the archive to the current configuration to see what is different.

#### *You do not have sufficient permissions*

The Directory Server should only be started by the user or role used to initially install the server. In most cases, if an attempt is made to start the server as a user or role other than the one used to create the initial configuration, then the server will fail to start, because the user will not have sufficient permissions to access files owned by the other user, such as database and log files. However, if the server was initially installed as a non-root user and then the server is started by the root account, then it can no longer be possible to start the server as a non-root user because new files that are created would be owned by root and could not be written by other users.

If the server was inadvertently started by root when it is intended to be run by a non-root user, or if you wish to change the user account that should be used to run the server, then it should be sufficient to simply change ownership on all files in the Directory Server installation, so that they are owned by the user or role under which the server should run. For example, if the Directory Server should be run as the "ds" user in the "other" group, then the following command can be used to accomplish this (invoked by the root user):

```
chown -R ds:other /ds/PingDirectory
```

#### The Server has crashed or shut itself down

You can first check the current server state by using the `bin/server-state` command. If the Directory Server was previously running but is no longer active, then the potential reasons include the following:

- The Directory Server was shut down by an administrator. Unless the server was forcefully terminated (for example, using "kill -9"), then messages are written to the `error` and `server.out` logs explaining the reason for the shutdown.
- The Directory Server was shut down when the underlying system crashed or was rebooted. If this is the case, then running the `uptime` command on the underlying system shows that it was recently booted.
- The Directory Server process was terminated by the underlying operating system for some reason (for example, the out of memory killer on Linux). If this happens, then a message will be written to the system error log.
- The Directory Server decided to shut itself down in response to a serious problem that had arisen. At present, this should only occur if the server has detected that the amount of usable disk space has become critically low, or if significant errors have been encountered during processing that left the server without any remaining worker threads to process operations. If this happens, then messages are written to the `error` and `server.out` logs (if disk space is available) to provide the reason for the shutdown.
- The JVM in which the Directory Server was running crashed. If this happens, then the JVM should dump a fatal error log (a `hs_err_pid{processID}.log` file) and potentially a core file.

In the event that the operating system itself crashed or terminated the process, then you should work with your operating system vendor to diagnose the underlying problem. If the JVM crashed or the server shut itself down for a reason that is not clear, then contact your authorized support provider for further assistance.

### Conditions for automatic server shutdown

All PingDirectory Server servers will shutdown in an out of memory condition, a low disk space error state, or for running out of file descriptors. The Directory Server will enter lockdown mode on unrecoverable database environment errors, but can be configured to shutdown instead with this setting:

```
$ dsconfig set-global-configuration-prop \
    --set unrecoverable-database-error-mode:initiate-server-shutdown
```

### The Server will not accept client connections

You can first check the current server state by using the `bin/server-state` command. If the Directory Server does not appear to be accepting connections from clients, then potential reasons include the following:

- The Directory Server is not running.
- The underlying system on which the Directory Server is installed is not running.
- The Directory Server is running but is not reachable as a result of a network or firewall configuration problem. If that is the case, then connection attempts should time out rather than be rejected.
- If the Directory Server is configured to allow secure communication via SSL or StartTLS, then a problem with the key manager and/or trust manager configuration can cause connections to be rejected. If that is the case, then messages should be written to the server access log for each failed connection attempt.
- If the Directory Server has been configured with a maximum allowed number of connections, then it can be that the maximum number of allowed client connections are already established. If that is the case, then messages should be written to the server access log for each rejected connection attempt.
- If the Directory Server is configured to restrict access based on the address of the client, then messages should be written to the server access log for each rejected connection attempt.
- If a connection handler encounters a significant error, then it can stop listening for new requests. If this occurs, then a message should be written to the server error log with information about the problem. Another solution is to restart the server. A third option is to restart the connection handler using the LDIF connection handler to make it available again. To do this, create an LDIF file that disables and then re-enables the connection handler, create the `config/auto-process-ldif` directory if it does not already exist, and then copy the LDIF file into it.

### The Server is unresponsive

You can first check the current server state by using the `bin/server-state` command. If the Directory Server process is running and appears to be accepting connections but does not respond to requests received on those connections, then potential reasons for this behavior include:

- If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available. If this is the case, then a stack trace obtained using the `jstack` command shows that all of the worker threads are busy and none of them are waiting for new requests to process.

A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the `ldapsearch` command for example, use the `--useAdministrativeSession` option. The requester must have the `use-admin-session` privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

#### Note:

If all of the worker threads are tied up processing the same operation for a long time, the server will also issue an alert that it might be deadlocked, which may not actually be the case. All threads might be tied up processing unindexed searches.

- If a request handler is stuck performing some expensive processing for a client connection, then other requests sent to the server on connections associated with that request handler is forced to wait until the request handler is able to read data on those connections. If this is the case, then only some of the connections can experience this behavior (unless there is only a single request handler, in which it will impact all connections), and stack traces obtained using the `jstack` command shows that a request handler thread is continuously blocked rather than waiting for new requests to arrive. Note that this scenario is a theoretical problem and one that has not appeared in production.
- If the JVM in which the Directory Server is running is not properly configured, then it can be forced to spend a significant length of time performing garbage collection, and in severe cases, could cause significant interruptions in the execution of Java code. In such cases, a stack trace obtained from a `pstack` of the native process should show that most threads are idle but at least one thread performing garbage collection is active. It is also likely that one or a small number of CPUs is 100% busy while all other CPUs are mostly idle. The server will also issue an alert after detecting a long JVM pause (due to garbage collection). The alert will include details of the pause.
- If the JVM in which the Directory Server is running has hung for some reason, then the `pstack` utility should show that one or more threads are blocked and unable to make progress. In such cases, the system CPUs should be mostly idle.
- If a network or firewall configuration problem arises, then attempts to communicate with the server cannot be received by the server. In that case, a network sniffer like `snoop` or `tcpdump` should show that packets sent to the system on which the Directory Server is running are not receiving TCP acknowledgement.
- If the system on which the Directory Server is running has become hung or lost power with a graceful shutdown, then the behavior is often similar to that of a network or firewall configuration problem.

If it appears that the problem is with the Directory Server software or the JVM in which it is running, then you need to work with your authorized support provider to fully diagnose the problem and determine the best course of action to correct it.

### The Server is slow to respond to client requests

If the Directory Server is running and does respond to clients, but clients take a long time to receive responses, then the problem can be attributable to a number of potential problems. In these cases, use the Periodic Stats Logger, which is a valuable tool to get per-second monitoring information on the Directory Server. The Periodic Stats Logger can save the information in csv format for easy viewing in a spreadsheet. For more information, see "Profiling Server Performance Using the Periodic Stats Logger". The potential problems that cause slow responses to client requests are as follows:

- The server is not optimally configured for the type of requests being processed, or clients are requesting inefficient operations. If this is the case, then the access log should show that operations are taking a long time to complete and they will likely be unindexed. In that case, updating the server configuration to better suit the requests, or altering the requests to make them more efficient, could help alleviate the problem. In this case, view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second. You can also run the `bin/status` command or view the status in the Administrative Console to see the Directory Server's Work Queue information (also see the next bullet point).
- The server is overwhelmed with client requests and has amassed a large backlog of requests in the work queue. This can be the result of a configuration problem (for example, too few worker thread configured), or it can be necessary to provision more systems on which to run the Directory Server software. Symptoms of this problem appear similar to those experienced when the server is asked to process inefficient requests, but looking at the details of the requests in the access log show that they are not necessarily inefficient requests. Run the `bin/status` command to view the Work Queue information. If everything is performing well, you should not see a large queue size or a server that is near 100% busy. The %Busy statistic is calculated as the percentage of worker threads that are busy processing operations.

```

--- Work Queue ---
: Recent : Average : Maximum
-----:-----:-----:-----

```

```
Queue Size : 10 : 1 : 10
% Busy      : 17 : 14 : 100
```

You can also view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second.

- The server is not configured to fully cache all of the data in the server, or the cache is not yet primed. In this case, `iostat` reports a very high disk utilization. This can be resolved by configuring the server to fully cache all data, and to load database contents into memory on startup. If the underlying system does not have enough memory to fully cache the entire data set, then it might not be possible to achieve optimal performance for operations that need data which is not contained in the cache. For more information, see [Disk-Bound Deployments](#).
- If the JVM is not properly configured, then it will need to perform frequent garbage collection and periodically pause execution of the Java code that it is running. In that case, the server error log should report that the server has detected a number of pauses and can include tuning recommendations to help alleviate the problem.
- If the Directory Server is configured to use a large percentage of the memory in the system, then it is possible that the system has gotten low on available memory and has begun swapping. In this case, `iostat` should report very high utilization for disks used to hold swap space, and commands like `cat /proc/meminfo` on Linux can report a large amount of swap memory in use. Another cause of swapping is if `swappiness` is not set to 0 on Linux. For more information, see [Disable File System Swapping](#).
- If another process on the system is consuming a significant amount of CPU time, then it can adversely impact the ability of the Directory Server to process requests efficiently. Isolating the processes (for example, using processor sets) or separating them onto different systems can help eliminate this problem.

### The Server returns error responses to client requests

If a large number of client requests are receiving error responses, then view the `logs/failed-ops` log, which is an access log for only failed operations. The potential reasons for the error responses include the following:

- If clients are requesting operations that legitimately should fail (for example, they are targeting entries that do not exist, are attempting to update entries in a way that would violate the server schema, or are performing some other type of inappropriate operation), then the problem is likely with the client and not the server.
- If a portion of the Directory Server data is unavailable (for example, because an online LDIF import or restore is in progress), then operations targeting that data will fail. Those problems will be resolved when the backend containing that data is brought back online. During the outage, it might be desirable to update proxies or load balancers or both to route requests away from the affected server. As of Directory Server version 3.1 or later, the Directory Server will indicate that it is in a degraded status and the Directory Proxy Server will route around it.
- If the Directory Server work queue is configured with a maximum capacity and that capacity has been reached, then the server begins rejecting all new requests until space is available in the work queue. In this case, it might be necessary to alter the server configuration or the client requests or both, so that they can be processed more efficiently, or it might be necessary to add additional server instances to handle some of the workload.
- If an internal error occurs within the server while processing a client request, then the server terminates the connection to the client and logs a message about the problem that occurred. This should not happen under normal circumstances, so you will need to work with your authorized support provider to diagnose and correct the problem.
- If a problem is encountered while interacting with the underlying database (for example, an attempt to read from or write to disk failed because of a disk problem or lack of available disk space), then it can begin returning errors for all attempts to interact with the database until the backend is closed and re-opened and the database has been given a change to recover itself. In these cases, the `je.info.*` file in the database directory should provide information about the nature of the problem.

## The Server must disconnect a client connection

If a client connection must be disconnected due to the expense of the client's request, such as an unindexed search across a very large database, perform the following:

- Find the client's connection ID by looking in the **cn=Active Operations,cn=monitor monitor** entry.

```
$ bin/ldapsearch -baseDN cn=monitor "cn=active operations" \
  --bindDN "cn=directory manager" \
  --bindPassword password
```

- The monitor entry will contain attribute values for **operation-in-progress**, which look like an access log message. Look for the value of **conn** in the client request that should be disconnected. In the following example, the client to be disconnected is requesting a search for **(description=expensive)**, which is on connection 6.

```
dn: cn=Active Operations,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-active-operations-monitor-entry
objectClass: extensibleObject
cn: Active Operations
num-operations-in-progress: 2
operation-in-progress: [15/Dec/2014:10:55:35 -0600] SEARCH conn=6 op=3
msgID=4
  clientIP="10.8.4.21"
  authDN="cn=appl,ou=applications,dc=example,dc=com" base="dc
    =example,dc=com" scope=wholeSubtree filter="(description=expensive)"
  attrs="A
    LL" unindexed=true
operation-in-progress: [15/Dec/2014:10:56:11 -0600] SEARCH conn=7 op=1
msgID=2
  clientIP="127.0.0.1" authDN="cn=Directory Manager,cn=Root
  DNs,cn=config" base="c
  n=monitor" scope=wholeSubtree filter="(cn=active operations)"
  attrs="ALL"
  num-persistent-searches-in-progress: 0
```

- With the connection ID value, create a file with the following contents, named **disconnect6.ldif**.

```
dn: ds-task-id=disconnect6,cn=scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-disconnect
ds-task-disconnect-connection-id: 6
ds-task-id: disconnect6
ds-task-class-name:
  com.unboundid.directory.server.tasks.DisconnectClientTask
```

- This LDIF file represents a task entry. The connection ID value 6 is assigned to **ds-task-disconnect-connection-id**. The value for **ds-task-id** value does not follow a specific convention. It must be unique among other task entries currently cached by the server.
- Disconnect the client and cancel the associated operation by adding the task entry to the server:

```
$ bin/ldapmodify --filename disconnect6.ldif \
  --defaultAdd --bindDN "cn=directory manager" \
  --bindPassword password
```

## Problems with the Administrative Console

If a problem arises when trying to use the Administrative Console, then potential reasons for the problem may include the following:

- The web application container used to host the console is not running. If an error occurs while trying to start it, then consult the logs for the web application container.
- If a problem occurs while trying to authenticate to the web application container, then make sure that the target Directory Server is online. If it is online, then the access log may provide information about the reasons for the authentication failure.
- If a problem occurs while attempting to interact with the Directory Proxy Server instance using the Administrative Console, then the access and error logs for that Directory Server instance might provide additional information about the underlying problem.

### Problems with the Administrative Console: JVM memory issues

**Console runs out of memory (PermGen).** An inadequate PermSize setting in the server, while hosting web applications like the Administrative Console may result in errors like this in the error log:

```
[02/Mar/2016:07:50:27.017 -0600] threadID=2 category=UTIL
severity=SEVERE_ERROR msgID=-1 msg="The server experienced an unexpected
error. Please report this problem and include this log file.
OutOfMemoryError: PermGen space
() \ncom.unboundid.directory.server.core.DirectoryServer.uncaughtException
(DirectoryServer.java:15783) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1057) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1052) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1052) \njava.lang.Thread.dispatchUncaughtException
(Thread.java:1986) \nBuild revision: 22496\n"
```

This is only relevant for servers running Java 7.

### Troubleshooting Global Index Growing Too Large

About this task

If the global index appears to be growing too large, you can reload from the backend directory servers.

Steps

- To override the configuration of the `prime-index-source` property, run the `reload-index` tool with the `--fromDS` subcommand.

Example:

You can do this on a one-off basis if the global index appears to be growing too large.

```
$ bin/reload-index \
--bindPassword password \
--baseDN "dc=example,dc=com" \
--fromDS
```

### Recovering forgotten Proxy User password

About this task

If you forget your `cn=Proxy User` password, you can recover it using different methods.

Steps

- To recover your password, do any of the following:  
Choose from:
  - The PingDirectory server supports a feature called password retirement that allows you to set a new password while allowing the current password to remain usable for a specified period of time. This can be used to set a new password for the account while still allowing the current password to remain temporarily available so that existing PingDirectoryProxy server instances will still be able to use the current password to authenticate until you can update them with the

new password. To enable password retirement, update the `password-retirement-behavior` property in the root password policy for all PingDirectory server instances to include a value of `retire-on-administrative-reset`, and set the `max-retired-password-age` property to indicate how long you want the current password to remain valid after setting a new password. Then, reset the Proxy User password for all of the PingDirectory server instances, and update all of the PingDirectoryProxy server instances to use the new password in their LDAP external server configuration.

- If you do not know the clear-text value for the password but you have other PingDirectoryProxy server instances set up to use that password, then you can use the encoded password value from the LDAP external server configuration entry of one of the existing PingDirectoryProxy servers when creating the LDAP external server for new PingDirectoryProxy server instances.
- Create a new root user in the directory server instances with the appropriate set of privileges and have the new proxy server instance use that account to authenticate. To use the new account, update all of the other proxy server instances.

### Providing information for support cases

If a problem arises that you are unable to fully diagnose and correct on your own, then contact your authorized support provider for assistance. To ensure that the problem can be addressed as quickly as possible, be sure to provide all of the information that the support personnel may need to fully understand the underlying cause by running the `collect-support-data` tool, and then sending the generated zip file to your authorized support provider. It is good practice to run this tool and send the ZIP file to your authorized support provider before any corrective action has taken place.

## SCIM 1.1 and 2.0 servlet extensions management

---

The PingDirectory Server provides two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure, fast, and simple way. SCIM is an alternative to LDAP, allowing identity data provisioning between cloud-based applications over HTTPS. One servlet implements SCIM 1.1 and the other servlet implements SCIM 2.

This section describes fundamental SCIM concepts and provides information on configuring SCIM on your server.

### Overview of SCIM 1.1 fundamentals

Understanding the basic concepts of SCIM can help you use the SCIM extension to meet your deployment needs. SCIM allows you to:

- **Provision identities.** Through the API, you have access to the basic create, read, update, and delete functions, as well as other special functions.
- **Provision groups.** SCIM also allows you to manage groups.
- **Interoperate using a common schema.** SCIM provides a well-defined, platform-neutral user and group schema, as well as a simple mechanism to extend it.

The SCIM extension implements the 1.1 version of the SCIM specification. Familiarize yourself with this specification to help you understand and make efficient use of the SCIM extension and the SCIM SDK. The SCIM specifications are located on the Simplecloud website.

#### Note:

SCIM 1.1 will be deprecated in a future release.

### Summary of SCIM 1.1 protocol support

PingDirectory Server supports all required features of the SCIM 1.1 protocol and most optional features. The following table describes SCIM features and whether they are supported.

## SCIM Protocol Support

| SCIM Feature                        | Supported                                                     |
|-------------------------------------|---------------------------------------------------------------|
| Etags                               | Yes                                                           |
| JSON                                | Yes                                                           |
| XML*                                | Yes                                                           |
| Authentication/Authorization        | Yes, via HTTP basic authentication or OAuth 2.0 bearer tokens |
| Service Provider Configuration      | Yes                                                           |
| Schema                              | Yes                                                           |
| User resources                      | Yes                                                           |
| Group resources                     | Yes                                                           |
| User-defined resources              | Yes                                                           |
| Resource retrieval via GET          | Yes                                                           |
| List/query resources                | Yes                                                           |
| Query filtering*                    | Yes                                                           |
| Query result sorting*               | Yes                                                           |
| Query result pagination*            | Yes (Directory Server, not Directory Proxy Server)            |
| Resource updates via PUT            | Yes                                                           |
| Partial resource updates via PATCH* | Yes                                                           |
| Resource deletes via DELETE         | Yes                                                           |
| Resource versioning*                | Yes (requires configuration for updated servers)              |
| Bulk*                               | Yes                                                           |
| HTTP method overloading             | Yes                                                           |
| Raw LDAP Endpoints**                | Yes                                                           |

\* denotes an optional feature of the SCIM protocol.

\*\* denotes a PingDirectory Server extension to the basic SCIM functionality.

### About the Identity Access API

The PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server support an extension to the SCIM 1.1 standard called the Identity Access API. The Identity Access API provides an alternative to LDAP by supporting CRUD (create, read, update, and delete) operations to access directory server data over an HTTP connection.

SCIM 1.1 and the Identity Access API are provided as a unified service through the SCIM HTTP Servlet Extension. The SCIM HTTP Servlet Extension can be configured to only enable core SCIM resources (e.g., 'Users' and 'Groups'), only LDAP object classes (e.g., `top`, `domain`, `inetOrgPerson`, or `groupOfUniqueNames`), or both. Because SCIM and the Identity Access API have different schemas, if both are enabled, there may be two representations with different schemas for any resources defined in the `scim-resources.xml` file: the SCIM representation and the raw LDAP representation. Likewise, because resources are exposed by an LDAP object class, and because these are hierarchical (e.g., `top`

--> person --> organizationalPerson --> inetOrgPerson, etc.), a client application can access an entry in multiple ways due to the different paths/URLs to a given resource.

This chapter provides information on configuring the SCIM and the Identity Access API services on the PingDirectory Server.

## Creating your own SCIM 1.1 application

To create your own System for Cross-domain Identity Management (SCIM) 1.1 application, you must download the SCIM 1.1 SDK.

SCIM is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 1.1 SDK is available for download at <https://github.com/pingidentity/scim>.

### Note:

The value of a read-only SCIM attribute can be set by a POST operation if the SCIM attribute is a custom attribute in the `scim-resource.xml` config file, but not if the SCIM attribute is a core SCIM attribute.

## Configuring SCIM 1.1

This section discusses details about the PingDirectory Server implementation of the SCIM protocol. Before reading this chapter, familiarize yourself with the SCIM Protocol specification, available on the Simplecloud website.

### Before You Begin

To set up your SCIM servlet extension, the Directory Server provides a `dsconfig` batch file, `scim-config-ds.dsconfig`, that contains the necessary commands to set up a SCIM extension, which is located in the `config` directory. The batch file assumes that the JKS key and trust manager providers are already enabled. Setup examples are presented in later sections.

The SCIM resource mappings are defined by the `scim-resources.xml` file located in the `config` directory. This file defines the SCIM schema and maps it to the LDAP schema. This file can be customized to define and expose deployment specific resources. See [Managing the SCIM Schema](#) for more information.

### Configuring the SCIM 1.1 servlet extension

The Directory Server provides a default SCIM HTTP Servlet Extension that can be enabled and configured using a `dsconfig` batch script located in the `config` directory. The script runs a series of commands that enables an HTTPS Connection Handler, increases the level of detail logged by the HTTP Detailed Access log publisher, and adds access controls to allow access to LDAP controls used by the SCIM Servlet Extension. There are additional optional configurations (e.g., changing the log format, enable `entryDN` virtual attribute and using VLV indexes) that you can make by altering the `dsconfig` batch script.

The SCIM resource mappings are defined by the `scim-resources.xml` file located in the `config` directory. This file defines the SCIM schema and maps it to the LDAP schema. This file can be customized to define and expose deployment specific resources. See [Managing the SCIM Schema](#) for more information.

The following procedures show how to configure SCIM on the server. The first example procedure shows the steps to manually configure SCIM without using the script. The second example procedure uses the `dsconfig` batch script to configure SCIM.

## Configuring the SCIM servlet extension

### Steps

1. To allow read access to operational attributes used by the SCIM Servlet Extension, add access controls on each of the backend -Directory Servers before you enable the System for Cross-domain Identity Management (SCIM) servlet extension.

Example:

Instead of the **dsconfig** interactive equivalent, the following example uses the non-interactive command to add access control instructions (ACIs) .

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-
id ||
  createTimeStamp || modifyTimeStamp")
  (version 3.0;acl "Authenticated read access to operational attributes
  \
  used by the SCIM servlet extension"; allow (read,search,compare)
  userdn="ldap:///all";)'
```

2. To enable the SCIM servlet extension, run the **dsconfig** batch file on the Directory Proxy Server server.

Example:

```
$ bin/dsconfig --batch-file config/scim-config-proxy.dsconfig
```

3. Edit the **dsconfig** batch file to use the correct request processor name and base distinguished names (DNs) for the **set-request-processor-prop** and **set-root-dse-backend-prop** commands.

For more information, see [Configuring LDAP Control Support on All Request Processors \(Proxy Only\)](#) on page 1472 and [SCIM 1.1 servlet extension authentication](#) on page 1008.

## Enabling resource versioning

### About this task

Resource versioning is enabled by default in new installations. Upgraded servers that had System for Cross-domain Identity Management (SCIM) enabled need additional configuration to enable resource versioning.

### Steps

1. Enable the **ds-entry-checksum** virtual attribute.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop \
  --name ds-entry-checksum \
  --set enabled:true
```

2. Remove any existing access controls required by SCIM for read access to operational attributes.

Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --remove 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-
unique-id || createTimeStamp || ds-create-time || modifyTimeStamp || ds-
update-time")
  (version 3.0;acl "Authenticated read access to operational attributes
  used by the SCIM servlet extension"; allow (read,search,compare)
  userdn="ldap:///all"'
```

- On the backend directory server, enable new access controls required by SCIM for read access to operational attributes with the following command.

**Note:**

If this access control instruction (ACI) is not present, problems will occur when a SCIM client tries to authenticate with a non-root distinguished name (DN).

```
$ bin/dsconfig set-access-control-handler-prop \
--add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-
id || createTimeStamp || ds-create-time || modifyTimestamp || ds-update-
time || ds-entry-checksum")
(version 3.0;acl "Authenticated read access to operational attributes
used by the SCIM servlet extension"; allow (read,search,compare)
userdn="ldap:///all"'
```

### Configuring LDAP Control Support on All Request Processors (Proxy Only)

You must configure support for the required LDAP controls on all request processors handling LDAP requests that result from System for Cross-domain Identity Management (SCIM) requests.

#### About this task

Change the request processor name that was provided as an example and repeat the command for all additional request processors.

#### Steps

- Use `dsconfig` to change the request processor name (provided as an example) and repeat the command for all additional request processors.

Use your deployment's request processor name.

Example:

```
$ bin/dsconfig set-request-processor-prop \
--processor-name dc_example_dc_com-req-processor \
--add supported-control-oid:1.2.840.113556.1.4.319 \
--add supported-control-oid:1.2.840.113556.1.4.473 \
--add supported-control-oid:2.16.840.1.113730.3.4.9
```

### SCIM 1.1 servlet extension authentication

The SCIM 1.1 servlet supports authentication using either the HTTP Basic authentication scheme, or OAuth 2.0 bearer tokens. When authenticating using HTTP Basic authentication, the SCIM 1.1 servlet attempts to correlate the user name component of the Authorization header to a DN in the Directory Server. If the user name value cannot be parsed directly as a DN, it is correlated to a DN using an Identity Mapper. The DN is then used in a simple bind request to verify the password.

In deployments that use an OAuth authorization server, the SCIM 1.1 extension can be configured to authenticate requests using OAuth bearer tokens. The SCIM 1.1 extension supports authentication with OAuth 2.0 bearer tokens (per RFC 6750) using an OAuth Token Handler Server SDK Extension. Because the OAuth 2.0 specification does not specify how contents of a bearer token are formatted, PingDirectory Server provides the token handler API to decode incoming bearer tokens and extract or correlate associated authorization DNs.

Neither HTTP Basic authentication nor OAuth 2.0 bearer token authentication are secure unless SSL is used to encrypt the HTTP traffic.

## Enabling HTTPS communications

To make the System for Cross-domain Identity Management (SCIM) HTTP connection handler use SSL (which is mandated by the SCIM specification), enable a Key Manager provider and Trust Manager provider.

### Steps

- To enable SSL during the Directory Server's initial setup, include the `--ldapsPort` and the `--generateSelfSignedCertificate` subcommands with the `setup` command.
- If your server already has a certificate that you would like to use:  
Choose from:
  - Set the `key-manager-provider` to the value you set when you enabled SSL in the Directory Server.
  - Define a new key manager provider.

For more information, see [Configuring HTTP Connection Handlers](#).

## Configuring basic authentication using an identity mapper

### About this task

By default, the SCIM servlet is configured to use the Exact Match Identity Mapper, which matches against the `uid` attribute. In this example, an alternate Identity Mapper is created so that clients can authenticate using `cn` values.

### Steps

1. Create a new Identity Mapper that uses a match attribute of `cn`.

Example:

```
$ bin/dsconfig create-identity-mapper \
  --mapper-name "CN Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:cn
```

2. Configure the SCIM servlet to use the new Identity Mapper.

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM \
  --set "identity-mapper:CN Identity Mapper"
```

## Enabling OAuth authentication

### About this task

To enable OAuth authentication, you need to create an implementation of the `OAuthTokenHandler` using the API provided in the Server SDK. For details on creating an `OAuthTokenHandler` extension, see the Server SDK documentation.

### Steps

1. Install your OAuth token handler on the server using `dsconfig`.

Example:

```
$ bin/dsconfig create-oauth-token-handler \
  --handler-name ExampleOAuthTokenHandler \
  --type third-party \
```

```
--set extension-
class:com.unboundid.directory.sdk.examples.ExampleOAuthTokenHandler
```

## 2. Configure the SCIM servlet extension to use it as follows:

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
--extension-name SCIM \
--set oauth-token-handler:ExampleOAuthTokenHandler
```

### Using HTTP basic authentication with bare UID on the Directory Proxy Server

Clients can authenticate to the System for Cross-domain Identity Management (SCIM) extension using HTTP basic authentication and a bare UID value.

About this task

When a SCIM extension is hosted by a Directory Proxy Server, you must explicitly configure the server with the names of subordinate base distinguished names (DNs) to search.

#### Note:

Make sure to specify your deployment's subordinate base DN.

Steps

- To configure the server with the names of subordinate base DN's, run the following command on the Directory Proxy Server for every base DN that you can access using SCIM.

```
$ bin/dsconfig set-root-dse-backend-prop \
--set subordinate-base-dn:dc=example,dc=com
```

### Verifying the SCIM 1.1 servlet extension configuration

About this task

You can verify the configuration of the SCIM 1.1 extension by navigating to a SCIM resource URL via the command line or through a browser window.

To verify the SCIM servlet extension configuration:

Steps

- Run **curl** to verify that the SCIM extension is running. The **-k** (or **--insecure**) option is used to turn off curl's verification of the server certificate, since the example Directory Server is using a self-signed certificate.

Example:

```
$ curl -u "cn=Directory Manager:password" \
-k "https://localhost:8443/scim/ServiceProviderConfigs"

{"schemas":["urn:scim:schemas:core:1.0"],"id":"urn:scim:schemas:core:1.0",
"patch":{"supported":true},"bulk":{"supported":true,"maxOperations":10000,
"maxPayloadSize":10485760},"filter":{"supported":true,"maxResults":100},
"changePassword":{"supported":true},"sort":{"supported":true},
"etag":{"supported":false},"authenticationSchemes":[{"name":"HttpBasic",
"description":"The HTTP Basic Access Authentication scheme. This scheme is
not considered to be a secure method of user authentication (unless used
in
conjunction with some external secure system such as SSL), as the user
```

```
name and password are passed over the network as cleartext.", "specUrl":
"http://www.ietf.org/rfc/rfc2617", "documentationUrl":
"http://en.wikipedia.org/wiki/Basic_access_authentication"]}]}
```

- If the user ID is a valid DN (such as `cn=Directory Manager`), the SCIM extension authenticates by binding to the Directory Server as that user. If the user ID is not a valid DN, the SCIM extension searches for an entry with that `uid` value, and binds to the server as that user. To verify authentication to the server as the user with the `uid` of `user.0`, run the following command:

Example:

```
$ curl -u "user.0:password" \
-k "https://localhost:8443/scim/ServiceProviderConfigs"
```

## Configuring advanced SCIM 1.1 extension features

The following sections show how to configure advanced SCIM 1.1 servlet extension features, such as bulk operation implementation, mapping SCIM resource IDs, and transformations.

### Managing the SCIM 1.1 schema

This section describes the SCIM schema and provides information on how to map LDAP schema to the SCIM resource schema.

#### About the SCIM schema

SCIM provides a common user schema and extension model, making it easier to interoperate with multiple Service Providers. The core SCIM schema defines a concrete schema for user and group resources that encompasses common attributes found in many existing schemas.

Each attribute is defined as either a single attribute, allowing only one instance per resource, or a multi-valued attribute, in which case several instances may be present for each resource. Attributes may be defined as simple, name-value pairs or as complex structures that define sub-attributes.

While the SCIM schema follows an object extension model similar to object classes in LDAP, it does not have an inheritance model. Instead, all extensions are additive, similar to LDAP Auxiliary Object Classes.

#### Mapping the LDAP schema to the SCIM resource schema

The resources configuration file is an XML file that is used to define the SCIM resource schema and its mapping to LDAP schema. The default configuration of the `scim-resources.xml` file provides definitions for the standard SCIM Users and Groups resources, and mappings to the standard LDAP `inetOrgPerson` and `groupOfUniqueNames` object classes.

The default configuration may be customized by adding extension attributes to the Users and Groups resources, or by adding new extension resources. The resources file is composed of a single `<resources>` element, containing one or more `<resource>` elements.

For any given SCIM resource endpoint, only one `<LDAPAdd>` template can be defined, and only one `<LDAPSearch>` element can be referenced. If entries of the same object class can be located under different subtrees or base DN's of the Directory Server, then a distinct SCIM resource must be defined for each unique entry location in the Directory Information Tree. This can be implemented in many ways. For example:

- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, and each running under a unique HTTP connection handler.
- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, each running under a single, shared HTTP connection handler, but each with a unique context path.

Note that LDAP attributes are allowed to contain characters that are invalid in XML (because not all valid UTF-8 characters are valid XML characters). The easiest and most-correct way to handle this is to make sure that any attributes that may contain binary data are declared using `"dataType=binary"` in the `scim-resources.xml` file. Likewise, when using the Identity Access API make sure that the underlying LDAP schema uses the Binary or Octet String attribute syntax for attributes which may contain binary data. This

will cause the server to automatically base64-encode the data before returning it to clients and will also make it predictable for clients because they can assume the data will always be base64-encoded.

However, it is still possible that attributes that are not declared as binary in the schema may contain binary data (or just data that is invalid in XML), and the server will always check for this before returning them to the client. If the client has set the content-type to XML, then the server may choose to base64-encode any values which are found to include invalid XML characters. When this is done, a special attribute is added to the XML element to alert the client that the value is base64-encoded. For example:

```
<scim:value base64Encoded="true">AAABPB0EBZc=</scim:value>
```

The remainder of this section describes the mapping elements available in the `scim-resources.xml` file.

#### *About the resource element*

A `resource` element has the following XML attributes:

- `schema`: a required attribute specifying the SCIM schema URN for the resource. Standard SCIM resources already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom resources using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the resource used to access it through the SCIM REST API.
- `mapping`: a custom Java class that provides the logic for the resource mapper. This class must extend the `com.unboundid.scim.ldap.ResourceMapper` class.

A resource element contains the following XML elements in sequence:

- `description`: a required element describing the resource.
- `endpoint`: a required element specifying the endpoint to access the resource using the SCIM REST API.
- `LDAPSearchRef`: a mandatory element that points to an `LDAPSearch` element. The `LDAPSearch` element allows a SCIM query for the resource to be handled by an LDAP service and also specifies how the SCIM resource ID is mapped to the LDAP server.
- `LDAPAdd`: an optional element specifying information to allow a new SCIM resource to be added through an LDAP service. If the element is not provided then new resources cannot be created through the SCIM service.
- `attribute`: one or more elements specifying the SCIM attributes for the resource.

#### *About the attribute element*

An `attribute` element has the following XML attributes:

- `schema`: a required attribute specifying the schema URN for the SCIM attribute. If omitted, the schema URN is assumed to be the same as that of the enclosing resource, so this only needs to be provided for SCIM extension attributes. Standard SCIM attributes already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom SCIM attributes using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the SCIM attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- `required`: an optional attribute indicating whether the SCIM attribute is required to be present in the resource. The default value is `false`.

An attribute element contains the following XML elements in sequence:

- **description:** a required element describing the attribute. Then just one of the following elements:
  - **simple:** specifies a simple, singular SCIM attribute.
  - **complex:** specifies a complex, singular SCIM attribute.
  - **simpleMultiValued:** specifies a simple, multi-valued SCIM attribute.
  - **complexMultiValued:** specifies a complex, multi-valued SCIM attribute.

#### *About the simple element*

A `simple` element has the following XML attributes:

- **dataType:** a required attribute specifying the simple data type for the SCIM attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `decimal`, `integer`, `string`.
- **caseExact:** an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A simple element contains the following XML element:

- **mapping:** an optional element specifying a mapping between the SCIM attribute and an LDAP attribute. If this element is omitted, then the SCIM attribute has no mapping and the SCIM service ignores any values provided for the SCIM attribute.

#### *About the complex element*

The `complex` element does not have any XML attributes. It contains the following XML element:

- **subAttribute:** one or more elements specifying the sub-attributes of the complex SCIM attribute, and an optional mapping to LDAP. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

#### *About the simpleMultiValued element*

A `simpleMultiValued` element has the following XML attributes:

- **childName:** a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard emails SCIM attribute is `email`.
- **dataType:** a required attribute specifying the simple data type for the plural SCIM attribute (i.e. the data type for the value sub-attribute). The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, `string`.
- **caseExact:** an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `simpleMultiValued` element contains the following XML elements in sequence:

- **canonicalValue:** specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.
- **mapping:** an optional element specifying a default mapping between the SCIM attribute and an LDAP attribute.

#### *About the complexMultiValued element*

A `complexMultiValued` element has the following XML attribute:

- **tag:** a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard addresses SCIM attribute is `address`.

A `complexMultiValued` element contains the following XML elements in sequence:

- **subAttribute:** one or more elements specifying the sub-attributes of the complex SCIM attribute. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.

#### *About the `subAttribute` element*

A `subAttribute` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is false.
- `required`: an optional attribute indicating whether the SCIM sub-attribute is required to be present in the SCIM attribute. The default value is false.
- `dataType`: a required attribute specifying the simple data type for the SCIM sub-attribute. The following values are permitted: binary, boolean, dateTime, integer, string.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is false.

A `subAttribute` element contains the following XML elements in sequence:

- `description`: a required element describing the sub-attribute.
- `mapping`: an optional element specifying a mapping between the SCIM sub-attribute and an LDAP attribute. This element is not applicable within the `complexMultiValued` element.

#### *About the `canonicalValue` element*

A `canonicalValue` element has the following XML attribute:

- `name`: specifies the value of the type sub-attribute. For example, work is the value for emails, phone numbers and addresses intended for business purposes.

A `canonicalValue` element contains the following XML element:

- `subMapping`: an optional element specifying mappings for one or more of the sub-attributes. Any sub-attributes that have no mappings will be ignored by the mapping service.

#### *About the `mapping` element*

A `mapping` element has the following XML attributes:

- `ldapAttribute`: A required element specifying the name of the LDAP attribute to which the SCIM attribute or sub-attribute map.
- `transform`: An optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described in the [Mapping LDAP Entries to SCIM Using the SCIM-LDAP API](#) section.

#### *About the `subMapping` element*

A `subMapping` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute that is mapped.
- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM sub-attribute maps.
- `transform`: an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described later. The available transformations are described in [Mapping LDAP Entries to SCIM Using the SCIM-LDAP API](#).

#### *About the `LDAPSearch` element*

An `LDAPSearch` element contains the following XML elements in sequence:

- `baseDN`: a required element specifying one or more LDAP search base DN's to be used when querying for the SCIM resource.

- **filter:** a required element specifying an LDAP filter that matches entries representing the SCIM resource. This filter is typically an equality filter on the LDAP object class.
- **resourceIDMapping:** an optional element specifying a mapping from the SCIM resource ID to an LDAP attribute. When the element is omitted, the resource ID maps to the LDAP entry DN. Note The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them via an ID attribute.

**Note:**

The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them via an ID attribute.

*About the `resourceIDMapping` element*

The `resourceIDMapping` element has the following XML attributes:

- **ldapAttribute:** a required element specifying the name of the LDAP attribute to which the SCIM resource ID maps.
- **createdBy:** a required element specifying the source of the resource ID value when a new resource is created by the SCIM consumer using a POST operation. Allowable values for this element include `scim-consumer`, meaning that a value must be present in the initial resource content provided by the SCIM consumer, or `Directory Server`, meaning that a value is automatically provided by the Directory Server (as would be the case if the mapped LDAP attribute is `entryUUID`).

The following example illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

```
<LDAPSearch id="userSearchParams">
  <baseDN>ou=people,dc=example,dc=com</baseDN>
  <filter>(objectClass=inetOrgPerson)</filter>
  <resourceIDMapping ldapAttribute="entryUUID" createdBy="directory"/>
</LDAPSearch>
```

*About the `LDAPAdd` element*

An `LDAPAdd` element contains the following XML elements in sequence:

- **DNTemplate:** a required element specifying a template that is used to construct the DN of an entry representing a SCIM resource when it is created. The template may reference values of the entry after it has been mapped using `{ldapAttr}`, where `ldapAttr` is the name of an LDAP attribute.
- **fixedAttribute:** zero or more elements specifying fixed LDAP values to be inserted into the entry after it has been mapped from the SCIM resource.

*About the `fixedAttribute` element*

A `fixedAttribute` element has the following XML attributes:

- **ldapAttribute:** a required attribute specifying the name of the LDAP attribute for the fixed values.
- **onConflict:** an optional attribute specifying the behavior when the LDAP entry already contains the specified LDAP attribute. The value `merge` indicates that the fixed values should be merged with the existing values. The value `overwrite` indicates that the existing values are to be overwritten by the fixed values. The value `preserve` indicates that no changes should be made. The default value is `merge`.

A `fixedAttribute` element contains one or more `fixedValue` XML element, which specify the fixed LDAP values.

**Validating the updated SCIM schema**

The PingDirectory Server SCIM extension is bundled with an XML Schema document, `resources.xsd`, which describes the structure of a `scim-resources.xml` resource configuration file. After updating the resource configuration file, you should confirm that its contents are well-formed and valid using a tool such as `xmllint`.

For example, you could validate your updated file as follows:

```
$ xmllint --noout --schema resources.xsd scim-resources.xml
scim-resources.xml validates
```

## Mapping SCIM resource IDs

The default `scim-resources.xml` configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. The `entryUUID` attribute, whose read-only value is assigned by the Directory Server, meets the requirements of the SCIM specification regarding resource ID immutability. However, configuring a mapping to the attribute may result in inefficient group processing, since LDAP groups use the entry DN as the basis of group membership. The resource configuration allows the SCIM resource ID to be mapped to the LDAP entry DN. However, the entry DN does not meet the requirements of the SCIM specification regarding resource ID immutability. LDAP permits entries to be renamed or moved, thus modifying the DN. Likewise, you can use the Identity Access API to change the value of an entry's RDN attribute, thereby triggering a MODDN operation.

A resource may also be configured such that its SCIM resource ID is provided by an arbitrary attribute in the request body during POST operations. This SCIM attribute must be mapped to an LDAP attribute so that the SCIM resource ID may be stored in the Directory Server. By default, it is the responsibility of the SCIM client to guarantee ID uniqueness. However, the UID Unique Attribute Plugin may be used by the Directory Server to enforce attribute value uniqueness. For information about the UID Unique Attribute Plugin, see "Working with the UID Unique Attribute plugin" in the *PingDirectory Server Administration Guide*.

### Note:

Resource IDs may not be mapped to virtual attributes. For more information about configuring SCIM Resource IDs, see "About the `<resourceIDMapping>` Element".

## Using pre-defined transformations

Transformations are required to change SCIM data types to LDAP syntax values. The following pre-defined transformations may be referenced by the transform XML attribute:

- `com.unboundid.scim.ldap.BooleanTransformation`. Transforms SCIM boolean data type values to LDAP Boolean syntax values and vice-versa.
- `com.unboundid.scim.ldap.GeneralizedTimeTransformation`. Transforms SCIM `dateTime` data type values to LDAP Generalized Time syntax values and vice-versa.
- `com.unboundid.scim.ldap.PostalAddressTransformation`. Transforms SCIM formatted address values to LDAP Postal Address syntax values and vice-versa. SCIM formatted physical mailing addresses are represented as strings with embedded new lines, whereas LDAP uses the `$` character to separate address lines. This transformation interprets new lines in SCIM values as address line separators.
- `com.unboundid.scim.ldap.TelephoneNumberTransformation`. Transforms LDAP Telephone Number syntax (E.123) to RFC3966 format and vice-versa.

You can also write your own transformations using the SCIM API described in the following section.

## Mapping LDAP entries to SCIM using the SCIM-LDAP API

In addition to the SCIM SDK, PingDirectory Server provides a library called SCIM-LDAP, which provides facilities for writing custom transformations and more advanced mapping.

You can add the SCIM-LDAP library to your project using the following dependency:

```
<dependency>
  <groupId>com.unboundid.product.scim</groupId>
  <artifactId>scim-ldap</artifactId>
  <version>1.5.0</version>
</dependency>
```

Create your custom transformation by extending the `com.unboundid.scim.ldap.Transformation` class. Place your custom transformation class in a jar file in the server's `lib` directory.

**Note:**

The Identity Access API automatically maps LDAP attribute syntaxes to the appropriate SCIM attribute types. For example, an LDAP `DirectoryString` is automatically mapped to a SCIM string.

### SCIM authentication

SCIM requests to the LDAP endpoints will support HTTP Basic Authentication and OAuth2 Authentication using a bearer token. There is existing support for this feature in the Directory Server and the Directory Proxy Server using the `OAuthTokenHandler` API (i.e., via a Server SDK extension, which requires some technical work to implement).

Note that our implementation only supports the HTTP Authorization header for this purpose; we do not support the form-encoded body parameter or URI query parameter mechanisms for specifying the credentials or bearer token.

### SCIM logging

The Directory Server already provides a detailed HTTP log publisher to capture the SCIM and HTTP request details. To be able to correlate this data to the internal LDAP operations that are invoked behind the scenes, the Access Log Publisher will use `origin=scim` in access log messages that are generated by the SCIM servlet.

For example, you will see a message for operations invoked by replication:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="replication" dn="uid=user.3,ou=people,dc=example,dc=com"
```

Likewise for SCIM messages, you will see a message like this:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="scim" dn="uid=user.3,ou=people,dc=example,dc=com"
```

### SCIM monitoring

There are two facilities that can be used to monitor the SCIM activity in the server.

- **HTTPConnectionHandlerStatisticsMonitorProvider** -- Provides statistics straight about total and average active connections, requests per connection, connection duration, processing time, invocation count, etc.
- **SCIMServletMonitorProvider** -- Provides high level statistics about request methods (POST, PUT, GET, etc.), content types (JSON, XML), and response codes, for example, `user-patch-404:26`.

The LDAP object class endpoints are treated as their own resource types, so that for requests using the Identity Access API, there will be statistics, such as `person-get-200` and `inetorgperson-post-401`.

## Configuring the Identity Access API

Once you have run the `<server-root>/config/scim-config-ds.dsconfig` script, the resources defined in the `scim-resources.xml` will be available as well as the Identity Access API. However, to allow SCIM access to the raw LDAP data, you must set a combination of configuration properties on the SCIM Servlet Extension using the `dsconfig` tool.

- **include-ldap-objectclass**. Specifies a multi-valued property that lists the object classes for entries that will be exposed. The object class used here will be the one that clients need to use when referencing Identity Access API resources. This property allows the special value `"*"` to allow all object classes. If `"*"` is used, then the SCIM servlet uses the same case used in the Directory Server LDAP Schema.

- **exclude-ldap-objectclass.** Specifies a multi-valued property that lists the object classes for entries that will not be exposed. When this property is specified, all object classes will be exposed except those in this list.
- **include-ldap-base-dn.** Specifies a multi-valued property that lists the base DN's that will be exposed. If specified, only entries under these base DN's will be accessible. No parent-child relationships in the DN's are allowed here.
- **exclude-ldap-base-dn.** Specifies a multi-valued property that lists the base DN's that will not be exposed. If specified, entries under these base DN's will not be accessible. No parent-child relationships in the DN's are allowed here.

Using a combination of these properties, SCIM endpoints will be available for all included object classes, just as if they were SCIM Resources defined in the `scim-resources.xml` file.

## Configuring the Identity Access API

### Steps

1. Ensure that you have run the `scim-config-ds.dsconfig` script to configure the SCIM interface. Be sure to enable the entryDN virtual attribute. See the Configure SCIM section for more information.
2. Set a combination of properties to allow the SCIM clients access to the raw LDAP data: `include-ldap-objectclass`, `exclude-ldap-objectclass`, `include-ldap-base-dn`, or `exclude-ldap-base-dn`.

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM --set 'include-ldap-objectclass:*' \
  --set include-ldap-base-dn:ou=People,dc=example,dc=com
```

Result: The SCIM clients now have access to the raw LDAP data via LDAP object class-based resources as well as core SCIM resources as defined in the `scim.resource.xml` file.

## Disabling core SCIM resources

### Steps

1. Open the `config/scim-resources.xml` file, and comment out or remove the `<resource>` elements that you would like to disable.
2. Disable and re-enable the HTTP Connection Handler, or restart the server to make the changes take effect. In general, changing the `scim-resources.xml` file requires a HTTP Connection Handler restart or server restart.

#### Note:

When making other changes to the SCIM configuration by modifying the SCIM HTTP Servlet Extension using `dsconfig`, the changes take effect immediately without any restart required.

## Verifying the Identity Access API configuration

### Steps

- Perform a curl request to verify the Identity Access API configuration.

Result:

```
$ curl -k -u "cn=directory manager:password" \
  -H "Accept: application/json" \
  "https://example.com/top/56c9fd6b-f870-35ef-9959-691c783b7318?
  attributes=entryDN,uid,givenName,sn,entryUUID"
```

```

    {"schemas":
["urn:scim:schemas:core:1.0", "urn:unboundid:schemas:scim:ldap:1.0"],
  "id": "56c9fd6b-f870-35ef-9959-691c783b7318",
  "meta": {"lastModified": "2013-01-11T23:38:26.489Z",
"location": "https://example.com:443/v1/top/56c9fd6b-
f870-35ef-9959-691c783b7318"},
  "urn:unboundid:schemas:scim:ldap:1.0": {"givenName": ["Rufus"], "uid":
["user.1"],
  "sn": ["Firefly"], "entryUUID": ["56c9fd6b-
f870-35ef-9959-691c783b7318"],
  "entrydn": "uid=user.1,ou=people,dc=example,dc=com"} }

```

## Monitoring the SCIM servlet extension

The SCIM SDK provides a command-line tool, `scim-query-rate`, that measures the SCIM query performance for your extension. The SCIM extension also exposes monitoring information for each SCIM resource, such as the number of successful operations per request, the number of failed operations per request, the number of operations with XML or JSON to and from the client. Finally, the Directory Server automatically logs SCIM-initiated LDAP operations to the default File-based Access Logger. These operations will have an `origin='scim'` attribute to distinguish them from operations initiated by LDAP clients. You can also create custom logger or request criteria objects that can track incoming HTTP requests, which the SCIM extension rewrites as internal LDAP operations.

### Testing SCIM query performance

You can use the `scim-query-rate` tool, provided in the SCIM SDK, to test query performance, by performing repeated resource queries against the SCIM server.

The `scim-query-rate` tool performs searches using a query filter or can request resources by ID. For example, you can test performance by using a filter to query randomly across a set of one million users with eight concurrent threads. The user resources returned to the client in this example is in XML format and includes the `userName` and `name` attributes.

```

scim-query-rate --hostname server.example.com --port 80 \
--authID admin --authPassword password --xml \
--filter 'userName eq "user.[1-1000000]"' --attribute userName \
--attribute name --numThreads 8

```

You can request resources by specifying a resource ID pattern using the `--resourceID` argument as follows:

```

scim-query-rate --hostname server.example.com --port 443 \
--authID admin --authPassword password --useSSL --trustAll \
--resourceName User \
--resourceID 'uid=user.[1-150000],ou=people,dc=example,dc=com'

```

The `scim-query-rate` tool reports the error `"java.net.SocketException: Too many open files"` if the open file limit is too low. You can increase the open file limit to increase the number of file descriptors.

### About the HTTP log publishers

HTTP operations may be logged using either a Common Log File HTTP Operation Log Publisher or a Detailed HTTP Operation Log Publisher. The Common Log File HTTP Operation Log Publisher is a built-in log publisher that records HTTP operation information to a file using the W3C common log format. Because the W3C common log format is used, logs produced by this log publisher can be parsed by many existing web analysis tools.

Log messages are formatted as follows:

- IP address of the client.
- RFC 1413 identification protocol. The Ident Protocol is used to format information about the client.

- The user ID provided by the client in an Authorization header, which is typically available server-side in the REMOTE\_USER environment variable. A dash appears in this field if this information is not available.
- A timestamp, formatted as "[dd/MM/yyyy:HH:mm:ss Z]"
- Request information, with the HTTP method followed by the request path and HTTP protocol version.
- The HTTP status code value.
- The content size of the response body in bytes. This number does not include the size of the response headers.

The HTTP Detailed Access Log Publisher provides more information than the common log format in a format that is familiar to administrators who use the File-Based Access Log Publisher.

The HTTP Detailed Access Log Publisher generates log messages such as the following. The lines have been wrapped for readability.

```
[15/Feb/2012:21:17:04 -0600] RESULT requestID=10834128
from="10.2.1.114:57555" method="PUT"
url="https://10.2.1.129:443/Aleph/Users/6272c691-
38c6-012f-d227-0dfae261c79e" authorizationType="Basic"
requestContentType="application/json" statusCode=200
etime=3.544 responseContentLength=1063
redirectURI="https://server1.example.com:443/Aleph/Users/6272c691-38c6-012f-
d227-0dfae261c79e"
responseContentType="application/json"
```

In this example, only default log publisher properties are used. Though this message is for a RESULT, it contains information about the request, such as the client address, the request method, the request URL, the authentication method used, and the Content-Type requested. For the response, it includes the response length, the redirect URI, the Content-Type, and the HTTP status code.

You can modify the information logged, including adding request parameters, cookies, and specific request and response headers. For more information, refer to the `dsconfig` command-line tool help.

### Monitoring resources using the SCIM extension

The monitor provider exposes the following information for each resource:

- Number of successful operations per request type (such as GET, PUT, and POST).
- Number of failed operations and their error codes per request type.
- Number of operations with XML or JSON from client.
- Number of operations that sent XML or JSON to client.

In addition to the information about the user-defined resources, monitoring information is also generated for the schema, service provider configuration, and monitor resources. The attributes of the monitor entry are formatted as follows:

```
{resource name}-resource-{request type}-{successful or error status code}
```

You can search for one of these monitor providers using an `ldapsearch` such as the following:

```
$ bin/ldapsearch --port 1389 bindDN uid=admin,dc=example,dc=com \
--bindPassword password --baseDN cn=monitor \
--searchScope sub "(objectclass=scim-servlet-monitor-entry)"
```

For example, the following monitor output was produced by a test environment with three distinct SCIM servlet instances, Aleph, Beth, and Gimel. Note that the first instance has a custom resource type called `host`.

```
$ bin/ldapsearch --baseDN cn=monitor \
'(objectclass=scim-servlet-monitor-entry)'
dn: cn=SCIM Servlet (SCIM HTTP Connection Handler),cn=monitor
```

## Managing the SCIM 2.0 Servlet Extension

The PingDirectory Server provides a servlet extension that implements version 2 of the System for Cross-domain Identity Management (SCIM) specification.

The SCIM 2.0 extension doesn't replace the existing SCIM 1.1 extension, and there are significant differences in how they're configured.

### Note:

Configure your SCIM configurations, such as attribute mappings, on the PingDirectoryProxy Server instead of on the backend PingDirectory servers.

## Supported SCIM 2.0 Endpoints

PingDirectory Server supports the following System for Cross-domain Identity Management (SCIM) 2.0 endpoints.

Endpoint	Description	Supported HTTP methods
/ServiceProviderConfig	<p>Provides metadata that indicates the PingDirectory Server's authentication scheme (OAuth 2.0) and its support for features that are optional in the SCIM standard.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/Schemas	<p>Lists the SCIM schemas that are configured for use on PingDirectory Server, and defines the various attributes available to resource types.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/Schemas/<schema>	<p>Retrieves a specific SCIM schema, as specified by the schema ID.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/ResourceTypes	<p>Lists all of the SCIM resource types that are configured for use on PingDirectory Server. Clients can use this information to determine the endpoint, core schema, and extension schemas of any resource types that the server supports.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/ResourceTypes/<resourceType>	<p>Retrieves a specific SCIM resource type, as specified by its ID.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/<resourceType>	<p>Creates a new resource (POST), or lists and filters resources (GET).</p>	<ul style="list-style-type: none"> <li>▪ GET</li> <li>▪ POST</li> </ul>

Endpoint	Description	Supported HTTP methods
<code>/&lt;resourceType&gt;/ .search</code>	Lists and filters resources. This is used as an alternative to passing query parameters in the URL.	POST
<code>/&lt;resourceType&gt;/&lt;resourceId&gt;</code>	Retrieves a single resource (GET), modifies a single resource (PUT, PATCH), or deletes a single resource (DELETE).	<ul style="list-style-type: none"> <li>▪ GET</li> <li>▪ PUT</li> <li>▪ PATCH</li> <li>▪ DELETE</li> </ul>

### Configuring SCIM 2.0 on Your Server

Configure your SCIM configurations on the Server.

- [Troubleshooting the SCIM 2.0 Servlet Extension](#) on page 1500
- [Disabling the SCIM 2.0 Servlet Extension](#) on page 1500

### Creating Your Own SCIM 2 Application

To create your own System for Cross-domain Identity Management (SCIM) 2.0 application, you must download the SCIM 2 SDK.

SCIM is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 2 SDK is available for download at [GitHub](#).

### Authentication Requirements for SCIM 2.0 Requests

All System for Cross-domain Identity Management (SCIM) requests on a PingDirectory Server must use OAuth 2.0 bearer token authentication.

Bearer tokens are evaluated using the SCIM 2 servlet extension's configured access token validators. Basic authentication is not supported.

In addition to requiring bearer tokens, the server does not process any SCIM requests unless it has at least one `encryption-settings` definition in its `encryption-settings` database. You can create the necessary definitions with the `encryption-settings` command-line tool.

For more information, see [Encrypting Sensitive Data](#) on page 685.

#### Note:

You must define encryption settings and ensure they match on the proxy and all backend PingDirectory servers.

## Defining Permissions for SCIM 2.0 Requests

Executing a System for Cross-domain Identity Management (SCIM) request on a server depends primarily on both the configured access control instructions (ACIs) in the server and the scopes used to authenticate the request present in the provided `OAuth` bearer token.

### Note:

You must define ACIs on the backend PingDirectory servers. Do not define ACIs on the Proxy server.

Internally, all SCIM 2.0 requests are processed using the `cn=SCIM2 Servlet, cn=Root DNs, cn=config` service account. Allowing a requested operation depends on the ACIs that apply to the operation. The `oauthscope` bind rule is useful because it allows the administrator to use the supplied `OAuth` scopes in ACI logic.

Because of implementation details, access to the `objectclass` operational LDAP attribute is necessary for SCIM requests to properly execute. Do not give the service account access to `objectclass` on a global level. Instead, add the ACI granting `objectclass` access to the LDAP subtree to expose to clients.

For more information, see [Configuring permissions for SCIM 2.0 operations](#) on page 1030.

### Note:

ACIs that don't use the `oauthscope` bind rule can still apply to requested operations.

An ACI that grants unconditional read access to any authenticated LDAP user also grants unconditional read access to SCIM requests regardless of the provided `OAuth` scopes. This is because the requests are processed through the service account.

## SCIM 2.0 Components

Unlike the System for Cross-domain Identity Management (SCIM) 1.1 servlet extension, the SCIM 2.0 system is configured through the administrative console or with the `dsconfig` command-line tool.

The SCIM 2.0 system consists of the following components:

### SCIM resource type

A SCIM resource type defines a class of resources, such as users or devices. Every SCIM resource type features at least one SCIM schema, which defines the attributes available to each resource. If you enable a SCIM resource type, it must have a designated LDAP structural objectclass and an associated base distinguished name (DN).

The two types of SCIM resource types, mapping and pass-through, differ based on the definitions of the SCIM schema the resource types use:

#### LDAP mapping SCIM

Requires an explicitly defined SCIM schema with explicitly defined mappings of SCIM attributes to LDAP attributes. Use a mapping SCIM resource type to exercise detailed control over the SCIM schema and its attributes and mappings.

#### LDAP pass-through SCIM

Does not use an explicitly defined SCIM schema. Instead, an implicit schema is generated dynamically based on the underlying LDAP schema. Use a pass-through SCIM resource type when you need to get started quickly

### SCIM schemas

Defines a collection of SCIM attributes, grouped under an identifier called a schema URN. Each SCIM resource type possesses a single core schema and can feature schema extensions, which act as secondary attribute groupings that the schema URN namespaces. SCIM Schemas are defined

independently of SCIM resource types, and multiple SCIM resource types can use a single SCIM schema as a core schema or schema extension.

#### SCIM attributes

Defines an attribute that is available under a SCIM schema. The configuration for a SCIM attribute defines its data type, regardless of whether it's required, single-valued, or multi-valued. When a SCIM attribute consists of SCIM sub-attributes, it's defined as a complex attribute.

#### SCIM sub-attributes

When a SCIM attribute consists of SCIM sub-attributes, it's defined as a complex attribute.

#### SCIM attribute mappings (mapping resource types only)

Defines the manner in which a SCIM resource type maps the attributes in its SCIM schemas to native LDAP attributes of the PingDirectory Server.

#### Correlated LDAP Data Views

Allows a single SCIM resource that consists of attributes that are retrieved from multiple LDAP entries. For more information, see [Correlated LDAP data views](#) on page 1024.

### Correlated LDAP data views

Correlated LDAP data views can be attached to a SCIM resource type to allow that resource type to use attributes from other LDAP entries. A SCIM resource type can have multiple data views configured.

Correlated LDAP data views share many configuration settings with SCIM resource types. The following exceptions are below:

- **primary-correlation-attribute:** The LDAP attribute from the SCIM Resource Type whose value will be used to match entries in the data view. This property must be defined.
- **secondary-correlation-attribute:** The LDAP attribute from the data view whose value will be matched with the primary-correlation-attribute. This property must be defined.
- **ldap-correlation-attribute-pair:** Optional correlation attribute pairs. If these are configured, entries between the SCIM resource type and the correlated LDAP data view must also have matching values for the specified attributes for them to be returned together.

#### Note:

A correlated LDAP Data View cannot provide attributes from more than one LDAP entry at a time. If there are multiple LDAP entries with secondary-correlation-attribute values that match the primary-correlation-attribute from the SCIM resource type's entry, an error will be thrown.

If the correlated LDAP data view is attached to a pass-through SCIM resource type, its attributes will appear as schema extensions, similar to the following:

```
{
  ...
  "uid": [
    "user.8"
  ],
  "entryDN": "uid=user.8,ou=people,dc=example,dc=com",
  "urn:pingidentity:schemas:correlated:Document": {
    "documentIdentifier": [
      "user.8"
    ],
    "description": [
      "This is the description for the document user.8 under
ou=Documents,dc=example,dc=com."
    ],
    ...
  },
}
```

```

...
"schemas": [
  "urn:pingidentity:schemas:correlated:Document",
  "urn:pingidentity:schemas:passthrough:PassthroughUsers"
]
}

```

If the correlated LDAP data view is attached to a Mapping SCIM resource type, its attributes must be mapped to a schema used by the SCIM resource type. This is done through the `correlated-ldap-data-view` property in a SCIM attribute mapping.

### Configuring an LDAP mapped SCIM resource type

Add a simple mapping System for Cross-domain Identity Management (SCIM) 2.0 resource type backed by the `inetOrgPerson` LDAP objectclass to a PingDirectoryProxy Server deployment.

#### About this task

To configure an LDAP mapped SCIM resource type:

#### Steps

1. Set up the PingDirectory Server backend server.
2. Export the `encryption-settings` definition with the tool's `export` subcommand.

Example:

For this example, use the default settings to use sample data and configured data encryption.

```
encryption-settings export --output-file exported-key
```

3. Set up the PingDirectoryProxy Server and import the `encryption-settings` definition file that was created in the previous step.
4. To configure the LDAP external server, use the `create-initial-proxy-config` tool.
5. Create the SCIM schema for the resource type to use.

Example:

```
dsconfig create-scim-schema \
--schema-name urn:pingidentity:schemas:User:1.0 \
--set display-name:User
```

6. Under this schema, add the following SCIM attributes.

```
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name displayName
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--set type:complex
dsconfig create-scim-subattribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--subattribute-name familyName
dsconfig create-scim-subattribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--subattribute-name formatted
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name userName
```

## 7. Create the LDAP mapping SCIM resource type on the PingDirectoryProxy Server.

Example:

```
dsconfig create-scim-resource-type \
--type-name Users \
--type ldap-mapping \
--set enabled:true \
--set endpoint:Users \
--set structural-ldap-objectclass:inetOrgPerson \
--set include-base-dn:ou=People,dc=example,dc=com \
--set lookthrough-limit:500 \
--set core-schema:urn:pingidentity:schemas:User:1.0
```

## 8. To create the SCIM attribute mappings, run the following commands.

```
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name displayName \
--set scim-resource-type-attribute:displayName \
--set ldap-attribute:displayName
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.formatted \
--set scim-resource-type-attribute:name.formatted \
--set ldap-attribute:cn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.familyName \
--set scim-resource-type-attribute:name.familyName \
--set ldap-attribute:sn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name userName \
--set scim-resource-type-attribute:userName \
--set ldap-attribute:uid \
--set searchable:true
```

## 9. Configure the SCIM2 HTTP Servlet Extension to use a Mock Access Token Validator.

### Note:

Never use Mock Access Token Validators in production environments or with sensitive data.

```
dsconfig create-access-token-validator \
--validator-name "SCIM2 Mock Validator" \
--type mock \
--set enabled:true
dsconfig set-http-servlet-extension-prop \
--extension-name SCIM2 \
--set "access-token-validator:SCIM2 Mock Validator"
```

- To confirm that the new resource type is successfully added, send the following request to the PingDirectoryProxy Server's SCIM `/ResourceTypes` endpoint.

**Note:**

The HTTP port can vary depending on the deployment configuration.

```
curl -k -X GET \
https://localhost:8443/scim/v2/ResourceTypes \
-H 'Authorization: Bearer {"active":true}'
```

**Result:**

The following JSON object is displayed in the response in the "Resources" array.

```
{
  ...
  "Resources": [{
    "schemas": ["urn:ietf:params:scim:schemas:core:2.0:ResourceType"],
    "id": "Users",
    "name": "Users",
    "endpoint": "Users",
    "schema": "urn:pingidentity:schemas:Users:1.0",
    "meta": {
      "resourceType": "ResourceType",
      "location": "https://localhost:8443/scim/v2/ResourceTypes/Users"
    }
  }]
  ...
}
```

**Configuring Permissions for SCIM 2.0 Operations Proxy**

Configure permissions so that POST requests with the `userAdd` scope succeed on a PingDirectoryProxy Server deployment.

**Before you begin**

Set up an LDAP mapping System for Cross-domain Identity Management (SCIM) 2.0 resource type for the `inetOrgPerson` objectclass.

For more information, see [Configuring an LDAP Mapping SCIM 2.0 resource type](#) on page 1025.

**About this task**

To configure permissions:

**Steps**

- Set the SCIM resource type property:

Choose from:

- If the SCIM resource type being targeted already has a value for the `create-dn-pattern` property, skip to step 2.
- To set the SCIM resource type property, run the following `dsconfig` command on the PingDirectoryProxy Server.

```
dsconfig set-scim-resource-type-prop \
--type-name Users \
```

```
--set create-dn-
pattern:entryUUID=generated,ou=People,dc=example,dc=com
```

2. Send the following request to the PingDirectoryProxy Server's SCIM `/Users` endpoint.

```
curl -k -X POST \
https://localhost:8443/scim/v2/Users/ \
-H 'Authorization: Bearer {"active":true}' \
-H 'Content-type: application/json' \
--data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'
```

 **Note:**

The HTTP port can vary depending on the deployment configuration.

**Example:**

The response from the server should have a status of 403 and should contain a correlation ID similar to the following.

```
{
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:Error"],
  "status": "403",
  "detail": "Request failed:
correlationID='faa707b3-5d48-42e6-9e78-2c8dbb1e2cac'"
}
```

This is the expected response since this SCIM request does not have the permission needed to write to an entry. For more information on viewing the full server error message, see [Troubleshooting the SCIM 2.0 Servlet Extension](#) on page 1500.

3. Add an access control instruction (ACI) to the backend server's `ou=People,dc=example,dc=com` subtree.
  - a. Run the following `ldapmodify` command for creating the ACI on the backend PingDirectory Server server (and not the PingDirectoryProxy Server) endpoint.

```
$ ldapmodify
dn:ou=People,dc=example,dc=com
changetype:modify
add:aci
aci:(version 3.0; acl "ACI for userAdd scope"; allow (add)
oauthscope="userAdd");)
```

 **Note:**

This ACI doesn't grant write access to attributes, which means modify operations will not succeed. For more information on ACI configurations, see [Overview of access control](#) on page 718.

This ACI grants permission to add entries to the specified subtree as long as the SCIM request contains the `userAdd` scope.

4. Send the POST request to the SCIM `/Users` endpoint again, and include the `userAdd` scope in the bearer token.

**Example:**

```
curl -k -X POST \
https://localhost:8443/scim/v2/Users \
```

```
-H 'Authorization: Bearer {"active":true, "scope":"userAdd"}' \
-H 'Content-type: application/json' \
--data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'
```

**Result:**

The response from the server contains the created SCIM resource, which also contains values for the name and username attributes similar to the following.

```
{
  "name":{
    "familyName":"User",
    "formatted":"Test"
  },
  "username":"user.test",
  "id":"6f9a89b8-e766-478c-9667-def049daf6bc",
  "meta":{
    "resourceType":"Users",
    "location":"https://localhost:8443/scim/v2/Users/6f9a89b8-e766-478c-9667-def049daf6bc"
  },
  "schemas":["urn:pingidentity:schemas:User:1.0"]
}
```

**SCIM 2.0 Searches**

You can cap the total number of resources that are matched by a search to prevent exhausting server resources.

The configuration for each System for Cross-domain Identity Management (SCIM) 2.0 resource type contains a `lookthrough-limit` property that defines this limit. The default `lookthrough-limit` value is 500.

If a search request exceeds the lookthrough limit, the client receives a 400 response with an error message similar to the following.

```
{ "detail": "The search request matched too many results", "schemas":
["urn:ietf:params:scim:api:messages:2.0:Error"], "scimType": "tooMany",
"status": "400" }
```

To prevent this error:

- The client must refine its search filter to return fewer matches.
- You should configure paged searches as shown in [Using paged SCIM searches](#) on page 1495.

*Using paged SCIM searches*

When searching large data sets, the results can be numerous and produce errors about a request matching too many results relative to the lookthrough limit. Paged searches avoid these errors and reduce memory usage.

Before you begin

**Note:**

The paged System for Cross-domain Identity Management (SCIM) searches feature is not available for entry-balanced data sets. To use paged SCIM searches, your SCIM service's backend servers must be LDAP directory servers.

Complete the following one-time operation. You only need to run the command once per PingDirectory Server.

**Tip:**

If you're not sure if you have run the command, you can run it again safely.

```
$ dsconfig set-request-processor-prop \
--processor-name <proxying-request-processor> \
--set supported-control-oid:2.16.840.1.113730.3.4.9 \
--set supported-control-oid:1.2.840.113556.1.4.473
```

*<proxying-request-processor>* is the request processor handling the entries targeted by the search.

**About this task**

PingDirectory Server does SCIM searches using LDAP requests. After you complete the following steps, PingDirectory Server creates LDAP requests that include request controls that ask the backend servers to sort and page the search results before returning the results.

These request controls are marked noncritical, meaning that if the backend server can't page the results, the backend server still returns the results. In this case, PingDirectory Server handles the sorting and paging itself.

If your SCIM searches result in an error because the request matched too many results, you can avoid the error by using paged searches. For more information, see [SCIM 2.0 Searches](#) on page 1495.

For each search:

**Steps**

1. Decide your SCIM search.

**Note:**

To get paged results, your search must include at least one of these parameters: **startIndex**, **count**, or **sortBy**.

**Example:**

Your search might look like the following.

```
https://<proxy-hostname>:<proxy-port>/scim/v2/Users/?filter=st eq
"TX"&sortBy=sn&sortOrder=ascending
```

This is the corresponding encoded version.

```
https://<proxy-hostname>:<proxy-port>/scim/v2/Users/?filter=st%20eq
%20%22TX%22&sortBy=sn&sortOrder=ascending
```

On your PingDirectory Server, collect some information to use later. To find the SCIM resource type, `structural-ldap-objectclass`, `include-base-dn`, and `include-filter` values, run the following command.

```
$ dsconfig get-scim-resource-type-prop --type-name <SCIM-resource-type-
name> \
--property structural-ldap-objectclass \
--property include-base-dn \
--property include-filter
```

2. For each backend server:
  - a. Create a Virtual List View (VLV) index for your search using `dsconfig create-local-db-vlv-index` with the following options.

Option	Description
<code>--index-name</code>	Names the index.
<code>--backend-name</code>	Specifies the name of the local database backend in which to place the index.  The default database backend for PingDirectory is <code>userRoot</code> .
<code>--set base-dn</code>	Specifies the desired base distinguished name (DN). This value must match the value of the <code>include-base-dn</code> property that you found in the previous step.
<code>--set scope</code>	Is always <code>whole-subtree</code> .
<code>--set filter</code>	<p>Specifies the filter.</p> <p>Specify <code>(objectclass=&lt;name-of-SCIM-resource-type-objectclass&gt;)</code></p> <p>where <code>&lt;name-of-SCIM-resource-type-objectclass&gt;</code> is the name of the objectclass used by the SCIM resource type property, which you found in the previous step.</p> <p>If the SCIM resource type has the <code>include-filter</code> property set, also specify that property value in the filter. For example, if the filter for the objectclass is <code>(objectclass=inetorgperson)</code> and the <code>include-filter</code> value is <code>(st=CA)</code>, specify the <code>--set filter</code> argument as <code>(&amp;(objectclass=inetorgperson)(st=CA))</code>.</p> <p>Specify the LDAP attributes for all the components of your SCIM search filter.</p> <p>For example, if a mapping SCIM resource type maps the LDAP attribute <code>st</code> to the SCIM attribute <code>address.region</code> and the SCIM search filter requires that <code>address.region eq TX</code>, then this filter must include <code>(st = TX)</code> instead of <code>(address.region = TX)</code>.</p>

Option	Description
<code>--set sort-order</code>	Specifies whether to sort ascending (+) or descending (-) and the LDAP attribute to sort by.  If the SCIM search doesn't specify the <code>sortBy</code> parameter, specify the sort order as <code>+entryUUID</code> .

Example:

Each SCIM search that you want to produce paged results must have its own VLV index.

Recall the original, decoded SCIM search, shown here.

```
https://<proxy-hostname>:<proxy-port>/scim/v2/Users/?filter=st eq
"TX"&sortBy=sn&sortOrder=ascending
```

To create a VLV index for that search, run the following command:

```
$ dsconfig create-local-db-avl-index --index-name sn \
--backend-name userRoot --set base-dn:ou=people,dc=example,dc=com \
--set scope:whole-subtree \
--set filter:"(&(objectclass=inetorgperson)(st=TX))" --set sort-order:
+sn
```

- b. Using the command line, stop the server, rebuild the index, start the server, and run the `rebuild-index` command specifying the base DN and the name of the index.

```
$ rebuild-index --baseDN <baseDN-value> --index <name-of-index>
```

Example:

```
$ stop-server
$ rebuild-index --baseDN dc=example,dc=com --index vlv.sn
$ start-server
```

3. Run your SCIM search filter.

**Note:**

The search can include only the filter you specified with `--set filter` in the earlier step without the `"(objectclass=<name-of-SCIM-resource-type-objectclass>)"` portion.

In addition to the Virtual List View request control, PingDirectory Server adds a Server Side request control to the LDAP request. These request controls require certain parameters be set. To satisfy this requirement, PingDirectory Server uses the following parameters.

Parameter	Default
<code>startIndex</code>	1
<code>count</code>	The value of the <code>lookthrough-limit</code> property of the SCIM resource type being searched. That default is 500.
<code>sortBy</code>	entryUUID  With this default, the results appear unsorted.

Parameter	Default
<code>sortOrder</code>	ascending

If the client does not provide values for one of the parameters, the search uses the corresponding default value shown in the table.

### SCIM 2.0 PATCH Operations

You can use a `PATCH` request to modify a System for Cross-domain Identity Management (SCIM) 2.0 resource that has one or more required SCIM 2.0 attributes.

The requester needs permissions to read the values of these required attributes and to write permissions for the attributes being modified, even if the `PATCH` request does not alter the requirements.

#### Example

You can modify an LDAP Mapping SCIM 2.0 resource type using the following schema definition, where `uid` and `cn` are mapped to their LDAP equivalents.

```
{
  "schemas": ["urn:ietf:params:scim:schemas:core:2.0:Schema"],
  "id": "urn:test:schema:person",
  "attributes": [
    {
      "name": "uid",
      "type": "string",
      "multiValued": false,
      "required": true,
      "caseExact": false,
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none"
    },
    {
      "name": "cn",
      "type": "string",
      "multiValued": false,
      "required": false,
      "caseExact": false,
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none"
    }
  ],
  ...
}
```

The following `PATCH` operation fails if the SCIM 2 service account does not have access to both `uid` and `cn`.

```
{
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:PatchOp"],
  "Operations": [{
    "op": "add",
    "path": "cn",
    "value": "new cn value"
  }]
}
```

## Troubleshooting the SCIM 2.0 Servlet Extension

To troubleshoot the SCIM 2.0 Servlet Extension, you must enable the Debug Trace Logger.

### About this task

For security reasons, error messages specifically regarding LDAP systems are suppressed and do not appear in the HTTP responses from the server. Instead, you will see something like the following.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": "400",
  "detail": "Request failed:
  correlationID='073eb1a8-8c51-48b3-83a0-380e1d4b4ab9'"
}
```

### Steps

- To view these messages, enable the Debug Trace Logger through the administrative console or with the following `dsconfig` command.

Example:

```
dsconfig set-log-publisher-prop --publisher-name "Debug Trace Logger" \
  --set enabled:true --add scim-message-type:error
```

Result:

After you enable the Debug Trace Logger, the server begins logging information related to SCIM operations to the `/logs/debug-trace` file, as in the following example.

```
[09/Jun/2020:05:23:10.992 -0500] HTTP REQUEST requestID=3
correlationID="073eb1a8-8c51-48b3-83a0-380e1d4b4ab9" product="Ping
Identity
Directory Server" instanceName="example" startupID="Xt9fJg=="
threadID=173
from=[0:0:0:0:0:0:1]:53978 method=POST
url="https://0:0:0:0:0:0:1:9443/scim/v2/Users"
```

#### Note:

The presence of `correlationID` in these messages allows for matching the ID in the HTTP responses to the messages in the `debug-trace` log so that the appropriate LDAP error message can be determined.

## Disabling the SCIM 2.0 Servlet Extension

If you do not need to expose data through the System for Cross-domain Identity Management (SCIM) 2 servlet, you can disable the SCIM 2.0 servlet extension.

### Steps

- Remove the SCIM 2 HTTP servlet extension from the HTTPS connection handler as well as from any other HTTP connection handlers.
- Restart the handler.

## Example

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --remove http-servlet-extension:SCIM2 \
  --set enabled:false

dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true
```

## Managing Server SDK Extensions

---

The PingDirectory Server provides support for any custom extensions that you create using the Server SDK. This chapter summarizes the various features and extensions that can be developed using the Server SDK.

### About the Server SDK

You can create extensions that use the Server SDK to extend the functionality of your Directory Server. Extension bundles are installed from a .zip archive or a file system directory. You can use the **manage-extension** tool to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

**Note:**

The **manage-extension** tool may only be used with Java extensions packaged using the extension bundle format. Groovy extensions do not use the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation, which describes the extension bundle format and how to build an extension.

### Available types of extensions

The Server SDK provides support for creating a number of different types of extensions for Ping Identity Server Products, including the PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server. Some of those extensions include:

#### Cross-Product Extensions

- Access Loggers
- Alert Handlers
- Error Loggers
- Key Manager Providers
- Monitor Providers
- Trust Manager Providers
- OAuth Token Handlers
- Manage Extension Plugins

#### PingDirectory Server Extensions

- Certificate Mappers
- Change Subscription Handlers
- Extended Operation Handlers
- Identity Mappers
- Password Generators
- Password Storage Schemes

- Password Validators
- Plugins
- Tasks
- Virtual Attribute Providers

### PingDirectoryProxy Server Extensions

- LDAP Health Checks
- Placement Algorithms
- Proxy Transformations

### PingDataSync Server Extensions

- JDBC Sync Sources
- JDBC Sync Destinations
- LDAP Sync Source Plugins
- LDAP Sync Destination Plugins
- Sync SourcesSync Destinations
- Sync Pipe Plugins

For more information on the Server SDK, see the documentation available in the SDK build.

## Command-Line Tools

---

The PingDirectory Server provides a full suite of command-line tools necessary to administer the server. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

### Available command-line tools

PingDirectoryProxy provides command-line tools you can run directly in interactive, non-interactive, or script mode.

#### Tools Help

For	Use this option	Example
Information about arguments and subcommands Usage examples	<code>--help</code>	<code>dsconfig --help</code>
A list of subcommands	<code>--help-subcommands</code>	<code>dsconfig --help-subcommands</code>
More information about a subcommand	<code>--help</code> with the subcommand	<code>dsconfig list-log-publishers --help</code>

#### Note:

For more information about command-line tools, see the Ping Identity Directory Server [Command-Line Tool Reference](#).

**Command-Line Tools**

authrate	Perform repeated authentications against an LDAP directory server where each authentication consists of a search to find a user is followed by a bind to verify the credentials for that user.
backup	<p>Back up one or more Directory Proxy Server backends.</p> <p>Each backend backup is stored in a separate backend backup directory. A backend backup directory may contain multiple backups of the backend. Each backend backup directory contains a <code>backup.info</code> file providing information about each backup in the directory and an archive file for each backup. The name of the archive file includes both the backend ID and the backup ID. The backup ID may be provided to the backup command, or an ID is generated from a current timestamp.</p> <p>Backups may be full or incremental. The archive file for incremental backups contains the incremental changes since a previous backup. Each backup can be optionally compressed, encrypted, hashed or signed. A backup taken on one system can be restored on another system.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Proxy Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
base64	Encode raw data using the base64 algorithm or decode base64-encoded data back to its raw representation.
collect-support-data	<p>Collect and package system information useful in troubleshooting problems. The information is packaged as a <code>.zip</code> archive that can be sent to a technical support representative.</p> <p>Information collected may include configuration files, server monitor entries, portions of log files, JVM thread stack dumps, system metrics, and other data that may be helpful in diagnosing problems, understanding server performance, or otherwise assisting with support requests. Although the tool will do its best to obscure or omit sensitive data, and the entire archive may be encrypted if you desire, you may wish to review the resulting support data archive to ensure verify its contents. Further, the archive will include a summary of any potential problems or concerns that are identified in the course of collecting the support data.</p>

<pre>config-diff</pre>	<p>Compares Directory Server configurations and produces a <b>dsconfig</b> batch file needed to bring the source inline with the target.</p> <p>Its uses include comparing multiple servers for configuration differences, producing a batch file to reconfigure a server from scratch from the out-of-the-box configuration, and comparing a local server against an expected configuration.</p> <p>Both the source and the target configurations can be retrieved over LDAP, accessed from the local server's file system, extracted from a specific file, or retrieved from every server in a configuration server group. Also, with the exception of accessing a configuration from a specific file, the source and/or target configurations can be compared as they existed at any point in the past, including the baseline, pre-installation configuration.</p> <p>Some configuration differences (those that will always differ between instances, like instance-name) are excluded by default to reduce the amount of spurious output, but these can be included by specifying the <b>--includeExpectedDifferences</b> command. Further differences can be excluded with the <b>--exclude</b> option.</p> <p>This tool attempts to generate a batch file that can be applied to the source server without any errors. However, there are some edge case configurations that the tool is not sophisticated enough to handle. For example, it cannot handle two peer configuration objects that would require swapping values for a property (for example, evaluation-order-index) that must be unique within the server. It will still generate a <b>dsconfig</b> batch file that includes these changes, but they might be rejected by the server. In these rare cases, the batch file can be hand edited so that it can be applied to a running server or it can be applied with the server shut down using <b>dsconfig --offline</b>.</p>
<pre>create-initial-proxy-config</pre>	<p>Create an initial Directory Server configuration.</p> <p>This tool is used to configure a basic Directory Proxy Server. The tool will prompt for basic information about your topology including directory server instances, their locations, and the credentials for communicating with them. This tool will record the configuration in a <b>dsconfig</b> batch file and apply the configuration to the local Directory Proxy Server.</p> <p>The following assumptions are made about the topology to expedite setup:</p> <ul style="list-style-type: none"> <li>▪ All servers will be accessible via a single user account.</li> <li>▪ All servers support the same communication security type.</li> <li>▪ All servers are Ping Identity, Nokia 8661, Sun Java System 5.x, 6.x, or 7.x, or Red Hat (including Fedora and 389) directory servers.</li> </ul> <p>If your topology does not meet these assumptions, use this tool to define a basic configuration and then use the <b>dsconfig</b> tool or the Administrative Console to customize the configuration.</p>
<pre>create-rc-script</pre>	<p>Create an RC script to start, stop, and restart the Directory Server on UNIX-based systems.</p>
<pre>create-systemd-script</pre>	<p>Create a <b>systemd</b> script to start and stop the Directory Server on Linux-based systems.</p>

deliver-one-time-password	Generate and deliver a single-use token to a user through some out-of-band mechanism. The user can provide that token to the password modify extended request in lieu of the user's current password in order to select a new password.
deliver-password-reset-token	Generate and deliver a single-use token to a user through some out-of-band mechanism. The user can provide that token to the password modify extended request in place of the user's current password to select a new password.
dsconfig	<p>View and edit the Directory Server configuration.</p> <p>This utility offers three primary modes of operation, the interactive mode, the non-interactive mode and batch mode. The interactive mode supports viewing and editing the configuration via an intuitive, menu driven environment. Running <b>dsconfig</b> in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the server. To start <b>dsconfig</b> in interactive command-line mode, simply invoke the <b>dsconfig</b> shell script or batch file without any arguments.</p> <p>The <b>dsconfig</b> non-interactive command-line mode provides a simple way to make arbitrary changes to the PingDirectoryProxy Server by invoking it on the command-line. If you want to use administrative scripts to automate the configuration process, then run the <b>dsconfig</b> command in non-interactive mode.</p> <p>The <b>dsconfig</b> tool provides a batching mechanism that reads multiple <b>dsconfig</b> invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting in that it minimizes LDAP connections and JVM invocations that normally occur with each <b>dsconfig</b> call. You can view the logs/config-audit.log file to review the configuration changes made to the PingDirectoryProxy Server and use them in the batch file.</p>

dsjavaproperties	<p>Configure the Java virtual machine (JVM) arguments used to run the Directory Server and associated tools.</p> <p>The options managed by this tool are stored in <code>config/java.properties</code>. Typically you should not edit that file directly but rather run this tool specifying <code>--jvmTuningParameter</code> arguments to customize JVM options appropriate for this system. It is necessary however that this tool be run in the event that <code>config/java.properties</code> must be edited by hand. Note that the changes will only apply to this Directory Proxy Server installation. No modifications will be made to your environment variables.</p> <p>Memory and other settings for the tool JVMs including the <code>start-server</code> tool can be tuned during initialization by specifying one or more instances of the <code>--jvmTuningParameter</code> option when invoking this tool. Supported values are as follows:</p> <ul style="list-style-type: none"> <li>▪ <code>NONE</code> Explicitly specify no parameters.</li> <li>▪ <code>PROXY_ENTRY_BALANCING</code> Increase the amount of memory used by the Directory Proxy Server in an entry-balanced environment in order to allow for better global index performance.</li> <li>▪ <code>AGGRESSIVE</code> This system is dedicated to running only this server. The amount of memory allocated to this server will be computed accordingly.</li> <li>▪ <code>SEMI_AGGRESSIVE</code> This system is shared by multiple server processes. The amount of memory allocated to this server will be computed accordingly.</li> </ul> <p>If no parameters are specified the parameters specified by the previous invocation of this tool or setup will be used. Use the <code>NONE</code> option to explicitly specify no parameters.</p>
dump-dns	<p>Obtain a listing of all of the distinguished names (DNs) for all entries below a specified base DN in the Directory Server.</p>
encrypt-file	<p>Encrypt or decrypt data using a key generated from a user-supplied passphrase, a key generated from an encryption settings definition, or a key shared among servers in the topology. The data to be processed can be read from a file or standard input, and the resulting data can be written to a file or standard output. You can use this command to encrypt and subsequently decrypt arbitrary data, or to decrypt encrypted backups, LDIF exports, and log files generated by the server.</p>
encryption-settings	<p>Manage the server encryption settings database.</p> <p>More information about the cipher algorithms and transformations available for use may be found in the Java Cryptography Architecture Reference Guide, as well as the Standard Algorithm Name Documentation for your chosen JDK implementation used by this server.</p>
enter-lockdown-mode	<p>Request that the Directory Server enter lockdown mode, during which it only processes operations requested by users holding the <code>lockdown-mode</code> privilege.</p> <p>While in lockdown mode, the Directory Proxy Server rejects all requests from users that do not hold the <code>lockdown-mode</code> privilege.</p>

<code>export-reversible-passwords</code>	Requests that the server export entries from a specified backend in LDIF form, including clear-text representations of any passwords encoded with a reversible storage scheme. This tool may only be used over a secure connection and when authenticated as a user with the <code>permit-export-reversible-passwords</code> privilege. The output will be encrypted using a key generated from either a user-supplied passphrase or an encryption settings definition.
<code>generate-totp-shared-secret</code>	Generate a shared secret that can be used to generate Time-based One-time Password (TOTP) authentication codes for use in authenticating with the <code>UNBOUNDID-TOTP SASL</code> mechanism, or in conjunction with the <code>validate TOTP password</code> extended operation.
<code>global-index-size</code>	Estimates the size in memory of one or more global indexes from the actual number of keys, the configured number of keys and the average key size. The estimate could be slightly higher or lower than the actual size. An estimate can be provided for more than one index in one invocation by providing multiple sets of options.
<code>identify-references-to-missing-entries</code>	This tool may be used to identify entries containing one or more attributes which reference entries that do not exist. This may require the ability to perform unindexed searches and/or the ability to use the simple paged results control.
<code>identify-unique-attribute-conflicts</code>	This tool may be used to identify unique attribute conflicts. That is, it may identify values of one or more attributes which are supposed to exist only in a single entry but are found in multiple entries.
<code>indent-ldap-filter</code>	Parse a provided LDAP filter string and displays it as a multi-line form that makes it easier to understand its hierarchy and embedded components. If possible, it also simplifies the provided filter in certain ways, such as removing unnecessary levels of hierarchy like an <code>AND</code> embedded in an <code>AND</code> .
<code>ldap-debugger</code>	Intercept and decode LDAP communication.

ldap-diff	<p>Compare the contents of two LDAP directory server servers.</p> <p>The <code>ldap-diff</code> tool outputs the difference between data stored in two LDAP servers into an LDIF file. This file could be used with the <code>ldapmodify</code> command to bring the source directory server in sync with the target directory server. The specific entries to compare can be controlled with the <code>--searchFilter</code> option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. Specific attributes can also be excluded by prepending a <code>^</code> character to the attribute. On Windows operating systems, excluded attributes must be quoted, for example, <code>"^attrToExclude"</code>. When retrieving entries from a PingDirectory Server, the <code>@objectClassName</code> notation can be used to compare only attributes that are defined for a given objectclass.</p> <p>This command can be used on servers actively being modified, without reporting false positives due to replication delays, by checking differing entries multiple times. By default, it will re-check each differing entry twice, pausing two seconds between checks. These settings can be configured with the <code>--numPasses</code> and <code>--secondsBetweenPass</code> options. The output is formatted so that delete operations come first, modify operations come next, and add operations come last. This gives the best chance that the resulting output file can be used to bring the source server into sync with the target server without causing any conflicts. This takes into account attribute uniqueness constraints as well as that child entries must be deleted before parents and parents must be added before children.</p> <p>The directory user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the PingDirectory Server, the out-of-the-box <code>cn=Directory Manager</code> user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry:</p> <ul style="list-style-type: none"><li>▪ <code>ds-cfg-default-root-privilege-name: unindexed-search</code></li><li>▪ <code>ds-cfg-default-root-privilege-name: bypass-acl</code></li><li>▪ <code>ds-rlim-size-limit: 0</code></li><li>▪ <code>ds-rlim-time-limit: 0</code></li><li>▪ <code>ds-rlim-idle-time-limit: 0</code></li><li>▪ <code>ds-rlim-lookthrough-limit: 0</code></li></ul> <p>For servers from other vendors, consult their documentation for configuring the proper privileges.</p> <p>The <code>ldap-diff</code> tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For directories that contain tens of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by <code>ldap-diff</code> can be customized by editing the <code>ldap-diff.java-args</code> setting in the <code>config/java.properties</code> file and running the <code>dsjavaproperties</code> command.</p>
-----------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

ldap-result-code	<p>Display and query LDAP result codes.</p> <p>This tool may be used to list all known defined LDAP result codes, retrieve the name of the result code with a given integer value, or search for all result codes with names containing a given substring.</p> <p>At most one of the <code>--list</code>, <code>--int-value</code>, and <code>--search</code> arguments may be provided. If none of them is provided, then the <code>--list</code> option will be chosen by default.</p>
ldapcompare	<p>Perform compare operations in an LDAP directory server. Compare operations may be used to efficiently determine whether a specified entry has a given value.</p> <p>The exit code for this tool will indicate whether processing was successful or unsuccessful, and to provide a basic indication of the reason for unsuccessful attempts. By default, it will use an exit code of zero (which corresponds to the LDAP 'success' result) if all compare operations completed with a result code of either 'compare false' or 'compare true' (integer values 5 and 6, respectively), but if the <code>--useCompareResultCodeAsExitCode</code> argument is provided, only one compare assertion is performed, and it yields an exit code of 'compare false' or 'compare true', then the numeric value for that result code will be used as the exit code. If any error occurs during processing, then the exit code will be a nonzero value that reflects the first error result that was encountered.</p> <p>The attribute type and assertion value to use for the compare operations will typically be provided as the first unnamed trailing argument provided on the command line. It should be formatted with the name or OID of the target attribute type followed by a single colon and the string representation of the assertion value. Alternatively, the attribute name or OID may be followed by two colons and the base64-encoded representation of the assertion value, or it may be followed by a colon and a less-than symbol to indicate that the assertion value should be read from a file (in which case the exact bytes of the file, including line breaks, will be used as the assertion value).</p> <p>The DN's of the entries to compare may either be provided on the command line as additional unnamed trailing arguments after the provided attribute-value assertion, or they may be read from a file whose path is provided using the <code>--dnFile</code> argument.</p> <p>If the attribute-value assertion is provided on the command line as an unnamed trailing argument, then the same assertion will be performed for all operations. If multiple types of assertions should be performed, then you may use the <code>--assertionFile</code> argument to specify the path to a file containing both attribute-value assertions and entry DN's.</p>
ldapdelete	<p>Delete one or more entries from an LDAP directory server. You can provide the DN's of the entries to delete using named arguments, as trailing arguments, from a file, or from standard input. Alternatively, you can identify entries to delete using a search base DN and filter.</p>
ldapmodify	<p>Apply a set of <code>add</code>, <code>delete</code>, <code>modify</code>, and/or <code>modify DN</code> operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the <code>ldifFile</code> argument. Change records must be separated by at least one blank line.</p>

ldappasswordmodify	<p>Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in <a href="#">RFC 3062</a>), a standard LDAP modify operation, or an Active Directory-specific modification.</p> <p>Unless the password change method is explicitly specified (using the <code>--passwordChangeMethod</code> argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password change method will be selected, using a regular LDAP modify to update the <code>unicodePwd</code> attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute.</p> <p>The new password to set for the user may be specified in one of several ways. It may be directly provided on the command line, read from a specified file, interactively prompted from the user, or automatically generated by this tool. If the new password is not specified using any of those methods, and if the password is to be updated using the password modify extended operation, then the new password field of the request will be left blank to indicate that the server should generate a new password for the user and include it in the response to the client. If no new password is specified and some other password change method is selected, then the tool will exit with an error.</p> <p>The current password for the user may also be specified. This is optional, although some servers may require a user to provide their current password when setting a new one. If a current password is provided (whether given as a command-line argument, read from a specified file, or interactively requested from the user), and if a regular LDAP modify operation is used to change the password, then the resulting modify request will include a delete of the current value and an add of the new value. If no current password is provided, then the modify request will replace any existing password(s) with the new value.</p>
ldapsearch	<p>Process one or more searches in an LDAP directory server.</p> <p>The criteria for the search request can be specified in a number of different ways, including providing all of the details directly via command-line arguments, providing all of the arguments except the filter via command-line arguments and specifying a file that holds the filters to use, or specifying a file that includes a set of LDAP URLs with the base DN, scope, filter, and attributes to return.</p> <p>See the examples below for a number of sample command lines for this tool.</p>

<p><code>ldif-diff</code></p>	<p>Compare the contents of two files containing LDIF entries. The output is an LDIF file containing the <code>add</code>, <code>delete</code>, and <code>modify</code> change records needed to convert the data in the source LDIF file into the data in the target LDIF file.</p> <p>This tool works best with small LDIF files because it reads the entire contents of the source and target LDIF files into memory so they can be quickly compared. If you encounter an out of memory error while running the tool, you may need to increase the amount of memory available to the JVM used to invoke it.</p> <p>The amount of memory available to the JVM may be customized by invoking the JVM with the <code>-Xms</code> and <code>-Xmx</code> arguments (which specify the initial and maximum amounts of memory that it may use, respectively). These arguments should be immediately followed (without any intervening space) by an integer and a unit to specify the amount of memory that may be used. The unit may be either <code>m</code> to indicate that the size is in megabytes, or <code>g</code> to indicate that it is in gigabytes. For example, <code>-Xms512m</code> indicates that the JVM should be given an initial heap size of 512 megabytes, while <code>-Xmx2g</code> indicates that it should be given a maximum heap size of two gigabytes.</p> <p>When invoking the <code>ldif-diff</code> tool included in the installation of a Ping Identity server product, you may edit the <code>config/java.properties</code> file to specify the arguments to use when invoking the JVM. After modifying the file, run the <code>dsjavaproperties</code> tool to ensure that those changes will be used for subsequent tool invocations.</p>
<p><code>ldifmodify</code></p>	<p>Apply a set of changes (including <code>add</code>, <code>delete</code>, <code>modify</code>, and <code>modify DN</code> operations) to a set of entries contained in an LDIF file. The changes will be read from a second file (containing change records rather than entries), and the updated entries will be written to a third LDIF file. Unlike <code>ldapmodify</code>, the <code>ldifmodify</code> cannot read the changes to apply from standard input.</p> <p>All of the change records will be read into memory before processing begins, so it is important to ensure that the tool is given enough memory to hold those change records. However, it will only operate on a single source entry at a time, so the size of the source LDIF file does not significantly impact the amount of memory that the tool requires.</p> <p>Note that the tool will attempt to correctly handle multiple changes affecting the same entry. However, because it only operates on one entry at a time, it cannot always behave in exactly the same way as if it were applying the changes over LDAP to a server populated with the source LDIF file. For example, it is not possible to reject an attempt to delete an entry that has subordinates, so any delete will be treated as a subtree delete.</p> <p>Further, not all types of <code>modify DN</code> change records are supported. In particular, <code>modify DN</code> change records are not permitted if they target any entry that has been targeted by a previous change record (for example, renaming an entry that was created by a previous <code>add</code> change record).</p> <p>Finally, it cannot perform other types of validation, like ensuring that all of the necessary superior entries exist when adding a new entry, or ensuring that a <code>modify DN</code> will not introduce a conflict with an existing entry.</p>

<code>ldifsearch</code>	Search one or more LDIF files to identify entries matching a given set of criteria.
<code>leave-lockdown-mode</code>	Request that the Directory Server leave lockdown mode and resume normal operation.  While in lockdown mode, the Directory Proxy Server rejects all requests from users that do not hold the <code>lockdown-mode</code> privilege.  Note that the Directory Proxy Server may place itself in lockdown mode under certain conditions (for example, if it detects a security problem like a malformed access control rule that may have otherwise resulted in exposure of sensitive data).
<code>list-backends</code>	List the backends and base DNs configured in Directory Server.
<code>load-ldap-schema-file</code>	Load the schema definitions contained in a specified LDIF file into the schema for a running server. This tool may only be used in conjunction with a server instance running on the local system.
<code>make-ldif</code>	Generate LDIF data based on a definition in a template file. See the server's <code>config/MakeLDIF</code> directory for example template files. In particular, the <code>examples-of-all-tags.template</code> file shows how to use all of the tags for generating values.
<code>manage-account</code>	Retrieve or update information about the current state of a user account. Processing will be performed using the password policy state extended operation, and you must have the <code>password-reset</code> privilege to use this extended operation.
<code>manage-certificates</code>	Manage certificates and private keys in a JKS, PKCS #12, PKCS #11, or BCFKS key store.
<code>manage-extension</code>	Install or update PingDirectoryProxy Server extension bundles.  An extension bundle is a package of extension(s) that utilize the Server SDK to extend the functionality of PingDirectoryProxy Server. Extension bundles are installed from a zip archive or file system directory. PingDirectoryProxy Server will be restarted if running to activate the extension(s).
<code>manage-profile</code>	Generate, compare, install, and replace server profiles.  Server profiles define a format for the configuration of a server, including <code>dsconfig</code> , initial DIT, setup arguments, server SDK extensions, and other files. These are combined into one concrete structure. This tool provides subcommands that can be used to generate a new profile from an existing server, to set up a new server, and to replace an existing server's profile with a different profile.  A template server profile file structure can be found in the <code>resource/</code> directory.
<code>manage-tasks</code>	Access information about pending, running, and completed tasks scheduled in the Directory Server.

manage-topology	<p>Tool to manage the topology registry.</p> <p>The topology registry is a branch of the configuration DIT (<code>cn=Topology,cn=config</code>). It stores all metadata about server instances, including their instance and listener certificates, secret keys, server groups and administrative user accounts. In addition, it also stores information about the replication topology (replication server ID and replication domain ID) when replication is enabled among servers in a Directory topology. Last but not least, it stores the license key required to install the server. Changes to the topology registry on one server are automatically mirrored to other servers in the topology. The <code>dsconfig</code> tool, configuration API or the management console may be used to make changes to the topology registry. This tool allows some additional capability such as exporting the contents of the registry as a JSON file.</p>
modrate	Perform repeated modifications against an LDAP directory server.
move-subtree	Move all entries in a specified subtree from one server to another.
oid-lookup	<p>Search the OID registry to retrieve information about items that match a given OID or name.</p> <p>The string to use to search the OID registry should be provided as an unnamed trailing argument. All items in the OID registry will be examined, and any items that contain the provided string in its OID, name, type, origin, or URL will be matched. If no search string is provided, the entire OID registry will be displayed.</p>
parallel-update	<p>Use multiple concurrent threads to apply a set of add, delete, modify, and modify DN operations read from an LDIF file.</p> <p>As with other tools like <code>ldapmodify</code>, changes in the LDIF file to be processed should be ordered such that if there are any dependencies between changes (for example, if one add change record creates a parent entry and another add change record creates a child of that parent), prerequisite changes come before the changes that depend on them. When this tool is preparing to process a change, it will determine whether the new change depends on any other changes that are currently in progress, and if so, will delay processing that change until its dependencies have been satisfied. If a change does not depend on any other changes that are currently being processed, then it can be processed in parallel with those changes.</p> <p>This tool will keep track of any changes that fail in a way that indicates they succeed if re-tried later (for example, an attempt to add an entry that fails because its parent does not exist, but its parent may be created later in the set of LDIF changes), and can optionally re-try those changes after processing is complete. Any changes that are not retried, as well as changes that still fail after the retry attempts, will be written to a rejects file with information about the reason for the failure so that an administrator can take any necessary further action upon them.</p>

<pre>prepare-external-server</pre>	<p>Prepare and a directory server for communication..</p> <p>This tool performs several functions that update a directory server to be used as an external server by the Directory Proxy Server. If you use the <code>create-initial-proxy-config</code> tool to define and prepare directory server instances use of this tool is unnecessary.</p> <p>Among other functions, this tool creates the proxy user account, sets the correct password, and configures the account with required privileges. If necessary you are prompted for manager credentials in order that the tool can perform any required modifications to the external server.</p> <p>When using this tool, specify the LDAP connection options to establish a connection to the external server. Other options are used to specify information about the Directory Proxy Server which this tool uses to configure the external server.</p> <p>If a secure connection will be used by the Directory Proxy Server to communicate with the external server you can supply the path and password of the truststore to have this tool populate the Directory Proxy Server's truststore with the server certificate of the external server.</p>
<pre>profile-viewer</pre>	<p>View information in data files captured by the Directory Server profiler.</p> <p>Profiler data files are generated by the Profiler plugin. To create these data files, set the <code>profile-action</code> attribute of the Profiler configuration object to <code>start</code> to begin collection. Set the <code>profile-action</code> attribute to <code>stop</code> to end collection and have the plugin write the file to <code>logs/profile.{timestamp}</code>.</p>
<pre>register-yubikeyp-otp-device</pre>	<p>Registers a YubiKey OTP device with the Directory Server for a specified user so that the device may be used to authenticate that user in conjunction with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. Alternately, it may be used to unregister one or more YubiKey OTP devices for a user so that they may no longer be used to authenticate that user.</p>
<pre>reload-http-connection-handler-certificates</pre>	<p>Reload HTTPS Connection Handler certificates.</p> <p>This tool schedules an operation to run within the Directory Proxy Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
<pre>reload-index</pre>	<p>Reload the contents of the global index.</p> <p>Reloads the contents of the global index for a given base DN. It is possible to reload all configured indexes in the global index (which includes the <code>rdn</code> index and all attribute indexes), or reload only those indexes specified by name.</p> <p>This tool schedules an operation to run within the Directory Proxy Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>

<pre>remove-attribute-type- from-schema</pre>	<p>Safely remove an attribute type definition from the server schema.</p> <p>The tool will perform an appropriate set of validation before actually removing the attribute type from the schema. The below conditions must be satisfied before the attribute type may be removed.</p> <ul style="list-style-type: none"> <li>▪ The requester must have the <code>update-schema</code> privilege.</li> <li>▪ The attribute type must not be referenced by any other schema element.</li> <li>▪ The attribute type must not be defined in any schema file that is included with the Directory Proxy Server. Only custom attribute types may be removed from the schema.</li> <li>▪ The attribute type must not be referenced in the server configuration (for example, it must not be indexed by any backend).</li> <li>▪ The attribute type must not be present in any entry that exists in any backend.</li> </ul> <p>This tool schedules an operation to run within the Directory Proxy Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
<pre>remove-backup</pre>	<p>Safely remove a backup and optionally all of its dependent backups from the specified Directory Server backend.</p> <p>This tool deletes the specified backup archive and updates the backup descriptor accordingly. If there are other (incremental) backups that depend on this backup, they will need to be removed before the base backup can be removed, unless you choose the <code>--force</code> option.</p> <p>If you choose the <code>--force</code> option, the specified backup and all other backups depending on it are removed. You can use the <code>--showDependencies</code> option to see what incremental backups depend on a given base backup.</p> <p>As an alternative to removing a specific backup, you can automatically remove backups outside of specified count or age criteria. The <code>--retainFullBackupCount</code> argument can be used to indicate that the specified number of full backups should be retained, and any other full backups in the directory are eligible to be removed (along any incremental backups that depend on them). The <code>--retainFullBackupAge</code> argument can be used to indicate that any full backups (and dependent incremental backups) older than the specified age are eligible to be removed.</p>
<pre>remove-defunct-server</pre>	<p>Remove a server from this server's topology.</p> <p>This tool will remove the specified server from the topology. In general, the <code>uninstall</code> tool should be used to remove a server from the topology. The <code>remove-defunct-server</code> tool should only be used if a prior attempt to uninstall a server was unsuccessful or the system where the server was installed is no longer available, leaving the server permanently inaccessible from the topology. If the defunct server is online and is able to reach other servers in the topology, running <code>remove-defunct-server</code> from it will cleanly remove it from the topology. If it cannot reach the other servers, then <b><code>remove-defunct-server</code></b> must also be run from one of the online servers.</p>

<pre>remove-object-class- from-schema</pre>	<p>Safely remove an object class definition from the server schema.</p> <p>The tool will perform an appropriate set of validation before actually removing the object class from the schema. The below conditions must be satisfied before the object class may be removed.</p> <ul style="list-style-type: none"> <li>▪ The requester must have the update-schema privilege.</li> <li>▪ The object class must not be referenced by any other schema element.</li> <li>▪ The object class must not be defined in any schema file that is included with the Directory Proxy Server. Only custom object classes may be removed from the schema.</li> <li>▪ The object class must not be referenced in the server configuration.</li> <li>▪ The object class must not be present in any entry that exists in any backend.</li> </ul> <p>This tool schedules an operation to run within the Directory Proxy Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
<pre>replace-certificate</pre>	<p>Replace the listener certificate for this Directory Server server instance.</p> <p>Only one backend may be restored at a time by the restore command. The Directory Proxy Server should be stopped unless task connection options are supplied for a running server. You can list the backups contained in a particular backend backup directory. A backup taken on one system can be restored on another system.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Proxy Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
<pre>restore</pre>	<p>Restore a backup of a Directory Server backend.</p> <p>Only one backend may be restored at a time by the restore command. The Directory Proxy Server should be stopped unless task connection options are supplied for a running server. You can list the backups contained in a particular backend backup directory. A backup taken on one system can be restored on another system.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Proxy Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
<pre>revert-update</pre>	<p>Revert this server package's most recent update.</p>
<pre>review-license</pre>	<p>Review and indicate your acceptance of the license agreement defined in <code>/legal/LICENSE.txt</code>.</p>

rotate-log	<p>Trigger the rotation of one or more log files.</p> <p>If the file argument is provided one or more times to specify the target log file paths, then only those log files will be rotated. If the file argument is not given, then the server will trigger rotation for all supported log files.</p> <p>You must have the <code>config-read</code> and <code>config-write</code> privileges to run this tool, and you must have the necessary access control rights to create and monitor entries in the task backend.</p> <p>This tool schedules an operation to run within the Directory Proxy Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
sanitize-log	<p>Sanitize the contents of a server log file to remove potentially sensitive information while still attempting to retain enough information to make it useful for diagnosing problems or understanding load patterns. The sanitization process operates on fields that consist of name-value pairs. The field name is always preserved, but field values might be tokenized or redacted if they might include sensitive information. Supported log file types include the file-based access, error, sync, and resync logs, as well as the operation timing access log and the detailed HTTP operation log. Sanitize the audit log using the <code>scramble-ldif</code> tool.</p>
schedule-exec-task	<p>Schedule an exec task to run a specified command in the server. To run an exec task, a number of conditions must be satisfied: the server's global configuration must have been updated to include <code>com.unboundid.directory.server.tasks.ExecTask</code> in the set of allowed-task values, the requester must have the 'exec-task' privilege, and the command to execute must be listed in the <code>exec-command-whitelist.txt</code> file in the server's <code>config</code> directory. The absolute path (on the server system) of the command to execute must be specified as the first unnamed trailing argument to this program, and the arguments to provide to that command (if any) should be specified as the remaining trailing arguments. The server root is used as the command's working directory, so any arguments that represent relative paths are interpreted as relative to that directory.</p>
search-and-mod-rate	<p>Perform repeated searches against an LDAP directory server and modify each entry returned.</p>
search-logs	<p>Search across log files to extract lines matching the provided patterns, like the <code>grep</code> command-line tool. The benefits of using this tool over <code>grep</code> are its ability to handle multi-line log messages, extract log messages within a given time range, and the inclusion of rotated log files.</p>
searchrate	<p>Perform repeated searches against an LDAP directory server.</p>
server-state	<p>View information about the current state of the Directory Server process.</p>
set-delegated-admin-aci	<p>Request that the Directory Server assign appropriate access control instruction (ACI) for configured delegated administrators of the Delegated Admin API.</p>

setup	<p>Perform the initial setup for the Directory Server instance.</p> <p>This tool features both interactive and non-interactive modes for accepting the product license terms and initially configuring a server instance.</p>
start-server	Start the Directory Server.
status	<p>Display basic server information.</p> <p>This tool prints information about the server, such as version, connection handlers, and data sources. Some information may not be available if the server is not running, or if authentication credentials are missing or do not have sufficient privileges, or if the invoking user does not have sufficient file system access rights.</p>
stop-server	<p>Stop or restart the server.</p> <p>This tool is used to stop or restart the local instance of the server (by omitting LDAP connection options), or a remote server (by interacting with it over LDAP). In addition, this tool is used to schedule the server for shutdown at a later time using the server's task interface.</p>
subtree-accessibility	List or update the set of subtree accessibility restrictions defined in the Directory Server.
sum-file-sizes	<p>Calculate the sum of the sizes for a set of files.</p> <p>This tool is used to find the sum of the sizes of one or more files. If any of the files specified is a directory then it will be recursively processed.</p>
summarize-access-log	Examine one or more access log files from Ping Identity, UnboundID, or Nokia/Alcatel-Lucent 8661 server products to display a number of metrics about operations processed within the server.
transform-ldif	Apply one or more changes to entries or change records read from an LDIF file, writing the updating records to a new file. This tool can apply a variety of transformations, including scrambling attribute values, redacting attribute values, excluding attributes or entries, replacing existing attributes, adding new attributes, renaming attributes, and moving entries from one subtree to another.
uninstall	<p>Uninstall Directory Server.</p> <p>This tool removes the entire server or individual server components from the file system. If this server is a member of an existing topology, you must first remove references to this server in the other servers using the remove-defunct-server tool.</p>
update	Update a deployed server so its version matches the version of this package.

validate-acis	<p>Validate a set of access control definitions contained in an LDAP server (including Oracle DSEE instances) or an LDIF file to determine whether they are acceptable for use in the Directory Server.</p> <p> <b>Note:</b></p> <p>Output generated by this tool is LDIF, but each entry in the output has exactly one ACI, so entries that have more than one ACI appear multiple times in the output with different ACI values.</p>
validate-file-signature	<p>Validate file signatures. For best results, file signatures should be validated by the same instance used to generate the file. However, it might be possible to validate signatures generated on other instances in a replicated topology.</p>
validate-ldap-schema	<p>Validate an LDAP schema read from one or more LDIF files.</p>
validate-ldif	<p>Validate the contents of an LDIF file against the server schema.</p>

## Saving Options in a File

### Creating a tools properties file

You can set properties that apply to all tools or are tool-specific. These properties serve as defaults for the command-line options they represent.

#### Steps

1. Use a text editor to open the default tools properties file (`config/tools.properties`) or a different properties file.

#### Note:

If you use a file other than `config/tools.properties`, invoke the tool with the `--propertiesFilePath` option to specify the path to your properties file.

2. Set or change properties that apply to all tools.

Use the standard Java properties file format (`name=value`) to set properties. For example, the following properties define a set of LDAP connection parameters.

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

```
baseDN=dc=example,dc=com
```

**Note:**

Properties files do not allow quotation marks of any kind around values.

Escape spaces and special characters.

Whenever you specify a path, do not use ~ to refer to the home directory. The server does not expand the ~ value when read from a properties file.

### 3. Set or change properties that apply to specific tools.

Tool-specific properties start with the name of the tool followed by a period. These properties take precedence over properties that apply to all tools. The following example sets two ports: one that applies to all tools (`port=1389`) and a tool-specific one that `ldapsearch` uses instead (`ldapsearch.port=2389`).

```
hostname=server1.example.com
port=1389
ldapsearch.port=2389
bindDN=cn=Directory\ Manager
```

### 4. Save your changes and close the file.

## Evaluation of command-line options and file options

You can specify options for a command-line tool on the command line, in a properties file, or both.

Options you specify on a tool's command line take priority over options in a properties file.

Consider the following scenarios.

Command-line options	Directory Server uses ...
No command-line options	The options in the default <code>&lt;server-root&gt;/config/tools.properties</code> file
Command-line options other than the <code>--propertiesFilePath &lt;my-properties-file&gt;</code> option	The command-line options, which take priority if the options are also in the <code>&lt;server-root&gt;/config/tools.properties</code> file The file options for options that are only in the default <code>&lt;server-root&gt;/config/tools.properties</code> file
Only the <code>--propertiesFilePath &lt;my-properties-file&gt;</code> option	The options in <code>&lt;my-properties-file&gt;</code>
The <code>--propertiesFilePath &lt;my-properties-file&gt;</code> option and other command-line options	The command-line options, which take priority if the options are also in <code>&lt;my-properties-file&gt;</code> The file options for options that are only in <code>&lt;my-properties-file&gt;</code>
The <code>--noPropertiesFile</code> option and other command-line options	Only the options you specify on the command line, ignoring the default properties file

### Example

Consider this example properties file that is saved as `<server-root>/bin/tools.properties`:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

Directory Server checks command-line options and file options to determine the options to use, as explained below.

- All options presented with the tool on the command line take precedence over any options in a properties file.

In the following example, the command runs with the options specified on the command line (`--port` and `--baseDN`). With the `port` value both on the command line and in the properties file, the command-line value takes priority. The command uses the `bindDN` and `bindPassword` values specified in the properties file.

```
$ bin/ldapsearch --port 2389 --baseDN ou=People,dc=example,dc=com \
  --propertiesFilePath bin/tools.properties "(objectclass=*)"
```

- If you specify the properties file using the `--propertiesFilePath` option and no other command-line options, Directory Server uses only the options in the specified properties file:

```
$ bin/ldapsearch --propertiesFilePath bin/tools.properties \
  "(objectclass=*)"
```

- If do not specify any command-line options, Directory Server attempts to locate the default properties file in the following location:

```
<server-root>/config/tools.properties
```

By moving your `tools.properties` file from `<server-root>/bin` to `<server-root>/config`, you do not have to specify the `--propertiesFilePath` option. That change shortens the previous command to the following command.

```
$ bin/ldapsearch "(objectclass=*)"
```

## Sample dsconfig batch files

The `config/sample-dsconfig-batch-files` directory contains **dsconfig** batch files that you can use to configure various aspects of the server. For example, these files can enable additional security capabilities or take advantage of features that might require customization from one environment to another.

Each file includes comments that describe the purpose and benefit of its configuration change. You can choose which of the changes you want to apply.

You need to customize some of the batch files to provide values that might vary from one environment to another. To apply a batch file that requires changes, copy it to another directory and edit the copy. Leave the files in the `config/sample-dsconfig-batch-files` directory unchanged so that they can be updated when you upgrade the server. To specify the path to the file that contains the changes to apply, use the **dsconfig** tool (`bin/dsconfig` on UNIX-based systems or `bat\dsconfig.bat` on Windows) with the `--batch-file` argument.

You should also provide the arguments needed to connect and authenticate to the server. The `--no-prompt` argument ensures that the tool does not block while waiting for input if any necessary arguments are missing. Consider this example.

```
bin/dsconfig --hostname localhost \
  --port 636 --useSSL --trustStorePath config/truststore \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPasswordFile admin-password.txt \
  --batch-file config/hardening-dsconfig-batch-files/reject-insecure-
  request.dsconfig \
  --no-prompt
```

## Running task-based tools

Directory Server has a Tasks subsystem that allows you to schedule basic operations, such as **backup**, **restore**, **rotate-log**, **schedule-exec-task**, **stop-server**, and others. All task-based tools require the `--task` option that explicitly indicates the tool is to run as a task rather than in offline mode.

The following table shows the options that you can use for task-based operations:

### Options for task-based operations

Option	Description
<code>--task</code>	Indicates that the tool is invoked as a task. The <code>--task</code> option is required. If you invoke a tool as a task without this <code>--task</code> option, then a warning message is displayed stating that it must be used. If the <code>--task</code> option is provided but the tool was not given the appropriate set of authentication arguments to the server, then an error message is displayed and the tool exits with an error.
<code>--start &lt;startTime&gt;</code>	Indicates the date and time, expressed in the format 'YYYYMMDDhhmmss', when the operation is to start.  A value of '0' causes the task to be scheduled for immediate execution.  After the scheduled run, the tool exits immediately.
<code>--dependency &lt;taskID&gt;</code>	Specifies the ID of a task upon which this task depends.  A task does not start execution until all its dependencies have completed execution.  You can use this option multiple times in a single command.
<code>--failedDependencyAction &lt;action&gt;</code>	Specifies the action this task takes if one of its dependent tasks fail.  Valid action values are: <ul style="list-style-type: none"> <li>▪ CANCEL (the default) Cancels the task.</li> <li>▪ DISABLE Disables the task so that it is not eligible to run until you manually enable it again.</li> <li>▪ PROCESS Runs the task.</li> </ul>
<code>--startAlert</code>	Generates an administrative alert when the task starts running.
<code>--errorAlert</code>	Generates an administrative alert when the task fails to complete successfully.
<code>--successAlert</code>	Generates an administrative alert when the task completes successfully.
<code>--startNotify &lt;emailAddress&gt;</code>	Specifies an email address to notify when the task starts running.  You can use this option multiple times in a single command.

Option	Description
<code>--completionNotify</code> <code>&lt;emailAddress&gt;</code>	Specifies an email address to notify when the task completes, regardless of whether it succeeded or failed.  You can use this option multiple times in a single command.
<code>--errorNotify</code> <code>&lt;emailAddress&gt;</code>	Specifies an email address to notify if an error occurs when this task executes.  You can use this option multiple times in a single command.
<code>--successNotify</code> <code>&lt;emailAddress&gt;</code>	Specifies an email address to notify when this task completes successfully.  You can use this option multiple times in a single command.

## Consent Solution Guide

---

### Introduction to the Consent Service and Consent API

---

This guide provides information for configuring and managing PingDirectory Server's Consent Service, which supports end-user control of personal data by collecting authorization from users and customers.

Companies gain loyalty and trust when they offer transparency and control to their users and customers regarding the personal data that is collected, processed, or shared.

For example, in Europe, the General Data Protection Regulation (GDPR) was designed specifically for allowing companies to collect and use valuable data about its users, while protecting the rights of citizens to control what is collected and used.

To support the collection and end-user control of personal data, PingDirectory Server includes schema and REST APIs that provide the ability to collect fine-grained data authorizations (consents) from users and customers.

#### Consent Service overview

The Consent Service is an HTTP-based REST API hosted by PingDirectory Server or PingDirectoryProxy Server.

Enterprises can integrate the following Consent Service features into their applications to give users transparency and control of their data privacy:

- The collection of consent from application users
- The enforcement of consent
- A user's management of his or her consent
- Auditing of consent actions

The following terms are used throughout this guide:

**Collaborators**

A list of individuals for whom access to this consent record is shared.

**Consent definition**

The terms of the fine-grained contract, which describes the data that can be processed or shared, and a purpose for processing or sharing the data. The consent definition is stored in the server configuration.

#### Consent localization

A child object of a definition that contains versioned, localized text for the consent definition, to be used when prompting an individual. This is stored in the server configuration.

#### Consent record

A record of a consent interaction with a user. Consent records are stored in the directory tree.

#### Subject

The individual whose data can be collected, processed, or shared.

#### Actor

The individual who granted, denied, or revoked consent. This is usually the same as the subject.

#### Audience

The entity, application, or service that is granted or denied access to a subject's data for a specific purpose.

## Consent API overview

PingDirectory and PingDirectoryProxy provide a REST API for managing an individual's consent to handle their data.

The PingDirectory Consent API enables the following authorization services for managing an individual's consent and data:

- Captures a user's consent for sharing or processing data
- Confirms a user's consent to share or process data has been granted
- The user can manage the consent that they have granted

The Consent REST API can be used as a component of a larger solution, such as a General Data Protection Regulation (GDPR) compliance system.

For more information on the Consent API, see the [PingDirectory Consent API Reference](#) and [How applications use the Consent API](#) on page 1525.

## How consents are collected

The Consent API allows the user to make the decision about sharing their data with other applications through a consent record.

User consent is collected by creating a consent record through the Consent API. In most cases, the Consent API client uses the consent localization data to construct an approval prompt that displays to the user. This prompt should include text describing what data is collected and for what purpose, allowing the user to make an informed decision about the value of sharing his or her data.

For example, a web application needing to collect consent for a user's browsing behavior uses the Consent API to look up the localizations for the **browsing-behavior** consent definition. It selects the localization appropriate for the user and use data from the localization resource to construct a consent prompt for display to the user. After the user is prompted and makes a decision, the client stores the decision by creating a new consent record through the Consent API.

## How consents are enforced

The Consent API can be used as a data source for making access control decisions and enforcing the user's consent.

If a data usage scenario requires consent, then the application or service can't process or access the data unless the user has provided consent. The entity that performs this consent check can be the application itself or some other service.

To perform a consent check, the Consent API client tries to correlate a data access request type with a consent definition. For example, if a web application needs to collect a user's browsing behavior, it can use the **browsing-behavior** consent definition. In this data collection scenario, the application searches the Consent API and checks for an existing consent grant for a consent record that matches the user and the **browsing-behavior** consent definition. If a match is found, then the application proceeds. If a match is not found, the application must collect consent from the user.

## How applications use the Consent API

The following example illustrates both consent capture and consent enforcement using the Consent API.

This example follows a user's journey on a website during which the company must gather consent to track the user's browsing behavior.

1. A user launches the company's application and authenticates.
2. The application wants to record the page visit but first checks if the user has granted consent to do so.
3. The application makes a call to the Consent API to determine if the **browsing-behavior** consent record exists for this user and whether consent been granted.
4. The API returns a result indicating that no consent record exists.
5. The application prompts the user for his or her consent.
6. The application calls the Consent API to retrieve the localization for the **browsing-behavior** consent, which includes the language that the application uses to produce a prompt for the user.
7. After the user makes a decision, the application stores the user's decision by creating a new consent record through a call to the Consent API.
8. Later, the user visits another page in the company's site, and the application wants to record the page visit, so it checks whether the user has granted consent to do so.
9. The application makes a call to the Consent API to get the **browsing-behavior** consent record for this user.
10. If the user's consent record agrees to have the company track his or her browsing behavior, the application can then make the appropriate calls to track browsing behavior.

This is consent enforcement.

## Configuring the Consent Service

---

This section provides information for installing and configuring the components to support the Consent Service.

Installing and configuring the Consent Service includes the following topics:

- [Configuration overview](#) on page 1526
- [Example configuration scenarios](#) on page 1526
- [Setting up with the configuration scripts](#) on page 1527
- [Setting up in a replicated PingDirectory Server environment](#) on page 1527
- [Configuration reference](#) on page 1528
- [Authorization](#) on page 1536

For more configuration information, see [PingDataSync Server Administration Guide](#).

## Configuration overview

Your Consent Service configuration can vary depending on client application capabilities, authentication methods used, and other factors.

By default, the Consent Service is not enabled. The setup and configuration process varies depending on the following factors:

- Whether client applications allow an individual to self-manage consents
- Whether some or all client applications can be privileged with the ability to manage all consents
- The HTTP authentication method used by client applications
- Whether consent records exist in the same directory as user entries

## Example configuration scenarios

Review the following client application scenarios to determine how to configure the Consent Service to meet your business needs.

### Directly managed consents

In this scenario, one or more client applications provide an interface for individuals to directly manage their own consent records. These applications can only manage consents for the currently authenticated user. In addition, there's a client application for consent administrators.

An OAuth 2 authorization server grants access tokens that the applications use to access the Consent API.

Configuration for this scenario includes:

1. Configure an OAuth 2 authorization server to issue a `urn:pingdirectory:consent` scope to individuals and a `urn:pingdirectory:consent_admin` scope to consent administrators.
2. Create an identity mapper to map subject identifiers used by the authorization server to LDAP distinguished names (DNs) used by the PingDirectory Server.
3. Configure an access token validator to validate tokens issued by the OAuth 2 authorization server.
4. Configure the Consent HTTP Servlet Extension to disable HTTP basic authentication and restart the HTTPS Connection Handler.
5. Configure the Consent Service to use the OAuth scopes and token validator.

### Indirectly managed consents (basic authentication)

In this scenario, an application uses a privileged service account to manage its users' consents. The application's privileged account can access any consent record, which gives the application the ability to perform operations that an individual user can't.

The following configuration steps describe the setup needed for the PingDataGovernance Server's Open Banking Account Requests service to use the Consent Service as its backend.

Configuration for this scenario includes:

1. Create a service account for the application.
2. Configure the Consent HTTP Servlet Extension to enable HTTP basic authentication and restart the HTTPS Connection Handler.
3. Create an identity mapper to map the consent record subject and actor attribute values to LDAP DN's.
4. Configure the Consent Service to use the application's service account.
5. Configure the Consent Service to use the identity mapper.

## Setting up with the configuration scripts

PingDirectory Server includes two configuration scripts that can serve as the starting point for setting up the Consent Service.

About this task

You can use one of the following two configuration scripts to start setting up the Consent Service:

- `consent-service-base-entries.ldif` - Import this LDIF script to create the base distinguished name (DN) where consent records are stored.
- `consent-service-cfg.dsconfig` - Import this script to configure and enable the Consent Service.

Both scripts are located in the `/resource/consent/` directory of the PingDirectory Server server root.

### Tip:

Carefully review and update both scripts to support your client application scenarios and business needs.

### Steps

Choose a configuration script to set up the Consent Service.

Choose from:

- Basic configuration with the `consent-service-base-entries.ldif` file.
  - a. Edit the LDIF script and change the location of where you want to store the consent records.
  - b. Import the LDIF script using the `ldapmodify` command. See the following example.

```
$ bin/ldapmodify --defaultAdd \  
--filename consent-service-base-entries.ldif
```

- Basic configuration with the `consent-service-cfg.dsconfig` file.
  - a. Search for **CHANGE-ME** and replace values.
  - b. Review configuration commands and make additional changes to match existing Ping environment parameters, application scenarios, and business needs.
  - c. Impost the script with the `dsconfig` command. See the following example.

```
$ bin/dsconfig --no-prompt \  
--batch-file consent-service-cfg.dsconfig
```

## Setting up in a replicated PingDirectory Server environment

Running the Consent Service setup script differs depending on if your environment has includes replicated PingDirectory Servers.

About this task

Setting up the Consent Service requires different steps depending on if replication is enabled in your environment or not.

### Tip:

If possible, you should setup the Consent Service after replication is enabled for the PingDirectory Servers.

For more information about server replication, see the [PingDirectory Server Administration Guide](#).

## Steps

Choose a Consent Service setup:

Choose from:

- If you are setting up the Consent Service after replication is enabled for PingDirectory Servers:
  - a. Configure the PingDirectory Servers to use a configuration group called `all-servers`.

 **Note:**

This ensures that configuration changes are applied to all servers in a topology.

```
$ bin/dsconfig set-global-configuration-prop \  
  --set configuration-server-group:all-servers
```

- b. Run the Consent Service setup script.

```
$ bin/dsconfig --no-prompt \  
  --batch-file resource/consent/consent-service-cfg.dsconfig \  
  --applyChangeTo server-group
```

- If you have set up the Consent Service on a standalone PingDirectory Server before enabling replication:

 **Note:**

In this example, DS1 is the original PingDirectory Server, and DS2 is the second server to be added as a replica.

- a. Run the `config-diff` command without arguments on DS1 to produce a batch file that contains configuration changes that will be applied to DS2.

```
$ bin/config-diff > config-changes.dsconfig
```

- b. Apply the `config-changes.dsconfig` file to DS2.

```
$ bin/dsconfig --no-prompt \  
  --batch-file config-changes.dsconfig \  
  --applyChangeTo single-server
```

- c. Restart DS2.
- d. Enable replication between the two servers.

## Configuration reference

Use this section as a reference for information about the Consent Service properties and configuration.

There are many configuration options for the Consent Service and application integration. The configuration scripts included with PingDirectory Server provide a starting point. Additional information about the Consent Service properties and configuration is provided as reference.

## General Consent Service configuration

The Consent Service configuration is used to control authorization behavior and determines where consent records are stored in the PingDirectory Server.

You configure the Consent Service properties using the `dsconfig set-consent-service-prop` command. You can use the Consent Service configuration script to configure the Consent Service properties, as show in the following example.

```
$ bin/dsconfig set-consent-service-prop \
  --set enabled:true \
  --set base-dn:ou=consents,dc=example,dc=com \
  --set "bind-dn:cn=consent service account" \
  --set unprivileged-consent-scope:urn:pingdirectory:consent \
  --set privileged-consent-scope:urn:pingdirectory:consent_admin \
  --set "consent-record-identity-mapper:User ID Identity Mapper"
```

## Consent Service properties

Property	Description	Required to enable service
<code>enabled</code>	If set to <code>true</code> , the property enables the Consent Service for handling client requests.	Yes
<code>base-dn</code>	Specifies a container distinguished name (DN) for consent record entries.	Yes
<code>bind-dn</code>	Specifies an internal service account used by the Consent Service to perform LDAP operations.	Yes
<code>service-account-dn</code>	Specifies one or more DN's of requesters that are considered privileged when using basic authentication.  If not defined, a requester is only considered privileged if it's mapped to a DN with the <code>bypass-ac1</code> privilege.	No
<code>unprivileged-consent-scope</code>	Specifies the name of the scope required for bearer tokens representing unprivileged requesters.	Yes
<code>privileged-consent-scope</code>	Specifies the name of the scope required for bearer tokens representing privileged requesters.	Yes
<code>consent-record-identity-mapper</code>	Specifies one or more identity mappers used to map consent record <code>subject</code> and <code>actor</code> values to DN's.  By default, these values are inferred from the authentication context, such as the bearer token subject.	No
<code>audience</code>	Specifies an <code>audience</code> claim value that the Consent Service requires to be present in bearer tokens that it accepts.	No

For the Consent Service to report itself as available to clients:

- The Consent Service must be enabled.
- The Consent Service base DN must be configured and must exist.
- The internal service account must be configured and exist.

- The internal service account must have the right to read, add, modify, and delete entries under the Consent Service base DN.

### Creating a container entry for consent records

Each consent record is a distinct entry in the PingDirectory Server. The Consent Service requires that these entries are stored under a common base distinguished name (DN).

About this task

The `base-dn` property of the Consent Service configuration defines the base DN. The Consent Service LDIF file sets the base DN.

To choose a different location to store consent records:

Steps

1. To create the Consent Service base DN, open a text editor and save the following to the `consent-service-base-dn.ldif` file.

Example:

```
dn: ou=consents,dc=example,dc=com
objectClass: top
objectClass: organizationalUnit
ou: consents
```

2. Use `ldapmodify` to add the entry.

Example:

```
$ bin/ldapmodify --defaultAdd --filename consent-service-base-dn.ldif
```

### Creating an internal service account

Create an internal LDAP connection to operate against consent records that are stored as LDAP entries.

About this task

The Consent Service uses an internal LDAP connection to operate against consent records that are stored as LDAP entries. The Consent Service authenticates the LDAP connection using a service account that must be created and dedicated solely to the Consent Service.

The Consent Service configuration script configures the internal service account using a topology administrator user. If needed, this can be changed to a root distinguished name (DN) user or a user DN whose entry is in the user backend. In all cases, the service account should exist in every LDAP server in the topology.

This service account must have:

- Full read and write access to the Consent Service base DN.
- The ability to read users' `isMemberOf` attribute.
- The right to use the following LDAP controls:
  - `IntermediateClientRequestControl` (1.3.6.1.4.1.30221.2.5.2)
  - `NameWithEntryUUIDRequestControl` (1.3.6.1.4.1.30221.2.5.44)
  - `RejectUnindexedSearchRequestControl` (1.3.6.1.4.1.30221.2.5.54)
  - `PermissiveModifyRequestControl` (1.2.840.113556.1.4.1413)
  - `PostReadRequestControl` (1.3.6.1.1.13.2)

For more information about configuring access, see [Managing Access Control](#) on page 718.

## Steps

1. To ensure the correct access, create a user with the `bypass-acl` privilege.

Example:

The following `dsconfig` command creates a topology admin user with the `bypass-acl` privilege.

```
$ dsconfig create-topology-admin-user \
  --user-name "Consent Service Account" \
  --set "description:Consent API service account" \
  --set "alternate-bind-dn:cn=consent service account" \
  --set first-name:Consent \
  --set inherit-default-root-privileges:false \
  --set last-name:Service \
  --set password:CHANGE-ME \
  --set privilege:bypass-acl
```

### Tip:

The `bypass-acl` privilege grants a broad level of access, so you might not want to grant this privilege to the Consent Service account.

2. Set this user as the `bind-dn` for the Consent Service.
3. To enable a targeted set of functionality for the Consent Service, add the following access control instruction (ACI).

Example:

The following example grants the access to the `cn=consent service account` DN using global ACIs.

```
# Grant access to the consent record base DN
ou=consents,dc=example,dc=com
dsconfig set-access-control-handler-prop --add 'global-aci:
(target="ldap:///ou=consents,dc=example,dc=com")(targetattr="*|+")(
(version 3.0; aci "Consent Service account access to consent record
data"; allow(all) userdn="ldap:///cn=consent service account";)'

# Grant access to the LDAP request controls used by the Consent Service.
dsconfig set-access-control-handler-prop --add 'global-aci:
(targetcontrol="1.3.6.1.4.1.30221.2.5.2||1.3.6.1.4.1.30221.2.5.44||
1.3.6.1.4.1.30221.2.5.54||1.2.840.113556.1.4.1413||1.3.6.1.1.13.2")
(version 3.0; aci "Consent Service account access to selected controls";
allow (read) userdn="ldap:///cn=consent service account";)'
```

## Configure an identity mapper

The Consent Service uses identity mappers to map requester identities, subject values, and actor values to distinguished names (DNs).

An identity mapper takes a user identifier string and correlates the identifier with the DN of a user entry. PingDirectory Server provides four different types of identity mappers.

### Identity mapper types and descriptions

Identity mapper type	Description
Exact match identity mapper	Maps a user identifier to a DN by searching for an entry with an attribute that exactly matches the identifier.

Identity mapper type	Description
Regular expression identity mapper	Similar to an exact match identity mapper, but allows a regular expression to be specified for more flexible matching.
Third-party identity mapper	A custom Java identity mapper implementation written using the Server SDK.
Groovy scripted identity mapper	A custom Groovy identity mapper implementation written using the Server SDK.

The Consent Service can be configured to use identity mappers for each of the following scenarios:

#### Requesters authenticating using basic authentication

Use the Consent HTTP Servlet Extension `identity-mapper` property to configure an identity mapper that takes the HTTP Basic authorization user name string to find the corresponding user's identity in the PingDirectory Server.

#### Requesters authenticating using bearer token authentication

Use the Access Token Validator `identity-mapper` property to configure an identity mapper that takes the subject or other claim value from the OAuth token to find the corresponding user's identity in the PingDirectory Server.

#### Consent record actor and subject values

Use the Consent Service `consent-record-identity-mapper` property to configure an identity mapper that takes these consent record attribute values and uses them to find the corresponding users' identities in the PingDirectory Server.

#### The consent record identity mapper

By default, the Consent Service sets the `subject`, `subjectDN`, `actor`, and `actorDN` values to the identity of the authenticated requester. If the requester uses basic authentication, then all values are set to the auth DN determined by the basic authentication identity mapper. If the requester uses bearer token authentication, then the `subject` and `actor` values are set to the bearer token's subject claim value, while the `subjectDN` and `actorDN` values are set to the auth DN determined by the access token validator identity mapper.

Privileged clients can manually set a consent record's `subject` and `actor` values. In those cases, the Consent Service's `consent-record-identity-mapper` property is used to map a consent record's `subject` and `actor` values to `subjectDN` and `actorDN` values, respectively.

#### Identity mapper configuration options

The Consent Service configuration script configures a single identity mapper to be used for all three scenarios. The provided identity mapper searches by `uid`, `cn`, or `entryUUID` attributes under the base DNs `cn=config` and `ou=people,dc=example,dc=com`.

The following configuration provides an example of an identity mapper that matches a user identifier to an LDAP entry with the same value in its `uid` attribute.

```
$ bin/dsconfig create-identity-mapper --mapper-name "User ID Exact Match" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid
```

This configuration shows another typical example: an identity mapper that matches a user identifier to an LDAP entry with the same value in its `entryUUID` attribute.

```
$ bin/dsconfig create-identity-mapper --mapper-name "EntryUUID Exact Match" \
  \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:entryUUID
```

This final example creates an identity mapper that matches a user identifier to an LDAP entry with the same value in either its `uid`, `cn`, or `entryUUID` attribute. This identity mapper also constrains its search to the `cn=config` and `ou=people,dc=example,dc=com` and `cn=config` base DN's. By default, the `cn=config` base DN is not searched and must be explicitly listed to be searched.

```
$ bin/dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-attribute:cn \
  --set match-attribute:entryUUID \
  --set match-base-dn:cn=config \
  --set match-base-dn:ou=people,dc=example,dc=com
```

### Authentication methods

The Consent Service supports the following HTTP authentication methods and the use of token validators for authorization.

#### Supported HTTP authentication methods

The Consent Service supports the following HTTP authentication methods that are enabled by default:

##### Basic authentication

With basic authentication, the client provides an encoded user name-password pair in the HTTP Authorization request header. When the Consent Service receives a request using basic authentication, it maps the user name credential to a distinguished name (DN) using an identity mapper. This DN is designated the `auth DN` and is used to make subsequent authorization decisions. The Consent Service then performs an LDAP bind using the DN and password to determine if the request can be processed.

##### Bearer token authentication

With bearer token authentication, the client provides an access token in the HTTP Authorization request header. The access token is always obtained by the client from an external OAuth 2 authorization server and encapsulates information "claims" about a user identity, the client identity, and the requests that the client is authorized to make.

The Consent servlet looks at the request's Authorization header to determine which authentication type is being used by the client.

#### Configuring token validators

PingDirectory Server must be configured to accept access tokens using one or both of the following access token validators:

##### PingFederate access token validator

Supports access tokens issued by a PingFederate authorization server. This validator verifies an access token and discovers its claims by making a request to the PingFederate server's token introspection endpoint.

 **Note:**

If you are using PingFederate 10.0 or earlier, ensure that PingFederate is configured to respond to OAuth and OpenID Connect (OIDC) requests selecting the check boxes mentioned in steps 2 and 3 in [Enabling the OAuth AS role](#).

Starting with PingFederate 10.1, these items are always enabled.

#### JWT access token validator

Supports signed or encrypted JSON web token (JWT) access tokens issued by an arbitrary authorization server. This validator checks an access token by cryptographically verifying the token's signature using a trusted public certificate. The token's claims are encoded in the token itself, so discovering the token's claims does not require an outgoing token introspection request.

The token validator uses its identity mapper to map the subject claim to a DN. This DN is designated the **auth DN** and is used along with the token's claims to make subsequent authorization decisions.

If PingDirectory Server is configured with at least one access token validator, the Consent Service uses this access token validator. If PingDirectory Server is configured with more than one access token validator, the validators are consulted in order until one is able to successfully authenticate the request. If PingDirectory Server is configured with multiple access token validators, but only one should be used by the Consent Service, the access token validator can be configured by setting the **access-token-validator** property of the Consent HTTP Servlet Extension.

 **Note:**

Configuring an access token validator for the Consent Service requires the following from the authorization server configuration:

- The values that the authorization server sets for **subject** claims must be mappable to a DN in the PingDirectory Server.
- The authorization server must be configured to authorize clients and grant scopes appropriately for privileged or unprivileged Consent API access.
- The authorization server must be configured to issue tokens with scopes corresponding to the Consent Service's **unprivileged-scope-name** and **privileged-scope-name** configuration.

See the authorization server's documentation for guidance.

#### Configuring basic authentication

Disable or enable basic authentication and configure an identity mapper for basic authentication.

#### About this task

By default, basic authentication is enabled. The settings are configured in the Consent HTTP Servlet Extension configuration.

 **Note:**

All of these configuration changes require the Consent servlet to be reloaded before they can take effect. To do this, see the last step.

## Steps

- To disable basic authentication, use the following command.

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Consent \
  --set basic-auth-enabled:false
```

- To enable basic authentication, use the following command.

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Consent \
  --set basic-auth-enabled:true
```

- To configure an identity mapper for basic authentication, use the following command.

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Consent \
  --set "identity-mapper:User ID Exact Match"
```

- To restart the connection handler that hosts the Consent servlet, use the following commands.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:false
```

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true
```

## Configuring bearer token authentication

Configure an access token validator.

### About this task

#### Note:

You can configure the Consent Service to use a single validator.

## Steps

- Configure an access token validator using `dsconfig`.

Example:

This example shows an access token validator configured on PingDirectory Server for a PingFederate server.

```
$ bin/dsconfig create-external-server \
  --server-name PingFederate \
  --type http \
  --set base-url:https://my-ping-federate-server:1443/
```

```
$ bin/dsconfig create-access-token-validator \
```

```
--validator-name "PingFederate Token Validator" \
--type ping-federate \
--set enabled:true \
--set "identity-mapper:User ID Exact Match" \
--set authorization-server:PingFederate \
--set client-id:id \
--set client-secret:secret
```

- Optional: If more than one access token validator is configured on PingDirectory Server, you can configure the Consent Service to use a single validator with the following command.

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
--extension-name Consent \
--set "access-token-validator:PingFederate Token Validator"
```

### Configuring Consent Service scopes

Configure the `privileged-consent-scope` and `unprivileged-consent-scope` for the Consent Service.

About this task

The Consent Service checks access tokens for a `subject` claim and uses an identity mapper to map the value to a distinguished name (DN), called the request DN or auth DN. If no request DN can be mapped, the request is rejected.

The Consent Service only accepts an access token with a scope that it is configured to recognize.

#### `unprivileged-consent-scope`

An unprivileged consent scope designates the requester as unprivileged. The scope's name is configured with the Consent Service's `unprivileged-consent-scope` property.

#### `privileged-consent-scope`

A privileged consent scope designates the requester as privileged. This is configured using the Consent Service's `privileged-consent-scope` property.

#### Note:

The authorization server must also be configured to issue tokens with these scopes.

Steps

- Configure the `privileged-consent-scope` and `unprivileged-consent-scope` for the Consent Service.

Example:

```
$ bin/dsconfig set-consent-service-prop \
--set unprivileged-consent-scope:consent \
--set privileged-consent-scope:consent_admin
```

## Authorization

The Consent Service's distinction between `privileged` and `unprivileged` requesters determines the type of operations that can be performed by requesters.

During the authorization phase, the Consent servlet performs checks on both the bearer token claims, if present, and the `auth DN` to determine if the requester is privileged or unprivileged. These are summarized in the following table.

## Available operations per requester type

Requester type	Description	Access determined by	Can create consent records	Can update consent records	Can delete consent records
Unprivileged	Requesters with no authority to operate on consent records other than their own.	<p>A requester is considered <code>unprivileged</code> if it does not meet any of the criteria for a <code>privileged</code> requester.</p> <p>If using bearer token authentication, the access token must include a scope named by the <code>unprivileged-consent-scope</code> property of the Consent Service configuration. Also, an unprivileged requester can only perform actions on consent records where the subject distinguished name (DN) matches the requester DN.</p>	<p>Yes.</p> <p>The subject/subjectDN and actor/actorDN values will be set based on the requester.</p>	Yes, if the requester DN matches the subject DN.	No
Privileged	A requester with the authority to perform any operation on any consent record.	<p>When using basic authentication, a requester is considered <code>privileged</code> if the requester DN either has the <code>bypass-acl</code> privilege or is listed in the <code>service-account-dn</code> property of the Consent Service configuration.</p> <p>If using bearer token authentication, the access token must include a scope named by the <code>privileged-consent-scope</code> property of the Consent Service configuration.</p>	Yes	Yes	Yes

## Bearer token check

If a bearer token was used, the following checks are performed:

- If the Consent Service's **audience** property is configured, the bearer token's audience claim must match the configured value.
- If the bearer token contains a scope matching the Consent Service's **privileged-scope-name** property, then the requester is considered privileged.
- If the bearer token doesn't contain a scope matching the Consent Service's **privileged-scope-name** property, the bearer token must have a scope matching the Consent Service's **unprivileged-scope-name** property, and the requester is considered unprivileged.

#### Basic authentication check

If basic authentication is used, the following checks are performed:

- If the **auth DN** has the LDAP privilege **bypass-ac1**, the requester is `privileged`.
- If the **auth DN** is listed in the Consent Service's **service-account-dn** property, the requester is `privileged`.
- If the **auth DN** isn't listed in the Consent Service's **service-account-dn** property, the requester is considered `unprivileged`.

## Managing Consents

---

This section provides information about the collection and end-user control of personal data as well as managing users' consents.

Managing users' consents includes the following topics:

- [Overview of consent management](#) on page 1538
- [Consent definitions and localizations](#) on page 1538
- [Perform an audit on consents](#) on page 1539
- [Logging](#) on page 1544
- [Correlating user and consent data](#) on page 1545
- [Troubleshooting the Consent Service](#) on page 1546

### Overview of consent management

Consent management involves more than collecting the user's consent.

In the consent management life cycle:

1. The terms of each consent contract are centrally managed.
2. The user reviews previously granted consents and potentially revokes some of them.
3. Companies trace the history of updates to any consent in order to resolve a dispute or respond to audit.

### Consent definitions and localizations

The Consent Service requires consent definitions and localizations, which collect and share a use's data and define the purpose for collecting and sharing this data.

Companies can centrally manage the language used when prompting a user to give consent to ensure a consistent user experience across multiple applications, such as mobile and web.

The Consent Service requires one or more consent definitions to be defined in the PingDirectory Server configuration. Each consent definition represents the combination of:

- The data to be collected or shared
- The purpose for collecting or sharing the data

For example, a consent definition could represent users' email addresses that are used to deliver a third party's email newsletter. A consent definition could also represent access to a user's network-connected IoT device that could be used for a home automation task controlled by a third party.

Each consent definition must have one or more localizations. A localization is a versioned object consisting of the data that a Consent API client needs to prompt a user for consent. When a consent record is accepted or denied by a Consent Service client, it must include a reference to a consent definition, locale, and version.

### Creating a consent definition and localization

Create and update a consent definition and localization.

#### Steps

- Create a consent definition using `dsconfig create-consent-definition`.

Example:

```
$ bin/dsconfig create-consent-definition \
  --definition-name email_newsletter \
  --set "display-name:Email newsletter"
```

- Create a localization for the consent definition using `dsconfig create-consent-definition-localization`.

Example:

```
$ bin/dsconfig create-consent-definition-localization \
  --definition-name email_newsletter \
  --localization-name en-US \
  --set version:1.0 \
  --set "data-text:Your email address" \
  --set "purpose-text:To receive newsletter updates"
```

- Update a localization and the version using `dsconfig set-consent-definition-localization-prop` and `set version`.

Example: The following example updates a localization and its version.

```
$ bin/dsconfig set-consent-definition-localization-prop \
  --definition-name email_newsletter \
  --localization-name en-US \
  --set version:1.1 \
  --set "data-text:Your preferred email address"
```

## Perform an audit on consents

The Consent Service offers two types of audit logs to track changes and to perform audits on Consent Service resources.

For examples of configuring either type of log, see the `<server-root>/resource/consent-service-cfg.dsconfig` script bundled with the server or [Logging](#) on page 1544.

This example uses the Consent Trace Logger, which represents Consent Service change events using the same field names used by the Consent API.

### Log Publishers

Log publisher	Log publisher type	Description
collaborators	Trace logger key	The collaborators value, available only when the resource type is <code>consent</code> .

Log publisher	Log publisher type	Description
Consent Trace Logger	file-based-trace	Records Consent Service events at the Consent API level. Change events are recorded using messages of type <code>audit</code> .
Consent LDAP Audit Logger	file-based-audit	Records data changes at the LDAP level. In combination with a Request Criteria configuration object, an LDAP audit logger can be configured to record changes to Consent Service resources only.

Trace logger keys for auditing

Trace logger audit messages consist of a timestamp, the `CONSENT_AUDIT` message type, and a set of key/value pairs.

**Note:**

The keys used in trace log audit messages vary depending on the type of resource.

The following table describes a subset of important keys.

Trace logger key	Description
<code>requestID</code>	A server-specific HTTP request ID. This value can be correlated with messages produced by other loggers.
<code>resourceType</code>	The type of Consent Service resource that was changed. Possible values are <code>definition</code> , <code>localization</code> , or <code>consent</code> .
<code>changeType</code>	The type of change recorded by this message. Possible values are <code>create</code> , <code>update</code> , or <code>delete</code> .
<code>attrsAdded</code>	A comma-delimited list of the attributes that were added to the resource.
<code>attrsUpdated</code>	A comma-delimited list of the attributes that were modified on the resource.
<code>attrsDeleted</code>	A comma-delimited list of the attributes that were removed from the resource.
<code>requestDN</code>	The distinguished name (DN) of the requester, which is available only when the resource type is <code>consent</code> .

Trace logger key	Description
<b>definitionID</b>	<p>The consent definition ID.</p> <p>The following list identifies the possible resource types and their definitions:</p> <p><b>definition</b></p> <p>Identifies the definition that was changed.</p> <p><b>localization</b></p> <p>Identifies the parent definition.</p> <p><b>consent</b></p> <p>Identifies the consent record's related definition.</p>
<b>locale</b>	<p>The locale.</p> <p>The following list identifies the possible resource types and their definitions:</p> <p><b>localization</b></p> <p>Identifies the localization in combination with the definition ID.</p> <p><b>consent</b></p> <p>Identifies the related localization combined with the definition ID.</p>
<b>consentID</b>	<p>The consent record ID, available only when the resource type is <code>consent</code>.</p>
<b>subject</b>	<p>The subject value, available only when the resource type is <code>consent</code>.</p>
<b>subjectDN</b>	<p>The subject's mapped LDAP DN.</p> <p>This is available only when the resource type is <code>consent</code>.</p>
<b>actor</b>	<p>The actor value.</p> <p>This is available only when the resource type is <code>consent</code>.</p>
<b>actorDN</b>	<p>The actor's mapped LDAP DN.</p> <p>This is available only when the resource type is <code>consent</code>.</p>
<b>audience</b>	<p>The audience value.</p> <p>This is available only when the resource type is <code>consent</code>.</p>
<b>status</b>	<p>The consent status.</p> <p>This is only available when the resource type is <code>consent</code>.</p> <p>Possible values are <code>pending</code>, <code>accepted</code>, <code>denied</code>, <code>revoked</code>, and <code>restricted</code>.</p>

Trace logger key	Description
<code>previousStatus</code>	The previous consent status, if applicable. This is only available when the resource type is <code>consent</code> .
<code>msg</code>	A multiline value that includes the complete body of the changed resource. If the action is an <code>update</code> or a <code>delete</code> , the resource's body before the change is included.

### Perform an audit

Consent resource changes for particular entities, such as a specific user or a specific consent definition, can be audited by searching the trace log using a combination of one of the message keys and the desired value.

For example, if an individual's LDAP distinguished name (DN) is known, the `subjectDN` key can be used to construct a text search for any audit log messages containing that DN. Any matching log messages constitute a history of that individual's consent activity.

### New consent record example

This example shows an audit log message that provides important values in a parseable key/value format and includes a complete new consent record.

```
[22/May/2018:18:02:42.584 -0500] CONSENT AUDIT requestID=57
requestDN="uid=user.0,ou=people,
  dc=example,dc=com" consentID="6cff325b-e092-4094-b7f9-5a30864b0d24"
subject="user.0" subjectDN="uid=user.0,
  ou=People,dc=example,dc=com" actor="user.0"
actorDN="uid=user.0,ou=People,dc=example,dc=com" audience="client1"
definitionID="cats" locale="en-US" status="accepted"
attrsAdded="actor,audience,createdDate,dataText,subject,
  purposeText,definition,id,updatedAt,actorDN,status,subjectDN"
changeType="create" resourceType="consent" msg="
New Consent Record:
  {'id':'6cff325b-e092-4094-
b7f9-5a30864b0d24','status':'accepted','subject':'user.0','subjectDN':'uid=user.0,
  ou=People,dc=example,dc=com','actor':'user.0','actorDN':'uid=user.0,ou=People,dc=exampl
  'client1','definition':{'id':'cats','version':'1.0','locale':'en-
US'},'dataText':'Collect data about your
  cats','purposeText':'To recommend cat food flavors that will satisfy and
  delight your feline companion',
  'createdDate':'2018-05-22T23:02:42.553Z','updatedAt':'2018-05-22T23:02:42.553Z'}"
```

### Updated consent record example

This example provides a complete consent record before and after it was updated. By reviewing the `attrsUpdated`, `status`, and `previousStatus` keys, you can determine that the status changed from `accepted` to `revoked`.

```
[22/May/2018:18:05:08.660 -0500] CONSENT AUDIT requestID=59
requestDN="uid=user.0,ou=people,
  dc=example,dc=com" consentID="6cff325b-e092-4094-b7f9-5a30864b0d24"
subject="user.0" subjectDN="uid=user.0,
```

```

ou=People,dc=example,dc=com" actor="user.0"
actorDN="uid=user.0,ou=People,dc=example,dc=com"
audience="client1" definitionID="cats" locale="en-US" status="revoked"
previousStatus="accepted"
attrsUpdated="status" changeType="update" resourceType="consent" msg="
Previous Consent Record:
  {'id':'6cff325b-e092-4094-
b7f9-5a30864b0d24','status':'accepted','subject':'user.0','subjectDN':'uid=user.0,
ou=People,dc=example,dc=com','actor':'user.0','actorDN':'uid=user.0,ou=People,dc=example,dc=com',
'audience':'client1','definition':
{'id':'cats','version':'1.0','locale':'en-US'},'dataText':'Collect
data about your cats','purposeText':'To recommend cat food flavors that
will satisfy and delight your
feline
companion','createdDate':'2018-05-22T23:02:42.553Z','updatedAtDate':'2018-05-22T23:02:42.553Z'}
Updated Consent Record:
  {'id':'6cff325b-e092-4094-
b7f9-5a30864b0d24','status':'revoked','subject':'user.0','subjectDN':
'uid=user.0,ou=People,dc=example,dc=com','actor':'user.0','actorDN':'uid=user.0,ou=People,dc=example,dc=com',
'audience':'client1','definition':
{'id':'cats','version':'1.0','locale':'en-US'},'dataText':
'Collect data about your cats','purposeText':'To recommend cat food
flavors that will satisfy and
delight your feline
companion','createdDate':'2018-05-22T23:02:42.553Z','updatedAtDate':'2018-05-22T23:05:08.655Z'}"

```

### Deleted consent record example

This example shows that a consent record has been deleted and provides a complete representation of the consent record before it was deleted.

```

[22/May/2018:18:06:35.071 -0500] CONSENT AUDIT requestID=61
requestDN="cn=directory manager"
consentID="6cff325b-e092-4094-b7f9-5a30864b0d24" subject="user.0"
subjectDN="uid=user.0,ou=People,
dc=example,dc=com" actor="user.0"
actorDN="uid=user.0,ou=People,dc=example,dc=com" audience="client1"
definitionID="cats" locale="en-US" status="revoked"
previousStatus="revoked" attrsDeleted="actor,audience,
createdDate,dataText,subject,purposeText,definition,id,updatedAtDate,actorDN,status,subjectDN"
changeType="delete"
resourceType="consent" msg="
Deleted Consent Record:
  {'id':'6cff325b-e092-4094-
b7f9-5a30864b0d24','status':'revoked','subject':'user.0','subjectDN':
'uid=user.0,ou=People,dc=example,dc=com','actor':'user.0','actorDN':'uid=user.0,ou=People,dc=example,dc=com',
'audience':'client1','definition':
{'id':'cats','version':'1.0','currentVersion':
'1.0','locale':'en-US'},'dataText':'Collect data about your
cats','purposeText':'To recommend cat food
flavors that will satisfy and delight your feline
companion','createdDate':'2018-05-22T23:02:42.553Z',
'updatedAtDate':'2018-05-22T23:05:08.655Z'}"

```

## Logging

Use the PingDirectory Server trace log publisher for logging events generated by HTTP service operations.

About this task

You can use the trace logger to observe, debug, and audit consent requests.

Steps

- Create a trace logger for all consent events using `dsconfig create-log-publisher`.

### Tip:

To create a log of consent audit events only, remove all message types except for `consent-message-type:audit`.

Example: The following example creates a trace logger for all consent events and summaries of HTTP requests and responses.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "Consent Trace Logger" \
  --type file-based-trace \
  --set "description:Records Consent API operations" \
  --set enabled:true \
  --set consent-message-type:audit \
  --set consent-message-type:consent-created \
  --set consent-message-type:consent-deleted \
  --set consent-message-type:consent-retrieved \
  --set consent-message-type:consent-search \
  --set consent-message-type:consent-updated \
  --set consent-message-type:definition-created \
  --set consent-message-type:definition-deleted \
  --set consent-message-type:definition-retrieved \
  --set consent-message-type:definition-search \
  --set consent-message-type:definition-updated \
  --set consent-message-type:error \
  --set consent-message-type:localization-created \
  --set consent-message-type:localization-deleted \
  --set consent-message-type:localization-retrieved \
  --set consent-message-type:localization-search \
  --set consent-message-type:localization-updated \
  --set http-message-type:request \
  --set http-message-type:response \
  --set 'exclude-path-pattern:/**/*.css' \
  --set 'exclude-path-pattern:/**/*.eot' \
  --set 'exclude-path-pattern:/**/*.gif' \
  --set 'exclude-path-pattern:/**/*.ico' \
  --set 'exclude-path-pattern:/**/*.jpg' \
  --set 'exclude-path-pattern:/**/*.js' \
  --set 'exclude-path-pattern:/**/*.png' \
  --set 'exclude-path-pattern:/**/*.svg' \
  --set 'exclude-path-pattern:/**/*.ttf' \
  --set 'exclude-path-pattern:/**/*.woff' \
  --set 'exclude-path-pattern:/**/*.woff2' \
  --set 'exclude-path-pattern:/console/**' \
  --set 'exclude-path-pattern:/console/**/template/**' \
  --set log-file:logs/consent-trace \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
```

```
--set "rotation-policy:Size Limit Rotation Policy"
```

## Correlating user and consent data

An organization that has been granted consent by a group of users can perform an LDAP search so that they can use the consent data in the aggregate.

### About this task

For this task, consider the example scenario where a marketing group has collected consent to send a newsletter by email. To find all the users that have granted consent to receive emails, the marketing group performs a search that lists all of the consent records where the consent definition is `email` and the status is `accepted`. Then, the marketing group must correlate these consent records to user entries and retrieve each user's email address.

Every consent record contains a `subject` field, the user whose data is collected and stored. You can configure the Consent Service so that it stores the subject's distinguished name (DN) in the `subjectDN` field.

### Steps

- Perform a search using the `ldapsearch` command.

Example:

#### Note:

The example includes the following modifications in the `ldapsearch` command:

- To correlate the consent record entries to user entries and retrieve each user entry's `mail` attribute value, `ping-consent-subject-dn` is used.
- To find all of the relevant consent record entries, the LDAP search specifies values where `ping-consent-definition.id` is `email` and the `ping-consent-status` is `accepted`.

```
$ bin/ldapsearch \
  --baseDN "ou=consents,dc=example,dc=com" \
  --searchScope sub \
  --joinRule "dn:ping-consent-subject-dn" \
  --joinBaseDN "ou=people,dc=example,dc=com" \
  --joinScope sub \
  --joinRequestedAttribute mail
  '&(ping-consent-
definition:jsonObjectFilterExtensibleMatch:={ "filterType" : "equals",
"field" : "id", "value" : "email" }) (ping-consent-state=accepted)' \
  1.1
```

- A consent record's `subjectDN` field is the `ping-consent-subject-dn` attribute.
- A consent record's status is in the `ping-consent-state` JSON attribute field.
- A consent record's definition ID is in the `ping-consent-definition.id` JSON attribute field.
- A user entry's email address is in the `mail` attribute.

### Result:

The example LDAP search returns the following results.

```
# Join Result Control:
#   OID: 1.3.6.1.4.1.30221.2.5.9
#   Join Result Code: 0 (success)
#   Joined With Entry:
```

```
#          dn: uid=user.0,ou=People,dc=example,dc=com
#          mail: user.0@example.com
dn: entryUUID=9e481010-8330-425a-
bbf1-6637de053d48,ou=Consents,dc=example,dc=com

# Result Code: 0 (success)
# Number of Entries Returned: 1
```

**Note:**

The `Join Result Control`: output specifies the mail value.

## Troubleshooting the Consent Service

This section provides general guidelines for troubleshooting the Consent Service and any connection issues.

When evaluating the configuration:

- Make sure that the Consent Service is enabled.
- Make sure that the Consent Service base distinguished name (DN) exists.
- Make sure that the Consent Service's service account has the correct permissions.
- If the Consent Service should accept bearer tokens, make sure that:
  - One or more access token validators are configured correctly.
  - The identity mappers for the access token validators are configured correctly.
  - The authorization servers are configured correctly to issue tokens that the Consent Service can accept. Check the `audience`, `privileged-consent-scope`, and `unprivileged-consent-scope` properties of the Consent Service configuration.
- If privileged users are defined, make sure that the members of the LDAP group are specified by the Consent Service configuration's `privileged-users-group-dn` property.
- If there are applications that allow individuals to manage their own consents, make sure that the system is properly configured to map `actor` and `subject` DN's. Check the Consent Service configuration's `consent-record-identity-mapper` property.

### Error cases

The following topic discusses troubleshooting possible error cases and solutions.

#### Consent Service is unavailable

If the Consent Service is unavailable, check the following:

- Ensure that the service is enabled and that communication with the service is available.
- Confirm that the service account for the Consent Service has been properly provisioned.
- If the Consent Service resides on a PingDirectoryProxy Server, make sure that the service account exists on the PingDirectoryProxy Server and all PingDirectory Servers behind the PingDirectoryProxy Server.

#### Requester lacks sufficient rights to perform operation

A request might be rejected with a 403 for the following reasons:

- The bearer token does not contain a required scope. Check the `privileged-consent-scope` and `unprivileged-consent-scope` properties of the Consent Service configuration.
- The bearer token does not contain a required `audience` claim. Check the `audience` property of the Consent Service configuration.

- Authentication was successful, but the requester is `unprivileged` and attempted to perform an operation that only a `privileged` requester can perform. For example, the requester attempted to act upon a consent record that it does not own, or it attempted to delete a consent record.

When using basic authentication, the requester must be listed in the Consent Service configuration `service-account-dn` property to be considered `privileged`.

Subject and actor do not match

Only a `privileged` requester can `create` or `modify` a consent record whose `subject` and `actor` values do not match.

Unindexed search

The Consent Service doesn't allow a client to make an unindexed search. In most cases, a client should be able to fix this by refining the search. For example, if a search by `subject` is unindexed, perform a search by `subject` and `definition ID`.

Search size limit exceeded

The Consent Service caps the maximum number of records that can be returned in a search result using its `search-size-limit` configuration property. This limit can be increased, or the client might be able to refine the search to produce fewer results.

## Delegated Admin Application Guide

---

Delegated Admin is an add-on to PingDirectory that enables the delegation of user and group management.

### Delegated Admin overview

---

Delegated Admin from Ping Identity is an add-on to PingDirectory that enables the delegation of user and group management.

### Introduction to Delegated Admin

Delegated Admin lets organizations assign responsibilities associated with the management of identities in PingDirectory Server to a subset of administrators.

These delegated administrators can be any user outside the organization's IT department, including a customer.

The following employees typically fulfill roles that involve at least a basic level of identity management:

- Help desk or customer service representatives who unlock and reset passwords
- Managers and Human Resources administrators who update employee profiles
- Application administrators who update identity attributes and manage access to applications

These employees represent strong candidates for inclusion in a group of delegated administrators.

### Features

Delegated Admin lets delegated administrators complete tasks across groups, subtrees, and entire organizations.

Tasks include:

- Create, view, and search user profiles.

- View user account information, including account status, last login time, and password expiration date.
- Update user attributes.
- Implement constructed attributes.
- Set attributes to `read-only`.
- Enable and disable accounts.
- Reset locked accounts.
- Create and edit groups.
- Manage the membership of groups and subgroups.
- Manage the roles of users and groups.
- Delete users, groups, and generic resource types.
- Implement custom UI form fields.
- Select user entries based on their distinguished names (DNs) without displaying the actual values of the DN.
- Preview and download reports about user profiles. Reporting provides the following features:
  - Capability to report for resources of a given type, or limited to members of a group
  - Ability to display multiple values per attribute for each user
  - Protection against spreadsheet formula injection
- Upload CSV files to add user, group membership, or organizational unit (OU) records.
- Trigger a password reset process for a user that invokes the self service password reset process defined by the business

## Installing Delegated Admin

---

Different options and procedures are available when you install Delegated Admin depending on your environment and the location of your installation.

Before attempting to install the application, you must complete the tasks in [Prerequisites](#) on page 1548 and in [Before you install](#) on page 1549.

### Installation locations

Delegated Admin can be installed in any of the following locations:

- PingDirectory Server, including replicated instances
- PingDirectoryProxy Server
- External web server

The location that you choose determines the steps that you must perform to install Delegated Admin.

### Prerequisites

Regardless of the location of your Delegated Admin installation, ensure the following Ping Identity products are installed and configured before attempting to install Delegated Admin.

Product	Description	Version
PingDirectory Server	Stores user-identity data. The HTTPS port that was configured during PingDirectory Server setup is required to install Delegated Admin.  For information about upgrading PingDirectory Server, see <a href="#">Upgrade PingDirectory Server</a> on page 1555.  For information about installing and configuring PingDirectory Server, see PingDirectory Server <a href="#">Administration Guide</a> .	See <a href="#">Compatibility matrix</a> on page 1589.

Product	Description	Version
PingFederate Server	Provides identities for authentication and authorization. For information about installing and configuring PingFederate Server, see <a href="#">Configuring PingFederate Server</a> on page 1590, or see the PingFederate Server Guide.	PingFederate 9.0.0 or later

## Supported browsers

- Chrome
- Firefox
- Internet Explorer 11 and later

## Obtaining the installation files

Obtain the Delegated Admin installation files.

### Steps

1. Download the Delegated Admin installation package, `pingdirectory-delegator-{version}.zip`, to the server on which you plan to install the application.
2. Extract the contents of the installation package.
3. Copy the folder named `/delegator` and its contents to the appropriate directory as shown in the following table.

Server	Directory
PingDirectory Server	<code>/webapps</code>
Replicated instance of PingDirectory Server	<code>/webapps</code>
PingDirectoryProxy Server	<code>/webapps</code>
External web server	Directory for web-based apps

## Before you install

To install Delegated Admin on PingDirectory Server or a replicated instance of PingDirectory Server, complete the relevant tasks in this section before installing the application.

### Preparing to install Delegated Admin on a PingDirectory Server

#### About this task

If you are installing Delegated Admin on a PingDirectory Server installation with `Install with sample data` chosen as the installation option, perform the following step.

Otherwise, proceed to [Obtaining the installation files](#) on page 1549.

### Steps

- Remove the relevant access control information (ACI) from the PingDirectory Server base entry.

For more information, see the LDIF file `delegator/remove-sample-directory-data-aci.ldif`.

## Preparing to install Delegated Admin on a replicated instance of PingDirectory Server

About this task

To install Delegated Admin on a replicated instance of PingDirectory Server, perform the following steps:

Steps

1. Make sure that replication is enabled for the PingDirectory Servers.

For information about enabling server replication, see the PingDirectory Server Administration Guide.

2. To ensure that configuration changes are applied to all the servers in your topology, configure the PingDirectory Servers to use a configuration group called **all-servers**.

Example:

```
$ bin/dsconfig set-global-configuration-prop \  
--set configuration-server-group:all-servers
```

3. If you are installing Delegated Admin on a replicated PingDirectory Server that had `Install with sample data` chosen as the installation option, remove the relevant ACI from the PingDirectory Server base entry.

Because replicated instances share the same data, perform this step against only one of the servers. For more information, see the LDIF file `delegator/remove-sample-directory-data-aci.ldif`.

If you're installing Delegated Admin on a PingDirectory Server installation that didn't have `Install with sample data` chosen as the installation option, proceed to [Obtaining the installation files](#) on page 1549.

## Installing the application

The steps for installing Delegated Admin depend on whether you are setting up the application in a Unix or Linux environment or in a Windows environment.

### Important:

In all environments, if port 443 is used but not specified in the PingFederate Base URL, do not assign a value to `window.PF_PORT`.

## Unix or Linux

About this task

To begin installing Delegated Admin in a Unix or Linux environment:

## Steps

- Run the following script in the `/delegator` directory from [Obtaining the installation files](#) on page 1549.

```
$ ./set-up-delegator.sh
```

### Result:

The system generates:

- A configuration file, `config.js`, located in the `/webapps/delegator/app` directory.
- A batch file, `delegated-admin.dsconfig`, in the `/webapps/delegator` directory.

The `setup` tool also generates several command-line prompts for completing the Delegated Admin installation. After you provide the distinguished name (DN) of the root user for your PingDirectory instance, you're prompted to enter information regarding your PingFederate server and the hosting location of the Delegated Admin web app. Enter your own values or press Enter to accept the default values.

### Note:

If you answer `y` to the `setup` script question `Is Delegated Admin being installed in a topology containing PingDirectoryProxy?`, the system also generates a batch file named `delegated-admin-for-proxy.dsconfig`.

## Windows

### About this task

To install Delegated Admin in a Windows environment.

### Steps

- In the Delegated Admin application directory, copy or rename the file `example.config.js` to `config.js`.  
`config.js` contains comments and placeholders for necessary information. For example, the Client ID that is required in this file must be one of the Client IDs that has been defined for the PingFederate configuration. This value represents the client intended for token issuance, such as `dadmin`.
- Open `config.js` in a text editor.
- Change the variable values to match your setup configuration.

<code>config.js</code> Variable	Value
<code>window.PF_HOST</code>	Public address of the PingFederate Server to which the application redirects the user's browser when logging on.
<code>window.PF_PORT</code>	PingFederate port number. If port 443 is used but not specified in the PingFederate Base URL, do not assign a value to <code>window.PF_PORT</code> .
<code>window.DADMIN_CLIENT_ID</code>	PingFederate Client ID for the application.

- Save your changes to `config.js`.

5. Concatenate the following files into a single file named `delegated-admin.dsconfig`:
  - `delegated-admin-template-common.dsconfig`
  - `delegated-admin-template-ds.dsconfig`
  - `delegated-admin-template-ds-or-proxy.dsconfig`
  - `delegated-admin-template-webapp.dsconfig`
6. Open `delegated-admin.dsconfig` in a text editor and replace the variables, `${variable}`, with actual values.
7. Save your changes to `delegated-admin.dsconfig`.

### All environments

Regardless of whether you are installing Delegated Admin in a Unix or Linux, or Windows environment, perform the relevant steps in this section after you complete the previous OS-specific tasks.

### PingDirectoryProxy Server

Before you begin

The following task assumes that when you ran the `setup` command, you answered `y` to the question `Is Delegated Admin being installed in a topology containing PingDirectoryProxy?`

About this task

If you are installing Delegated Admin on PingDirectoryProxy Server, you must configure the Proxy instance using the `delegated-admin-for-proxy.dsconfig` script as described in [All locations except PingDirectoryProxy Server](#) on page 1553.

You must also perform the following steps to configure all instances of PingDirectory Server:

Steps

1. Apply the commands from the `delegated-admin.dsconfig` batch file to all instances of PingDirectory Server.

```
$ ./bin/dsconfig \
  --bindDN "cn=Directory Manager" \
  --bindPassword <password> \
  --no-prompt \
  --batch-file webapps/delegator/delegated-admin.dsconfig \
  --applyChangeTo server-group
```

2. Apply the commands from the `delegated-admin.dsconfig` batch file to all instances of PingDirectory Server, as explained in [Replicated instances of PingDirectory Server](#) on page 1552.

### Replicated instances of PingDirectory Server

About this task

Perform the following task if you are installing Delegated Admin on one or more replicated instances of PingDirectory Server.

Steps

- Apply the following commands in `delegated-admin.dsconfig` to each instance.

```
$ ./bin/dsconfig \
  --bindDN "cn=Directory Manager" \
  --bindPassword <password> \
  --no-prompt \
  --batch-file webapps/delegator/delegated-admin.dsconfig \
```

```
--applyChangeTo server-group
```

## External web server

### Before you begin

The following steps assume that when you ran the `setup` command, you answered `n` to the question `Will the web app be hosted in PingDirectory?`

### About this task

To install Delegated Admin on an external web server:

### Steps

1. Open `config.js` in a text editor.
2. Change the variable values to specify the location of PingDirectory Server.

<code>config.js</code> Variable	Value
<code>window.DS_HOST</code>	Host name of PingDirectory Server
<code>window.DS_PORT</code>	HTTPS port of PingDirectory Server

To view an example outline that features these settings, see `example.config.js`.

3. Save your changes to `config.js`.
4. Create a CORS policy for the Delegated Admin HTTP servlet extension, where `<origin>` represents the public name of the host, proxy, or load balancer that presents the Delegated Admin web application.

Example:

```
dsconfig create-http-servlet-cross-origin-policy
  --policy-name "Delegated Admin Cross-Origin Policy"
  --set "cors-allowed-methods: GET"
  --set "cors-allowed-methods: OPTIONS"
  --set "cors-allowed-methods: POST"
  --set "cors-allowed-methods: DELETE"
  --set "cors-allowed-methods: PATCH"
  --set "cors-allowed-origins: <origin>"

dsconfig set-http-servlet-extension-prop
  --extension-name "Delegated Admin"
  --set "cross-origin-policy:Delegated Admin Cross-Origin Policy"
```

5. Optional: If you will be enabling admins to run Delegated Admin reports in your configuration, run `dsconfig` with the `set-http-servlet-cross-origin-policy-prop` option.

Example:

```
dsconfig set-http-servlet-cross-origin-policy-prop \
  --policy-name "Delegated Admin Cross-Origin Policy" \
  --set cors-exposed-headers:Content-Disposition
```

## All locations except PingDirectoryProxy Server

### About this task

To continue installing Delegated Admin on a PingDirectory Server or an external web server:

## Steps

- Run the following command with `delegated-admin.dsconfig` on the appropriate server.

Example:

```
$ ./bin/dsconfig \
  --bindDN "cn=Directory Manager" \
  --bindPassword <password> \
  --no-prompt \
  --batch-file webapps/delegator/delegated-admin.dsconfig
```

## Next steps

After you finish installing Delegated Admin, visit <https://webserverHost:httpPort/delegator> to view the application's **Sign On** window.

### Note:

At this time, you cannot sign on to Delegated Admin because the rights of the delegated administrators have not been configured. For more information about configuring administrative rights, the REST resource type, session timeout values, and other properties, see [Configuring Delegated Admin](#) on page 1559.

After you configure Delegated Admin, [verify that the application is installed](#) and working successfully.

## Upgrading Delegated Admin

Ping Identity periodically issues software with new features, enhancements, and fixes for improved performance. Administrators can use the PingDirectory Server's `update` tool to upgrade the current code version.

This sections presents some update scenarios and the related implications to consider when upgrading your version of Delegated Admin.

## Upgrade considerations

Consider the following points when upgrading your version of Delegated Admin.

### Considerations

### Note:

If you are running Delegated Admin 3.5 or earlier, upgrade it to the latest version to use PingDirectory 8.0 or later. For information about the compatibility between Delegated Admin and PingDirectory Server versions, see the [Compatibility matrix](#) on page 1589.

Perform the following steps to enable the `Initiate Password Reset` menu option on user entries. This feature is enabled for new installs via the `delegated-admin.dsconfig` script run on install.

- Run the following command to enable the plugin needed for triggering Initiate Password Reset:

```
dsconfig set-plugin-prop \
  --plugin-name "Modifiable Password Policy State Plugin" \
  --set enabled:true --set "base-dn:${searchbasedn}" \
  --set "filter:(|(objectClass=person)(objectClass=ds-cfg-user))"
```

2. Run the following command to add a DA attribute to the users rest type for `ds-pwp-modifiable-state-json`:

```
dsconfig create-delegated-admin-attribute \
--type-name users \
--attribute-type ds-pwp-modifiable-state-json \
--set "display-name:Modifiable Password Policy State" \
--set display-order-index:9999
```

To use the functionality where a help desk agent can trigger a password reset for a user, the Modifiable Password Policy State Plugin must be enabled on the Directory Server that serves as a resource backend.

**Note:**

When you install Delegated Admin 4.6, this plugin is enabled. If you are upgrading from a previous version of Delegated Admin, you must manually enable the plugin and add the `ds-pwp-modifiable-state-json` attribute as a Delegated Admin attribute.

## Upgrade PingDirectory Server

The following sections describe upgrading PingDirectory Server.

Before attempting to upgrade Delegated Admin to the current version, ensure that you are running 8.0.0.0 or later of PingDirectory Server.

**Note:**

If you are already running PingDirectory Server 8.0.0.0 or later, go to [Upgrade the application](#) on page 1558.

For more information about the compatibility of Delegated Admin with different versions of PingDirectory Server and PingFederate Server, see [Compatibility matrix](#) on page 1589.

### Overview and considerations

The process of upgrading PingDirectory Server involves downloading and extracting a new version of the PingDirectory Server `.zip` file on the server to be updated and running the `update` utility with the `--serverRoot` or `-R` option value from the new root server pointing to the installation to be upgraded.

You should consider the following when upgrading replicating servers:

- Upgrade affects only the server being upgraded.  
The process does not alter the configuration of other servers.
- The `update` tool verifies that the version of Java that is installed meets the new server requirements.  
To simplify the process, install the version of Java that is supported by the new server before running the tool.
- To be safe, backup the user data (`userRoot`) before an upgrade.

Restoring from a backup could be necessary if all other servers in the replication topology have been upgraded and a database or encoding change in the new server version prevents the database from being used with the older server version. The `update` and `revert-update` utilities issue a warning when this is the case.

- Temporarily raise the replication purge delay for all servers in the topology to cover the expected downtime for maintenance.

This results in a temporary increase in disk usage for the replicationChanges database stored in `<server-root>/changelogDb`.

- Replication does not need to be disabled on a server before an upgrade.

- Ensure upgraded servers are working as expected before upgrading the last server in the topology.
- Enable new features after all replicating servers are upgraded.

**Tip:**

For additional considerations, see the [Planning your upgrade guide](#).

**Upgrading servers in a topology**

An update to the current PingDirectory Server release includes the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts.

Before you begin

Before you can update and migrate the admin backend, the following conditions must be satisfied:

- Run the update tool and provide LDAP authentication options to the peer servers of the server being updated. The `update` tool connects to the peer servers of the server being updated to obtain the necessary information to populate the topology registry.
- On every server in the topology, configure the encryption protocol requested, either plain, TLS, StartTLS, or SASL, for an LDAP connection.
- Ensure the LDAP credentials are present on every server in the topology.
- Ensure the users related to the LDAP credentials have permissions to read from the admin backend and the config backend of every server in the topology. For example, you can use a root DN user that has `inherit-default-privileges` set to true, such as the `cn=Directory Manager` user, that exists on every server.
- The instance name is set on every server and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server is uniquely identified by its instance name. After the name is set, it cannot be changed.

**Tip:**

If needed, use the following command to set the instance name of a server prior to the update.

```
$ bin/dsconfig set-global-configuration-prop \
  --set instance-name:uniqueName
```

**Important:**

This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than a 7.x to a 7.x version and is not applicable to any updates to a server version of 8.x or later.

About this task

Upgrade to a server that uses a topology registry to store network configuration, administrator user accounts, and keys information, as well as migrate the information from the previous server version. The following requirements must be met:

- When the first server is being updated, all other servers in the topology are online.
- When updating additional servers, all topology information was obtained from one of the servers that has already been updated.

- The users related to the provided LDAP credentials have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server and is unique across all servers in the topology.

## Steps

1. To make clustered configuration changes in a mixed-version cluster, choose one of the following options:

Choose from:

- Update each server to the same version.
- Temporarily split up the cluster by changing the `cluster-name` property on the server instance configuration objects.

### Note:

Changes to clustered configurations are not allowed in mixed-version clusters. This applies to configuration in the `cn=Cluster, cn=config` subtree and only applies to servers with matching cluster names.

2. Make clustered configuration changes again to mirror these changes across the topology.

Result:

When all of these conditions are met, the cluster-wide configuration is synchronized on all servers in the topology.

### Note:

Older versions have some topology configuration under the `cn=cluster, cn=config` JSON attribute and field constraints. These items do not support mirrored cluster-wide configuration data. In an update, avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree master. If additional configuration steps are needed, see step 4.

3. To synchronize the cluster-wide configuration data across all servers in the topology, run the `config-diff` tool on each pair of servers to determine the differences, and use `dsconfig` to update each instance using the `config-diff` output.

Example:

```
$ bin/config-diff --sourceHost hostName \  
  --sourcePort port \  
  --sourceBindDN bindDN \  
  --sourceBindPassword password \  
  --targetHost hostName \  
  --targetPort port \  
  --targetBindDN bindDN \  
  --targetBindPassword password
```

## Upgrading PingDirectory Server

About this task

To upgrade PingDirectory Server:

## Steps

1. Download and extract the new version of PingDirectory Server to a location outside the existing server's installation.

Assume that the existing server installation resides in `/prod/PingDirectory` and that the new server version is extracted to `/home/stage/PingDirectory`.

2. To upgrade the existing PingDirectory Server, run the **update** tool that is provided with the new server package.

```
$ /home/staging/PingDirectory/update --serverRoot /prod/PingDirectory
```

### Note:

If the tool detects any degree of customization, it might prompt for confirmation on server configuration changes.

## Upgrade the application

Upgrade Delegated Admin to improve security.

In Delegated Admin 3.3.0 and earlier, the setup script assigned a cross-origin resource sharing (CORS) policy to the Delegated Admin HTTP servlet extension. This policy is potentially insecure because the CORS setting **Allowed-Origin** permits requests that use a wildcard to allow requests from any origin.

Unless you have made changes to secure this policy, remove it.

```
dsconfig set-http-servlet-extension-prop --extension-name "Delegated Admin"
--reset "cross-origin-policy"
dsconfig delete-http-servlet-cross-origin-policy --policy-name "Delegated
Admin Cross-Origin Policy"
```

### Important:

Beginning with Delegated Admin 3.2.0 and PingDirectory Server 7.2.1.0, the following configuration changes were made:

- **delegated-admin-resource-type** was replaced with **rest-resource-type**.
- **delegated-administrator** was replaced with **delegated-admin-rights** and **delegated-admin-resource-rights**.

As a result, Delegated Admin 3.0.2 or earlier requires PingDirectory Server 7.2.0.1 or earlier. Similarly, Delegated Admin 3.2.0 or later requires PingDirectory Server 7.2.1.0 or later.

The **update** tool converts earlier configurations to new configuration definitions. This tool is used during the process of upgrading PingDirectory Server.

The migrated Delegated Admin configuration features a `group` REST resource type for the structural object classes `groupOfNames` and `groupOfUniqueNames`. If the original user's resource type configuration includes a value for `Org Search Filter`, then the migrated configuration also features a generic `orgs` REST resource type with the structural object class `organizationalUnit` as the parent resource type of users. If necessary, change the structural object class on the resource type configuration after the Delegated Admin update completes.

### Note:

If you change the structural object class, you must stop the server to proceed with the update.

The `delegated-admin-template.dsconfig` file has been updated to allow for `generate-password` extended requests and password validation details request controls. This change is not applied during an update. You must run the following two `dsconfig` commands when updating PingDirectory Delegated Admin to Version 4.0.0.

```
dsconfig set-access-control-handler-prop --add \
'global-aci:(extop="1.3.6.1.4.1.30221.2.6.62")(version 3.0; \
acl "Authenticated access to the generate-password extended \
request for the Delegated Admin API"; allow (read) userdn="ldap:///all";)'
```

```
dsconfig set-access-control-handler-prop \
--add 'global-aci:(targetcontrol="1.3.6.1.4.1.30221.2.5.40")\
(version 3.0;acl "Authenticated access to the password validation details \
request \
control for the Delegated Admin API"; allow (read) userdn="ldap:///all";)'
```

#### Tip:

For additional considerations, see the [Planning your upgrade guide](#).

To upgrade Delegated Admin on PingDirectory Server, perform the following steps:

1. Extract the contents of the Delegated Admin upgrade .zip file.
2. Rename the original `delegator` folder to retain a backup copy of the earlier version.
3. Copy the extracted folder named `delegator` to the PingDirectory Server folder named `webapps`.
4. Copy the `{OriginalDelegatorFolder}/app/config.js` configuration file to the new `delegator` folder.
5. Restart PingDirectory Server.

For more information, see the PingDirectory Server Administration Guide.

## Configuring Delegated Admin

---

This section describes the necessary configuration to support Delegated Admin after the application is installed successfully.

At a minimum, you must configure the following properties on PingDirectory Server:

- Delegated administrator rights
- REST resource type
- Attributes and attribute searching

### Configuration overview

Delegated Admin must have a PingDirectory Server and PingFederate Server installed.

For installation instructions, see the documentation for each product.

The process of configuring support for Delegated Admin on PingDirectory Server includes the following tasks:

- Configure users as Delegated Admin administrators.
- Configure attributes and attribute searching.
- Configure groups whose management requires delegation.

The process of configuring PingFederate Server includes the following tasks:

- Configure PingFederate as the identity provider for Delegated Admin.
- Configure PingFederate as the OAuth server for Delegated Admin.

- Register Delegated Admin as a client.
- Register PingDirectory Server as an OAuth token validator client.

## Authentication configuration

The delegated administrator signs on to Delegated Admin through the PingFederate Server, which is configured as the authentication server and OpenID Connect (OIDC) provider.

PingFederate validates the user's credentials against PingDirectory Server, encapsulates information **claims** about the user's identity, and issues an access token to Delegated Admin, which presents the token to PingDirectory Server in the HTTP Authorization request header.

### Interaction with PingDirectory Server

PingDirectory Server is configured to accept access tokens by using access token validators. The values that PingFederate Server sets for the access token **sub** claim must be mappable to a distinguished name (DN) in PingDirectory Server. Setting up an access token validator for use with Delegated Admin requires some coordination with the server configuration. In the suggested default configuration, the access token contains the entryUUID of the administrator user entry in the **sub** claim. This value is mapped back to a PingDirectory Server entry by using an Exact Match Identity Mapper.

### Authorization by PingDirectory Server

After validation, PingDirectory Server checks the Delegated Admin configuration for authorization of the delegated administrator. Users or groups of users are authorized as delegated administrators in the PingDirectory Server Administrative Console, or with the **dsconfig** tool.

### Configure authentication

One of the prerequisites to installing Delegated Admin is to configure the following OAuth clients within PingFederate:

- Delegated Admin, which obtains an OIDC token that describes the authenticated user. For more information, see [Configuring Delegated Admin as a new client \(create OAuth client for Delegated Admin\)](#) on page 1595.
- PingDirectory Server itself, which calls PingFederate to validate the OIDC token that Delegated Admin passes to it. For more information, see [Configuring PingDirectory Server as the token validator \(create OAuth client for PingDirectory\)](#) on page 1594.

## Configuring delegated administrator rights on PingDirectory Server

To delegate users or groups as administrators, use the PingDirectory Server Administrative Console (Delegated Admin rights and resource rights) or the **dsconfig create-delegated-admin-rights** and **create-delegated-admin-resource-rights** commands.

### About this task

To use Delegated Admin, an administrator must possess more than valid credentials and an access token that PingDirectory Server can validate. They must possess rights that are designated through the PingDirectory Server configuration.

#### Admin Permissions

##### create

The administrator can create new resources of this type.

##### read

The administrator can read resources of this type.

## Admin Permissions

 **Note:**

The `create`, `delete`, `manage-group-membership`, and `update` permissions require the `read` permission.

### update

The administrator can edit resources of this type.

### delete

The administrator can delete resources of this type.

### reference

The administrator can reference resources when selecting a parent during the creation of another resource. With the reference permission specified, the administrator can use a parent REST resource type without seeing the option to manage the parent resource type. For example, if the parent type for users is Organizational Unit, the administrator can have reference rights to the Organizational Unit resource type only. The administrator can create users without seeing the **Manage Organizational Unit** navigation option.

The administrator can reference resource types in Delegated Admin attributes. For example, the administrator can select user entries from a list based on their distinguished names (DNs) without displaying the actual values of the DN.

### manage-group-membership

The administrator can manage the membership of a group resource by adding or removing members. This permission is only applicable to group resource types.

### download

The administrator can download reports for resources of this type. With this permission, the **Download Report** button shows on the **Reporting** page for the administrator.

### upload

The administrator can upload a `.csv` file to import resources of this type. With this permission, the **Upload File** button shows on the **Reporting** page for the administrator.

 **Note:**

For the parent resource type to be available for the creation of new entries under the parent, the `read` or `reference` permission must be specified.

To prevent changes that might break the configuration of the app, the app does not allow changes to RDN attributes of a resource entry DN, for resources referenced in the Delegated Admin server configuration. This includes the following configuration elements:

- `admin-user-DN` and `admin-group-DN` of Admin Rights
- `resource-subtree` and `resources-in-group` of Admin Resource Rights

For example, if an Admin Rights configuration contains `admin-group-DN: cn=Admin Group,dc=example,dc=com` and some administrator has rights to modify that particular group through the app, then the `cn` attribute of that group can't be changed without invalidating the configuration. The attribute label has a lock icon and a message indicating that the value can only be changed by a server administrator.

The example commands that follow illustrate the configuration options for delegated administration and are performed on PingDirectory Server.

**Note:**

Administrators who manage only specific subtrees can't create users in an organization that does not reside under, or at the same level as, one of the subtrees.

### Steps

- Restrict an administrator to manage users in specified subtrees.

Example:

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name admin1 \
  --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com" \
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name admin1 \
  --rest-resource-type users \
  --set admin-scope:resources-in-specific-subtrees \
  --set "resource-subtree:ou=org1,dc=example,dc=com" \
  --set admin-permission:create \
  --set admin-permission:read \
  --set admin-permission:update \
  --set admin-permission:delete \
  --set enabled:true
```

- Restrict an administrator to managing the member users of one or more specified groups.

Example:

In the following example, assume the existence of a static or dynamic group entry whose members include the users to be managed.

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name admin1 \
  --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com" \
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name admin1 \
  --rest-resource-type users \
  --set admin-scope:resources-in-specific-groups \
  --set "resources-in-group:cn=User Group,dc=example,dc=com" \
  --set admin-permission:read \
  --set admin-permission:update \
  --set enabled:true
```

- Assign the delegated admin rights to a group REST resource type that matches the specified group.

For more information, see [Manage groups](#).

- Rather than delegate a single user as an administrator, delegate an entire group of users as administrators.

For more information about PingDirectory Server administrators and configuring dynamic and static groups, see the PingDirectory Server Administration Guide.

Example:

In this example, groups can be configured to manage specific subtrees or groups with the **resources-in-specific-subtrees** or **resources-in-group** setting for the **admin-scope**.

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name admin-group1 \
  --set "admin-group-dn:cn=Admin Group,ou=people,dc=example,dc=com"
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name admin-group1 \
  --rest-resource-type users \
  --set admin-scope:all-resources-in-base \
  --set admin-permission:create \
  --set admin-permission:read \
  --set admin-permission:update \
  --set admin-permission:delete \
  --set enabled:true
```

## Parameterized Delegated Administrator Rights

Delegated Admin rights can be parameterized so that a single definition provides a pattern for new administrators.

This allows a privileged administrator for a hosting company to use Delegated Admin to onboard a new tenant administrator to manage resources for the tenant's own organization. Using parameterized rights eliminates the need for PingDirectory Server configuration changes to create a new administrator.

In the following example, it's assumed that there are three REST resource types configured:

- orgs
- groups
- users

The users resource type has the parent resource type orgs.

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name "Tenant Admin" \
  --set enabled:true \
  --set 'admin-group-dn:cn=($1),ou=groups,dc=example,dc=com'

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name "Tenant Admin" \
  --rest-resource-type users --set enabled:true \
  --set admin-permission:create \
  --set admin-permission:read --set admin-permission:update \
  --set 'resource-subtree:ou=($1),dc=example,dc=com'

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name "Tenant Admin" \
  --rest-resource-type orgs --set enabled:true \
  --set admin-permission:reference \
  --set 'resource-subtree:ou=($1),dc=example,dc=com'
```

A privileged admin can perform the following steps to onboard a new tenant in Delegated Admin:

- Add a new `org` for the tenant.

- Add a new `group` with the same name as the new `org`, representing the tenant admins.
- Add a new `user` representing an initial tenant admin.
- Add the new tenant admin user to the tenant admin group

The tenant admin user can now sign on to the app and manage users for their own organization.

## Configuring user self-service

PingFederate Server provides end users with the ability to self-service their own profiles.

About this task

Additional configuration steps must be taken in both PingDirectory Server and PingFederate to enable users whom delegated administrators create to manage their own profiles through the PingFederate local identity profile-management feature.

### Note:

Import the Ping Federate LDIF first in PingDirectoryProxy Server and then in PingDirectory Server. Constructed attributes need to be created only in PingDirectoryProxy Server. Creating and rebuilding indexes (part of the self-service configuration) is done on PingDirectory Server.

### Steps

1. Configure PingFederate for profile management.

To allow users to change their passwords, enable **Allow Password Changes** in the HTML Form Adapter. You must make this change if you want to create passwords that the user must change on the first use. For example PingFederate configuration steps, see [Customer IAM configuration](#).

[Setting up PingDirectory for customer identities](#) in the PingFederate Administrator's Manual includes some of the following required steps on PingDirectory Server.

2. To create passwords that the user must change on the first use after account creation or a password reset, configure a PingDirectory password policy to force users to change their passwords.

Example:

This policy requires that you enable **Allow Password Changes** as mentioned above.

```
dsconfig set-password-policy-prop --policy-name "Default Password Policy" \
--set force-change-on-add:true --set force-change-on-reset:true
```

Result:

With these changes, when a user signs on to the PingFederate self-service page, the page prompts the user to change their password.

3. Import the required additional LDAP schema provided by PingFederate into PingDirectory Server.
  - a. On PingFederate Server, copy the LDIF file `local-identity-pingdirectory.ldif` from the following location: `<pf_install>/pingfederate/server/default/conf/local-identity/ldif-scripts/local-identity-pingdirectory.ldif`.
  - b. Use the `scp` command to securely copy the LDIF file to your local machine.

4. Update the LDAP schema.
  - a. Sign on to the PingDirectory Server Administrative Console.
  - b. Go to **LDAP Schema # Schema Utilities**.
  - c. Click **Import Schema Element**.
  - d. Copy the schema changes from the file `<pf_install>/pingfederate/server/default/conf/local-identity/ldif-scripts/local-identity-pingdirectory.ldif`.
  - e. Paste the schema changes into the text area.
  - f. Click **Import**.
5. Create an equality index for the pf-connected-identity attribute.

```
$ bin/dsconfig create-local-db-index \
  --backend-name userRoot \
  --index-name pf-connected-identity \
  --set index-type:equality
```

6. After adding the index, use the rebuild-index utility to build the indexes.

Example:

For instance, the following sample builds the required index.

```
$ bin/rebuild-index \
  --baseDN "dc=example,dc=com" \
  --index pf-connected-identity
```

7. Configure PingDirectory Server Composed Attributes.

In previous versions of Delegated Admin, the remaining configuration was achieved by setting a constructed attribute on the user REST resource type. In the latest version, composed attribute plugins should be used instead as they provide the following advantages:

- The populate-composed-attribute-values tool can be used to enable self-service for any existing users.
- Self-service is enabled for any users not created through the Delegated Admin app.

Configure two Composed Attribute Plugins as follows:

**Note:**

`<users-base-dn>` and `<users-object-class>` must be replaced with the search base DN and structural object class of your REST Resource Type.

```
$ bin/dsconfig create-plugin \
  --plugin-name pf-connected-identities \
  --type composed-attribute \
  --set enabled:true \
  --set attribute-type:objectClass \
  --set value-pattern:pf-connected-identities \
  --set target-attribute-exists-during-initial-population-behavior:merge-existing-and-composed-values \
  --set "include-base-dn:<users-base-dn>" \
  --set "include-filter:(objectClass=<users-object-class>)"

$ bin/dsconfig create-plugin \
  --plugin-name pf-connected-identity \
  --type composed-attribute \
  --set enabled:true \
  --set attribute-type:pf-connected-identity \
  --set "value-pattern:auth-source=pf-local-identity:user-id={entryUUID}" \
```

```
--set "include-base-dn:<users-base-dn>" \
--set "include-filter:(objectClass=<users-object-class>)" "
```

If you configure composed attribute plugins as described after upgrading an existing deployment, then you should remove the old constructed attribute configuration as follows.

```
$ bin/dsconfig set-rest-resource-type-prop --type-name users \
--remove auxiliary-ldap-objectclass:pf-connected-identities \
--remove post-create-constructed-attribute:pf-connected-identity \
--remove update-constructed-attribute:pf-connected-identity
```

- Optional: Enable self-service for any existing users not already linked to PingFederate.

```
$ bin/populate-composed-attribute-values -h <host> -p <port> -D
"cn=Directory Manager" -w <password>
```

## Configuring attributes and attribute search on PingDirectory Server

Use the Delegated Admin installation file to configure attributes and attribute search.

About this task

The file that installs Delegated Admin specifies the following values:

- Object class of user entries through `structural-ldap-objectclass:inetOrgPerson`
- Number of user attributes to expose

### Note:

Delegated Admin supports the following attribute types:

- Boolean
- Integer
- String
- DateTime
- Distinguished name (DN)
- Custom attributes
- Constructed attributes
- Multivalued attributes

### Steps

- If necessary, change the attribute that is designated as the primary attribute.

Example:

```
$ bin/dsconfig set-rest-resource-type-prop \
--type-name users \
--set primary-display-attribute-type:mail
```

- Configure any additional user attributes to appear in Delegated Admin by specifying the LDAP attribute type to expose and by providing a display name for it.

Example:

```
$ bin/dsconfig create-delegated-admin-attribute \
--type-name users \
--attribute-type customAttr
--set "display-name:My custom attribute"
```

3. Configure attributes with distinguished name (DN) syntax on resource types to provide a reference from one resource to another.

Such an attribute is the standard LDAP `manager` attribute.

The referencing resource doesn't have to be the same type of resource as the referenced resource. Delegated Admin allows the referenced resource to be selected without displaying the actual value of the DN.

Example:

In this example, the `manager` attribute is included in the `users` resource type, and its value is constrained to reference only resources of type `managers`. The `managers` REST Resource Type is assumed to have already been defined.

```
$ bin/dsconfig create-delegated-admin-attribute \
  --type-name users \
  --attribute-type manager \
  --set display-name:Manager \
  --set reference-resource-type:managers
```

Example:

Additionally, the Delegated Admin resource rights for the administrator must provide either read or reference permission to `managers`.

```
$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name Admin \
  --rest-resource-type managers \
  --set enabled:true \
  --set admin-permission:reference \
  --set admin-scope:all-resources-in-base
```

For more information about resource rights and permissions, see [Configuring delegated administrator rights on PingDirectory Server](#) on page 1560.

4. Use the following command to set the search filter, where `%%` represents the search text entered in the web application.

Example:

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set 'search-filter-pattern:(|(cn=%%*) (mail=%%*) (uid=%%*))'
```

When search text is entered in Delegated Admin, the property `search-filter-pattern` specifies which attributes to search in PingDirectory Server. To satisfy the query, define the appropriate attribute indexes for PingDirectory Server. For more information, see the PingDirectory Server Administration Guide.

5. To manage users whose profiles feature a large number of attributes, place the attributes in logical groupings, called attribute categories, and give them a specific display order.

Example:

The following commands create attribute categories and specify their display order.

```
$ bin/dsconfig create-delegated-admin-attribute-category \
  --display-name "Basic Information" \
  --set display-order-index:1

$ bin/dsconfig create-delegated-admin-attribute-category \
  --display-name "Contact Information" \
  --set display-order-index:2
```

```
$ bin/dsconfig create-delegated-admin-attribute-category \
  --display-name "Other Attributes" \
  --set display-order-index:3
```

6. The following example commands assign attributes to a category and specify the display order of each attribute within its category.

Example:

```
$ bin/dsconfig set-delegated-admin-attribute-prop \
  --type-name users \
  --attribute-type cn \
  --set "attribute-category:Basic Information" \
  --set display-order-index:1

$ bin/dsconfig set-delegated-admin-attribute-prop \
  --type-name users \
  --attribute-type sn \
  --set "attribute-category:Basic Information" \
  --set display-order-index:2
```

Unassigned attributes are displayed in a miscellaneous category.

7. For multivalued LDAP attributes, indicate whether the application should present them as multivalued.

If not specified, the attributes are presented in the application as single-valued, even if the LDAP schema definition for the attribute allows multiple values.

**Note:**

This setting does not apply to attributes that are handled by custom UI form fields.

Example:

```
$ bin/dsconfig set-delegated-admin-attribute-prop \
  --type-name users \
  --attribute-type mail \
  --set multi-valued:true
```

### Constructed attributes

A constructed attribute is an attribute whose value is computed from values that are assigned to other attributes. For example, the system might construct a full- or common-name attribute, `cn`, from values that are assigned to the standard `givenName` and `sn` attributes, as follows.

```
dsconfig create-constructed-attribute
  --attribute-name ReqConstructedCN --set attribute-type:cn \
  --set 'value-pattern:{givenName} {sn}'
```

Beginning with Delegated Admin 3.5.0 and PingDirectory Server 7.3.0.1, the value of a constructed attribute can be updated automatically whenever the value of a source attribute is not only created, but also when it is edited.

```
dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set post-create-constructed-attribute:ReqConstructedCN \
  --set update-constructed-attribute:ReqConstructedCN
```

In these examples, a change to the value of `givenName` or `sn` forces a corresponding change to the value of `cn`. Attributes that contribute to a required constructed attribute are identified in the UI as **Required**

even if they were not originally designated as such. Because `cn` is a required attribute in this example, `givenName` and `sn` are also required.

#### Note:

An attribute's capability of being changed after its creation is called its mutability.

As with standard attributes, constructed attributes are stored as LDAP attributes in a database like PingDirectory Server.

### Setting an attribute to read-only

About this task

Beginning with Delegated Admin 3.5.0 and PingDirectory Server 7.3.0.1, you can set user access to standard and constructed attributes to `read-only` and `read/write`. You should restrict access to constructed attributes to `read-only`. Read-only attributes do not appear on the UI pages that are associated with the creation of users groups and other objects.

Steps

- Use the `dsconfig` tool to set a standard or constructed attribute as `read-only`.

Example:

```
dsconfig set-delegated-admin-attribute \
  --type-name users \
  --attribute-type modifyTimestamp \
  --set mutability:read-only
```

Example: The following example resets a standard or constructed attribute from `read-only` to `read/write`.

```
dsconfig set-delegated-admin-attribute \
  --type-name users \
  --attribute-type modifyTimestamp \
  --reset mutability
```

## Users and groups

You can configure delegated administrators to manage users and groups in PingDirectory Server.

Configuring delegated administrators involves the following:

- Create new entries.
- Read, view, and search existing entries.
- Edit and update existing entries.
- Edit referenced items.

For example, if a delegated administrator is viewing an item that references a user, the delegated administrator can edit that user's information inline.

The following sections describe users and groups in more detail.

### Enable user creation

Enable the creation of new users and resources by configuring either a parent entry distinguished name (DN) or parent resource type where new users will be located.

If you configure a parent DN, the entry that it references must exist in PingDirectory Server. All new users are created in this single location. If necessary, use `ldapmodify` to create the parent entry. For

more information about the `ldapmodify` tool or about command-line help, see the PingDirectory Server Administration Guide. Alternatively, if a parent resource type is configured, the administrator can choose the specific resource where the new user is created.

**Note:**

Delegated Admin cannot list organizations in which the delegated administrator is unable to manage user entries. Administrators who manage only specific subtrees cannot create users in an organization that does not reside under, or at the same level as, one of the subtrees.

The following example specifies a single location for new users on PingDirectory Server.

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set "parent-dn:ou=people,dc=example,dc=com" \
  --reset parent-resource-type
```

The setup script creates a resource type named `orgs`, which works with entries that feature the `organization` `objectClass`.

The following example shows that any organization resource can function as the location for new users on PingDirectory Server.

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --reset parent-dn \
  --set parent-resource-type:orgs
```

A different resource type can be created for `organizationalUnit` `objectClass` entries, as follows.

```
$ bin/dsconfig create-rest-resource-type \
  --type-name orgUnits \
  --set "display-name:Organizational Units" \
  --set primary-display-attribute-type:ou \
  --set "search-filter-pattern: (&(objectClass=organizationalUnit) (ou=%%))" \
  --set structural-ldap-objectclass:organizationalUnit \
  --set enabled:false

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name orgUnits \
  --attribute-type ou \
  --set "display-name:Organizational Unit"

$ bin/dsconfig set-rest-resource-type-prop \
  --type-name orgUnits \
  --set enabled:true
```

The new resource type can be referenced as a `parent-resource-type`.

By default, new entries are named by their server-generated `entryUUID` values. To change this behavior, configure the LDAP `RDN` attribute.

**Note:**

The `RDN` attribute type must also be configured as a Delegated Admin attribute. For more information, see [Configuring attributes and attribute search on PingDirectory Server](#) on page 1566. Do not set read-only attributes as the `RDN` attribute.

In the following example, `uid` names new entries and becomes a required attribute.

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set create-rdn-attribute-type:uid
```

New users are always created with their configured structural LDAP `objectclass`. One or more auxiliary LDAP `objectclasses` can be specified, as the following example shows.

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set auxiliary-ldap-objectclass:ubidPersonAux
```

When existing users without all of the specified auxiliary `objectclasses` are edited, the missing `objectclasses` are updated automatically.

By default, the password field appears at the top of the **Create User** form outside any category. The next example adds the password field to the Required fields category and sets the location of the field to 2.

```
dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set "password-attribute-category:Required fields" \
  --set password-display-order-index:2
```

#### Note:

If the server does not require a password, you can leave the password field blank when you create a user. Without a password, the user can't sign on to [Configuring user self-service](#) on page 1564.

### Enabling Account Information tab content

The Delegated Admin GUI's **Account Information** tab provides information about a user account. For Delegated Admin to display the user account information, you must enable the **Password Policy State JSON** virtual attribute for the users object class. You can then configure the information that appears.

#### Steps

1. For each PingDirectory instance that contains users, enable the `Password Policy State JSON` virtual attribute for the users object class.

#### Note:

You don't need to enable this virtual attribute on PingDirectoryProxy instances.

For example, the following command enables the virtual attribute for users with the person object class, which includes users whose REST resource type structural object class is derived from person, such as `inetOrgPerson`.

```
$ bin/dsconfig set-virtual-attribute-prop \
  --name "Password Policy State JSON" \
  --set enabled:true \
  --set require-explicit-request-by-name:true \
  --set "filter:(objectClass=person)" \
```

```
--no-prompt --applyChangeTo server-group
```

After you enable the virtual attribute, delegated administrative users can access account information for a user in the Delegated Admin GUI.

The **Account Information** tab provides account status by default. To display the last login time and the password expiration date, you must set their properties. You configure these items per password policy.

When not configured, these entries appear as follows:

#### LAST LOGIN

Last login time not available. However, that entry is also given when the user has not logged in)

#### PASSWORD EXPIRATION

Password expiration date has not been enabled

You can configure these items in the Administrative Console or by using the `dsconfig` tool interactively or non-interactively. The following steps use the non-interactive approach.

2. Decide the password policy for which you want to enable the last login time and password expiration date.

For more information, see [Managing password policies](#) on page 811.

```
dsconfig list-password-policies
```

3. Decide whether to include the last login time.

To include the last login time, decide which property to set. You can set either of the following properties:

- `maximum-recent-login-history-successful-authentication-count`
- `last-login-time-format`

If you use this property, make sure the `last-login-time-attribute` has its default value `ds-pwp-last-login-time`.

Values for `last-login-time-format` include:

- `yyyyMMddHHmmss 'Z'` for second-level accuracy
- `yyyyMMdd` for day-level accuracy

4. Decide whether to include the password expiration date.

To include this information, set the property `max-password-age`

5. Set the desired password policy properties.

Example:

```
$bin/dsconfig set-password-policy-prop \
  --policy-name "<password_policy_name>" \
  --set maximum-recent-login-history-successful-authentication-
count:<count_value> \
  --set "max-password-age:<password_age_value>" \
  --no-prompt --applyChangeTo server-group
```

## Manage groups

The administrative scope for users determines which users are visible to the group administrator.

You can use `dsconfig` to delegate a user as a group administrator. An administrator can be configured to edit users as well as to manage group memberships.

- The group administrator can view, add, and remove any of the users within their administrative scope to the membership of groups within the groups' administrative scope.
- Static groups can be nested.
- Users who belong indirectly to a group through nesting are visible as group members but cannot be removed.
- Users can be removed only from the group of which they are a member. For example, an Employees group might include a Developers group as a nested member. In this scenario, a user in the Developers group is a direct member of that group and an indirect member of Employees. This member can be removed only when viewing the Developers group, not when viewing the Employees group.
- If a group is configured as a dynamic or virtual static group rather than a static group, then the group and its members are visible, but the group membership cannot be modified.

In the following example, all users in the subtree `ou=org1,dc=example,dc=com` are visible.

```
$ bin/dsconfig create-delegated-admin-rights \
--rights-name group-admin1 \
--set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com"
--set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
--rights-name group-admin1 \
--rest-resource-type groups \
--set admin-scope:resources-in-specific-subtrees \
--set "resource-subtree:ou=Groups,dc=example,dc=com" \
--set admin-permission:manage-group-membership \
--set admin-permission:create \
--set admin-permission:read \
--set admin-permission:update \
--set admin-permission:delete \
--set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
--rights-name group-admin1 \
--rest-resource-type users \
--set admin-scope:resources-in-specific-subtrees \
--set "resource-subtree:ou=org1,dc=example,dc=com" \
--set admin-permission:read \
--set enabled:true
```

### Set group attributes

The default settings for group attributes specify `cn` and `description` as group attributes, with `cn` used for the group title in Delegated Admin. To create the default settings, use the following commands with a search DN and parent DN ("`dc=example,dc=com`").

```
$ bin/dsconfig create-rest-resource-type \
--type group \
--type-name groups \
--set "display-name:Groups" \
--set enabled:false \
--set "search-base-dn:dc=example,dc=com" \
--set primary-display-attribute-type:cn \
--set resource-endpoint:groups \
--set "search-filter-pattern:(cn=%%*)" \
--set structural-ldap-objectclass:groupOfUniqueNames
--set parent-dn:dc=example,dc=com

$ bin/dsconfig create-delegated-admin-attribute \
--type-name groups \
```

```

--attribute-type cn \
--set "display-name:Name"

$ bin/dsconfig create-delegated-admin-attribute \
--type-name groups \
--attribute-type description \
--set "display-name:Description"

$ bin/dsconfig set-rest-resource-type-prop \
--type-name groups \
--set enabled:true

```

### Set group search filter

When entering text to search for groups, the groups' **search-filter-pattern** property specifies the attributes to be searched in PingDirectory Server. To satisfy the query, define the appropriate attribute indexes for PingDirectory Server. The default setting searches the attribute `cn` for the search text, which is represented by `%%`.

Use the following command to set the group search filter.

```

$ bin/dsconfig set-rest-resource-type-prop \
--type-name groups \
--set 'search-filter-pattern:(cn=*%%*)'

```

### Create a group

You can add users as members to groups that delegated administrators create and manage. You can also add subgroups as members to a group.

The configuration for each delegated group type consists of the following elements:

#### Group REST resource type

Defines the attributes to locate groups in the directory information tree (DIT).

#### Parent DN or Parent resource type

Specifies the location in which to create groups in the DIT.

- To specify a parent distinguished name (DN) for a resource type, enter the value in the **Parent DN** text box in the **Resource Creation** section. The parent DN is often identical to the search base DN, such as `ou=customers,ou=Groups,dc=example,dc=com`.
- To specify a parent resource type, select a value from the **Parent Resource Type** list in the **Resource Creation** section. Delegated administrators are subsequently presented with a list box that lets them select a resource, and the group is created under the selected parent resource. If you specify a parent resource type, set a value for the **Primary Display Attribute Type** in the **Delegated Admin** section. This setting determines the values that are displayed in the Delegated Admin GUI. For example, a primary display attribute type of `ou` displays the `ou` value in the list box for each resource within the parent resource type.

#### Attributes

These attributes are presented to the delegated administrators.

To configure a group REST resource type, go to **Configuration # REST Resource Types** page in the PingData Administrative Console.

When creating or editing a REST resource type, the **Search Base DN** field in the **General Configuration** section determines the data structure that is searched in Delegated Admin, and the **Display Name** field in the **Delegated Admin** section specifies the label of the REST resource in the Delegated Admin GUI.

PingData Administrative Console		Delegated Admin GUI
UI field	Window and section	UI field on New Group page
Display Name	<b>Configuration # REST Resource Types.</b> Create or edit a REST resource type, and then go to the <b>Delegated Admin</b> section.	Select a <code>Type</code> label
REST Resource Type	<b>Configuration # Delegated Admin Rights.</b> Create or edit Delegated Admin rights, and then click <b>New Delegated Admin Resource Rights.</b>	Select a <code>Type</code> option
Parent Resource Type	<b>Configuration # REST Resource Types.</b> Create or edit a REST resource type, and then go to the <b>Resource Creation</b> section.	Display name for parent resource type
Display Name	<b>Configuration # REST Resource Types.</b> Create or edit a REST resource type, and then go to the <b>Delegated Admin Attributes</b> section. Click <b>New Delegated Admin Attribute.</b>	Additional fields such as <code>CN</code> , <code>Description</code> , <code>Business Category</code> , and <code>Organization</code>

### Adding a user to a group

You can add users to groups from the **Manage Users** page and from the **Manage Groups** page in the GUI.

When the delegated admin rights for a user REST resource type have the `resources-in-specific-groups` admin scope, a user is added to one of the configured groups when you create the user.

### Adding a new user to a configured group

About this task

When the delegated admin rights for a user REST resource type has admin scope `resources-in-specific-groups` (and only in this case), a user is added to one of the configured groups when the user is created:

- For admins having rights to only one group, the new user is automatically added to that group. No field for `Select Group` displays.
- For admins having rights to more than one group, the admin selects a group to add the user to in the `Select Group` list.
- Admins can select from both static and dynamic groups.
- For dynamic groups, in addition to selecting the group, the new entry must also match criteria for membership of that group.

For example, in a dynamic group of members with `uid=user.111*`, the `uid` starts with `user.111`.

In order for an administrator to create a new user in that group, they must:

Steps

1. In the `Select Group` list, select the group name.
2. Enter the value for `uid` that starts with `user.111`.

### Adding a user from the Manage Users window

You can add users to groups using the **Manage Users** window in the Delegated Admin GUI.

#### Steps

1. In the Delegated Admin GUI, go to the **Manage Users** window.
  2. Use the search field to search for the user to add to a group.
  3. Click the **Expand** icon on the appropriate user profile.
  4. To edit the user profile, click the **Pencil** icon.
  5. Click the **Group Membership** tab.
  6. Use the search field to search for the appropriate group.
  7. To add the user to the respective group, in the **Nonmember Groups** list, click **+**.
- Result: The group moves to the **Member Groups** list.

### Adding a user from the Manage Groups window

You can add users to groups using the **Manage Groups** window in the Delegated Admin GUI.

#### Steps

1. In the Delegated Admin GUI, go to the **Manage Groups** window.
  2. Use the search field to search for the appropriate group.
  3. Click the **Expand** icon on the appropriate group profile.
  4. To edit the group profile, click the **Pencil** icon.
  5. Use the search field to search for the appropriate user.
  6. To add the respective user to the group, in the **Nonmembers** list, click **+**.
- Result: The user moves to the **Members** list.

## Generic resource types

Use generic resource types to manage LDAP entries that are neither users nor groups.

You can perform the following actions with generic resource types:

- Create new entries.
- Read, view, and search existing entries.
- Edit and update existing entries.
- Edit referenced items.

For example, a generic resource type can represent a device or used for organizational unit branch entries that are parents of other resources.

### Defining a generic resource type

You can define generic resources for any structural LDAP object class, and they can function as members of a group.

#### Steps

1. Define a generic resource type.

The following example enables the management of device entries.

Example:

```
$ bin/dsconfig create-rest-resource-type \
  --type-name device \
  --set enabled:true \
  --set resource-endpoint:device \
  --set "display-name:Device" \
```

```

--set structural-ldap-objectclass:device \
--set search-base-dn:dc=example,dc=com \
--set parent-dn:dc=example,dc=com \
--set 'search-filter-pattern:(cn=%%*)' \
--set primary-display-attribute-type:cn

$ bin/dsconfig create-delegated-admin-attribute \
--type-name device \
--attribute-type cn \
--set "display-name:Device Name" \
--set display-order-index:1

$ bin/dsconfig create-delegated-admin-attribute \
--type-name device \
--attribute-type serialNumber \
--set "display-name:Serial Number" \
--set display-order-index:2

```

2. Create Delegated Admin resource rights for the generic resource type.

Generic resource administrators must have read access to the user resource. For more information, see [Configuring delegated administrator rights on PingDirectory Server](#) on page 1560.

## Setting up a DN reference attribute

A REST resource type can reference or edit other REST resource types based on a distinguished name (DN) without the full DN value. The following task, performed by the system admin, grants the Delegated Admin this ability.

### About this task

In this task, the Delegated Admin attribute used for reference must be in DN syntax, such as `manager`, `entryDN`, or `seeAlso`.

### Steps

1. To use a resource type for DN reference, either:  
Choose from:
  - Use an existing REST resource type.
  - [Create a new REST resource type](#).
2. To add a reference delegated admin attribute, run `dsconfig` with the `create-delegated-admin-attribute` option using the following syntax.

Example:

```

dsconfig create-delegated-admin-attribute \
--type-name users \
