<b>PingDirectory.....</b>	<b>20</b>
<b>Release Notes.....</b>	<b>21</b>
PingDirectory Server Release Notes.....	21
PingDirectory Server 8.3.0.9 release notes.....	21
PingDirectory Server 8.3.0.8 release notes.....	22
PingDirectory Server 8.3.0.7 release notes.....	23
PingDirectory Server 8.3.0.6 release notes.....	24
PingDirectory Server 8.3.0.5 release notes.....	27
PingDirectory Server 8.3.0.3 release notes.....	28
PingDirectory Server 8.3.0.2 release notes.....	29
PingDirectory Server 8.3.0.1 release notes.....	29
PingDirectory Server 8.3.0.0 Release Notes.....	31
PingDirectory Server previous releases.....	55
PingDirectoryProxy Server Release Notes.....	138
PingDirectoryProxy Server 8.3.0.9 release notes.....	138
PingDirectoryProxy Server 8.3.0.8 release notes.....	139
PingDirectoryProxy Server 8.3.0.7 release notes.....	139
PingDirectoryProxy Server 8.3.0.6 release notes.....	140
PingDirectoryProxy Server 8.3.0.5 release notes.....	142
PingDirectoryProxy Server 8.3.0.3 release notes.....	142
PingDirectoryProxy Server 8.3.0.2 release notes.....	143
PingDirectoryProxy Server 8.3.0.1 release notes.....	143
PingDirectoryProxy Server 8.3.0.0 release notes.....	144
PingDirectoryProxy Server previous releases.....	158
PingDataMetrics Server Release Notes.....	207
PingDataMetrics Server 8.3.0.9 release notes.....	207
PingDataMetrics Server 8.3.0.8 release notes.....	207
PingDataMetrics Server 8.3.0.7 release notes.....	207
PingDataMetrics Server 8.3.0.6 release notes.....	207
PingDataMetrics Server 8.3.0.5 release notes.....	210
PingDataMetrics Server 8.3.0.3 release notes.....	210
PingDataMetrics Server 8.3.0.2 release notes.....	210
PingDataMetrics Server 8.3.0.1 release notes.....	210
PingDataMetrics Server 8.3.0.0 release notes.....	212
PingDataMetrics Server previous releases.....	222
Delegated Admin Release Notes.....	257
Delegated Admin 4.6 release notes.....	257
Delegated Admin previous releases.....	258
PingDataSync Server Release Notes.....	266
PingDataSync Server 8.3.0.9 release notes.....	266
PingDataSync Server 8.3.0.8 release notes.....	267
PingDataSync Server 8.3.0.7 release notes.....	267
PingDataSync Server 8.3.0.6 release notes.....	267
PingDataSync Server 8.3.0.5 release notes.....	270
PingDataSync Server 8.3.0.3 release notes.....	270
PingDataSync Server 8.3.0.2 release notes.....	271
PingDataSync Server 8.3.0.1 release notes.....	271

PingDataSync 8.3.0.0 release notes.....	272
PingDataSync Server previous releases.....	284

## **PingDirectory Server Administration Guide..... 327**

Introduction to PingDirectory Server.....	328
Server features.....	328
Administration framework.....	330
Server tools location.....	330
Installing PingDirectory Server.....	330
Prepare your environment.....	331
Getting the installation packages.....	340
Signing on to the Administrative Console.....	340
Directory Server folder layout.....	341
make-ldif template format.....	342
Server installation modes.....	354
Before you begin.....	354
Ping license keys.....	355
Setting up the Directory Server in interactive mode.....	356
Installing the Directory Server in non-interactive mode.....	358
Installing a lightweight server.....	359
Uninstalling the Server.....	360
Uninstalling the server in interactive mode.....	360
Uninstalling the server in non-interactive mode.....	361
Uninstalling selected components in non-interactive mode.....	362
Upgrading the Server.....	362
Upgrade overview and considerations.....	362
Upgrading servers in a topology.....	363
Upgrading the Directory Server.....	366
Reverting an update.....	367
Getting Started with Directory Server.....	368
Multiple backends.....	369
Importing data.....	369
Running the server.....	371
Stopping the Directory Server.....	373
Scheduling a server shutdown.....	374
Restarting the server.....	374
Running the server as a Microsoft Windows service.....	374
Running the status tool.....	375
Tuning the Server.....	377
About minimizing disk access.....	377
Memory allocation and database cache.....	378
Database preloading.....	382
Databases on storage area networks, network-attached storage, or running in virtualized environments.....	384
Database cleaner.....	385
Compacting common parent DNs.....	385
Setting the import thread count.....	386
JVM properties for server and command-line tools.....	386
Tuning for disk-bound deployments.....	387
Uncached attributes and entries.....	388
JVM garbage collection using CMS.....	391
Configuring the Server.....	394
About the configuration tools.....	394
About the dsconfig configuration tool.....	394
Using dsconfig in interactive command-line mode.....	394

Using dsconfig in non-interactive mode.....	398
Getting the equivalent dsconfig non-interactive mode command.....	400
Using dsconfig batch mode.....	400
Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth tokens.....	402
About recurring tasks and task chains.....	403
Using exec tasks.....	406
Topology configuration.....	407
Servers and certificates.....	409
Using the Configuration API.....	458
Working with the Directory REST API.....	472
Configuring the Server using the Administrative Console.....	474
Generating a summary of configuration components.....	477
Administrator account classes.....	477
Using separate administrator accounts.....	478
Unpredictable identifiers for server administrators.....	480
Secure communication for server administrators.....	480
Managing root user accounts.....	480
Default root privileges.....	481
Configuring administrator accounts.....	483
Configuring a global administrator.....	487
Configuring server groups.....	488
Client connection policy configuration.....	490
Securing the Server with lockdown mode.....	502
Configuring maximum shutdown time.....	503
About working with referrals.....	503
Configuring a read-only server.....	506
Configuring HTTP access for the Directory Server.....	507
DNS caching.....	519
IP address reverse name lookups.....	520
Configuring traffic through a load balancer.....	520
Working with the Referential Integrity plugin.....	521
Working with the Unique Attribute plugin.....	521
Working with the Purge Expired Data plugin.....	522
Configuring uniqueness across attribute sets.....	524
Working with the Last Access Time plugin.....	528
Working with the Pass-Through Authentication plugin.....	528
Troubleshooting server performance issues.....	533
Configuring the Directory Server for Oracle compatibility.....	537
Supporting unindexed search requests.....	538
Syncing passwords to PingOne.....	538
Single sign-on with the PingDirectoryServer administrative console.....	539
Configuring Soft Deletes.....	548
About soft deletes.....	549
General tips on soft deletes.....	549
Configuring soft deletes on the Server.....	551
Searching for soft deletes.....	554
Undeleting a soft-deleted entry using the same RDN.....	556
Undeleting a soft-deleted entry using a new RDN.....	557
Modifying a soft-deleted entry.....	558
Hard deleting a soft-deleted entry.....	559
Configuring soft deletes by connection criteria.....	560
Configuring soft deletes by request criteria.....	561
Configuring soft-delete automatic purging.....	562
Soft and hard delete processes.....	563
Soft delete controls and tool options.....	565

Monitoring soft deletes.....	566
Disabling soft deletes as a global configuration.....	570
Importing and exporting data.....	571
Importing data.....	571
Running an offline import.....	572
Running an online LDIF import.....	574
Adding entries to an existing Directory Server.....	576
Filtering data import.....	576
Exporting data.....	577
Encrypting LDIF exports and signing LDIF files.....	578
Filtering data exports.....	580
Scrambling data files.....	581
Backing Up and Restoring Data.....	582
About backing up and restoring data.....	582
Retaining backups.....	583
Moving or restoring a user database.....	589
Comparing the data in two Directory Servers.....	589
Reverting or replaying changes.....	593
Working with Groups.....	594
Overview of groups.....	595
About the isMemberOf and isDirectMemberOf virtual attribute.....	595
Using static groups.....	597
Using dynamic groups.....	602
Using virtual static groups.....	608
Creating nested groups.....	611
Maintaining referential integrity with static groups.....	613
Monitoring the group membership cache.....	615
Using the entry cache to improve the performance of large static groups.....	616
Tuning the index entry limit for large groups.....	617
Summary of commands to search for group membership.....	618
Migrating Oracle groups.....	619
Working with Indexes.....	622
Overview of indexes.....	622
General tips on indexes.....	622
Index types.....	624
System indexes.....	625
Managing local DB indexes.....	626
Composite indexes.....	629
JSON indexes.....	631
Working with local DB VLV indexes.....	632
Working with filtered indexes.....	635
Tuning indexes.....	636
Managing Entries.....	641
Searching entries.....	641
Working with the matching entry count control.....	647
Adding entries.....	648
Deleting entries using ldapdelete.....	652
Deleting entries using ldapmodify.....	652
Modifying entries using ldapmodify.....	653
Working with the parallel-update tool.....	659
Working with the watch-entry Tool.....	661
Working with LDAP transactions.....	661
Working with Virtual Attributes.....	663
Viewing the list of default virtual attributes.....	663
Viewing the list of default virtual attributes using dsconfig non-interactive mode.....	665
Viewing virtual attribute properties.....	665

Enabling a virtual attribute.....	666
Creating user-defined virtual attributes.....	667
Creating mirror virtual attributes.....	670
Editing a virtual attribute.....	671
Deleting a virtual attribute.....	672
Working with Composed Attributes.....	672
Virtual attribute limitations.....	672
Overview of composed attributes.....	673
Composed attribute plugin configuration properties.....	674
Populate composed attribute values task.....	681
Composed attribute dependency considerations.....	682
Schema validation considerations.....	682
Replication considerations.....	683
Synchronization Server considerations.....	683
Directory Proxy Server considerations.....	684
Troubleshooting considerations.....	684
Security considerations.....	684
Limitations of composed attributes relative to virtual attributes.....	684
Encrypting Sensitive Data.....	685
About encrypting and protecting sensitive data.....	685
About backing up and restoring the encryption-settings definitions.....	693
Configuring sensitive attributes.....	699
Configuring global sensitive attributes.....	703
Excluding a global sensitive attribute on a client connection policy.....	703
Working with the LDAP Changelog.....	704
Overview of the LDAP changelog.....	705
Viewing the LDAP changelog properties.....	710
Enabling the LDAP changelog.....	710
Changing the LDAP changelog database location.....	711
Viewing the LDAP changelog parameters in the Root DSE.....	713
Viewing the LDAP changelog using ldapsearch.....	714
Indexing the LDAP changelog.....	716
Tracking virtual attribute changes in the LDAP changelog.....	717
Managing Access Control.....	718
Overview of access control.....	718
Access token validators.....	730
Working with targets.....	737
Examples of common access control rules.....	742
Validating ACIs before migrating data.....	744
Migrating ACIs from Oracle to PingDirectory Server.....	746
Working with privileges.....	749
Working with proxied authorization.....	754
Working with parameterized ACIs.....	763
\$attr.attrName macro.....	764
Managing the Schema.....	764
About the schema.....	764
About the Schema Editor.....	764
Default Directory Server schema files.....	765
Extending the Directory Server schema.....	766
About managing attribute types.....	768
Creating a new attribute over LDAP.....	773
Managing object classes.....	774
Managing an object class over LDAP.....	778
Creating a new object class using the Schema Editor.....	780
Extending the schema using a custom schema file.....	780
About managing matching rules.....	783

About managing attribute syntaxes.....	791
Using the Schema Editor utilities.....	797
Modifying a schema definition.....	797
Deleting a schema definition.....	798
Managing schema checking.....	798
Managing matching rule uses.....	800
Managing DIT content rules.....	801
Managing name forms.....	802
Managing DIT structure rules.....	803
About managing JSON attribute values.....	804
Configuring JSON attribute constraints.....	805
Managing password policies.....	811
Viewing password policies.....	811
About the password policy properties.....	813
Access log.....	815
Modifying an existing password policy.....	819
Creating new password policies.....	819
Deleting a password policy.....	822
Modifying a user's password.....	822
Enabling YubiKey authentication.....	825
Enabling social sign-on.....	825
Managing user accounts.....	826
Disabling password policy evaluation.....	829
About managing password validators.....	830
Managing Replication.....	837
Overview of replication.....	837
Replication versus synchronization.....	838
Replication terminology.....	839
Replication architecture.....	842
Replication deployment planning.....	843
Enabling replication.....	846
Deploying a basic replication topology.....	849
Example deployment with non-interactive dsreplication.....	854
Configuring assured replication.....	857
Managing the topology.....	865
Advanced configuration.....	868
Modifying the replication purge delay.....	869
Configuring a single listener-address for the replication server.....	870
Monitoring replication.....	871
Replication best practices.....	873
Replication conflicts.....	874
Troubleshooting replication.....	879
Replication reference.....	883
Advanced topics reference.....	906
Managing Logging.....	915
Default Directory Server logs.....	915
Types of log publishers.....	916
Managing access and error log publishers.....	921
Managing file-based access log publishers.....	921
Generating access logs summaries.....	925
About log compression.....	927
About log signing.....	927
About encrypting log files.....	928
Creating new log publishers.....	930
Configuring log rotation.....	931
Configuring log rotation listeners.....	932

Configuring log retention.....	933
Configuring filtered logging.....	934
Managing Admin Alert Access Logs.....	935
Managing the Syslog-Based Access Log Publishers.....	936
Managing the File-Based Audit Log Publishers.....	940
Managing the JDBC Access Log Publishers.....	941
Managing the File-Based Error Log Publisher.....	946
Managing the Syslog-Based Error Log Publisher.....	947
Creating File-Based Debug Log Publishers.....	948
Managing Monitoring.....	949
The monitor backend.....	949
Monitoring disk space usage.....	951
Monitoring with the PingDataMetrics Server.....	952
About the collection of system monitoring data.....	952
Monitoring key performance indicators by application.....	953
Configuring the external Servers.....	953
Preparing the servers monitored by the PingDataMetrics Server.....	953
Configuring the Processing Time Histogram plugin.....	954
Setting the connection criteria to collect SLA statistics by application.....	954
Proxy considerations for tracked applications.....	955
Monitoring using SNMP.....	955
SNMP implementation.....	955
Configuring SNMP.....	956
MIBS.....	959
Monitoring with the Administrative Console.....	959
Accessing the Processing Time Histogram.....	960
Monitoring with JMX.....	960
Running JConsole.....	961
Monitoring the Directory Server using JConsole.....	962
Monitoring using the LDAP SDK.....	963
Monitoring over LDAP.....	963
Profiling server performance using the Stats Logger.....	963
Enabling and configuring the StatsD monitoring endpoint.....	965
Adding custom logged statistics to a Periodic Stats Logger.....	967
Updating the Global Configuration.....	970
Monitoring PingDirectory metrics with Splunk.....	970
Sending PingDirectory metrics with StatsD.....	970
Using the Directory Server app for Splunk.....	972
Managing Notifications and Alerts.....	972
Account status notifications.....	973
Administrative alert handlers.....	977
Configuring the JMX connection handler and alert handler.....	977
Configuring the SMTP alert handler.....	978
Configuring the SNMP subagent alert handler.....	979
Email account status notification handler.....	979
Working with the Alerts Backend.....	995
Working with alarms, alerts, and gauges.....	997
Testing alerts and alarms.....	998
Managing SCIM Servlet Extensions.....	1002
SCIM 1.1 and 2.0 servlet extensions management.....	1002
Managing Server SDK Extensions.....	1037
About the Server SDK.....	1037
Available types of extensions.....	1037
DevOps and infrastructure-as-code.....	1038
Limitations when automating PingDirectory Server deployments.....	1038
Server profiles.....	1038

Topology-management tools.....	1044
Deployment automation.....	1045
Troubleshooting PingDirectory Server.....	1050
Directory Server gauges.....	1051
Working with the collect-support-data tool.....	1057
Directory Server Troubleshooting information.....	1060
About the monitor entries.....	1065
Directory Server troubleshooting tools.....	1065
Troubleshooting resources for Java applications.....	1068
Command-Line Tools.....	1086
Available command-line tools.....	1086
Saving options in a file.....	1107
Sample dsconfig batch files.....	1109
Running task-based tools.....	1110

## **PingDirectoryProxy Server Administration Guide..... 1111**

Introduction to PingDirectoryProxy Server.....	1111
Overview of the PingDirectory Server features.....	1111
Overview of the Directory Server components and terminology.....	1112
Server component architecture.....	1119
Directory Server configuration overview.....	1122
Installing PingDirectoryProxy Server.....	1123
Before you begin.....	1123
Preparing the operating system.....	1127
Getting the installation packages.....	1132
Signing on to the Administrative Console.....	1132
Ping license keys.....	1133
Installing the Directory Proxy Server.....	1134
Directory Server folder layout.....	1140
Uninstalling the Server.....	1141
Uninstalling the server in interactive mode.....	1142
Uninstalling the server in non-interactive mode.....	1143
Uninstalling selected components in non-interactive mode.....	1143
Upgrading the PingDirectoryProxy Server.....	1143
Upgrade overview and considerations.....	1144
Upgrading servers in a topology.....	1144
Upgrading the Directory Proxy Server.....	1146
Reverting an update.....	1147
Getting Started with Directory Server.....	1148
Running the server.....	1148
Stopping the Directory Server.....	1151
Scheduling a server shutdown.....	1151
Restarting the server.....	1151
Running the server as a Microsoft Windows service.....	1152
Configuring the Directory Proxy Server.....	1153
About the configuration tools.....	1153
Using the create-initial-proxy-config tool.....	1153
Configuring a standard Directory Proxy Server deployment.....	1154
About the dsconfig configuration tool.....	1157
Using dsconfig in interactive command-line mode.....	1157
Changing the dsconfig object menu.....	1158
Using dsconfig in non-interactive mode.....	1159
Using dsconfig batch mode.....	1160
Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth tokens.....	1161

Topology configuration.....	1163
Using the Configuration API.....	1165
Working with the Directory REST API.....	1179
Generating a summary of configuration components.....	1181
Configuring server groups.....	1182
DNS caching.....	1184
IP address reverse name lookups.....	1185
Configuring traffic through a load balancer.....	1185
Managing root user accounts.....	1186
Default root privileges.....	1186
Configuring locations.....	1188
Configuring batched transactions.....	1192
Configuring server health checks.....	1193
Configuring LDAP external servers.....	1196
Servers and certificates.....	1202
Configuring load balancing.....	1251
Configuring HTTP connection handlers.....	1262
Configuring proxy transformations.....	1268
Configuring request processors.....	1270
Configuring server affinity.....	1272
Configuring subtree views.....	1273
Client connection policy configuration.....	1274
Configuring globally unique attributes.....	1280
Configuring the Global Referential Integrity plugin.....	1282
Configuring an Active Directory Server back-end.....	1283
Setting up SSO to PingDirectory from PingOne.....	1284
Managing Access Control.....	1288
Overview of access control.....	1288
Access token validators.....	1300
Working with targets.....	1307
Examples of common access control rules.....	1312
Validating ACIs before migrating data.....	1314
Migrating ACIs from Oracle to PingDirectory Server.....	1316
Working with privileges.....	1320
Deploying a Standard Directory Proxy Server.....	1325
Introduction.....	1325
Automatic server discovery.....	1326
Creating a standard multi-location deployment.....	1338
Expanding the deployment.....	1346
Merging two data sets using proxy transformations.....	1352
Deploying an Entry-Balancing Directory Proxy Server.....	1361
Deploying an entry-balancing proxy configuration.....	1361
Rebalancing your entries.....	1373
Managing the global indexes in entry-balancing configurations.....	1376
Working with alternate authorization identities.....	1383
Managing Entry-Balancing Replication.....	1386
Overview of replication in an entry-balancing environment.....	1386
Replication prerequisites in an entry-balancing deployment.....	1387
About the --restricted argument of the dsreplication command-line Tool.....	1388
Checking the status of replication in an entry-balancing deployment.....	1389
Example of configuring entry-balancing replication.....	1389
Managing the Directory Proxy Server.....	1395
Managing logs.....	1395
Types of log publishers.....	1400
Creating new log publishers.....	1400
About log compression.....	1402

About log signing.....	1402
About encrypting log files.....	1402
Configuring log rotation.....	1405
Configuring log rotation listeners.....	1405
Configuring log retention.....	1406
Setting resource limits.....	1407
Monitoring the Directory Proxy Server.....	1409
Working with alarms, alerts, and gauges.....	1412
Administrative alert handlers.....	1416
Working with virtual attributes.....	1418
Managing Monitoring.....	1419
The monitor backend.....	1419
Monitoring disk space usage.....	1421
Monitoring with the PingDataMetrics Server.....	1422
Monitoring using SNMP.....	1425
Monitoring with the Administrative Console.....	1429
Accessing the Processing Time Histogram.....	1430
Monitoring with JMX.....	1430
Monitoring using the LDAP SDK.....	1433
Monitoring over LDAP.....	1433
Profiling server performance using the Stats Logger.....	1433
Enabling and configuring the StatsD monitoring endpoint.....	1438
DevOps and Infrastructure as Code.....	1439
Server profiles.....	1440
Troubleshooting PingDirectoryProxy Server.....	1445
Garbage Collection Diagnostic Information.....	1445
Working with the Troubleshooting Tools.....	1446
Directory Server troubleshooting tools.....	1447
Troubleshooting resources for Java applications.....	1452
SCIM 1.1 and 2.0 servlet extensions management.....	1468
Overview of SCIM 1.1 fundamentals.....	1468
Creating your own SCIM 1.1 application.....	1470
Configuring SCIM 1.1.....	1470
Configuring advanced SCIM 1.1 extension features.....	1475
Configuring the Identity Access API.....	1481
Monitoring the SCIM servlet extension.....	1483
Managing the SCIM 2.0 Servlet Extension.....	1486
Managing Server SDK Extensions.....	1501
About the Server SDK.....	1501
Available types of extensions.....	1501
Command-Line Tools.....	1502
Available command-line tools.....	1502
Saving Options in a File.....	1519
Sample dsconfig batch files.....	1521
Running task-based tools.....	1522
<b>Consent Solution Guide.....</b>	<b>1523</b>
Introduction to the Consent Service and Consent API.....	1523
Consent Service overview.....	1523
Consent API overview.....	1524
How consents are collected.....	1524
How consents are enforced.....	1525
How applications use the Consent API.....	1525
Configuring the Consent Service.....	1525
Configuration overview.....	1526

Example configuration scenarios.....	1526
Setting up with the configuration scripts.....	1527
Setting up in a replicated PingDirectory Server environment.....	1527
Configuration reference.....	1528
Authorization.....	1536
Managing Consents.....	1538
Overview of consent management.....	1538
Consent definitions and localizations.....	1538
Perform an audit on consents.....	1539
Logging.....	1544
Correlating user and consent data.....	1545
Troubleshooting the Consent Service.....	1546

## **Delegated Admin Application Guide..... 1547**

Delegated Admin overview.....	1547
Introduction to Delegated Admin.....	1547
Features.....	1547
Installing Delegated Admin.....	1548
Installation locations.....	1548
Prerequisites.....	1548
Supported browsers.....	1549
Obtaining the installation files.....	1549
Before you install.....	1549
Installing the application.....	1550
Next steps.....	1554
Upgrading Delegated Admin.....	1554
Upgrade considerations.....	1554
Upgrade PingDirectory Server.....	1555
Upgrade the application.....	1558
Configuring Delegated Admin.....	1559
Configuration overview.....	1559
Authentication configuration.....	1560
Configuring delegated administrator rights on PingDirectory Server.....	1560
Parameterized Delegated Administrator Rights.....	1563
Configuring user self-service.....	1564
Configuring attributes and attribute search on PingDirectory Server.....	1566
Users and groups.....	1569
Generic resource types.....	1576
Setting up a DN reference attribute.....	1577
Differentiating resource types within the same subtree.....	1580
Configuring a resource's summary display in the Delegated Admin GUI.....	1580
Customizing UI form fields.....	1581
Setting up email invitations for a new user.....	1583
Enabling the referential integrity plugin.....	1586
Enabling log tracing.....	1586
Specify a custom hostname and port for your Directory Server.....	1587
Changing the application logo.....	1587
Configure the session timeout.....	1588
Verifying the installation.....	1588
Reporting.....	1588
Compatibility matrix.....	1589
Configuring PingFederate Server.....	1590
Configuring PingFederate as the identity provider.....	1590
Configuring the OAuth server.....	1592

Configuring PingDirectory Server as the token validator (create OAuth client for PingDirectory).....	1594
Configuring Delegated Admin as a new client (create OAuth client for Delegated Admin).....	1595
Setting Cross-Origin Resource Sharing (CORS) settings.....	1596
Optional configuration tasks.....	1596

## **PingDataSync Server Administration Guide.....1596**

Introduction to PingDataSync Server.....	1597
Overview of PingDataSync Server.....	1597
Data synchronization process.....	1597
Synchronization modes.....	1599
PingDataSync operations.....	1599
Configuration components.....	1601
Sync flow examples.....	1603
Sample synchronization.....	1607
Installing PingDataSync Server.....	1608
System requirements.....	1609
Upgrade overview and considerations.....	1612
Install the JDK.....	1612
Optimize the Linux operating system.....	1612
Ping license keys.....	1616
Installing PingDataSync.....	1617
Signing on to the Administrative Console.....	1618
Server folders and files.....	1618
Start and stop the server.....	1619
Run the server as a Microsoft Windows service.....	1620
Uninstalling the Server.....	1621
Update servers in a topology.....	1622
Revert an update.....	1623
Install a failover server.....	1625
Administrative accounts.....	1626
Configuring PingDirectory Server.....	1626
Configuration checklist.....	1627

# PingDirectory

---

The PingDirectory suite of products includes the PingDirectory server, the PingDirectoryProxy server, the Delegated Admin application, the PingDataSync server, and the PingDataMetrics server.

## Release Notes

### Current

- [PingDirectory Server](#)
- [PingDirectoryProxy Server](#)
- [PingDataMetrics Server](#)
- [Delegated Admin](#)
- [PingDataSync Server](#)

### Previous releases

- [PingDirectory Server](#)
- [PingDirectoryProxy Server](#)
- [PingDataMetrics Server](#)
- [Delegated Admin](#)
- [PingDataSync Server](#)

## Get Started with PingDirectory

### PingDirectory

A high-performance, extensible LDAP directory.

- [Introduction to PingDirectory Server](#) on page 328
- [Installing PingDirectory Server](#) on page 330
- [Uninstalling the Server](#) on page 360
- [Signing on to the Administrative Console](#) on page 340

### PingDirectoryProxy

A fast and scalable LDAPv3 gateway for the PingDirectory server.

- [Introduction to PingDirectoryProxy Server](#) on page 1111
- [Installing PingDirectoryProxy Server](#) on page 1123
- [Uninstalling the Server](#) on page 360
- [Signing on to the Administrative Console](#) on page 340

### Delegated Admin

An add-on to PingDirectory that enables the delegation of user and group management.

- [Introduction to Delegated Admin](#) on page 1547
- [Installing Delegated Admin](#) on page 1548

### PingDataSync

An efficient, Java-based server that provides high throughput, low latency, and bidirectional real-time synchronization between two endpoint topologies.

- [Introduction to PingDataSync Server](#) on page 1597
- [Installing PingDataSync Server](#) on page 1608
- [Uninstalling the Server](#) on page 1621
- [Signing on to the Administrative Console](#) on page 340

### PingDataMetrics

Collects performance data from PingDirectory.

- [Introduction to PingDataMetrics Server](#) on page 1857
- [Installing the PingDataMetrics Server](#) on page 1860
- [Uninstalling the Server](#) on page 1874
- [Signing on to the Administrative Console](#) on page 1869

### Use PingDirectory

- [Best Practices: PingDirectory Operational Support](#)
- [PingDirectory Server Administration Guide](#) on page 327
- [PingDirectoryProxy Server Administration Guide](#) on page 1111
- [Delegated Admin Application Guide](#) on page 1547
- [PingDataSync Server Administration Guide](#) on page 1596
- [PingDataMetrics Server Administration Guide](#) on page 1857

### Troubleshoot PingDirectory

- [Troubleshooting PingDirectory Server](#) on page 1050
- [Troubleshooting PingDirectoryProxy Server](#) on page 1445
- [Troubleshooting PingDataSync Server](#) on page 1818
- [Troubleshooting PingDataMetrics Server](#) on page 1970

### Learn More

- [Try PingDirectory](#)
- [PingDirectory Community Page](#)
- [PingDirectory Customer Training \(existing customers only\)](#)
- [Partner Portal \(partners\)](#)

## Release Notes

---

### PingDirectory Server Release Notes

---

#### PingDirectory Server 8.3.0.9 release notes

The release notes for the 8.3.0.9 release of the PingDirectory Server.

#### Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server.

Ticket ID	Description
DS-45767	Fixed an issue in which the server would always reject an operation with a request control that the client did not have permission to use, regardless of the control's criticality. It will continue to reject the operation if the disallowed control has a criticality of true, but if the criticality is false, the server will continue processing the operation as if that control had not been requested.
DS-47076	Fixed an issue where attempting to change a password that's within the minAge now responds with an UNABLE_TO_PERFORM code rather than INVALID_CREDENTIALS.
DS-47184	Resolved a performance issue that caused the dsreplication enable command to take in excess of 90 minutes to complete, in topologies of 25 or more PingDirectory servers.
DS-47319	Fixed an issue where the temporary filename prefix used in combination with an index name could exceed the maximum filename length of 255 characters.
DS-47343	Fixed an internal error that could cause a replicated PingDirectory Server topology to have unstable master selection.
DS-47405	<p>Added the configuration property <code>insignificant-config-archive-base-dn</code> to the Config File Handler backend. This property can be used to control the rate at which the configuration archive grows by removing files that record only changes under the specified base DN(s).</p> <p>If an existing configuration entry is updated, but all of the changes are restricted to one or more of these base DNs, then the updated configuration will be added to the configuration archive, but that archived configuration file may be removed after the next configuration change.</p> <p>By default, this property will apply to the topology registry subtree.</p>
DS-47632	Fixed a security issue that could potentially affect customers using Delegated Admin. Customers are advised to apply a maintenance patch or upgrade to the latest supported versions of the PingDirectory Server. The Delegated Admin application is unaffected and does not require updating. Additional details are provided in SECADV039.

## PingDirectory Server 8.3.0.8 release notes

The release notes for the 8.3.0.8 release of the PingDirectory Server.

### Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server.

Ticket ID	Description
DS-45638	Fixed an issue where resource limits for the topology admin user created during replication enable were not set.
DS-46392	Fixed an issue in which the server could prevent users from changing their own passwords with the password modify extended operation if their account was in a "must change password" state and the request passed through the PingDirectoryProxy Server.

## PingDirectory Server 8.3.0.7 release notes

The release notes for the 8.3.0.7 release of the PingDirectory Server.

### Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server.

Ticket ID	Description
DS-44648	Addressed an issue where symmetric keys were not being sanitized in the <code>config-audit.log</code> .
DS-45044	Fixed an issue with the <code>dsreplication</code> tool where baseDNs and restricted baseDNs were improperly handled as case sensitive.
DS-45546	Fixed an issue that caused the encode-password tool to fail when the AES256 password storage scheme is enabled.
DS-45567	Fixed an issue where a replication initialize task that ran longer than the configured connection idle-timeout-limit would cause the initialize to fail.
DS-45714	Fixed an issue that allowed replication protocol messages to be dropped.
DS-45863	Resolved an issue where SCIM POST requests that violated a unique attribute constraint received an error response with status 400 (Bad Request) instead of 409 (Conflict).
DS-45960	Fixed an issue that caused replication enablement to fail if there is at least one topology-wide administrator with no password.

Ticket ID	Description
DS-46017	Resolved an issue with slow response time on PingDirectory servers configured with a large number (10,000 or more) of virtual static groups.
DS-46332	The replication server now continues to handle incoming replication connections even when there is an unexpected exception.
DS-46436	Fixed an issue where new servers could not be enabled into a large topology.

## PingDirectory Server 8.3.0.6 release notes

The release notes for the 8.3.0.6 release of PingDirectory Server.

### Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of PingDirectory Server.

Ticket ID	Description
DS-40796	To enhance initialization performance, the <code>dsreplication initialize-all</code> command now initializes multiple target servers in parallel when the <code>--parallel</code> option is used (subject to the <code>--parallelLimit</code> option). The <code>--sameLocationOnly</code> and <code>--destinationInstanceName</code> options may be used to limit the destinations that are initialized.
DS-41468	Fixed an issue that prevented the server from refreshing the monitor data used to detect and warn about an upcoming certificate expiration. This could cause the server to continue to warn about an expiring certificate even after that certificate had been replaced.
DS-45162	Added support for new extended operations that can be used to help manage the server's listener and inter-server certificates. Updated the <code>replace-certificate</code> tool to add support for replacing and purging certificates in a remote instance, and to allow skipping validation for the new certificate chain.

Ticket ID	Description
DS-45449	Updated the server to create the <code>esTokenizer.ping</code> file if it does not exist for a backend containing encrypted data. This file may be needed to open the database environment for a backend containing encrypted indexes, but it would not have been automatically created when upgrading from a pre-7.0 server to a later version with support for encrypted indexes.

Ticket ID	Description
DS-45480, DS-45636	<ul style="list-style-type: none"> <li>▪ Updated the topology registry to allow using issuer certificates when determining whether to trust the certificate chain presented by another server in the topology. Previously, a server's certificate chain would only be trusted if the server certificate itself was found in the topology registry. Now, a certificate chain may be trusted if either the peer certificate or any of its issuers is found in the topology registry.</li> <li>▪ Updated the <code>replace-certificate</code> tool to add new <code>list-topology-registry-listener-certificates</code> and <code>list-topology-registry-inter-server-certificates</code> subcommands that can be used to display a list of the listener or inter-server certificates for a specified server instance in the topology registry.</li> <li>▪ Updated the <code>replace-certificate</code> tool to add a new <code>add-topology-registry-listener-certificate</code> subcommand that can be used to add one or more certificates to the set of listener certificates for an instance in the topology registry. This subcommand does not alter the contents of any key store, and it may be used to add an issuer certificate to the topology registry or to add a new peer listener certificate in advance of actually activating that certificate on the server.</li> <li>▪ Updated the <code>replace-certificate</code> <code>replace-listener-certificate</code> subcommand to add <code>--topology-registry-update-type</code> and <code>--trust-store-update-type</code> arguments that allow indicating which types of certificates to include in the topology registry and trust store, respectively. Available options include suppressing the update, only adding the listener certificate itself, only adding the listener certificate's issuers, or adding both the listener certificate and its issuers.</li> <li>▪ Updated the <code>replace-certificate</code> <code>replace-listener-certificate</code> subcommand to add an <code>--ignore-current-listener-certificate-validity-window</code> argument that will allow the tool to establish a connection to the server even if its certificate has expired or is not yet valid so that a non-valid certificate can be replaced.</li> </ul>
DS-45647	Resolved an issue where SCIM POST requests that violated a unique attribute constraint got an internal error instead of the expected SCIM error response.

Ticket ID	Description
DS-45786	Fixed a PingDirectory server issue that could cause an internal error to be logged while monitoring database statistics for read-only backends.
DS-45788	Fixed an issue where the Directory Rest API returns an HTTP 500 error response when trying to retrieve a SCIM entry whose corresponding LDAP entry contains a valid Generalized Time Syntax attribute value not matching the specific format <code>YYYYMMDDhhmmssZ</code> .
DS-45815	Updated PingDirectory products to use Kafka v2.8.1 which resolves CVE-2021-38153.

## PingDirectory Server 8.3.0.5 release notes

The release notes for the 8.3.0.5 release of PingDirectory Server.

The 8.3.0.4 release contained internal code improvements that are included in 8.3.0.5.

### Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-43959, DS-44924	Added new global configuration properties that can be used to impose limits on the maximum number of attributes that can be present in an <code>add</code> request and the maximum number of modifications in a <code>modify</code> request, which can be used to avoid potential denial of service attacks. Both limits are set to 1000 by default, which is likely to be adequate for all legitimate use cases, and neither property affects the number of values that may be provided for an attribute.
DS-45032	Addressed an issue that caused <code>remove-defunct-server</code> to hang when performing replication artifact cleanup in non-interactive mode.
DS-45115	Fixed a PingDirectory Server performance issue involving high CPU usage when writing LDAP data to certain clients using TLSv1.3 connection security.

Ticket ID	Description
DS-45124	Removed <code>-XX:RefDiscoveryPolicy=1</code> from the default <code>start-server</code> Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.
DS-45154	Fixed an issue where a server with a newly initialized database (through <code>dsreplication initialize</code> ) could go into lockdown mode and report that the server may have missed one or more update(s). This generally occurred only if the initialized server was restarted right after initialization completed.
DS-45190	Added support for the use of Java Development Kits (JDKs) obtained through BellSoft.
DS-45203	Resolved a performance issue that could cause servers installed using a server encryption option to spend several minutes waiting in phase <code>Initializing Crypto Manager</code> during server startup.

## PingDirectory Server 8.3.0.3 release notes

The release notes for the 8.3.0.3 release of PingDirectory Server.

### Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
<ul style="list-style-type: none"> <li>▪ DS-44280</li> <li>▪ DS-45027</li> <li>▪ DS-45037</li> </ul>	Fixed an issue where <code>manage-profile</code> <code>replace-profile</code> did not correctly handle keystore files with a <code>.bcfks</code> extension while in FIPS-140-2-compliant mode.
DS-44623	Fixed an issue that caused an internal root account (used for processing certain types of internal operations) to be subject to the server's default password policy. With some password policy configurations, if a Directory Proxy Server attempted to perform an internal operation that targeted data in a backend Directory Server, that operation could have been incorrectly rejected.

## PingDirectory Server 8.3.0.2 release notes

The release notes for the 8.3.0.2 release of PingDirectory Server.

### Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of PingDirectory Server.

Ticket ID	Description
DS-37117	Fixed an issue where the Directory REST API encountered internal server errors while processing entries whose attributes have LDAP tagging options.
DS-42961	To help with replication backlog analysis, the replication summary monitor will now include a <code>replica-partial-backlog</code> attribute that will show how each origin replica contributes partial backlog with the <code>per-origin-replication-backlog</code> property. The <code>replica-partial-backlog</code> attribute will also show the change numbers used for the calculation.
DS-44892	Addressed a connection error in <code>remove-defunct-server</code> when the tool tried to migrate secret keys on a single-instance topology (i.e., a server that is not part of a replication topology). The tool now only moves secret keys if the server is part of a topology.
DS-44904	Fixed a race condition that could sporadically cause an error when backing up an encrypted backend.

## PingDirectory Server 8.3.0.1 release notes

### Critical fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or `remove-defunct-server` tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose

access to keys that had been used for reversible password encryption when removing servers from the topology.

**Note:**

Since this change only applies to the most recent version of `dsreplication disable` or `remove-defunct-server`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past `dsreplication disable` or `remove-defunct-server` could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you may lose access to secret keys from servers that are removed from the topology.

- Fixed in: 8.3.0.1
- Introduced in: 7.0.0.0
- Support identifiers: DS-44591

#### Known issues and limitations

Customers should use composite indexes when keys are expected to match large numbers of entries. Composite indexes are much more efficient at dealing with large ID sets than exploded indexes. For more information, see [Composite indexes](#) on page 629 and [About the exploded index format](#) on page 637.

#### Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-44081	Addressed an issue where proxied authorization would fail in rare cases for usernames with 57 or 58 characters and distinguished names (DNs) with 108 or 109 characters.

Ticket ID	Description
DS-44591	<p>Fixed an issue where secret keys under <code>cn=Topology,cn=config</code> could be lost when removing a server from the topology. ## PingDirectory Server 8.3.0.0 Release Notes

The release notes for the 8.3.0.0 release of PingDirectory Server.

### Enhancements

These are new features for this release of PingDirectory Server:

- PingDirectory Server can now be configured to run in a mode compliant with the Federal Information Processing Standard (FIPS) 140-2. For PingDirectory Server to be FedRAMP compliant, it must be configured to support the FIPS 140-2 standard. This compliance will allow PingDirectory Server to be deployed for customers requiring FedRAMP compliance. Servers running in FIPS 140-2-compliant

mode will not be compatible with servers running in the default non-FIPS-compatible mode. For more information, see [Introduction to FIPS 140-2 compliance](#) on page 1998.

**Note:**

You cannot have FIPS-compliant and non-FIPS-compliant servers in the same topology, and you can't replicate between them. However, you can use the Synchronization Server.

**Note:**

FIPS-compliant servers must store certificates in BCFKS key stores. The JKS and PKCS12 key store types used by non-FIPS servers cannot be used in FIPS-compliant mode.

**Note:**

Anything that relies on the non-FIPS-compliant Bouncy Castle Library (Argon2, bcrypt, scrypt) won't be available in FIPS-compliant mode. To provide better support for the FIPS 140-2 standard, the Bouncy Castle library is now being shipped with the PingDirectory products. This does not impact upgrades for customers who already have a copy of the library.

- PingDirectory Server administrators use passphrases to secure access to external servers, trust stores, the encryption settings database and encrypted data in the changelog. However, these passphrases were typically stored in plain text. This release provides support for a passphrase provider API so that administrators can obtain these passphrases from secure alternative locations. Currently supported alternatives include a HashiCorp Vault, an obscured value password provider, a file-based provider, an environment variable, or other third-party passphrase provider written using the Server SDK.
- In the previous release, the ability to single sign-on from the PingOne admin portal was implemented. Rounding out this functionality, the administrative console can now accept bearer tokens from other OpenID Connect (OIDC) applications or identity providers such as PingFederate.
- The Administrative console is used to view and modify the configuration of an existing instance. Several features have been added to improve administering PingDirectory Server instances that are running in containers.
- Server profiles can now be easily created and downloaded to the local machine.
- Admins can also create and download the output from the `collect-support-data` tool used for troubleshooting issues. Additionally, the console now can display the associated command line options (such as `dsconfig`) needed to create the current object being viewed.
- Many CIAM customer use cases require a one-to-many relationship that can be retrieved as JSON either through REST API or SCIM API. The new Join Virtual Attribute Provider generates a JSON formatted value that represents content from related entries.
- The capability to filter JSON field values in constructed values has been added. Including a JSON object filter in parentheses after a JSON field name will indicate that for each attribute value, the named field value will only be extracted if the attribute value matches the provided filter. This allows, for example, when used in a Constructed Attribute Mapping's `value-pattern` property, for a given field value to only be mapped for values that match a given filter. For information about the syntax and use of this capability, see the config reference guide for Constructed Attribute Mappings.
- Customers can now use the PingDirectory Server Splunk Application for monitoring the PingDirectory Server topology. This application is available here: <https://splunkbase.splunk.com/app/5523/>

#### Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in [Upgrade overview and considerations](#) on page 362.

## Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Avoid lockdown due to missing changes during enable caused by a missing timestamp that indicates the enable time. The problem resulted in change numbers and error messages with dates around the year 1970.
  - DS-44037
  - Fixed in 8.3.0.0
  - Introduced in 8.2.0.0
- Deprecated support for incremental backups. Incremental backups are still available but may be removed in a future release. There have been a number of issues around the use of incremental backups in the past, and there are better alternatives that make incremental backup unnecessary. LDIF exports are both more portable and more compressible than full backups and can therefore be taken more frequently than full backups while consuming less disk space. In addition, the extract-data-recovery-log-changes tool can be used in conjunction with either LDIF exports or full backups to extract and replay changes recorded in the data recovery log since the time the LDIF export or backup was created.
  - DS-44431
  - Fixed in 8.3.0.0
  - Introduced in 7.0.1.4
- Fixed an issue where new replicas incorrectly went into lockdown mode after initialization.
 

This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.

  - Fixed in: 8.2.0.0
  - Introduced in: 8.1.0.0
  - Support identifiers: DS-42790 SF#00695648
- Fixed an issue in which adding or modifying a server group would result in a 404.
  - DS-41436
  - Fixed in 8.3.0.0
  - Introduced in 7.0.1.4
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.3.0.0
  - Support identifiers: DS-40955
- Fixed a memory leak when performing SCIM queries on the PingDirectory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395

- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-41762 SF#00675207 SF#00683777
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - \* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that

were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc\_example\_dc\_com\_sn.equality': InvalidKeyException: The provided passphrase is invalid."
  - Fixed in: 7.2.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-37313
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have

been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.\*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

- Fixed in: 7.0.0.0
- Introduced in: 5.2.0.6
- Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
  - Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942

- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
  - 1) Server B had not received changes directly from a client for a long time (beyond the purge delay),
  - 2) Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
  - 3) Server A is shutdown, and
  - 4) While Server A is shutdown, the Server B processes one or more changes directly from the client.
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the

changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.

- Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
  - 1) Server B had not received changes directly from a client for a long time (beyond the purge delay),
  - 2) Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
  - 3) Server A is shutdown, and
  - 4) While Server A is shutdown, the Server B processes one or more changes directly from the client.
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an `IllegalStateException` that references "exploded-index-background-deletes" when there are several backend exploded indexes.
  - Fixed in: 6.0.0.0
  - Introduced in: 4.6.0.0
  - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
  - Fixed in: 5.0.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow

a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
  - Fixed in: 4.6.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-10470
- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
  - Fixed in: 4.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-9268 SF#2002
- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
  - Fixed in: 4.0.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing `get-changelog-batch-requests` at the same time that live traffic is happening.
  - Fixed in: 3.6.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-7422

- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-5656
- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
  - Fixed in: 3.2.0.0
  - Introduced in: 3.1.0.0
  - Support identifiers: DS-3592

#### Known issues and limitations

- The option to download `collect-support-data` or to generate a server profile using the admin console will not work when logged in with single sign-on.

#### Resolved issues

The following issues have been resolved with this release of the PingDirectory Server.

Ticket ID	Description
DS-8	The Administrative Console now shows a <code>dsconfig</code> command to create the current object from scratch on the edit page.
DS-14833	Updated the logic that the server uses to escape distinguished names. Previously, it would always escape all non-ASCII characters. It will no longer escape printable non-ASCII characters (including letters, numbers, spaces, dashes, punctuation, and symbols). It will continue to escape ASCII control characters, non-printable non-ASCII characters, and non-ASCII characters in non-UTF-8 values.

Ticket ID	Description
DS-15746	<p>Added a passphrase provider mechanism, which can be used to obtain clear-text passphrases, API keys, or other types of secrets that are needed by server components like those that interact with external servers or certificate key stores. Available passphrase provider implementations include:</p> <ul style="list-style-type: none"><li>* A provider that stores an obscured representation of the passphrase directly in the server configuration.</li><li>* A provider that reads the passphrase from a file on the server filesystem. The file may optionally be encrypted with a key from the server's encryption settings database.</li><li>* A provider that can obtain the passphrase from an environment variable set in the server's process.</li><li>* A provider that can obtain the passphrase from a HashiCorp Vault instance.</li></ul> <p>Components of the server that have been updated to support using passphrase providers include:</p> <ul style="list-style-type: none"><li>* LDAP, JDBC, SCIM, and SMTP external servers.</li><li>* File-based key and trust manager providers.</li><li>* The PKCS #11 key manager provider.</li><li>* The changelog password encryption plugin.</li><li>* The Twilio alert handler and OTP delivery mechanism.</li><li>* The UNBOUNDID-YUBIKEY-OTP SASL mechanism handler.</li></ul> <p>The Server SDK has been updated to provide support for creating custom passphrase provider implementations and to allow extensions to retrieve secrets from passphrase providers configured in the server.</p>

Ticket ID	Description
DS-38427,DS-43896	<p>Updated the dbtest tool to provide access to additional detail about data in local DB backends. This includes:</p> <ul style="list-style-type: none"> <li>* Updated the dump-database-container subcommand so that when it is dumping the contents of the id2entry database, it provides additional information about the entry's encoding, including whether it is compressed, whether it is encrypted, and whether it has any uncached attributes.</li> <li>* Updated the dump-database-container subcommand so that when it is dumping the contents of the id2entry database, you can optionally restrict the output to include only entries that match a specified filter.</li> <li>* Updated the dump-database-container subcommand to provide more useful information when dumping the contents of the state database, including the index name and a human-readable representation of the trust state.</li> <li>* Updated the dump-database-container subcommand to provide more useful information when dumping the contents of the recent changes database, including the target entry DN and entryUUID values, the change type, the change time, the replication CSN, information about the original client request, and an LDIF representation of the change.</li> <li>* Added a new dump-attribute-tokens subcommand that can display information about the attribute description tokens that have been defined for the backend.</li> <li>* Added a new dump-object-class-tokens subcommand that can display information about the object class set tokens that have been defined for the backend.</li> <li>* Added a new dump-dn-tokens subcommand that can display information about the DN compaction tokens that have been defined for the backend.</li> <li>* Added a new dump-metadata subcommand that can display information from the backend's metadata database.</li> </ul>

Ticket ID	Description
DS-39157,DS-39158,DS-43848	<p>The Server SDK ServerContext class has been updated to provide a new set of methods for writing messages to the server's trace log publishers using various log severity levels. These methods replace an existing API that only supported recording debug messages, which should not be enabled in production environments.</p> <p>Administrators can configure the server's trace log publishers to enable or disable message types on a per-severity basis using a trace log publisher's extension-message-type property.</p>
DS-41815	Fixed an issue with the copy/paste functionality in the Administrative Console.
DS-41857	Fixed an issue that prevented the server from including search result entry attributes whose types are subordinates of the requested attribute types.
DS-41911	In order to reduce the time it takes for "setup" to run the testing of Java options that "setup" does will now be cached and stored in a directory. By default the directory is "logs/option-cache" relative to the server root, but an alternative directory can be specified via setup option "--optionCacheDirectory". If a directory is specified it must be created prior to running setup.
DS-41951, DS-41326	<p>The Administrative Console can now download either a collect-support-data file or a server profile from the managed server. This can be done through the Status page. These operations require that a 'csd-files/' and a 'profile-files/' directory be present in the server root by default, but this can be customized through the ldap.csd-destination-folder and ldap.profile-destination-folder settings, which can be found in the Console's application.yml configuration file.</p> <p>Downloading collect-support-data files is disabled by default when using the PingDataConsole Docker image. It also strongly recommended to avoid downloading collect-support-data files from servers that are running in a container.</p>

Ticket ID	Description
DS-41998	<p>Added a remove-object-class-from-schema tool that can be used to safely remove an object class definition from the server schema. It will first ensure that the object class is not in use, and it will also clean up any metadata references to that object class that may exist if the class has been used in the past.</p> <p>The remove object class processing can also be requested programmatically through an administrative task.</p>
DS-42401,DS-43754	<p>Updated the manage-profile replace-profile subcommand to detect changes to files referenced in setup-arguments.txt when those files are outside of the server profile</p>
DS-42937	<p>The Administrative Console now allows users to specify the LDAP server they wish to bind to using the query parameters 'ldap-hostname' and 'ldaps-port' when the console is configured for SSO. This allows a single console instance to administer multiple PingData servers. Note that an LDAPS scheme is always assumed because an encrypted connection is always required for SSO.</p>
DS-43024	<p>Updated the purge expired data plugin to support deleting entries with multiple concurrent threads. Deletes will still be performed in a single thread by default, and this is the recommended configuration for most deployments, but the value of the num-delete-threads configuration property may be increased if expired entries accumulate faster than a single thread can delete them.</p>
DS-43189	<p>Fixed a performance issue in PingDirectory Server when the index entry limit is exceeded on an exploded index with an index entry limit of several million entries.</p>
DS-43224	<p>Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.</p>
DS-43435	<p>Fix a bug that prevented offline changes to mirrored configuration with manage-profile replace-profile.</p>
DS-43441	<p>Fixed "Reverse DNS resolution" warning during setup. This warning was a result of performing a reverse DNS lookup on link local addresses, which is now avoided. This is mostly only relevant to IPv6.</p>

Ticket ID	Description
DS-43576	Added the ability to retry operation failures from replication if the failures are likely due to dependent writes being played out of order. This issue only affected environments that were sending writes to different servers, and also were not able to use the appropriate level of replication assurance. To enable this setting, update the on-replay-failure-wait-for-dependent-ops-timeout configuration property on a replication domain.
DS-43596	Added a new oid-lookup command-line tool that can be used to retrieve information about a given object identifier or to retrieve the object identifier for an item with a given name.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43666	Fixed an issue in which a server in lockdown mode could incorrectly allow an operation to be processed if a connection authenticated as a user with the lockdown-mode privilege issued a request with an alternate authorization identity that did not have the lockdown-mode privilege. The server now requires that both the authentication and authorization identities have the lockdown-mode privilege.

Ticket ID	Description
DS-43685	<p>Added three new virtual attribute types that can generate JSON-formatted values with content from entries that are related to the entry that contains them, much like using the LDAP join request control. The new types of virtual attributes include:</p> <ul style="list-style-type: none"> <li>* The DN join virtual attribute expects a specified attribute in an entry to contain the DNs of the entries to be joined. For example, if the manager attribute is used to hold the DN of an employee's manager, then the DN join virtual attribute can be used to provide a JSON-formatted representation of the manager's entry in the employee's entry.</li> <li>* The reverse DN join virtual attribute expects a specified attribute in entries to be joined to contain the DN of the entry in which the virtual attribute to appear. For example, if the manager attribute is used to hold the DN of an employee's manager, then the reverse DN join virtual attribute can be used to provide JSON-formatted representations of the entries of a manager's direct reports in the manager's entry.</li> <li>* The equality join virtual attribute expects related entries have values in common for the same or different attribute. For example, if the data includes account entries that contain an accountNumber attribute, and if it also includes user entries with an an accountNumber attribute that match the account number from their associated account, then the equality join virtual attribute can be used to include a JSON-formatted representation of the account entry in the entries for the users associated with that account, or to include JSON-formatted representations of the entries for the associated users in an account entry.</li> </ul>
DS-43700	<p>Updated the ldap-result-code tool to provide support for additional output formats, including JSON, CSV, and tab-delimited text.</p>
DS-43713	<p>Added a new "must change password" account status notification type that can be used to take a configured action whenever a user successfully authenticates but will be required to choose a new password before being allowed to request any other operations.</p>

Ticket ID	Description
DS-43719	<p>Added the capability to filter JSON field values in constructed values. Including a JSON object filter in parentheses after a JSON field name will indicate that for each attribute value, the named field value will only be extracted if the attribute value matches the provided filter. This allows, for example, when used in a Constructed Attribute Mapping's value-pattern property, for a given field value to only be mapped for values that match a given filter. For information about the syntax and use of this capability, see the config reference guide for Constructed Attribute Mappings.</p>
DS-43737	<p>Updated the SCIM 2 servlet so that it provides an option to map the presented bearer token to a local user in the server. If the token can be mapped to a local user, then that account will be used as the authorization identity for the requested operation rather than the default authorization identity of "cn=SCIM2 Servlet,cn=Root DNs,cn=config". If this option is enabled and the mapping is successful, then all associated log messages, changelog records, and creatorsName and modifiersName attribute updates will use the DN of the mapped user rather than that of the SCIM2 Servlet user. Requested operations will be processed using the access rights granted to that user, as well as rights granted to any OAuth scopes included in the access token. The server's global access control rules have been updated so that an appropriate minimum set of rights should be granted for access tokens that include the "scim2" scope.</p> <p>If the presented access token cannot be mapped to a local user, then you can indicate whether the request should be rejected or whether it should be processed as before using the default "cn=SCIM2 Servlet,cn=Root DNs,cn=config" authorization identity.</p>
DS-43745	<p>Fix an issue in the server causing PingDirectory 8.2.0.0 to be incompatible with version 4.2.0 of the Delegated Admin app, which prevented upgrade to Delegated Admin version 4.4.0 without some downtime.</p>
DS-43770	<p>Fixed an issue that could prevent pre-operation add plugins created with the Server SDK from accessing some changes to the content of the add operation. For example, a Server SDK pre-operation add plugin could not access an attribute created by a composed attribute plugin that had been invoked before the Server SDK plugin.</p>

Ticket ID	Description
DS-43787,DS-43788,DS-43795	Added the ability to implement custom SCIM Sub-Resource Type Handlers using the Server SDK. A SCIM Sub-Resource Type Handler defines a child type of a SCIM resource type that you can use to offer extended features not defined by the SCIM 2.0 standard.
DS-43809	Fixed an issue in which the server could report that certain types of were not indexed even though they were covered by an applicable composite index. Any searches that were actually processed correctly made use of the composite index, but it could have caused the server to reject some valid configuration changes that will only be permitted if proper indexing is in place.
DS-43817	Fixed an issue where PingDirectory Server sometimes reports erroneous warnings about duplicate jar files.
DS-43836	<p>Updated the PingDirectory Server's support for the get user resource limits control to make it possible to exclude information about the user's group membership from the response control. This can improve the performance of bind operations that use this control, especially in servers with a large number of dynamic groups.</p> <p>Also, updated the Directory Proxy Server's use of the get user resource limits control when passing through bind requests to the PingDirectory Server. If it can verify that the PingDirectory Server supports this new feature, the PingDirectoryProxy Server will request that the server exclude group membership information from the get user resource limits response control.</p>
DS-43838	Updated the server's support for the uniqueness request control so that if a conflict prevention details entry is requested, the server may be able to use a minimal version of the proposed target entry instead of a full copy. This can help improve performance when using this option.
DS-43884	Fixed issues with the import-ldif tool when invoked with the --addMissingRDNAttributes argument. It could fail to add missing RDN attribute values to an entry if the attribute type is required by any of that entry's object classes. It could also result in entries with multiple values for single-valued attribute types.

Ticket ID	Description
DS-43890	Fixed an issue with dsjavaproperties --initialize that prevented changing the JVM tuning parameter using the --jvmTuningParameter command line argument.
DS-43898	Addressed an issue where the backend would store an incorrect count for a database key that had exceeded the index entry limit. This would only happen for composite indexes when the server started up after not being shut down cleanly. Normal search processing was unaffected, but the matching entry count request control processing would return incorrect results.
DS-43916	Added cipher stream provider and passphrase provider implementations with support for the Amazon AWS Secrets Manager service. The Amazon Secrets Manager cipher stream provider can be used to protect the contents of the encryption settings with a key derived from a secret retrieved from the Secrets Manager service. The Amazon Secrets Manager passphrase provider can be used to obtain clear-text secrets needed for processing within the server from the Secrets Manager service.
DS-43926	Significantly improved the performance of delete and modify operations that require removing IDs from very large composite index ID sets.
DS-43935	Updated manage-profile replace-profile to run a shorter process when applying dsconfig changes that require administrative actions.
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the oidc-trust-store-file and oidc-trust-store-type settings. Also, you can set the console to skip hostname and/or certification verification through the oidc-strict-hostname-verification and oidc-trust-all configuration settings.
DS-43950	Fixed an issue where PingDirectoryProxy Server failed to install on JDKs that lack support for AES-256 encryption.

Ticket ID	Description
DS-43992	<p>Increased the parallelism within import-ldif when flushing intermediate index files to disk to improve import throughput.</p> <p>Reduced the number of intermediate index files that are written out during the first phase of import-ldif. This avoids running out of file descriptors when initializing the indexes especially in environments with lots of indexes or lots of entries.</p>
DS-43999	<p>Updated the server to allow the operation purpose control to be used for operations that are part of an LDAP transaction.</p>
DS-44010	<p>Updated the server to allow obtaining client secrets from a passphrase provider as an alternative to storing an obscured representation of the secret directly in the configuration. Updated components include:</p> <ul style="list-style-type: none"> <li>* The OpenID Connect client secret needed for single sign-on to the admin console</li> <li>* The OAuth client secret needed to connect to the PingOne service</li> <li>* The client secret needed in conjunction with the PingFederate access token validator</li> </ul>
DS-44025	<p>Addressed an issue where the server was incorrectly displaying an "Unknown vendor" warning when using JDKs obtained on Red Hat and Ubuntu systems.</p>
DS-44037	<p>Avoid lockdown due to missing changes during enable caused by a missing timestamp that indicates the enable time. The problem resulted in change numbers and error messages with dates around the year 1970.</p>
DS-44039	<p>Updated the messages in the interactive modes of "dsreplication enable" and "dsreplication initialize" to help clarify the prompts. This includes a summary printed for interactive "dsreplication initialize" (and initialize-all) to highlight the servers and baseDNs that will be updated.</p>

Ticket ID	Description
DS-44054,DS-44091,DS-44100,DS-44104,DS-44135,DS-44239	<p data-bbox="849 216 1464 373">Added a FIPS 140-2-compliant mode to the server. This mode may be enabled by running setup with the --fips argument, or by including the --fips argument in the setup-arguments.txt file when using manage-profile setup.</p> <p data-bbox="849 394 1464 835">Servers running in FIPS 140-2-compliant mode are not compatible with those running in non-compliant mode. FIPS 140-2-compliant mode cannot be enabled after setup (including when upgrading an existing instance, whether using update or manage-profile replace-profile). It can only be enabled when the instance is initially configured. Further, servers running in FIPS 140-2-compliant mode cannot replicate with or participate in the same topology as servers not running in FIPS-compliant mode. If you wish to migrate an existing deployment to use FIPS 140-2-compliant mode, you must install create a new topology of servers running in FIPS-compliant mode and migrate the data into it.</p> <p data-bbox="849 856 1464 1108">In addition, servers running in FIPS 140-2-compliant mode will not be allowed to use the Argon2, bcrypt, or scrypt password storage schemes, as they rely on non-FIPS-approved algorithms. The PBKDF2 password storage scheme is approved and may be used in FIPS-compliant mode, but it requires passwords to have a minimum length of 14 bytes.</p> <p data-bbox="849 1129 1464 1381">Setup has also been updated to make it possible to initialize the certificate key and trust stores with certificate data read from PEM files. These options are available in both FIPS 140-2-compliant and non-FIPS-compliant modes, and can help make it easier to set up the server with existing certificates that are not available in a key or trust store that setup supports.</p>

Ticket ID	Description
DS-44057	<p>Improved the behavior that the server exhibits for attempts to configure it with an invalid set of TLS cipher suites.</p> <p>Previously, if a connection handler was configured with an explicit set of TLS cipher suites, and if none of those cipher suites was supported by the underlying JVM, the server would log a message for each unsupported suite and would fall back to using a default set of suites. This could lead to cases in which the server ran with a different set of cipher suites than expected, and the warning log messages might be overlooked.</p> <p>The server will now reject an attempted configuration change that would leave it without any valid cipher suites. For the sake of preserving backward compatibility, and helping to avoid issues around upgrading the server or JVM version, it will still allow attempts to configure the set of cipher suites using one or more invalid suite names as long as the server would still be able to offer at least one valid suite, and it will still log a warning message about each invalid cipher suite referenced in the configuration.</p>
DS-44061	<p>Fixed a NullPointerException that could occur when using manage-profile replace-profile with a server profile that configured a StatsD monitoring endpoint.</p>
DS-44106	<p>Updated the StatsD Monitoring Endpoint to support sending custom tags with each metric message. Custom tags will be appended at the end of each StatsD message as comma-separated key-value pairs.</p>
DS-44187	<p>Included the Bouncy Castle library with the server, which is needed to support certain cryptographic functionality, like the Argon2, bcrypt, and scrypt password storage schemes. It was not previously included with the server over concerns around compliance with U.S. export control regulations around strong encryption, but those concerns have been alleviated. You no longer need to obtain the library for yourself if you wish to use any of the functionality that requires it, and the Argon2, bcrypt, and scrypt password storage schemes are now enabled by default in the out-of-the-box configuration.</p>

Ticket ID	Description
DS-44192	<p>Updated the default set of TLS protocols and cipher suites that the server will support. As TLSv1 and TLSv1.1 are no longer considered secure (see RFC 8996 for additional information), the server will only support TLSv1.2 and TLSv1.3 (if supported by the JVM) by default. The server will also no longer enable support for TLS cipher suites that use the SHA-1 digest algorithm (which is also no longer considered secure and is not needed for TLSv1.2 or TLSv1.3) or that use the RSA key exchange algorithm (which does not support forward secrecy).</p> <p>If you need to enable support for legacy TLS protocols or cipher suites, you may do so through the server configuration. This can be enabled on a per-connection-handler basis using the <code>ssl-protocol</code> and <code>ssl-cipher-suite</code> configuration properties. Alternatively, you may use the <code>ssl-protocol</code> and <code>ssl-cipher-suite</code> properties in the crypto manager configuration to set default values that will be used by connection handlers that do not explicitly specify values for those properties.</p>
DS-44204	<p>Fixed an issue in which the PingDirectoryProxy Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.</p>
DS-44247	<p>Added a <code>rewrite-search-filters</code> configuration property to the <code>isMemberOf</code> virtual attribute. This allows <code>isMemberOf</code> searches targeting dynamic groups to be processed more efficiently because the filter of the dynamic group can be substituted into the original search filter. This yields extensive speedup of paged searches across a large dynamic group. The default setting, <code>'within-group-scope'</code>, will only enhance the search filter if the scope of the search fully contained with the scope of the group. This avoids slowing down <code>isMemberOf</code> searches with dynamic groups whose filter matches many users but base DN does not.</p>
DS-44259	<p>Fixed an issue that could prevent password policy state changes made through the <code>ds-pwp-modifiable-state-json</code> operational attribute from being properly replicated.</p>

Ticket ID	Description
DS-44292	Updated the server's support for the ds-pwp-modifiable-state-json operational attribute to make it possible to modify this attribute in conjunction with other attributes in the same modification, and also to include modify operations targeting this attribute in LDAP transactions or atomic multi-update operations.
DS-44293	Fixed an issue that could prevent operations included in a multi-update extended operation from being logged. Also, improved the log message for the multi-update extended result to provide more useful information about the operation that failed.
DS-44297	Added global ACIs that allow clients to use the LDAP assertion and permissive modify request controls by default.
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.
DS-44390	Fixed an issue where logs from setting up a new server could be lost when running the manage-profile replace-profile subcommand.
DS-44410	When deployed to a web application server such as Apache Tomcat, the Administrative Console will now write log messages to the application server's console output by default.
DS-44420	Updated the PKCS #11 key manager provider to make it possible to dynamically load the PKCS #11 provider with a specific configuration, rather than requiring the administrator to update configuration files that are part of the JVM installation. The manage-certificates tool has also been updated to support interacting with PKCS #11 key stores, and many LDAP command-line tools also provide improved support for using PKCS #11 key stores for access to client certificates.

Ticket ID	Description
DS-44436	Addressed an issue in which attempting to add a member that already existed in a non-default server group would cause an error. Adds of duplicate members are now ignored and no errors are thrown.
DS-44531	Updated the manage-profile replace-profile command to avoid printing warnings for offline config changes from the new server profile.

## PingDirectory Server previous releases

Release notes for previous versions of PingDirectory Server are included for reference.

### PingDirectory 8.2.0.8 release notes

The release notes for the 8.2.0.8 release of the PingDirectory server.

#### Critical fixes

This release of the PingDirectory server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the PingDirectory server.

Ticket ID	Description
DS-45164	Updated Jetty Server to version 9.4.44.
DS-45813	Updated PingDirectory products to use Kafka v2.8.1.
DS-45863	Resolved an issue where SCIM POST requests that violated a unique attribute constraint received an error response with status 400 (Bad Request) instead of 409 (Conflict).
DS-46017	Resolved an issue with slow response time on PingDirectory servers configured with a large number (10,000 or more) of virtual static groups.

### PingDirectory Server 8.2.0.7 release notes

The release notes for the 8.2.0.7 release of PingDirectory Server.

#### Critical fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or `remove-`

**defunct-server** tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

**Note:**

Since this change only applies to the most recent version of **remove-defunct-server** and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past `dsreplication` and **remove-defunct-server** could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

- Fixed in: 8.2.0.7
- Introduced in: 7.0.0.0
- Support identifiers: DS-44591

Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-42961	To help with replication backlog analysis the replication summary monitor will now include a <code>replica-partial-backlog</code> attribute that will show how each origin replica contributes partial backlog with the <code>per-origin-replication-backlog</code> property. The <code>replica-partial-backlog</code> attribute will also show the change numbers used for the calculation.
DS-43959, DS-44924	Added new global configuration properties that can be used to impose limits on the maximum number of attributes that can be present in an <code>add</code> request and the maximum number of modifications in a <code>modify</code> request, which can be used to avoid potential denial of service attacks. Both limits are set to 1000 by default, which is likely to be adequate for all legitimate use cases, and neither property affects the number of values that may be provided for an attribute.

Ticket ID	Description
DS-44591	<p>Fixed an issue where secret keys under <code>cn=Topology,cn=config</code> could be lost when removing a server from the topology. When a server is removed via the <code>dsreplication disable</code> or <code>remove-defunct-server</code> tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.</p> <p>The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.</p> <p> <b>Note:</b></p> <p>Since this change only applies to the most recent version of <code>remove-defunct-server</code> and <code>dsreplication disable</code>, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past <code>dsreplication</code> and <code>remove-defunct-server</code> could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.</p>
DS-44892	<p>Addressed a connection error in <code>remove-defunct-server</code> when the tool tried to migrate secret keys on a single-instance topology (i.e., a server that is not part of a replication topology). The tool now only moves secret keys if the server is part of a topology.</p>
DS-45032	<p>Addressed an issue that caused <code>remove-defunct-server</code> to hang when performing replication artifact cleanup in non-interactive mode.</p>
DS-45115	<p>Fixed a Ping Directory Server performance issue involving high CPU usage when writing LDAP data to certain clients using TLSv1.3 connection security.</p>

Ticket ID	Description
DS-45124	Removed <code>-XX:RefDiscoveryPolicy=1</code> from the default start-server Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.
DS-45154	Fixed an issue where a server with a newly initialized database (through <code>dsreplication initialize</code> ) could go into lockdown mode and report that the server may have missed one or more update(s). This generally occurred only if the initialized server was restarted right after initialization completed.
DS-45190	Added support for the use of JDKs obtained through BellSoft.
DS-45449	Updated the server to create the <code>esTokenizer.ping</code> file if it does not exist for a backend containing encrypted data. This file may be needed to open the database environment for a backend containing encrypted indexes, but it would not have been automatically created when upgrading from a pre-7.0 server to a later version with support for encrypted indexes.
DS-45654	Resolved an issue where SCIM POST requests that violated a unique attribute constraint got an internal error instead of the expected SCIM error response.

### PingDirectory Server 8.2.0.6 release notes

#### Critical fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-43576	Added the ability to retry operation failures from replication if the failures are likely due to dependent writes being played out of order. This issue only affected environments that were sending writes to different servers, and also were not able to use the appropriate level of replication assurance. To enable this setting, update the <code>on-replay-failure-wait-for-dependent-ops-timeout</code> configuration property on a replication domain.
DS-43632	Fixed an issue where the <code>format</code> field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43898	Addressed an issue where the backend would store an incorrect count for a database key that had exceeded the index entry limit. This would only happen for composite indexes when the server started up after not being shut down cleanly. Normal search processing was unaffected, but the matching entry count request control processing would return incorrect results.
DS-43999	Updated the server to allow the operation purpose control to be used for operations that are part of an LDAP transaction.
DS-44259	Fixed an issue that could prevent password policy state changes made through the <code>ds-pwp-modifiable-state-json</code> operational attribute from being properly replicated.

### PingDirectory Server 8.2.0.5 release notes

#### Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-44025	Fixed an issue where the server was incorrectly displaying an <code>Unknown vendor</code> warning when using JDKs obtained on Red Hat and Ubuntu systems.

Ticket ID	Description
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a <code>must change password</code> state. The server will now only permit the operation if it attempts to set a new password for the target user.

### PingDirectory Server 8.2.0.3 release notes

#### Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

#### No critical issues have been identified

#### Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-43926	Significantly improved the performance of delete and modify operations that require removing IDs from very large composite index ID sets.

### PingDirectory Server 8.2.0.2 release notes

#### Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

#### No critical issues have been identified

#### Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.
DS-43838	Updated the server's support for the uniqueness request control so that if a conflict prevention details entry is requested, the server may be able to use a minimal version of the proposed target entry instead of a full copy. This can help improve performance when using this option.

Ticket ID	Description
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the <code>oidc-trust-store-file</code> and <code>oidc-trust-store-type</code> settings. Also, you can set the console to skip hostname and/or certification verification through the <code>oidc-strict-hostname-verification</code> and <code>oidc-trust-all</code> configuration settings.

## PingDirectory Server 8.2.0.1 Release Notes

### Critical Fixes

### Resolved Issues

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

### No critical issues have been identified

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-43024	Updated the purge expired data plugin to support deleting entries with multiple concurrent threads. Deletes will still be performed in a single thread by default, and this is the recommended configuration for most deployments, but the value of the <code>num-delete-threads</code> configuration property may be increased if expired entries accumulate faster than a single thread can delete them.
DS-43745	Fix an issue in the server causing PingDirectory 8.2.0.0 to be incompatible with version 4.2.0 of the Delegated Admin app, which prevented upgrade to Delegated Admin version 4.4.0 without some downtime.
DS-43770	Fixed an issue that could prevent pre-operation add plugins created with the Server SDK from accessing some changes to the content of the add operation. For example, a Server SDK pre-operation add plugin could not access an attribute created by a composed attribute plugin that had been invoked before the Server SDK plugin.

## PingDirectory Server 8.2 release notes

### Enhancements

These are new features for this release of PingDirectory Server:

- To improve our support for containerization, PingDirectory Server can now determine that it is running in a container and stores this state in the `isDocker` property within the System Information monitor (`cn=System Information, cn=monitor`).
- The Administrative Console now supports using OpenID Connect for admin SSO, allowing you to set up the PingOne administration console to have one-click SSO access without typing a password.
- To ensure that PingDirectory Server is protected against online password guessing attacks, PingDirectory Server can now inject a delay before sending failure responses back to the client for basic HTTP authentication failures.
- The Dictionary password validator includes approximately 10,000 more entries in the dictionary file and can now check for capitalization, reversed passwords, leading or trailing non-alphabetical characters and ignore diacritical marks.
- A new operational attribute has been defined to contain information about recent successful and failed bind attempts. Also, you can configure the server to maintain recent login history such as the number of records of successful and/or failed authentication attempts.
- The `setup` command can now create a populated `config/tools.properties` file from the properties set either on the command or input using interactive mode. There are several modes for adding the bind password to the file. By default, no properties file is created unless the `--populateToolPropertiesFile` argument is used (non-interactive mode) or the option to create the file is specified while running setup.
- The `validate-ldap-schema` tool has been added allowing for administrators to verify any LDIF file used to create schema and/or entries and report any potential issues they may contain.
- Typically, passwords are only validated when they are set, changed or reset for an entry. However, this might lead to a weak password since these events are infrequent. PingDirectory Server now supports the ability to periodically run password validation on bind requests. By default, this is not enabled but can be added to any password policy by setting both the `bind-password-validator` and the `minimum-bind-password-validation-frequency` properties. If, at the time of the bind, the password does not meet the specified password policies, the `bind-password-validation-failure-action` property specifies what action to take like requiring a password change.
- Customers want a better way to perform a sorted search on a large dataset using SCIM 2.0. In this version of PingDirectory Server, SCIM searches with the proper search parameters can be returned in pages. The PingDirectory Server needs to be configured with Virtual List View (VLV) indexes for the desired SCIM Resource Type.
- You can now configure password policies to keep a record of recent login history, successes, and failures, per account. The possible configuration options include tracking every success and failure or collapsing to a single event per day.
- To improve logging and monitoring, administrators can now configure the Syslog, Audit Log, HTTP Operation Log, and the Sync Log to produce output in the JSON format so other tools can more easily consume the information. These log publishers are disabled by default.

### Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in [Upgrade overview and considerations](#) on page 362.

### Known issues and limitations

The following are known issues in the current version of PingDirectory Server:

When signing on to the Administrative Console, you must specify an LDAPS port in the **Server** field. For example, to use port 636, you would specify `pingdirectory:636`. If you do not specify a port, you get a

```
"Server
  unavailable"
```

message.

## Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-644, DS-42031	Added a new <code>validate-ldap-schema</code> tool that can be used to examine schema definitions in a set of LDIF files and report any issues that it detects.
DS-1766	Updated the <code>ldap-diff</code> tool to make it possible to control the column at which long lines should be wrapped. Previously, long lines were always wrapped at 80 characters. Now, no wrapping is performed by default, but the <code>--wrapColumn</code> argument can be used to enable wrapping with a specified maximum line length.
DS-5040	Improved the <code>dsframework</code> tool to support multivalued server properties.
DS-5143, DS-11035	<p>Updated support for logging access and error log messages to a syslog server. While the server previously supported logging these messages to a syslog server (through the "syslog-based access log publisher" and "syslog-based error log publisher" logger implementations), these loggers used an older version of the syslog protocol (described in RFC 3164) and only offered support for communicating over UDP.</p> <p>These loggers are still available for legacy backward compatibility, but we now also offer new "syslog text access log publisher" and "syslog text error log publisher" implementations that use a newer version of the syslog protocol (syslog version 1, described in RFC 5424) and support communicating over UDP or the more reliable TCP. When using TCP, it is also possible to encrypt communication with TLS, and it is possible to configure multiple servers for better redundancy. These loggers use the same space-delimited text format as the former loggers.</p> <p>We also offer new "syslog JSON access log publisher" and "syslog JSON error log publisher" implementations that offer the same set of capabilities, but that format the message text as JSON objects, which can be more easily parsed by third-party software.</p>

Ticket ID	Description
DS-7475, DS-7605, DS-11725, DS-37707, DS-40342, DS-41940	<p>Made several improvements to the parallel-update tool, which can use multiple concurrent threads for improved performance when applying add, delete, modify, and modify DN changes read from an LDIF file. The enhancements include:</p> <ul style="list-style-type: none"> <li>▪ Added support for several additional controls, including proxied authorization, manageDsaIT, ignore NO-USER-MODIFICATION, password update behavior, operation purpose, name with entryUUID, assured replication, replication repair, suppress operational attribute update, and suppress referential integrity updates. The tool also now supports specifying arbitrary controls for inclusion in add, bind, delete, modify, and modify DN requests.</li> <li>▪ Made its communication more robust. The tool would previously establish connections only when it was first started, but it can now detect when a connection is no longer valid and can re-establish connections as needed to continue processing. Further, if an operation failed because it was attempted on an invalid connection, that operation can be automatically retried immediately on a newly established connection.</li> <li>▪ Added support for failover directory servers. You can now provide the --hostname and --port arguments multiple times to specify information about multiple directory server instances. In the event that the first server listed is not available (or becomes unavailable in the middle of processing), it can automatically try establishing a connection to an alternative server to continue processing there.</li> <li>▪ Improved the ability to determine whether all changes were processed successfully. Previously, the tool would always use an exit code of zero if it was able to attempt all of the changes read from the LDIF file, even if some of the changes were not successfully applied. That is still the default behavior, but a new --useFirstRejectResultCodeAsExitCode argument can be used to indicate that if any operations are rejected, the result code from the first rejected operation should be used as the exit code.</li> <li>▪ Added support for encrypted LDIF files. If the LDIF file was encrypted with a key from the server's encryption settings database, then the tool will automatically attempt to retrieve the appropriate key. Otherwise, the new --encryptionPassphraseFile argument can be used to supply the encryption passphrase, or the passphrase can be interactively requested from the user.</li> <li>▪ The tool is now parallel by default. Previously, if you did not specify a value for the --numThreads argument, it would use a single thread. It now defaults to using eight threads.</li> <li>▪ The tool now provides a --followReferrals argument that allows it to automatically attempt to follow any referrals that are returned.</li> <li>▪ The tool now provides a menu-driven interactive mode that can be used to provide values for all of the command-line arguments.</li> </ul>
DS-10320, DS-12550, DS-12551, DS-12552, DS-42116, DS-42162, DS-42179, DS-42222, DS-42223, DS-42224, DS-42225, DS-42416, DS-42437	<p>Added a config/sample-dsconfig-batch-files directory with set of well commented dsconfig batch files that may be useful in enabling or configuring a variety of features in the server.</p>

Ticket ID	Description
DS-10775	<p>Updated the dictionary password validator to support additional options:</p> <ul style="list-style-type: none"> <li>▪ It can now ignore non-alphabetic characters that appear at the beginning or end of the password before checking the dictionary.</li> <li>▪ It can strip characters of diacritical marks, including accents, cedillas, circumflexes, diaereses, tildes, and umlauts, before checking the dictionary. If this option is used, then any character with such a mark will be replaced with a base version of the character without that mark (for example, a lowercase letter n with a tilde over it would be replaced with just a lowercase letter n).</li> <li>▪ You can define maps with information about character substitutions to use for checking alternative versions of the provided password. For example, if you indicate that "0" might map to "o", "1" or "!" might map to "i", "7" might map to "t", and "3" might map to "e", then the validator can reject a proposed password of "pr0h1b!73d" if the dictionary contains the word "prohibited".</li> <li>▪ It can reject a proposed password if a value from the provided dictionary makes up more than a specified percentage of that password.</li> </ul>
DS-11524, DS-41860, DS-42112	<p>Added support for new administrative alert types:</p> <ul style="list-style-type: none"> <li>▪ We have added a new admin alert account status notification handler, which can generate administrative alerts whenever an applicable account status notification is generated within the server. For example, this account status notification handler can be added to the root password policy to generate an alert whenever a root user's password is updated or their account is locked as a result of too many failed authentication attempts. A separate alert type has been defined for each account status notification type.</li> <li>▪ We have added a new "privilege-assigned" administrative alert that can be raised whenever a new entry is added or an existing entry is updated to include one or more privileges.</li> <li>▪ We have added a new "insecure-request-rejected" administrative alert that can be raised whenever the server rejects a request as a result of the reject-insecure-requests global configuration property.</li> </ul>
DS-13853	<p>Added support for the OAUTHBEARER SASL mechanism (as described in RFC 7628) to allow LDAP clients to authenticate with OAuth 2.0 bearer tokens.</p>
DS-15123	<p>Updated the password policy to add support for maintaining a history of recent successful and failed bind attempts for each account. A new "get recent login history" control can be used to obtain this history during a successful bind, and it can also be obtained from the ds-pwp-state-json virtual attribute or the password policy state extended operation.</p>
DS-15848, DS-42360	<p>Added support for invoking a specified set of password validators during bind operations. If the password used to authenticate fails to satisfy one or more of the configured validators, the bind attempt can be rejected, the user can be forced to change their password, or the server can generate an account status notification to take some alternative action (for example, notifying the end user or server administrators).</p>
DS-15864	<p>Replaced the ldappasswordmodify tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.</p>

Ticket ID	Description
DS-17422, DS-37387	<p>Added a new "Modifiable Password Policy State" plugin with support for a new ds-pwp-modifiable-state-json operational attribute whose value is a JSON object with fields that reflect elements of the associated user's current password policy state. Authorized clients may replace the value of that attribute (with a modify request using LDAP or with a PUT or PATCH request using the Directory REST API) to update that user's password policy state. Elements of the password policy state that may be updated include:</p> <ul style="list-style-type: none"> <li>▪ The time the user's password was last changed</li> <li>▪ The user's account activation time</li> <li>▪ The user's account expiration time</li> <li>▪ The user's password expiration warned time</li> <li>▪ Whether the account is administratively disabled</li> <li>▪ Whether the account is locked as a result of too many failed authentication attempts</li> <li>▪ Whether the user will be required to change their password before they will be allowed to perform any other operations</li> </ul>
DS-17664	<p>Fixed an issue that could cause the server to return the password expired control (as defined in draft-vchu-ldap-pwd-policy) in response to a bind request that included invalid credentials. The server will now only return that control if the provided credentials were valid.</p> <p>The password policy configuration has also been updated to make it possible to better specify when the server should return the password expired or password expiring control. Previously, the server would only return these controls if the bind request did not include the password policy request control (as defined in draft-behera-ldap-password-policy), as the response to that control may also indicate whether the user's password is expired or is about to expire. This is still the default behavior, but it is now possible to configure the server to return the password expired or password expiring control when appropriate, even if the password policy response control will also be returned. Alternatively, the server can be configured to never return the password expired or password expiring controls.</p>
DS-17903	<p>Updated setup to provide a --populateToolPropertiesFile argument that will allow it to populate the config/tools.properties file with default values for command-line tool arguments. If requested, properties will be provided for the server address, port, and communication security, and may also include a default bind DN and optionally a bind password. When running setup interactively, it will now prompt to determine which properties (if any) should be populated in the properties file.</p>
DS-36088	<p>Updated the crypto manager to make it possible to augment the set of enabled TLS cipher suites with specific suites to add to or remove from the default set of enabled suites. To enable one or more suites in addition to those in the default set, prefix the names of those suites with the "+" symbol. To disable one or more suites in the default set of enabled suites, prefix the names of those suites with the "-" symbol. This was already possible when configuring cipher suites for the LDAP and HTTP connection handlers, but it was not an option for the crypto manager.</p>
DS-38110	<p>Updated the System Information monitor with an "isDocker" attribute to identify if the server is running in a Docker container.</p>

Ticket ID	Description
DS-38118, DS-42495	<p>Made several updates related to the server's handling of data written to standard output and standard error:</p> <ul style="list-style-type: none"> <li>▪ The server can now be configured to rotate the logs/server.out file once it reaches a given size, and it will retain a configurable number of those log files. By default, the server will rotate the file once it reaches 100 megabytes and will keep up to ten files.</li> <li>▪ To better facilitate capturing log data in containerized environments, the server now supports writing JSON-formatted access and error log messages to the JVM's original standard output and error streams (which will be separate from the server.out file when the server is started with the --nodetach argument).</li> <li>▪ It is now possible to prevent the server from logging messages during startup in non-JSON format. It is also possible to prevent messages about administrative alerts from being written to standard error, or to write those messages in JSON format. These options are especially useful when using JSON-based logging to the console in no-detach mode, as they can help ensure that everything written to standard output and standard error will be formatted as JSON objects.</li> </ul>
DS-38816, DS-41995	<p>Updated support for the uniqueness request control to provide a more reliable mechanism for preventing conflicts that arise from operations processed concurrently in the same or different servers. If indicated in the request control, a temporary conflict prevention details entry can be added to the server before searching for existing conflicts, and that entry can be detected during pre-commit processing for other operations with uniqueness request controls that attempt to make a conflicting change.</p> <p>The server has also been updated to make it possible to generate an administrative alert if a uniqueness conflict is detected during post-commit processing for the uniqueness request control. Even though the conflict cannot be prevented at this stage in processing, the alert can let administrators know about it as soon as it happens so they can take any appropriate corrective action.</p>
DS-38868	<p>Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.</p>
DS-39257	<p>The <b>dsreplication enable</b> subcommand options <code>--preferredID1</code> and <code>--preferredID2</code> allow you to specify a preferred value for new replicationIDs for the first and second server respectively. By default, replication IDs are randomly chosen. The lowest unused value that is greater than or equal to the value specified is used, subject to being even or odd as required. Replication server IDs must be even, and replicaIDs must be odd. Each value specified must be in the range [0, 32766] inclusive. If the maximum value is reached while searching, the search wraps to 0.</p>
DS-39789	<p>Updated the JVM memory usage monitor provider to fix an issue that could prevent the monitor from reporting the total amount of memory held by all memory consumers. Also, fixed an issue that could cause the memory-consumer attribute to use an incomplete message for consumers without a defined maximum size and added an additional memory-consumer-json attribute whose values are JSON objects with data that can be more easily extracted by automated processes.</p>

Ticket ID	Description
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-40967	Eliminated a misleading error message that could be logged at startup if the server was configured with one or more ACIs that only apply when using specific SASL mechanisms.
DS-41228	Missing changes will now be detected when the backend is reverted and there are insufficient changes in the changelog database. When in this particular missing changes state the local replica will not accept changes from the local replication server.
DS-41230	To assist with recovering from the split-brain state the "dsreplication initialize" command will have a new "--force" option that overrides the lockdown check.
DS-41350	Fixed an issue where disabling certain backends (such as 'alarms') caused an internal monitor to log unnecessary error messages every few seconds, about not being able to gather data from that backend.  Note that deliberately disabling the 'alarms' backend is not recommended in normal operation, but may occur during backup/restore operations.
DS-41521	The SCIM 2 service on PingDirectory and PingDirectoryProxy now automatically generates a Swagger 2 specification document based on the server's SCIM 2 configuration. To view this document, go to <a href="https://&lt;your-server&gt;/api-docs">https://&lt;your-server&gt;/api-docs</a> in a web browser.
DS-41707	To help with multi-tenant and delegated admin ACI parameterization implement the (\$attr.attrName) macro. In particular the (\$attr.attrName) macro can be used to build bind DNs.
DS-41865	PingDirectory and PingDirectoryProxy can now perform SCIM 2 paged searches on result sets greater than the configured lookthrough limit. To perform such a search, you must first configure a virtual list view (VLV) index.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-41989	Fixed an issue that could result in duplicate column headers being produced by the Periodic Stats Logger, even when the header-prefix-per-column attribute was set to true.
DS-42045	Updated the Stats Collector Plugin with a new generate-collector-files configuration property. When using the plugin exclusively for providing metrics to one or more StatsD Monitoring Endpoints, set this property to false to prevent unnecessary I/O.

Ticket ID	Description
DS-42059, DS-42060	<p>Updated setup to add options for improving communication security:</p> <ul style="list-style-type: none"> <li>▪ Non-interactive setup now offers a <code>--rejectInsecureRequests</code> argument that will configure the server to reject any request received over a connection that is not encrypted with SSL or StartTLS.</li> <li>▪ Non-interactive setup now offers a <code>--rejectUnauthenticatedRequests</code> argument that will configure the server to reject any request received over a connection that is not authenticated (or that is authenticated as the anonymous user).</li> <li>▪ Interactive setup now allows you to configure the server with the LDAP connection handler disabled (which was already an option when using non-interactive setup), or enabled but only for communication encrypted with StartTLS.</li> </ul> <p>The <code>--rejectInsecureRequests</code> and <code>--rejectUnauthenticatedRequests</code> arguments can also be used with <code>manage-profile</code> by including them in the <code>setup-arguments.txt</code> file of the server profile.</p>
DS-42061	<p>Updated the interactive command-line tool framework to prefer establishing secure LDAP connections over insecure connections. Previously, when prompting for the information needed to establish a connection, the default option was to create an unencrypted LDAP connection. Now, tools will default to creating an SSL-encrypted connection if the server supports it, or to creating a StartTLS-encrypted connection if that is available but SSL is not. Tools will also default to using streamlined settings when establishing secure connections. Previously, they would always prompt about how to determine whether the server's certificate chain should be trusted. When using the streamlined settings, the tools will only prompt about certificates that cannot automatically be considered trusted using information in the JVM's default trust store, the server's default trust store (<code>config/truststore</code>), or the server's topology registry.</p>
DS-42062	<p>Updated the root password policy so that LDAP bind responses for root users and topology administrators will be delayed by one second after five consecutive failed authentication attempts.</p>
DS-42063	<p>Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non-LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.</p>
DS-42115	<p>Updated the server's command-line tool framework to make it easier and more convenient to communicate with the server over a secure connection when no trust-related arguments are provided. Most non-interactive tools will now check the server's default trust store, the topology registry, and the JVM's default trust store to see if the presented certificate chain can be automatically trusted without the need to prompt the user. If the presented chain cannot be automatically trusted, the user may be interactively prompted to determine whether it should be trusted.</p>

Ticket ID	Description
DS-42157, DS-43033	<p>Updated the CRAM-MD5 and DIGEST-MD5 mechanism handlers so that they are no longer considered secure. Although the credentials are encoded in transit, their protection relies on the weak MD5 digest. Further, they require that user passwords be encoded in a reversible form so the server can retrieve them in the clear for use in authentication processing, which increases the risk that they will be exposed in a data breach. This primarily affects the ability to use these SASL mechanisms over an unencrypted connection for users that are required to authenticate in a secure manner (for example, if their password policy has require-secure-authentication set to true, or if their entry has a ds-auth-require-secure-authentication operational attribute with a value of true).</p> <p>These SASL mechanisms are still enabled by default for legacy backward compatibility purposes, but we discourage their use. To assist with that, we have also provided a sample dsconfig batch file that can be used to disable these SASL mechanism handlers.</p>
DS-42164, DS-43015	<p>Added a new AES256 password storage scheme that can encode passwords with 256-bit AES encryption. Although non-reversible schemes are recommended in most deployments, reversible schemes may be necessary under certain circumstances, and the new scheme provides support for stronger encryption and better integrity protection than the existing 128-bit AES scheme.</p> <p>The key used to encrypt passwords will be derived from an encryption settings definition. Clients with access to an AES256-encoded password and the passphrase used to encrypt it may obtain the original plaintext representation of the password. The UnboundID LDAP SDK for Java provides support for decoding and decrypting these passwords through the AES256EncodedPassword class, and the Javadoc for that class provides documentation that may be used to implement support those passwords in other programming languages.</p>
DS-42199	<p>Optimized some searches commonly used by the status tool. This should improve the performance of the tool in more complex or large-scale environments.</p>
DS-42265	<p>Upgrade to jetty 9.4</p>
DS-42276	<p>Fixed an issue where using the encryption-settings tool to import definitions with the set-preferred flag could result in none of the imported definitions being set as the preferred definition.</p>
DS-42279	<p>Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.</p>
DS-42298	<p>Replaced the Idifsearch, Idifmodify, and Idif-diff command-line tools with more full-featured and robust implementations.</p>
DS-42331	<p>Replaced the ldapcompare tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).</p>
DS-42347	<p>Updated the server to use /dev/urandom (on non-Windows systems where that path exists and is readable) instead of /dev/random as the primary source for secure random data. Attempts to read from /dev/random can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from /dev/urandom will not block, and the data that it provides is no less secure than data from /dev/random in any way that matters for the server.</p>

Ticket ID	Description
DS-42349, DS-43209, DS-43210, DS-43323, DS-43324	<p>Added support for JSON-formatted audit loggers, which complement the existing file-based LDIF-formatted error logger. The JSON-formatted audit log messages provide a record of changes to data in the server and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server.</p> <p>Added support for JSON-formatted HTTP operation loggers, which complement the existing file-based loggers using the W3C common log format and a proprietary space-delimited text format. The JSON-formatted HTTP operation log messages provide a record of interaction with HTTP clients and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server.</p> <p>Fixed an issue that caused JSON-formatted loggers to use a timestamp format that was not strictly compliant with the ISO 8601 format described in RFC 3339. Timestamps incorrectly omitted the colon between the hour and minute components of the time zone offset.</p>
DS-42362	Fixed an issue in which the server could incorrectly evaluate a matched values request control containing an extensible match filter that specified both an attribute type and a matching rule. The server incorrectly used the attribute type's equality matching rule instead of the matching rule specified in the filter.
DS-42373	Fixed an issue where unindexed LDAP searches filtered on virtual attributes sometimes omitted objectClass from the returned result.
DS-42381	Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.
DS-42405	Fixed an issue that could raise an internal error when trying to undelete a non-soft-deleted entry.
DS-42438	Fixed an issue that could cause the remove-defunct-server tool to not remove certain replication attributes when run with a topology json file.
DS-42504	Updated manage-profile replace-profile to set encryption settings definitions defined in the newer server profile as preferred in the encryption settings db.
DS-42505	Previously, even if LDAP SDK debug logging was enabled, messages would be suppressed while running dsreplication. Now if LDAP SDK debug logging is enabled, messages will get printed to the console while running dsreplication.
DS-42527	Fixed an issue that could cause an exception when creating a resource in SCIM 1.1 using certain types of DNTemplate.
DS-42547	Fixed an issue where manage-profile generate-profile would print "null" as the generated profile directory when writing to an existing directory.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42609	Fixed an issue in which the Consent API could fail to decode certain credentials when using basic authentication.

Ticket ID	Description
DS-42632	Added support for creating or importing a key pair configuration object using an elliptic curve (EC) key algorithm. You can use this to designate the encryption key pair for a JWT access token validator that handles EC-encrypted access tokens.
DS-42634	The JWT Access Token Validator can now validate JWT access tokens signed using the elliptic curve digital signature algorithms ES256, ES384, and ES512.
DS-42635	<p>The JWT Access Token Validator can now validate JWT access tokens encrypted using elliptic curve cryptographic algorithms. The following key encryption algorithms are now supported in addition to RSA-OAEP: ECDH-ES, ECDH-ES+A128KW, ECDH-ES+A192KW, and ECDH-ES+A256KW.</p> <p>To support best practices for JWT security, you must now also configure the JWT Access Token Validator with explicit allow lists for key encryption and content encryption algorithms. For backward compatibility, the key encryption allow list defaults to RSA-OAEP, while the content encryption allow list defaults to A128CBC-HS256, A192CBC-HS384, and A256CBC-HS512. We recommend setting both allow lists to the strict minimum set of algorithms needed by the Access Token Validator.</p>
DS-42651	Updated the manage-profile replace-profile subcommand to better support updating the server's keystore and truststore files. When using the --generateSelfSignedCertificate argument in a server profile's setup-arguments.txt file, the server will maintain the original keystore and truststore files during replace-profile. Otherwise, replace-profile will use the keystore and truststore specified in the profile's setup-arguments.txt file.
DS-42667	Updated the server to set a unique cluster name when started for the first time.
DS-42669, DS-42748	<p>Updated the online dsconfig step of the manage-profile replace-profile subcommand to support getting LDAP connection arguments from a tools.properties file on the server being updated.</p> <p>Fixed an issue where boolean LDAP connection arguments like --useSSL and --trustAll would cause manage-profile replace-profile to fail when applying dsconfig online.</p>
DS-42673	Updated the manage-profile setup subcommand to fail if the start-server command has a non-zero exit code.
DS-42681, DS-42684	Performance statistics generated by the Sideband API can now be published by the Periodic Stats Logger. To enable this, use the "included-http-servlet-stat" property of the Periodic Stats Logger.
DS-42687	Upgrade to Jetty 9.4.30
DS-42720	Updated the ds-pwp-state-json virtual attribute provider to include information about the requirements that passwords must satisfy for adds, self password changes, administrative password resets, and binds.
DS-42740	Fixed an issue where the dsconfig ilst subcommand would not display requested properties.

Ticket ID	Description
DS-42749	To support best practices for JWT security, you must now configure the JWT Access Token Validator with an explicit list of the JWT signing algorithms that it accepts. For backward compatibility, this list defaults to the RSA signing algorithms RS256, RS384, and RS512, but we recommend setting this list to the strict minimum set of signing algorithms needed by the Access Token Validator.
DS-42751	Added new <code>override-status-code</code> and <code>additional-response-contents</code> attributes to the Availability State HTTP Servlet Extension. These new attributes can be used to customize the response code and JSON response body of the servlet.
DS-42756	Fixed a bug where backup retention attempted to purge old backups out of order, which lead to errors.
DS-42790	Fixed an issue where new replicas incorrectly went into lockdown mode after initialization.  This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.
DS-42815	Added a <code>remove-attribute-type-from-schema</code> tool that can be used to safely remove an attribute type definition from the server schema. It will ensure that the attribute type is not in use, and it will clean up metadata references to that attribute type that could have previously required re-importing the data before the attribute type could actually be removed from the schema.  The remove attribute type processing can also be requested programmatically through an administrative task.
DS-42834	Fixed an issue that could inappropriately allow HTTP-based clients (for example, those using SCIM, the Directory REST API, or the Consent API) to issue requests when the server is in lockdown mode.
DS-42850	Fixed a typo in the password-expiring template that caused "password_expiration_time_of_day" to be printed instead of the password expiration time.
DS-42861	Updated the <code>manage-profile</code> tool logs to include the duration of each step the tool takes. The new <code>--verbose</code> argument can also be used to display timing information in the tool's console output.
DS-42865	Added an aggregate identity mapper that uses Boolean AND or OR combinations of other identity mappers.
DS-42866	Updated the exact match and regular expression identity mappers to make it possible to only include entries matching a given filter.
DS-42872	Added a JSON-formatted stats logger to the server's default configuration. The stats logger is disabled by default.
DS-42886	Updated non-interactive setup (including <code>manage-profile</code> setup) to allow the password for the initial root user to be provided in pre-encoded form using the PBKDF2, SSHA256, SSHA384, or SSHA512 password storage scheme. This eliminates the need to have access to the clear-text password when setting up the server.

Ticket ID	Description
DS-42922	Fixed a bug where restoring an incremental backup could result in the server not being able to start.
DS-42926	Fixed an issue where Ping Directory products configured to run as Microsoft Windows services were sometimes unable to automatically restart following an unplanned reboot, due to errors reading a corrupted server status file.
DS-42939	The Administrative Console configuration settings have been updated to account for the new SSO functionality.
DS-42952	For Windows only, there can be a hang on start when global configuration property <code>startup-error-logger-output-location</code> is set to values that contain <code>standard-error</code> . For Windows only, <code>standard-error</code> values are silently mapped to equivalent <code>standard-output</code> values.
DS-42963	Updated the <code>manage-profile generate-profile</code> subcommand to ignore files larger than 100 megabytes when generating a server profile. Fixed an issue where many large files in the server root could cause the tool to run out of memory.
DS-43027	Added a new <code>--adminPasswordFile</code> argument to the <code>manage-topology add-server</code> command, to allow specifying the administrator password with a file rather than with the command line.
DS-43043	Fixed an issue where paged subtree searches posted to the Directory Rest API failed with error message: "Unable to decode the cookie in the simple paged results control value", whenever the search returned entries with DN length approaching or exceeding 127 characters.
DS-43047	Fixed an issue that could result in <code>isMemberOf</code> and <code>isDirectMemberOf</code> attributes not being updated appropriately when updating groups with multiple threads.
DS-43064	Fixed an issue that caused the server to return an <code>objectClassViolation</code> result code instead of the more appropriate <code>attributeOrValueExists</code> result code when trying to modify an entry to add an object class that already exists in that entry.

Ticket ID	Description
DS-43068	<p>Added a new export-reversible-passwords tool that can be used to create an LDIF export containing the clear-text representations of reversibly encoded passwords. The export may optionally include non-password attributes from the entries, entries containing non-reversible passwords, and entries without passwords. This tool can be used to help rotate the keys used to encrypt passwords if the need arises.</p> <p>There are a number of safeguards in place to help ensure that this tool cannot be used inappropriately. These include:</p> <ul style="list-style-type: none"> <li>▪ The tool invokes the export over LDAP and therefore requires that the server be online. It cannot be invoked with the server offline.</li> <li>▪ The tool can only be invoked by a user with the permit-export-reversible-passwords privilege. This privilege is not granted to any users (even root users) by default.</li> <li>▪ The tool can only be used if the server is configured with an instance of the "export reversible passwords" extended operation handler. The requester must also have access control permission to invoke this extended operation.</li> <li>▪ The tool can only be run from the server system itself and the request must be received over the loopback interface. The export cannot be requested by a remote client.</li> <li>▪ The request must be issued over a secure connection.</li> <li>▪ The output file will be written to the server filesystem. It may only be written to a file that is beneath the instance root, and that file must not already exist (although its parent directory must exist).</li> <li>▪ The exported file will be encrypted using the UnboundID LDAP SDK for Java's PassphraseEncryptedOutputStream, using a key generated from either a user-supplied passphrase or an encryption settings definition. This encrypted file may be directly imported by the import-ldif tool. If the contents of the file are needed, the LDAP SDK may be used to access its contents programmatically, or the encrypt-file tool may be used to decrypt it.</li> <li>▪ The server will generate administrative alert notifications whenever it begins and ends the export process.</li> </ul>
DS-43073, DS-43198	<p>Added support for ID Token Validators, which validate the integrity and content of ID tokens issued by OpenID Connect providers. Use these validators with the OAuth Bearer SASL Mechanism Handler to enable single sign-on (SSO) for the Administrative Console using an OpenID Connect provider such as PingOne. Currently, only PingOne is supported for SSO.</p>
DS-43074	<p>Added three built-in identity mappers that you can use to look up administrative accounts stored in the server configuration: Root DN Users, Topology Admin Users, and All Admin Users.</p>

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"> <li>▪ When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.</li> <li>▪ When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.</li> <li>▪ When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li> </ul>
DS-43305	Increased the maximum number of RDN components that a DN may have from 50 to 100.
DS-43376	Updated log publisher logic to reduce the amount of CPU that the server consumes when it is idle.
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43517	Updated the jose4j library used for JWT signing and encryption to version 0.7.2.
DS-43651	The Security Guide is now available online at <a href="https://pingidentity.com">pingidentity.com</a> . The guide has been removed from the server packaging.

Ticket ID	Description
DS-43666	Fixed an issue in which a server in lockdown mode could incorrectly allow an operation to be processed if a connection authenticated as a user with the lockdown-mode privilege issued a request with an alternate authorization identity that did not have the lockdown-mode privilege. The server now requires that both the authentication and authorization identities have the lockdown-mode privilege.

## Critical fixes

### Critical Fixes

### Critical Fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue that could inappropriately allow HTTP-based clients (for example, those using SCIM, the Directory REST API, or the Consent API) to issue requests when the server is in lockdown mode.
  - Fixed in: 8.2.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-42834
- Fixed an issue where new replicas incorrectly went into lockdown mode after initialization.

This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.

- Fixed in: 8.2.0.0
- Introduced in: 8.1.0.0
- Support identifiers: DS-42790 SF#00695648
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.3.0.0
  - Support identifiers: DS-40955
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788

- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578

- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc\_example\_dc\_com\_sn.equality': InvalidKeyException: The provided passphrase is invalid."
  - Fixed in: 7.2.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-37313
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that

were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.\*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

- Fixed in: 7.0.0.0
- Introduced in: 5.2.0.6
- Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
  - Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the

changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.

- Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
  - 1) Server B had not received changes directly from a client for a long time (beyond the purge delay),
  - 2) Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
  - 3) Server A is shutdown, and
  - 4) While Server A is shutdown, the Server B processes one or more changes directly from the client.
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216

- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
  - 1) Server B had not received changes directly from a client for a long time (beyond the purge delay),
  - 2) Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
  - 3) Server A is shutdown, and
  - 4) While Server A is shutdown, the Server B processes one or more changes directly from the client.
    - Fixed in: 6.2.0.0
    - Introduced in: 3.5.0.0
    - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an `IllegalStateException` that references "exploded-index-background-deletes" when there are several backend exploded indexes.
  - Fixed in: 6.0.0.0
  - Introduced in: 4.6.0.0
  - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
  - Fixed in: 5.0.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be

considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
  - Fixed in: 4.6.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-10470
- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
  - Fixed in: 4.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-9268 SF#2002
- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
  - Fixed in: 4.0.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing get-changelog-batch-requests at the same time that live traffic is happening.
  - Fixed in: 3.6.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-5656

- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
  - Fixed in: 3.2.0.0
  - Introduced in: 3.1.0.0
  - Support identifiers: DS-3592

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where new replicas incorrectly went into lockdown mode after initialization.
 

This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.

Fixed in: 8.2.0.0

Introduced in: 8.1.0.0

Support identifiers: DS-42790 SF#00695648
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.3.0.0
  - Support identifiers: DS-40955
- Fixed a memory leak when performing SCIM queries on the PingDirectory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788

- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.\*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

- Fixed in: 7.0.0.0
- Introduced in: 5.2.0.6
- Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
  - Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the

changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.

- Fixed in: 6.2.0.0
- Introduced in: 2.1.4.0
- Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
  - 1) Server B had not received changes directly from a client for a long time (beyond the purge delay),
  - 2) Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
  - 3) Server A is shutdown, and
  - 4) While Server A is shutdown, the Server B processes one or more changes directly from the client.
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3

### PingDirectory Server 8.1.0.6 release notes

The release notes for the 8.1.0.6 release of PingDirectory Server.

#### Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-42961	To help with replication backlog analysis, the replication summary monitor now includes a 'replica-partial-backlog' attribute that shows how each origin replica contributes partial backlog with the 'per-origin-replication-backlog' property. The 'replica-partial-backlog' attribute also shows the change numbers used for the calculation.
DS-43898	Addressed an issue where the backend would store an incorrect count for a database key that had exceeded the index entry limit. This only happened for composite indexes when the server started up after not being shut down cleanly. Normal search processing was unaffected, but the matching entry count request control processing would return incorrect results.
DS-43959, DS-44924	<p>Added new global configuration properties that can be used to impose limits on the maximum number of attributes that can be present in an <b>add</b> request and the maximum number of modifications in a <b>modify</b> request, which can be used to avoid potential denial of service attacks.</p> <p>Both limits are set to 1000 by default, which is likely to be adequate for all legitimate use cases, and neither property affects the number of values that can be provided for an attribute.</p>

## **PingDirectory Server 8.1.0.5 release notes**

### Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"><li>* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.</li><li>* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.</li><li>* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li></ul>

Ticket ID	Description
DS-43576	Added the ability to retry operation failures from replication if the failures are likely due to dependent writes being played out of order. This issue only affected environments that were sending writes to different servers, and also were not able to use the appropriate level of replication assurance. To enable this setting, update the on-replay-failure-wait-for-dependent-ops-timeout configuration property on a replication domain.
DS-44037	Avoid lockdown due to missing changes during enable caused by a missing timestamp that indicates the enable time. The problem resulted in change numbers and error messages with dates around the year 1970.
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

### PingDirectory Server 8.1.0.2 Release Notes

#### Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where new replicas incorrectly went into lockdown mode after initialization. This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default.

Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.

- Fixed in: 8.1.0.2
  - Introduced in: 8.1.0.0
  - Support identifiers: DS-42790 SF#00695648
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.3.0.0
  - Support identifiers: DS-40955
- Fixed a memory leak when performing SCIM queries on PingDirectory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578

- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc\_example\_dc\_com\_sn.equality': InvalidKeyException: The provided passphrase is invalid."
  - Fixed in: 7.2.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-37313
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.\*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.6
  - Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the

entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.

- Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746

- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an `IllegalStateException` that references "exploded-index-background-deletes" when there are several backend exploded indexes.
  - Fixed in: 6.0.0.0
  - Introduced in: 4.6.0.0
  - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
  - Fixed in: 5.0.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.
  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782
- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
  - Fixed in: 4.6.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-10470

- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
  - Fixed in: 4.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-9268 SF#2002
- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
  - Fixed in: 4.0.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing get-changelog-batch-requests at the same time that live traffic is happening.
  - Fixed in: 3.6.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-5656
- Update PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
  - Fixed in: 3.2.0.0
  - Introduced in: 3.1.0.0
  - Support identifiers: DS-3592

#### Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.

Ticket ID	Description
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-42438	Fixed an issue that could cause the remove-defunct-server tool to not remove certain replication attributes when run with a topology json file.
DS-42687	Upgrade to Jetty 9.4.30
DS-42790	<p>Fixed an issue where new replicas incorrectly went into lockdown mode after initialization.</p> <p>This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.</p>

## PingDirectory Server 8.1 Release Notes

### Upgrade Considerations

Important considerations for upgrading to this version of PingDirectory Server:

#### Important:

If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

- If you have upgraded a server that is in a cluster (that has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you can create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- The `bypass-pw-policy privilege` was intended to provide a way for administrators to bypass certain password restrictions that would normally be imposed when managing passwords for other users. A user with this privilege could use it to bypass password validation for their own entry. The

**bypass-pw-policy** privilege now only applies when changing another user's password (that is, an administrative password reset), and only in the following scenarios:

- A user with this privilege will be permitted to set pre-encoded passwords.
- A user with this privilege will be permitted to set passwords that would otherwise be rejected by one or more password validators.
- A user with this privilege will be permitted to set passwords that match the current password or that are in the password history.

The privilege will only apply when changing the password for another user, and it will have no effect for a self password change. Further, a user with this privilege will no longer be exempted from any other restrictions in their own password policy. Before upgrading, you should search for users that have the `bypass-pw-policy` privilege and check for compatibility issues. You can use the existing password validators and a custom password policy to enforce passwords for administrative users.

- Missing changes will now be detected when the backend is reverted and there are insufficient changes in the changelog database. When in this particular missing-changes state the local replica will not accept changes from the local replication server.
- Fixed an issue in which the server could incorrectly evaluate a matched values request control containing an extensible match filter that specified both an attribute type and a matching rule. The server incorrectly used the attribute type's equality matching rule instead of the matching rule specified in the filter.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.
- Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.

### Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.3.0.0
  - Support identifiers: DS-40955

- Fixed a memory leak when performing SCIM queries on PingDirectory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
  - The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
  - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server,

realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Furthermore, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you

may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.\*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

- Fixed in: 7.0.0.0
- Introduced in: 5.2.0.6
- Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
  - Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942

## What's New

These are new features for this release of PingDirectory Server:

- The `collect-support-data` tool will now collect additional files if Delegated Admin is configured within PingDirectory Server. These files include the `config.js` configuration file, the version file, and any custom files used to create customized UI fields. This information can be useful when troubleshooting issues with the Delegated Admin application.
- In an ongoing effort to improve the use of containers for PingDirectory Server, several features have been implemented:
  - The `--outputFile` option has been added to the `collect-support-data` tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the `collect-support-data` tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
    - For the `collect-support-data` tool, you can now specify either a path, a file name, or a path and file name for the resulting `csd` file. This means an administrator can run the `collect-support-data` tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
    - The `collect-support-data` tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
    - The `manage-profile` command used for creating server profiles can also be run as a recurring task from the Administration Console. Running `manage-profile` as a task creates an archive

file that can be downloaded with the HTTP File Servlet. This allows updated server profiles to be created from PingDirectory Server running in a container.

- A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this and the `--remoteServer` option added to the `collect-support-data` tool itself can be used to send the request to another server. In other words, you can now run `collect-support-data` on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- The SCIMv2 REST API was added to PingDirectory Server 8.0. Now developers can "join" separate objects into one query that allows PingDirectory Server to present distinct objects in LDAP as a single SCIM Resource object. There are two general scenarios where this functionality will be used:
  - Primary and Secondary resources, where the secondary resource is represented as a field of the primary resource
  - Composite resources, where the SCIM endpoint server stitches together scattered data into a coherent resource with which the user can interact
- PingDirectory Server has a Consent REST API that allows users to create and store consents. This new feature now allows users to search for consents that have been granted to them by another party.
- PingDirectory Server now supports the ability to create composed attributes that are derived from other attributes like virtual attributes. However, composed attributes can be stored in the backend, they are persistent and can be indexed.
- To address the need for clients to obtain information about account and password policy states, a new virtual attribute **Password Policy State JSON**, that is a JSON object, provides read-only access to a number of account state and password policy state properties. Since the value is a JSON object, it should be easily consumable by HTTP clients using SCIM and the Directory REST API.
- PingDirectory Server currently has an HTTP file servlet extension that can be used to access files on the server filesystem. This can be used for several purposes such as serving static HTML pages. In this version, the HTTP file servlet now supports basic authentication. Users can authenticate with either a distinguished name or username. Additionally, a new file servlet will be configured automatically when creating a PingDirectory Server instance. This servlet will have as the base directory the install directory for the instance and can be used to access items such as configuration, log files, and backups.. Directory indexing is enabled so you can browse available files. When using this file servlet, authentication is required, and access is restricted to users with the `file-servlet-access` privilege.
- To assist with recovering from the split-brain state the "dsreplication initialize" command will have a new "--force" option that overrides the lockdown check.
- Missing changes will now be detected when the backend is reverted and there are insufficient changes in the changelog database. While in this particular missing-changes state, the local replica will not accept changes from the local replication server.

#### Known Issues/Workarounds

The following are known issues in the current version of PingDirectory Server:

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

#### Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.
DS-1103,DS-41138,DS-41956,DS-41957	<p>Updated the password policy configuration to add support for alternate failure lockout actions, which can customize the behavior the server exhibits for an account with too many outstanding authentication failures. Available implementations include:</p> <ul style="list-style-type: none"> <li>* A "Lock Account" action that will prevent the user from authenticating or from being used as an alternate authorization identity. This matches the behavior that the server exhibited in the past when the password policy was configured to lock accounts after too many failed authentication attempts, and it remains the default behavior unless an alternative is configured.</li> <li>* A "Delay Bind Response" action that will allow the user to authenticate if they provide the correct credentials and their account is not otherwise unusable, but it will delay the bind response (regardless of its ultimate success or failure) by a specified duration to limit the rate at which an attacker can attempt to guess the password. The account will be permitted as an alternate authorization identity without any delay imposed for those operations.</li> <li>* A "No Operation" action that will not prevent or otherwise interfere with the ability to use the account to authenticate or as an alternate authorization identity, but it will still be reported as having too many failed authentication attempts for the purposes of account status notifications, the password policy state extended operation, and the password policy state JSON virtual attribute.</li> </ul>
DS-10216	Updated the GSSAPI SASL mechanism handler to support integrity and confidentiality protection for client communication.

Ticket ID	Description
DS-11505	<p>Changed the behavior the server exhibits for users with the bypass-pw-policy privilege. Although this privilege was primarily intended to allow administrators to be exempted from certain password policy restrictions while managing other user accounts, it also previously exempted the user from restrictions that should be imposed by their own password policy.</p> <p>As a result of these changes, the bypass-pw-policy privilege now only permits the following:</p> <ul style="list-style-type: none"> <li>* An account with this privilege will be permitted to set pre-encoded passwords in other user entries, regardless of the value of the allow-pre-encoded-passwords setting in the target user's password policy. This does not apply when the privileged user is changing their own password.</li> <li>* An account with this privilege will be permitted to set passwords in other user entries that would otherwise be rejected by one or more password validators configured in the target user's password policy. This does not apply when the privileged user is changing their own password.</li> <li>* An account with this privilege will be permitted to set passwords in other user entries when the new password is in the target user's password history. This does not apply when the privileged user is changing their own password.</li> </ul> <p>If the previous behavior (in which a privileged user is not subject to password policy restrictions for their own account) is desired, the user should be assigned a password policy that is not configured with the restrictions that are not wanted.</p>
DS-36573	The minimum required heap size for installing PingDirectory Server has been increased to 768 MB. Other product sizes are unchanged.
DS-36726	Improved performance when adding entries that match very large composite index keys.
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.

Ticket ID	Description
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-38585	Added gauge "Replication Purge Delay" in order to protect against missing changes. The new gauge will have a warning and critical threshold with respect to the effective purge delay, which can be configured by selecting "Gauges" in dsconfig.
DS-38790	Added support for a new ds-pwp-state-json virtual attribute, whose value is a JSON object that provides information about the state and configuration for the password policy with which that entry is associated.
DS-38879	Added a populate composed attribute values task that can be used to update existing entries with composed attribute values without the need to export data to LDIF and re-import. A command-line tool to invoke the task is also provided.
DS-38879	Added a "composed attribute" plugin that allows creating attributes whose values are constructed from the values of other attributes in the same entry. Its behavior is similar to that of the constructed virtual attribute, but composed values are actually stored in the entry rather than being dynamically generated at the time the entry is retrieved, and therefore may be indexed. Composed attribute values may be generated when entries are created by LDAP add operations or in an LDIF import, and their values may be updated if the source attributes are changed by modify or modify DN operations.
DS-39238	Updated the attribute value password validator to provide the ability to specify a minimum substring length when determining whether to reject a proposed password because it contains the value of another attribute in the entry.

Ticket ID	Description
DS-39442	Added the X-Frame-Options header in the Administrative console to prevent clickjacking attacks.
DS-39539,DS-41417,DS-41478	Fixed an issue where the manage-profile replace-profile subcommand was unable to create new local DB backends through dsconfig. Also fixed an issue where replace-profile could not export and re-import data from a server with multiple backends.
DS-39649,DS-40115	Optimized the searches for replication data performed by the status tool.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-39911	Updated the character set password validator to make it possible to require that a proposed password contain characters from at least a specified minimum number of character sets. For example, you may define four optional sets containing lowercase letters, uppercase letters, numeric digits, and symbols, and then require that proposed passwords include characters from at least three of those sets.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.
DS-40379	Fixed an issue that could cause the load-balancing-algorithm-name configuration property of a directory server instance to be lost when joining a topology.
DS-40530	Fixed XSS vulnerabilities in the Administrative console.
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.

Ticket ID	Description
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40817	PATCH operations on SCIM 2 for PingDirectory Server now require that the value of the <b>schemas</b> attribute in the request body to be "urn:ietf:params:scim:api:messages:2.0:PatchOp", in accordance with RFC 7644.
DS-40869	Made JSON the default SCIM 1.1 response content type for requests that did not specify an accept content type.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-40902	Fixed an issue that could cause the server to report an error when disabling a PingOne pass-through authentication plugin.
DS-40951	Improved import-ldif indexing performance.
DS-40953	Added detection for buffer issues that could cause connections to get stuck during TLS handshake.
DS-40955	Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.

Ticket ID	Description
DS-41033	Before starting replication calculates the total backlog for each replica by adding up the outstanding changes for each remote replica. With this change obsolete replicas will no longer be included in the calculation.
DS-41051	Improved the logic used to determine an appropriate replication database cache size. The previous fixed size of 5MB was found to be too small in some cases, and the replication database could grow larger than expected. In deployments in which the JVM has access to at least 500MB of memory, the replication database cache will now be permitted to use up to 10% of that memory. The former 5MB cache size will still be used in deployments with access to less than 500MB of memory.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41056	Updated the dictionary of commonly used passwords to include new values from studies released at the end of 2019.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41079	Trimming of replication changes database no longer gets stuck when the sequence number of the first change is greater than the sequence number of the last change, which can happen when "dsreplication initialize" is used to initialize a target with changes that are older than the changes the target previously had.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.

Ticket ID	Description
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on PingDirectory Server.
DS-41215	Updated the manage-profile replace-profile subcommand to check for encryption-related arguments in setup-arguments.txt when determining if an export and re-import of user data is necessary.
DS-41221	A new collaborator field has been added to consents. This field is for storing users with whom the consent has been shared with, in order to search consents that have been shared with a user.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41239	Missing changes are now detected for new replicas that have not yet had any changes.
DS-41252	Obsolete changes are now removed from the replication database of the target system when the target system is initialized.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.

Ticket ID	Description
DS-41270	Fixed an intermittent hang in dsreplication initialize due to replication failing to send an internal replication message. When the hang happens a message containing "the destination server is currently unavailable" is logged on the target of the initialize. The fix is to retry sending the internal replication message.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41441	Changed a validator error to a warning since it was deemed to be relatively harmless. The validator error was "Validator Error: The server experienced an unexpected error. Please report this problem and include this log file. Received an update requiring replication assurance, but without a location option"
DS-41465	Obsolete replicas will no longer be purged by default. To turn on the purging of obsolete replicas use "dsconfig" to set "replication-purge-obsolete-replicas" to true in the global configuration.

Ticket ID	Description
DS-41471	Added a global ACI that grants clients access to the pre-read and post-read request controls by default. The server will only process these controls if the requester has permission to perform the associated write operation, and the entries returned will only include attributes the requester has permission to read.
DS-41516	Added a --addBaseEntry argument to dsreplication enable. This argument can be used to add a base entry when enabling replication for an empty base DN.
DS-41622	The use-administrative-operation-request-control property is now hidden on unsupported products.
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41763	Updated the server behavior when returning entries in response to a search request in which the client explicitly specified a list of attributes to be returned. If any of the requested attributes exists in the entry but is not defined in the server schema, the server would have previously returned that attribute with a name formatted in all lowercase characters. The attribute will now be returned with a name that uses the same capitalization that the client used for it in the list of requested attributes.
DS-41818	Added the --zip argument to the manage-profile generate-profile subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to /instance-root by authenticated users with the file-servlet-access privilege will be granted access to files within the server instance root.

Ticket ID	Description
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has <code>memory.swappiness</code> set to a nonzero value.
DS-41851	Enabled Correlated LDAP Data Views for SCIM 2 resource types on PingDirectory Server and PingDirectoryProxy Server.
DS-41939	Fixed an issue with in which the server may not generate an account status notification for the account-updated notification type for modify operations unless the operation also qualifies for other types of account status notifications.
DS-41941	Fixed an issue that prevented enabling the LDAP changelog backend with the <code>manage-profile replace-profile</code> tool.
DS-41987	Updated the PUT request in the consent service to reject requests that have duplicate collaborators to make it consistent with POST and PATCH requests.
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a <code>NullPointerException</code> if a server was configured with a custom global result code map.
DS-42387	Updated the <code>manage-profile generate-profile</code> subcommand to exclude files in the <code>ldif/</code> and <code>bak/</code> directories by default when generating a server profile. If necessary, you can manually include those directories using the <code>--includePath</code> argument.

### PingDirectory Server 8.0.0.5 release notes

#### Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.

### PingDirectory Server 8.0.0.4 release notes

#### Critical fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
  - Fixed in: 8.0.0.4
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-41762 SF#00675207 SF#00683777

#### Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-42381	Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.
DS-43999	Updated the server to allow the operation purpose control to be used for operations that are part of an LDAP transaction.

### PingDirectory Server 8.0.0.3 release notes

#### Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

**No critical issues have been identified**

#### Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-42373	Fixed an issue where unindexed LDAP searches filtered on virtual attributes sometimes omitted objectClass from the returned result.
DS-42922	Fixed a bug where restoring an incremental backup could result in the server not being able to start.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"> <li>▪ When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.</li> <li>▪ When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.</li> <li>▪ When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li> </ul>

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at <a href="https://pingidentity.com">pingidentity.com</a> and has been removed from the server packaging.

### PingDirectory Server 8.0.0.2 Release Notes

#### Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

#### No critical issues have been identified

#### Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-39539,DS-41417,DS-41478	Fixed an issue where the manage-profile replace-profile subcommand was unable to create new local DB backends through dsconfig. Also fixed an issue where replace-profile could not export and re-import data from a server with multiple backends.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41033	Before starting replication calculates the total backlog for each replica by adding up the outstanding changes for each remote replica. With this change obsolete replicas will no longer be included in the calculation.
DS-41051	Improved the logic used to determine an appropriate replication database cache size. The previous fixed size of 5MB was found to be too small in some cases, and the replication database could grow larger than expected. In deployments in which the JVM has access to at least 500MB of memory, the replication database cache will now be permitted to use up to 1% of that memory. The former 5MB cache size will still be used in deployments with access to less than 500MB of memory.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41079	Trimming of replication changes database no longer gets stuck when the sequence number of the first change is greater than the sequence number of the last change, which can happen when "dsreplication initialize" is used to initialize a target with changes that are older than the changes the target previously had.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.

Ticket ID	Description
DS-41215	Updated the manage-profile replace-profile subcommand to check for encryption-related arguments in setup-arguments.txt when determining if an export and re-import of user data is necessary.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41252	Obsolete changes are now removed from the replication database of the target system when the target system is initialized.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41658	Fixed an issue where schema changes to a user-defined object class with one or more subordinate classes were not written to the schema file until additional schema changes were made.
DS-41939	Fixed an issue with in which the server may not generate an account status notification for the account-updated notification type for modify operations unless the operation also qualifies for other types of account status notifications.

Ticket ID	Description
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42812	Upgrade to jetty 9.4.30
DS-42815	<p>Added a remove-attribute-type-from-schema tool that can be used to safely remove an attribute type definition from the server schema. It will ensure that the attribute type is not in use, and it will clean up metadata references to that attribute type that could have previously required re-importing the data before the attribute type could actually be removed from the schema.</p> <p>The remove attribute type processing can also be requested programmatically through an administrative task.</p>
DS-43043	Fixed an issue where paged subtree searches posted to the Directory Rest API failed with error message: "Unable to decode the cookie in the simple paged results control value", whenever the search returned entries with DN length approaching or exceeding 127 characters.

### PingDirectory Server 8.0.0.1 Release Notes

#### Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on PingDirectory Server.
  - Fixed in: 8.0.0.1
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301

- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788

The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

- Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
- Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
  - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Furthermore, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users,

nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

- Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
- Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc\_example\_dc\_com\_sn.equality': InvalidKeyException: The provided passphrase is invalid."
  - Fixed in: 7.2.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-37313
- Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
  - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's

tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.\*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
  - Fixed in: 7.0.0.0
  - Introduced in: 5.2.0.5
  - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

- Fixed in: 7.0.0.0
- Introduced in: 5.2.0.6
- Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
  - Fixed in: 7.0.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074

- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where:
  - Server B had not received changes directly from a client for a long time (beyond the purge delay),
  - Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
  - Server A is shutdown, and
  - While Server A is shutdown, the Server B processes one or more changes directly from the client.
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.2.0.3
  - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
  - Fixed in: 6.2.0.0
  - Introduced in: 2.1.4.0
  - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
  - Fixed in: 6.2.0.0
  - Introduced in: 5.0.0.0
  - Support identifiers: DS-12216

- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where:
  - Server B had not received changes directly from a client for a long time (beyond the purge delay),
  - Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
  - Server A is shutdown, and
  - While Server A is shutdown, the Server B processes one or more changes directly from the client.
  - Fixed in: 6.2.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.1.0
  - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an `IllegalStateException` that references "exploded-index-background-deletes" when there are several backend exploded indexes.
  - Fixed in: 6.0.0.0
  - Introduced in: 4.6.0.0
  - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
  - Fixed in: 5.0.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

**Note:**

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be

considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
  - Fixed in: 4.6.0.0
  - Introduced in: 4.5.1.0
  - Support identifiers: DS-10470
- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
  - Fixed in: 4.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-9268 SF#2002
- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
  - Fixed in: 4.0.0.0
  - Introduced in: 3.5.0.0
  - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing get-changelog-batch-requests at the same time that live traffic is happening.
  - Fixed in: 3.6.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-5656

- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
  - Fixed in: 3.2.0.0
  - Introduced in: 3.1.0.0
  - Support identifiers: DS-3592

## Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40902	Fixed an issue that could cause the server to report an error when disabling a PingOne pass-through authentication plugin.
DS-40951	Improved import-ldif indexing performance.
DS-41206	Fixed a memory leak when performing SCIM queries on the PingDirectory Server.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.

Ticket ID	Description
DS-41280	The Admin Console is now deployable to an external container running Java 11 with no further downloads or updates necessary.
DS-41206	Fixed a memory leak when performing SCIM queries on the PingDirectory Server.

## PingDirectory Server 8.0.0.0 Release Notes

### Upgrade considerations

#### Important:

If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

For other upgrade considerations, see [Upgrade overview and considerations](#).

### Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
  - Fixed in: 8.0.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-40788

### What's New

These are new features for this release of the PingDirectory Server:

- Improved end user experience with several feature additions to user e-mail notifications. Now administrators can configure the server to send multi-part emails, including plain text and HTML. Also, in addition to changes to account state, such as when a user account is locked, administrators can configure notifications to send whenever any configured profile attributes are changed. For example, this can be used for confirmations of self-service account changes, or as notifications for changes made by administrators.
- Better insight to server health and the performance of connected applications. Administrators can now push metrics to application insight and monitoring applications such as Splunk using two new methods. A new StatsD monitoring endpoint pushes metrics to StatsD-compatible services. Also, the periodic stats logger has been updated to use JSON-format log files, greatly simplifying the use of log forwarding tools like Splunk's Universal Forwarder or Elastic's FileBeats.
- Several password-related improvements. A new password validator has been added that rejects passwords known to have been breached or stolen, as collected by the [haveibeenpwned.com](https://haveibeenpwned.com) service. Also, administrators can take advantage of a new Argon2 algorithm and password storage scheme, as well as new options to the PBKDF2 algorithm and password storage scheme.

- New SCIMv2 REST API to create, read, update, and delete (CRUD) users and other resources using JSON over HTTP. This complements the Directory REST API introduced in 7.2. While the Directory REST API is intended for custom application development, the SCIMv2 REST API is more intended for integrations with third party software and services. With SCIMv2, administrators configure the data conventions used in PingDirectory Server – resource types that map to directory object classes, their attributes, and their locations within the Directory Information Tree (DIT).
- A new tool to easily update the security certificates used by the server. The `replace-certificate` tool allows administrators to replace the certificates presented by the server for external client connections, both HTTPS and LDAPS. If required, the `replace-certificate` also allows the administrator to replace the certificates used for inter-server communication, like replication.

### Known Issues/Workarounds

The following are known issues in this version of the PingDirectory Server:

- The following are suggested solutions for problems with slow DNS:
  - Maintain a connection pool in the client app rather than opening new connections for each bind.
  - Add appropriate records, including PTR records, to DNS.
  - Add options `timeout:1` in the `/etc/resolv.conf` file and/or options `single-request`.
  - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory Server's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- SCIM2 PATCH operations require ACI read permissions for any required attributes in the resource's SCIM schema, even if the operation itself does not modify the required attribute itself. Otherwise, PATCH operations will fail with the error message "Applying patch ops results in an invalid resource". The following is an example of an ACI to grant read permission to the required attributes for pass-through SCIM resource types of objectClass `inetOrgPerson` for a particular oauth scope:
 

```
aci: (targetfilter="(objectClass=inetOrgPerson)")
      (targetattr="objectClass||uid||cn||givenName||sn") (version 3.0; acl
      "Allow read access to inetOrgPerson required attributes with OAuth scope
      inetOrgPersonScope"; allow (read) oauthscope="inetOrgPersonScope";)
```
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.
  - **Workaround:** Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.
- The working directory value used by exec tasks is not implemented for recurring exec tasks.
- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
  - `groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2`
  - `groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2`

**Workaround:** Deploy the Console in an external container using JDK 8.

### Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-17278	Added a <code>cn=Server Status Timeline,cn=monitor</code> monitor entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37042	Added an account status notification handler that can send multi-part email messages (including a plain-text part, HTML part, and optional attachments) in response to notable events affecting user accounts.
DS-37745	Added support for an <code>oauthscope</code> access control bind rule, which can be used to grant or deny access control permissions based on a set of scopes associated with an OAuth token.
DS-37859	Added the <code>--exportImportLocalDBData</code> option to the <code>revert-update</code> tool. This option will perform an export and re-import of any local db backends if there are changes that require it between the two versions. The new option does not handle the LDAP changelog and replication changelog.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, <code>endpoint-cache-refresh</code> , has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the <code>Resource</code> column in the output of <code>status</code> . This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.
DS-38243	Added a password validator that can use the <a href="https://haveibeenpwned.com/">Pwned Passwords service (https://haveibeenpwned.com/)</a> to reject passwords that are known to have been compromised in data breaches.
DS-38371	Added a password storage scheme that uses the Argon2i password hashing algorithm. This scheme requires the free and open source Bouncy Castle library cryptographic, which is not included with the server. This library must be obtained from <a href="https://bouncycastle.org/">https://bouncycastle.org/</a> and placed in the server <code>lib</code> directory before the storage scheme may be used.
DS-38528	Added support for a <code>generate password</code> request control that can be included in an <code>add</code> request to request that the server generate a password for the new entry. The generated password will be provided to the client in a corresponding response control.

Ticket ID	Description
DS-38560	Updated <code>manage-profile replace-profile</code> to apply configuration changes directly, when possible. If the new server profile used by <code>replace-profile</code> has changed only the <code>dsconfig</code> batch files from the original profile, then only the <code>dsconfig</code> files are applied. If no changes are detected between profiles, <code>replace-profile</code> takes no action. If changes other than <code>dsconfig</code> are detected, the full <code>replace-profile</code> process is followed.
DS-38699	Avoid sending replication messages for LDAP operations where the required associated replication information is missing.
DS-38777	Added support for updating the server version during <code>manage-profile replace-profile</code> . The server must have been originally set up with a server profile.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-38863	Updated the <code>manage-profile setup</code> subcommand to set a server's cluster name to match its instance name by default. This prevents servers in the same replication topology from being in the same cluster, reducing the risk of unintentionally overwriting parts of an existing server's configuration in a DevOps environment. The <code>--useDefaultClusterName</code> argument can be used to leave the cluster name unchanged.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions.  Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the <code>remove-defunct-server</code> tool's <code>--ignoreOnline</code> option. When using <code>--ignoreOnline</code> in a mixed-version environment, all servers must support the option.
DS-39099	Fixed an issue where error log notifications were generated regardless of whether the account status notification handler has the property enabled or disabled.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit <a href="https://groovy-lang.org">groovy-lang.org</a> and view the Groovy 2.5 release notes.  As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code> , download the appropriate jar file from <a href="https://groovy-lang.org">groovy-lang.org</a> and place it in the server's <code>lib/extensions</code> directory.

Ticket ID	Description
DS-39253	Added a <code>replace-certificate</code> tool, which can help an administrator replace the listener or inter-server certificate for a server instance.
DS-39325	<p>Removed the legacy product-specific scripts for starting and stopping the server. These include:</p> <ul style="list-style-type: none"> <li>▪ <code>start-ds</code> and <code>stop-ds</code> for PingDirectory Server</li> <li>▪ <code>start-proxy</code> and <code>stop-proxy</code> for PingDirectoryProxy Server</li> <li>▪ <code>start-sync</code> and <code>stop-sync</code> for Data Sync Server</li> <li>▪ <code>start-metrics-engine</code> and <code>stop-metrics-engine</code> for Data Metrics Server</li> </ul> <p>These legacy scripts had been deprecated for several releases in favor of the more general <code>start-server</code> and <code>stop-server</code> scripts, and they displayed a warning message about their pending removal if they were invoked.</p> <p>If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general <code>start-server</code> and <code>stop-server</code> scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point at the <code>start-server</code> and <code>stop-server</code> scripts.</p>
DS-39347	Fixed an issue where Delegated Admin would not work properly if the name of the REST Resource Type was not the same as the resource endpoint.
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as <code>X-VALUE-REGEX</code> ), this could cause unexpected or incorrect behavior.
DS-39525, DS-39526	<p>Delegated Admin enhancements for constructed attributes.</p> <ul style="list-style-type: none"> <li>▪ Allow a required attribute to be read-only if it is constructed.</li> <li>▪ Add a configured list of "Update Constructed Attributes" on the REST resource type, similar to the "Post Create Constructed Attributes", so that constructed attributes can be updated when dependent attributes change.</li> <li>▪ Handle constructed attributes which reference other constructed attributes.</li> </ul>
DS-39589	Fixed an issue that could cause access log messages for bind and StartTLS results to report the client connection policy that had previously been assigned to the connection rather than the new policy that is in place as a result of the operation.
DS-39592	HTTP External Servers have a new attribute, <code>ssl-cert-nickname</code> , which defines the alias of a specific certificate within their keystore to be used as a client certificate.

Ticket ID	Description
DS-39603	Fixed an issue where Server SDK extensions could not be configured by <code>dsconfig</code> batch files in the <code>manage-profile</code> tool.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.
DS-39654	Added support for the <code>--topologyFilePath</code> argument to the <code>manage-topology add-server</code> subcommand.
DS-39671	Updated the <code>manage-topology add-server</code> subcommand to require being run from the older server in a mixed-version environment.
DS-39693	Fixed an issue where Delegated Admin search results were truncated and invalid upon encountering a Directory entry containing a Boolean or Integer syntax attribute whose values were invalid because they did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results and a warning message is logged to the server errors log.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39762	Added support for a "generate password" extended operation that can be used to request that the server generate one or more passwords that may be suggested as possible values when creating a new user or changing the password for an existing user.
DS-39787	Fix verify-index errors on multibyte UTF-8 strings.
DS-39796	Added support for two new account status notification types. The account-created notification type can be used to generate a notification whenever a new entry is created in an add request that matches a given set of criteria. The account-updated notification type can be used to generate a notification whenever an entry is updated in a modify or modify DN request that matches a given set of criteria.
DS-39797	<p>Updated the account status notification handler framework to make several new properties available for use in constructing notification messages. These properties provide information about the password policy configuration and the user's password policy state, including:</p> <ul style="list-style-type: none"> <li>▪ The time the notification was generated</li> <li>▪ The DN of the account with which the notification is associated</li> <li>▪ The time the account password was last changed</li> <li>▪ Whether the account is in a usable state and information about any issues that might affect its usability</li> <li>▪ Whether the account is administratively disabled</li> <li>▪ Whether the account is expired or not yet active</li> <li>▪ Information about any account lockout that may be in effect</li> <li>▪ Information about password expiration</li> <li>▪ Whether a new password was generated for a self-change or administrative reset</li> </ul>

Ticket ID	Description
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39872	Updated Summarize Access Log Rotation Listener and Copy Log File Rotation Listener to run on a background thread.
DS-39873	Fixed an issue that allowed replicated subtree deletes to cause OutOfMemory errors on replicas. Also fixed a related issue that would cause the replication log to fill up with mild errors.
DS-39882	Fixed an issue that could prevent the simple request criteria from properly evaluating a target entry filter or group membership for a modify DN operation after the change had already been applied to the backend.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40114	Added a new <code>cn=Status Health Summary,cn=monitor</code> monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.
DS-40154	Fixed an issue where the restore tool was not restoring all dependencies of an incremental backup.
DS-40177	Fixed an issue that could interfere with the server's ability to purge an earlier, full backup when the following conditions are satisfied: Retention is used. Multiple levels of incremental backups depend on the full backup."
DS-40210	Fixed an issue that prevented uniqueMembers from adding themselves to a groupOfUniqueNames.
DS-40249	Fix an issue where an LDAP search across entry-balanced server sets sometimes returned 0 (success) even though all servers in one of the sets failed with a timeout. The search should return 52 (unavailable) in this situation.
DS-40317	Created a new function that takes index objects rather than the counts so that we can avoid adding to a <code>long.max_value</code> , creating a long overflow.
DS-40354	Fixed a problem with <code>config-diff</code> when writing properties that span multiple lines using the <code>--prettyPrint</code> argument.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.

Ticket ID	Description
DS-40409	Updated the <code>ldif-diff</code> tool so that it provides a <code>--stripTrailingSpaces</code> option that can cause the LDIF parser to strip off illegal trailing spaces rather than reject the associated entry or change record.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40543	Updated <code>manage-profile replace-profile</code> to copy the tool log file to the server being updated.
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40561	Fixed an issue that prevented assured replication from working for requests received via SCIM or the REST API.
DS-40674	Added the <code>--addMissingRdnAttributes</code> argument to <code>manage-profile setup</code> . This argument can be used when including LDIF files in the server profile. It will automatically add any missing RDN values to the set of entry attributes when they are not already present.
DS-40730	Updated the <code>encrypt-file</code> tool to prevent using the same path for both the input file and the output file.
DS-40744	Fixed an issue with the interaction between deprecated password storage schemes and forced password reset. If a user's password is reset by an administrator using a password storage scheme that is subsequently configured as deprecated, the act of re-encoding the password with the new default scheme would have incorrectly cleared the password reset flag.
DS-40771	Added a <code>--duration</code> argument to <code>collect-support-data</code> . When used, only the log files covering the specified duration before the current time will be collected.
DS-40788	Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
DS-40799	Fixed an issue in which an account that had been temporarily locked after too many failed authentication attempts could become re-locked with fewer than the expected number of subsequent failed attempts after the previous lockout period had elapsed.

## PingDirectoryProxy Server Release Notes

---

### PingDirectoryProxy Server 8.3.0.9 release notes

The release notes for the 8.3.0.9 release of the PingDirectoryProxy Server.

#### Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## PingDirectoryProxy Server 8.3.0.8 release notes

The release notes for the 8.3.0.8 release of the PingDirectoryProxy Server.

### Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

**No critical issues have been identified**

### Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-45798	In PingDirectoryProxy Server, "manage-profile replace-profile" sometimes failed with an error similar to the following: The tool was unable to merge configuration from the existing server into the new server: LDAPException(resultCode=80 (other) ... This fix ensures that the configuration is loaded prior to the merge that the error message refers to.
DS-46392	Fixed an issue in which the server could prevent users from changing their own passwords with the password modify extended operation if their account was in a "must change password" state and the request passed through the PingDirectoryProxy Server.

## PingDirectoryProxy Server 8.3.0.7 release notes

The release notes for the 8.3.0.7 release of the PingDirectoryProxy Server.

### Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server.

Ticket ID	Description
DS-46129	Updated the PingDirectoryProxy Server to expose the <code>maximum-attributes-per-add-request</code> and <code>maximum-modifications-per-modify-request</code> properties in the global configuration. These properties were previously only visible in the PingDirectory Server configuration, but they also apply to requests that pass through the PingDirectoryProxy Server.

## PingDirectoryProxy Server 8.3.0.6 release notes

The release notes for the 8.3.0.6 release of PingDirectoryProxy Server.

### Critical fixes

This release of the DirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of PingDirectoryProxy Server.

Ticket ID	Description
DS-41468	Fixed an issue that prevented the server from refreshing the monitor data used to detect and warn about an upcoming certificate expiration. This could cause the server to continue to warn about an expiring certificate even after that certificate had been replaced.
DS-45162	Added support for new extended operations that can be used to help manage the server's listener and inter-server certificates. Updated the <code>replace-certificate</code> tool to add support for replacing and purging certificates in a remote instance, and to allow skipping validation for the new certificate chain.

Ticket ID	Description
DS-45480, DS-45636	<ul style="list-style-type: none"> <li>▪ Updated the topology registry to allow using issuer certificates when determining whether to trust the certificate chain presented by another server in the topology. Previously, a server's certificate chain would only be trusted if the server certificate itself was found in the topology registry. Now, a certificate chain may be trusted if either the peer certificate or any of its issuers is found in the topology registry.</li> <li>▪ Updated the <code>replace-certificate</code> tool to add new <code>list-topology-registry-listener-certificates</code> and <code>list-topology-registry-inter-server-certificates</code> subcommands that can be used to display a list of the listener or inter-server certificates for a specified server instance in the topology registry.</li> <li>▪ Updated the <code>replace-certificate</code> tool to add a new <code>add-topology-registry-listener-certificate</code> subcommand that can be used to add one or more certificates to the set of listener certificates for an instance in the topology registry. This subcommand does not alter the contents of any key store, and it may be used to add an issuer certificate to the topology registry or to add a new peer listener certificate in advance of actually activating that certificate on the server.</li> <li>▪ Updated the <code>replace-certificate</code> <code>replace-listener-certificate</code> subcommand to add <code>--topology-registry-update-type</code> and <code>--trust-store-update-type</code> arguments that allow indicating which types of certificates to include in the topology registry and trust store, respectively. Available options include suppressing the update, only adding the listener certificate itself, only adding the listener certificate's issuers, or adding both the listener certificate and its issuers.</li> <li>▪ Updated the <code>replace-certificate</code> <code>replace-listener-certificate</code> subcommand to add an <code>--ignore-current-listener-certificate-validity-window</code> argument that will allow the tool to establish a connection to the server even if its certificate has expired or is not yet valid so that a non-valid certificate can be replaced.</li> </ul>
DS-45815	Updated PingDirectory products to use Kafka v2.8.1 which resolves CVE-2021-38153.

## PingDirectoryProxy Server 8.3.0.5 release notes

The release notes for the 8.3.0.5 release of PingDirectoryProxy Server.

The 8.3.0.4 release contained internal code improvements that are included in 8.3.0.5.

### Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-45124	Removed <code>-XX:RefDiscoveryPolicy=1</code> from the default <code>start-server</code> Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.
DS-45190	Added support for the use of Java Development Kits (JDKs) obtained through BellSoft.

## PingDirectoryProxy Server 8.3.0.3 release notes

The release notes for the 8.3.0.3 release of PingDirectoryProxy Server.

### Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
<ul style="list-style-type: none"> <li>▪ DS-44280</li> <li>▪ DS-45027</li> <li>▪ DS-45037</li> </ul>	Fixed an issue where <code>manage-profile</code> <code>replace-profile</code> did not correctly handle keystore files with a <code>.bcfks</code> extension while in FIPS-140-2-compliant mode.
DS-44623	Fixed an issue that caused an internal root account (used for processing certain types of internal operations) to be subject to the server's default password policy. With some password policy configurations, if a Directory Proxy Server attempted to perform an internal operation that targeted data in a backend Directory Server, that operation could have been incorrectly rejected.

## PingDirectoryProxy Server 8.3.0.2 release notes

The release notes for the 8.3.0.2 release of PingDirectoryProxy Server.

### Critical fixes

This release of the DirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## PingDirectoryProxy Server 8.3.0.1 release notes

### Critical Fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or `remove-defunct-server` tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

#### Note:

Since this change only applies to the most recent version of `dsreplication disable` or `remove-defunct-server`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past `dsreplication disable` or `remove-defunct-server` could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you may lose access to secret keys from servers that are removed from the topology.

- Fixed in: 8.3.0.1
- Introduced in: 7.0.0.0
- Support identifiers: DS-44591

### Resolved Issues

The following issues have been resolved with this release of the DirectoryProxy Server.

Ticket ID	Description
DS-44591	<p>Fixed an issue where secret keys under <code>cn=Topology,cn=config</code> could be lost when removing a server from the topology. When a server is removed via the <code>dsreplication disable</code> or <code>remove-defunct-server</code> tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.</p> <p>The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.</p> <div data-bbox="850 835 1468 1350" style="border: 1px solid black; padding: 5px;"> <p> <b>Note:</b></p> <p>Since this change only applies to the most recent version of <code>remove-defunct-server</code> and <code>dsreplication disable</code>, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. If you run the tool from an older server, it will not include this fix, and you may lose access to secret keys from servers that are removed from the topology.</p> </div>

## PingDirectoryProxy Server 8.3.0.0 release notes

### Enhancements

These are new features for this release of PingDirectoryProxy Server:

- The Administrative consoles are extensively used to view and modify the configuration of an existing instance. The console now can display the associated `dsconfig` command needed to create the current object being viewed.
- In the previous release, the ability to single sign-on from the the PingOne administration console portal was implemented. Rounding out this functionality, the administrative console can now accept bearer tokens from other OpenID Connect applications or IdPs such as PingFederate.

### Critical fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue in which adding or modifying a server group would result in a 404.
  - DS-41436
  - Fixed in 8.3.0.0
  - Introduced in 7.0.1.4
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-41762 SF#00675207 SF#00683777
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578

- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - \* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be

considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
  - Fixed in: 4.5.0.0
  - Introduced in: 4.1.0.7
  - Support identifiers: DS-9726
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854

#### Known issues and limitations

- The option to download `collect-support-data` or to generate a server profile using the admin console will not work when logged in with single sign-on.

#### Resolved issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-8	The Administrative Console now shows a <code>dsconfig</code> command to create the current object from scratch on the edit page.

Ticket ID	Description
DS-15746	<p>Added a passphrase provider mechanism, which can be used to obtain clear-text passphrases, API keys, or other types of secrets that are needed by server components like those that interact with external servers or certificate key stores. Available passphrase provider implementations include:</p> <ul style="list-style-type: none"><li>* A provider that stores an obscured representation of the passphrase directly in the server configuration.</li><li>* A provider that reads the passphrase from a file on the server filesystem. The file may optionally be encrypted with a key from the server's encryption settings database.</li><li>* A provider that can obtain the passphrase from an environment variable set in the server's process.</li><li>* A provider that can obtain the passphrase from a HashiCorp Vault instance.</li></ul> <p>Components of the server that have been updated to support using passphrase providers include:</p> <ul style="list-style-type: none"><li>* LDAP, JDBC, SCIM, and SMTP external servers.</li><li>* File-based key and trust manager providers.</li><li>* The PKCS #11 key manager provider.</li><li>* The changelog password encryption plugin.</li><li>* The Twilio alert handler and OTP delivery mechanism.</li><li>* The UNBOUNDID-YUBIKEY-OTP SASL mechanism handler.</li></ul> <p>The Server SDK has been updated to provide support for creating custom passphrase provider implementations and to allow extensions to retrieve secrets from passphrase providers configured in the server.</p>

Ticket ID	Description
DS-36257,DS-43909	<p>Updated the logic the server uses to maintain the entry-balancing global index. Improvements include:</p> <ul style="list-style-type: none"> <li>* In some cases, the server could have incorrectly populated attribute indexes in the course of processing an add operation. This could have led to scenarios in which the global index had incomplete information for some attribute values, which could have caused the PingDirectoryProxy Server to only return entries from a subset of the backend sets that contained those entries. Global attribute indexes now provide a guaranteed-unique configuration property, and they will now only be populated with new records after an add operation for indexes that are marked as guaranteed unique.</li> <li>* Global attribute indexes were previously not updated for add operations that contained an indexed attribute in the RDN but that attribute was not included in the set of attributes for the add operation. The appropriate index updates will now be performed for the operation.</li> <li>* The global index was previously not updated for operations that were part of a successful transaction or multi-update extended operation. The appropriate updates will now be made.</li> <li>* Global attribute indexes were previously not updated as a result of modifications used to remove specific attribute values from an entry. Indexes that are marked as guaranteed unique will now be updated for delete modifications that list the values to remove from the entry.</li> <li>* Global attribute indexes were previously not updated for delete operations. The server has been updated so that if the entry's RDN includes attributes for which there are indexes marked as guaranteed unique, the index will be updated to remove those RDN values.</li> </ul>
DS-39157,DS-39158,DS-43848	<p>The Server SDK ServerContext class has been updated to provide a new set of methods for writing messages to the server's trace log publishers using various log severity levels. These methods replace an existing API that only supported recording debug messages, which should not be enabled in production environments.</p> <p>Administrators can configure the server's trace log publishers to enable or disable message types on a per-severity basis using a trace log publisher's extension-message-type property.</p>

Ticket ID	Description
DS-41815	Fixed an issue with the copy/paste functionality in the Administrative Console.
DS-41911	In order to reduce the time it takes for "setup" to run the testing of Java options that "setup" does will now be cached and stored in a directory. By default the directory is "logs/option-cache" relative to the server root, but an alternative directory can be specified via setup option "--optionCacheDirectory". If a directory is specified it must be created prior to running setup.
DS-41951, DS-41326	<p>The Administrative Console can now download either a collect-support-data file or a server profile from the managed server. This can be done through the Status page. These operations require that a 'csd-files/' and a 'profile-files/' directory be present in the server root by default, but this can be customized through the ldap.csd-destination-folder and ldap.profile-destination-folder settings, which can be found in the Console's application.yml configuration file.</p> <p>Downloading collect-support-data files is disabled by default when using the PingDataConsole Docker image. It also strongly recommended to avoid downloading collect-support-data files from servers that are running in a container.</p>
DS-42401,DS-43754	Updated the manage-profile replace-profile subcommand to detect changes to files referenced in setup-arguments.txt when those files are outside of the server profile
DS-42937	The Administrative Console now allows users to specify the LDAP server they wish to bind to using the query parameters 'ldap-hostname' and 'ldaps-port' when the console is configured for SSO. This allows a single console instance to administer multiple PingData servers. Note that an LDAPS scheme is always assumed because an encrypted connection is always required for SSO.
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.
DS-43435	Fix a bug that prevented offline changes to mirrored configuration with manage-profile replace-profile.

Ticket ID	Description
DS-43441	Fixed "Reverse DNS resolution" warning during setup. This warning was a result of performing a reverse DNS lookup on link local addresses, which is now avoided. This is mostly only relevant to IPv6.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43737	<p>Updated the SCIM 2 servlet so that it provides an option to map the presented bearer token to a local user in the server. If the token can be mapped to a local user, then that account will be used as the authorization identity for the requested operation rather than the default authorization identity of "cn=SCIM2 Servlet,cn=Root DNs,cn=config". If this option is enabled and the mapping is successful, then all associated log messages, changelog records, and creatorsName and modifiersName attribute updates will use the DN of the mapped user rather than that of the SCIM2 Servlet user. Requested operations will be processed using the access rights granted to that user, as well as rights granted to any OAuth scopes included in the access token. The server's global access control rules have been updated so that an appropriate minimum set of rights should be granted for access tokens that include the "scim2" scope.</p> <p>If the presented access token cannot be mapped to a local user, then you can indicate whether the request should be rejected or whether it should be processed as before using the default "cn=SCIM2 Servlet,cn=Root DNs,cn=config" authorization identity.</p>
DS-43745	Fix an issue in the server causing PingDirectory 8.2.0.0 to be incompatible with version 4.2.0 of the Delegated Admin app, which prevented upgrade to Delegated Admin version 4.4.0 without some downtime.
DS-43787,DS-43788,DS-43795	Added the ability to implement custom SCIM Sub-Resource Type Handlers using the Server SDK. A SCIM Sub-Resource Type Handler defines a child type of a SCIM resource type that you can use to offer extended features not defined by the SCIM 2.0 standard.
DS-43804	Updated the PingDirectoryProxy Server to allow forwarding the assured replication request control by default.

Ticket ID	Description
DS-43817	Fixed an issue where Directory Server sometimes reports erroneous warnings about duplicate jar files.
DS-43836	<p>Updated the Directory Server's support for the get user resource limits control to make it possible to exclude information about the user's group membership from the response control. This can improve the performance of bind operations that use this control, especially in servers with a large number of dynamic groups.</p> <p>Also, updated the PingDirectoryProxy Server's use of the get user resource limits control when passing through bind requests to the Directory Server. If it can verify that the Directory Server supports this new feature, the PingDirectoryProxy Server will request that the server exclude group membership information from the get user resource limits response control.</p>
DS-43890	Fixed an issue with dsjavaproperties --initialize that prevented changing the JVM tuning parameter using the --jvmTuningParameter command line argument.
DS-43908	Fixed an issue that caused the PingDirectoryProxy Server to return error code 81 (server down) instead of 52 (unavailable) when adding an entry while a dataset was unavailable.
DS-43916	Added cipher stream provider and passphrase provider implementations with support for the Amazon AWS Secrets Manager service. The Amazon Secrets Manager cipher stream provider can be used to protect the contents of the encryption settings with a key derived from a secret retrieved from the Secrets Manager service. The Amazon Secrets Manager passphrase provider can be used to obtain clear-text secrets needed for processing within the server from the Secrets Manager service.
DS-43935	Updated manage-profile replace-profile to run a shorter process when applying dsconfig changes that require administrative actions.
DS-43939	Fixed an issue where Ping Directory Proxy sometimes returns incorrect result code 80 ("Other") or 81 ("Server down") instead of 32 ("No Such Entry") when adding child entries with missing parents to an entry-balanced set with only one backend server.

Ticket ID	Description
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the <code>oidc-trust-store-file</code> and <code>oidc-trust-store-type</code> settings. Also, you can set the console to skip hostname and/or certification verification through the <code>oidc-strict-hostname-verification</code> and <code>oidc-trust-all</code> configuration settings.
DS-43950	Fixed an issue where Directory Server failed to install on JDKs that lack support for AES-256 encryption.
DS-44010	Updated the server to allow obtaining client secrets from a passphrase provider as an alternative to storing an obscured representation of the secret directly in the configuration. Updated components include: <ul style="list-style-type: none"><li>* The OpenID Connect client secret needed for single sign-on to the admin console</li><li>* The OAuth client secret needed to connect to the PingOne service</li><li>* The client secret needed in conjunction with the PingFederate access token validator</li></ul>
DS-44025	Addressed an issue where the server was incorrectly displaying an "Unknown vendor" warning when using JDKs obtained on Red Hat and Ubuntu systems.

Ticket ID	Description
DS-44054,DS-44091,DS-44100,DS-44104,DS-44135,DS-44239	<p>Added a FIPS 140-2-compliant mode to the server. This mode may be enabled by running setup with the --fips argument, or by including the --fips argument in the setup-arguments.txt file when using manage-profile setup.</p> <p>Servers running in FIPS 140-2-compliant mode are not compatible with those running in non-compliant mode. FIPS 140-2-compliant mode cannot be enabled after setup (including when upgrading an existing instance, whether using update or manage-profile replace-profile). It can only be enabled when the instance is initially configured. Further, servers running in FIPS 140-2-compliant mode cannot replicate with or participate in the same topology as servers not running in FIPS-compliant mode. If you wish to migrate an existing deployment to use FIPS 140-2-compliant mode, you must install create a new topology of servers running in FIPS-compliant mode and migrate the data into it.</p> <p>In addition, servers running in FIPS 140-2-compliant mode will not be allowed to use the Argon2, bcrypt, or scrypt password storage schemes, as they rely on non-FIPS-approved algorithms. The PBKDF2 password storage scheme is approved and may be used in FIPS-compliant mode, but it requires passwords to have a minimum length of 14 bytes.</p> <p>Setup has also been updated to make it possible to initialize the certificate key and trust stores with certificate data read from PEM files. These options are available in both FIPS 140-2-compliant and non-FIPS-compliant modes, and can help make it easier to set up the server with existing certificates that are not available in a key or trust store that setup supports.</p>

Ticket ID	Description
DS-44057	<p>Improved the behavior that the server exhibits for attempts to configure it with an invalid set of TLS cipher suites.</p> <p>Previously, if a connection handler was configured with an explicit set of TLS cipher suites, and if none of those cipher suites was supported by the underlying JVM, the server would log a message for each unsupported suite and would fall back to using a default set of suites. This could lead to cases in which the server ran with a different set of cipher suites than expected, and the warning log messages might be overlooked.</p> <p>The server will now reject an attempted configuration change that would leave it without any valid cipher suites. For the sake of preserving backward compatibility, and helping to avoid issues around upgrading the server or JVM version, it will still allow attempts to configure the set of cipher suites using one or more invalid suite names as long as the server would still be able to offer at least one valid suite, and it will still log a warning message about each invalid cipher suite referenced in the configuration.</p>
DS-44061	<p>Fixed a NullPointerException that could occur when using manage-profile replace-profile with a server profile that configured a StatsD monitoring endpoint.</p>
DS-44106	<p>Updated the StatsD Monitoring Endpoint to support sending custom tags with each metric message. Custom tags will be appended at the end of each StatsD message as comma-separated key-value pairs.</p>
DS-44122	<p>Fixed an issue that caused cipher stream provider configuration options to be hidden.</p>
DS-44187	<p>Included the Bouncy Castle library with the server, which is needed to support certain cryptographic functionality, like the Argon2, bcrypt, and scrypt password storage schemes. It was not previously included with the server over concerns around compliance with U.S. export control regulations around strong encryption, but those concerns have been alleviated. You no longer need to obtain the library for yourself if you wish to use any of the functionality that requires it, and the Argon2, bcrypt, and scrypt password storage schemes are now enabled by default in the out-of-the-box configuration.</p>

Ticket ID	Description
DS-44192	<p>Updated the default set of TLS protocols and cipher suites that the server will support. As TLSv1 and TLSv1.1 are no longer considered secure (see RFC 8996 for additional information), the server will only support TLSv1.2 and TLSv1.3 (if supported by the JVM) by default. The server will also no longer enable support for TLS cipher suites that use the SHA-1 digest algorithm (which is also no longer considered secure and is not needed for TLSv1.2 or TLSv1.3) or that use the RSA key exchange algorithm (which does not support forward secrecy).</p> <p>If you need to enable support for legacy TLS protocols or cipher suites, you may do so through the server configuration. This can be enabled on a per-connection-handler basis using the <code>ssl-protocol</code> and <code>ssl-cipher-suite</code> configuration properties. Alternatively, you may use the <code>ssl-protocol</code> and <code>ssl-cipher-suite</code> properties in the crypto manager configuration to set default values that will be used by connection handlers that do not explicitly specify values for those properties.</p>
DS-44204	<p>Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a PingDirectoryProxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.</p>
DS-44316	<p>Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.</p>
DS-44390	<p>Fixed an issue where logs from setting up a new server could be lost when running the <code>manage-profile replace-profile</code> subcommand.</p>
DS-44410	<p>When deployed to a web application server such as Apache Tomcat, the Administrative Console will now write log messages to the application server's console output by default.</p>

Ticket ID	Description
DS-44420	Updated the PKCS #11 key manager provider to make it possible to dynamically load the PKCS #11 provider with a specific configuration, rather than requiring the administrator to update configuration files that are part of the JVM installation. The manage-certificates tool has also been updated to support interacting with PKCS #11 key stores, and many LDAP command-line tools also provide improved support for using PKCS #11 key stores for access to client certificates.
DS-44436	Addressed an issue in which attempting to add a member that already existed in a non-default server group would cause an error. Adds of duplicate members are now ignored and no errors are thrown.
DS-44531	Updated the manage-profile replace-profile command to avoid printing warnings for offline config changes from the new server profile.

## PingDirectoryProxy Server previous releases

Release notes for previous versions of PingDirectoryProxy Server are included for reference.

### PingDirectoryProxy 8.2.0.8 release notes

The release notes for the 8.2.0.8 release of the PingDirectoryProxy server.

#### Critical fixes

This release of the PingDirectoryProxy server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the PingDirectoryProxy server.

Ticket ID	Description
DS-45164	Updated Jetty Server to version 9.4.44.
DS-45813	Updated PingDirectory products to use Kafka v2.8.1.

### PingDirectoryProxy Server 8.2.0.7 release notes

The release notes for the 8.2.0.7 release of PingDirectoryProxy Server.

#### Critical fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or `remove-defunct-server` tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

**Note:**

Since this change only applies to the most recent version of `remove-defunct-server` and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past `dsreplication` and `remove-defunct-server` could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

- Fixed in: 8.2.0.7
- Introduced in: 7.0.0.0
- Support identifiers: DS-44591

#### Resolved Issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-44591	<p>Fixed an issue where secret keys under <code>cn=Topology,cn=config</code> could be lost when removing a server from the topology. When a server is removed via the <code>dsreplication disable</code> or <code>remove-defunct-server</code> tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.</p> <p>The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.</p> <p> <b>Note:</b></p> <p>Since this change only applies to the most recent version of <code>remove-defunct-server</code> and <code>dsreplication disable</code>, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past <code>dsreplication</code> and <code>remove-defunct-server</code> could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.</p>
DS-45124	<p>Removed <code>-XX:RefDiscoveryPolicy=1</code> from the default start-server Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.</p>
DS-45190	<p>Added support for the use of JDKs obtained through BellSoft.</p>

### PingDirectoryProxy Server 8.2.0.6 release notes

#### Critical fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## Resolved issues

The following issues have been resolved with this release of the DirectoryProxy Server.

Ticket ID	Description
DS-36257, DS-43909	<p>Updated the logic the server uses to maintain the <code>entry-balancing</code> global index. Improvements include:</p> <ul style="list-style-type: none"> <li>▪ In some cases, the server could have incorrectly populated attribute indexes in the course of processing an <code>add</code> operation. This could have led to scenarios in which the global index had incomplete information for some attribute values, which could have caused the Directory Proxy Server to only return entries from a subset of the backend sets that contained those entries. Global attribute indexes now provide a <code>guaranteed-unique</code> configuration property, and they will now only be populated with new records after an <code>add</code> operation for indexes that are marked as guaranteed unique.</li> <li>▪ Global attribute indexes were previously not updated for <code>add</code> operations that contained an indexed attribute in the relative distinguished name (RDN) but that attribute was not included in the set of attributes for the <code>add</code> operation. The appropriate index updates will now be performed for the operation.</li> <li>▪ The global index was previously not updated for operations that were part of a successful transaction or <code>multi-update</code> extended operation. The appropriate updates will now be made.</li> <li>▪ Global attribute indexes were previously not updated as a result of modifications used to remove specific attribute values from an entry. Indexes that are marked as guaranteed unique will now be updated for delete modifications that list the values to remove from the entry.</li> <li>▪ Global attribute indexes were previously not updated for <code>delete</code> operations. The server has been updated so that if the entry's RDN includes attributes for which there are indexes marked as guaranteed unique, the index will be updated to remove those RDN values.</li> </ul>
DS-43632	<p>Fixed an issue where the <code>format</code> field is omitted from the list of operational attribute schemas in the Directory REST API.</p>

## PingDirectoryProxy Server 8.2.0.5 release notes

### Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-44025	Fixed an issue where the server was incorrectly displaying an <code>Unknown vendor</code> warning when using JDKs obtained on Red Hat and Ubuntu systems.
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.

## PingDirectoryProxy Server 8.2.0.2 release notes

### Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

**No critical issues have been identified**

### Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.
DS-43939	Fixed an issue where PingDirectoryProxy Server sometimes returns incorrect result code 80 ("Other") or 81 ("Server down") instead of 32 ("No Such Entry") when adding child entries with missing parents to an entry-balanced set with only one backend server.

Ticket ID	Description
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the <code>oidc-trust-store-file</code> and <code>oidc-trust-store-type</code> settings. Also, you can set the console to skip hostname and/or certification verification through the <code>oidc-strict-hostname-verification</code> and <code>oidc-trust-all</code> configuration settings.

## PingDirectoryProxy Server 8.2.0.1 Release Notes

### Critical Fixes

### Resolved Issues

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

### No critical issues have been identified

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-43745	Fix an issue in the server causing PingDirectory Server 8.2.0.0 to be incompatible with version 4.2.0 of the Delegated Admin app, which prevented upgrade to Delegated Admin version 4.4.0 without some downtime.

## PingDirectoryProxy Server 8.2 release notes

### Enhancements

The following is a new feature for this release of PingDirectoryProxy Server:

- With SCIMv2, client applications might need to perform a sorted search on a large dataset. In this version of PingDirectory, SCIMv2 searches with the proper search parameters come back in pages.
- The Administrative Console now supports using OpenID Connect for admin SSO, allowing you to set up the PingOne administration console to have one-click SSO access without typing a password.

### Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in [Upgrade overview and considerations](#) on page 1144.

### Known issues and limitations

The following are known issues in the current version of PingDirectoryProxy Server:

When signing on to the Administrative Console, you must specify an LDAPS port in the **Server** field. For example, to use port 636, you would specify `pingdirectory:636`. If you do not specify a port, you get a

```
"Server
  unavailable"
```

message.

#### Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-644, DS-42031	Added a new <code>validate-ldap-schema</code> tool that can be used to examine schema definitions in a set of LDIF files and report any issues that it detects.
DS-5040	Improved the <code>dsframework</code> tool to support multivalued server properties.
DS-5143, DS-11035	<p>Updated support for logging access and error log messages to a syslog server. While the server previously supported logging these messages to a syslog server (through the "syslog-based access log publisher" and "syslog-based error log publisher" logger implementations), these loggers used an older version of the syslog protocol (described in RFC 3164) and only offered support for communicating over UDP.</p> <p>These loggers are still available for legacy backward compatibility, but we now also offer new "syslog text access log publisher" and "syslog text error log publisher" implementations that use a newer version of the syslog protocol (syslog version 1, described in RFC 5424) and support communicating over UDP or the more reliable TCP. When using TCP, it is also possible to encrypt communication with TLS, and it is possible to configure multiple servers for better redundancy. These loggers use the same space-delimited text format as the former loggers.</p> <p>We also offer new "syslog JSON access log publisher" and "syslog JSON error log publisher" implementations that offer the same set of capabilities, but that format the message text as JSON objects, which can be more easily parsed by third-party software.</p>

Ticket ID	Description
DS-7475, DS-7605, DS-11725, DS-37707, DS-40342, DS-41940	<p>Made several improvements to the parallel-update tool, which can use multiple concurrent threads for improved performance when applying add, delete, modify, and modify DN changes read from an LDIF file. The enhancements include:</p> <ul style="list-style-type: none"> <li>* Added support for several additional controls, including proxied authorization, manageDsaIT, ignore NO-USER-MODIFICATION, password update behavior, operation purpose, name with entryUUID, assured replication, replication repair, suppress operational attribute update, and suppress referential integrity updates. The tool also now supports specifying arbitrary controls for inclusion in add, bind, delete, modify, and modify DN requests.</li> <li>* Made its communication more robust. The tool would previously establish connections only when it was first started, but it can now detect when a connection is no longer valid and can re-establish connections as needed to continue processing. Further, if an operation failed because it was attempted on an invalid connection, that operation can be automatically retried immediately on a newly established connection.</li> <li>* Added support for failover directory servers. You can now provide the --hostname and --port arguments multiple times to specify information about multiple directory server instances. In the event that the first server listed is not available (or becomes unavailable in the middle of processing), it can automatically try establishing a connection to an alternative server to continue processing there.</li> <li>* Improved the ability to determine whether all changes were processed successfully. Previously, the tool would always use an exit code of zero if it was able to attempt all of the changes read from the LDIF file, even if some of the changes were not successfully applied. That is still the default behavior, but a new --useFirstRejectResultCodeAsExitCode argument can be used to indicate that if any operations are rejected, the result code from the first rejected operation should be used as the exit code.</li> <li>* Added support for encrypted LDIF files. If the LDIF file was encrypted with a key from the server's encryption settings database, then the tool will automatically attempt to retrieve the appropriate key. Otherwise, the new --encryptionPassphraseFile argument can be used to supply the encryption passphrase, or the passphrase can be interactively requested from the user.</li> <li>* The tool is now parallel by default. Previously, if you did not specify a value for the --numThreads argument, it would use a single thread. It now defaults to using eight threads.</li> <li>* The tool now provides a --followReferrals argument that allows it to automatically attempt to follow any referrals that are returned.</li> <li>* The tool now provides a menu-driven interactive mode that can be used to provide values for all of the command-line arguments.</li> </ul>
DS-10320, DS-12550, DS-12551, DS-12552, DS-42116, DS-42162, DS-42179, DS-42222, DS-42223, DS-42224, DS-42225, DS-42416, DS-42437	<p>Added a config/sample-dsconfig-batch-files directory with set of well commented dsconfig batch files that may be useful in enabling or configuring a variety of features in the server.</p>

Ticket ID	Description
DS-10775	<p>Updated the dictionary password validator to support additional options:</p> <ul style="list-style-type: none"> <li>* It can now ignore non-alphabetic characters that appear at the beginning or end of the password before checking the dictionary.</li> <li>* It can strip characters of diacritical marks, including accents, cedillas, circumflexes, diaereses, tildes, and umlauts, before checking the dictionary. If this option is used, then any character with such a mark will be replaced with a base version of the character without that mark (for example, a lowercase letter n with a tilde over it would be replaced with just a lowercase letter n).</li> <li>* You can define maps with information about character substitutions to use for checking alternative versions of the provided password. For example, if you indicate that "0" might map to "o", "1" or "l" might map to "i", "7" might map to "t", and "3" might map to "e", then the validator can reject a proposed password of "pr0h1b!73d" if the dictionary contains the word "prohibited".</li> <li>* It can reject a proposed password if a value from the provided dictionary makes up more than a specified percentage of that password.</li> </ul>
DS-11524, DS-41860, DS-42112	<p>Added support for new administrative alert types:</p> <ul style="list-style-type: none"> <li>* We have added a new admin alert account status notification handler, which can generate administrative alerts whenever an applicable account status notification is generated within the server. For example, this account status notification handler can be added to the root password policy to generate an alert whenever a root user's password is updated or their account is locked as a result of too many failed authentication attempts. A separate alert type has been defined for each account status notification type.</li> <li>* We have added a new "privilege-assigned" administrative alert that can be raised whenever a new entry is added or an existing entry is updated to include one or more privileges.</li> <li>* We have added a new "insecure-request-rejected" administrative alert that can be raised whenever the server rejects a request as a result of the reject-insecure-requests global configuration property.</li> </ul>
DS-12143	<p>Updated the PingDirectoryProxy Server to improve support for the PLAIN, UNBOUNDID-DELIVERED-OTP, UNBOUNDID-TOTP, and UNBOUNDID-YUBIKEY-OTP SASL mechanisms. Previously, the PingDirectoryProxy Server itself performed all of the processing for those SASL mechanisms and would only work if the PingDirectoryProxy Server could retrieve the appropriate encoded credentials from the backend Directory Server. It will now forward the bind request to the backend server for processing, which allows it to work in deployments in which the backend server prevents the PingDirectoryProxy Server from accessing the stored credentials.</p>
DS-13853	<p>Added support for the OAUTHBEARER SASL mechanism (as described in RFC 7628) to allow LDAP clients to authenticate with OAuth 2.0 bearer tokens.</p>
DS-15848, DS-42360	<p>Added support for invoking a specified set of password validators during bind operations. If the password used to authenticate fails to satisfy one or more of the configured validators, the bind attempt can be rejected, the user can be forced to change their password, or the server can generate an account status notification to take some alternative action (for example, notifying the end user or server administrators).</p>

Ticket ID	Description
DS-15864	Replaced the ldappasswordmodify tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.
DS-17903	Updated setup to provide a --populateToolPropertiesFile argument that will allow it to populate the config/tools.properties file with default values for command-line tool arguments. If requested, properties will be provided for the server address, port, and communication security, and may also include a default bind DN and optionally a bind password. When running setup interactively, it will now prompt to determine which properties (if any) should be populated in the properties file.
DS-36088	Updated the crypto manager to make it possible to augment the set of enabled TLS cipher suites with specific suites to add to or remove from the default set of enabled suites. To enable one or more suites in addition to those in the default set, prefix the names of those suites with the "+" symbol. To disable one or more suites in the default set of enabled suites, prefix the names of those suites with the "-" symbol. This was already possible when configuring cipher suites for the LDAP and HTTP connection handlers, but it was not an option for the crypto manager.
DS-38110	Updated the System Information monitor with an "isDocker" attribute to identify if the server is running in a Docker container.
DS-38118, DS-42495	<p>Made several updates related to the server's handling of data written to standard output and standard error:</p> <ul style="list-style-type: none"> <li>* The server can now be configured to rotate the logs/server.out file once it reaches a given size, and it will retain a configurable number of those log files. By default, the server will rotate the file once it reaches 100 megabytes and will keep up to ten files.</li> <li>* To better facilitate capturing log data in containerized environments, the server now supports writing JSON-formatted access and error log messages to the JVM's original standard output and error streams (which will be separate from the server.out file when the server is started with the --nodetach argument).</li> <li>* It is now possible to prevent the server from logging messages during startup in non-JSON format. It is also possible to prevent messages about administrative alerts from being written to standard error, or to write those messages in JSON format. These options are especially useful when using JSON-based logging to the console in no-detach mode, as they can help ensure that everything written to standard output and standard error will be formatted as JSON objects.</li> </ul>
DS-38816, DS-41995	<p>Updated support for the uniqueness request control to provide a more reliable mechanism for preventing conflicts that arise from operations processed concurrently in the same or different servers. If indicated in the request control, a temporary conflict prevention details entry can be added to the server before searching for existing conflicts, and that entry can be detected during pre-commit processing for other operations with uniqueness request controls that attempt to make a conflicting change.</p> <p>The server has also been updated to make it possible to generate an administrative alert if a uniqueness conflict is detected during post-commit processing for the uniqueness request control. Even though the conflict cannot be prevented at this stage in processing, the alert can let administrators know about it as soon as it happens so they can take any appropriate corrective action.</p>

Ticket ID	Description
DS-38868	Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.
DS-39789	Updated the JVM memory usage monitor provider to fix an issue that could prevent the monitor from reporting the total amount of memory held by all memory consumers. Also, fixed an issue that could cause the memory-consumer attribute to use an incomplete message for consumers without a defined maximum size and added an additional memory-consumer-json attribute whose values are JSON objects with data that can be more easily extracted by automated processes.
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-40967	Eliminated a misleading error message that could be logged at startup if the server was configured with one or more ACIs that only apply when using specific SASL mechanisms.
DS-41350	Fixed an issue where disabling certain backends (such as 'alarms') caused an internal monitor to log unnecessary error messages every few seconds, about not being able to gather data from that backend.  Note that deliberately disabling the 'alarms' backend is not recommended in normal operation, but may occur during backup/restore operations.
DS-41521	The SCIM 2 service on PingDirectory and PingDirectoryProxy now automatically generates a Swagger 2 specification document based on the server's SCIM 2 configuration. To view this document, go to <a href="https://&lt;your-server&gt;/api-docs">https://&lt;your-server&gt;/api-docs</a> in a web browser.
DS-41865	PingDirectory and PingDirectoryProxy can now perform SCIM 2 paged searches on result sets greater than the configured lookthrough limit. To perform such a search, you must first configure a virtual list view (VLV) index.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-41989	Fixed an issue that could result in duplicate column headers being produced by the Periodic Stats Logger, even when the header-prefix-per-column attribute was set to true.
DS-42045	Updated the Stats Collector Plugin with a new generate-collector-files configuration property. When using the plugin exclusively for providing metrics to one or more StatsD Monitoring Endpoints, set this property to false to prevent unnecessary I/O.

Ticket ID	Description
DS-42059, DS-42060	<p>Updated setup to add options for improving communication security:</p> <ul style="list-style-type: none"> <li>* Non-interactive setup now offers a <code>--rejectInsecureRequests</code> argument that will configure the server to reject any request received over a connection that is not encrypted with SSL or StartTLS.</li> <li>* Non-interactive setup now offers a <code>--rejectUnauthenticatedRequests</code> argument that will configure the server to reject any request received over a connection that is not authenticated (or that is authenticated as the anonymous user).</li> <li>* Interactive setup now allows you to configure the server with the LDAP connection handler disabled (which was already an option when using non-interactive setup), or enabled but only for communication encrypted with StartTLS.</li> </ul> <p>The <code>--rejectInsecureRequests</code> and <code>--rejectUnauthenticatedRequests</code> arguments can also be used with <code>manage-profile</code> by including them in the <code>setup-arguments.txt</code> file of the server profile.</p>
DS-42061	<p>Updated the interactive command-line tool framework to prefer establishing secure LDAP connections over insecure connections. Previously, when prompting for the information needed to establish a connection, the default option was to create an unencrypted LDAP connection. Now, tools will default to creating an SSL-encrypted connection if the server supports it, or to creating a StartTLS-encrypted connection if that is available but SSL is not. Tools will also default to using streamlined settings when establishing secure connections. Previously, they would always prompt about how to determine whether the server's certificate chain should be trusted. When using the streamlined settings, the tools will only prompt about certificates that cannot automatically be considered trusted using information in the JVM's default trust store, the server's default trust store (<code>config/truststore</code>), or the server's topology registry.</p>
DS-42062	<p>Updated the root password policy so that LDAP bind responses for root users and topology administrators will be delayed by one second after five consecutive failed authentication attempts.</p>
DS-42063	<p>Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non-LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.</p>
DS-42115	<p>Updated the server's command-line tool framework to make it easier and more convenient to communicate with the server over a secure connection when no trust-related arguments are provided. Most non-interactive tools will now check the server's default trust store, the topology registry, and the JVM's default trust store to see if the presented certificate chain can be automatically trusted without the need to prompt the user. If the presented chain cannot be automatically trusted, the user may be interactively prompted to determine whether it should be trusted.</p>

Ticket ID	Description
DS-42157, DS-43033	<p>Updated the CRAM-MD5 and DIGEST-MD5 mechanism handlers so that they are no longer considered secure. Although the credentials are encoded in transit, their protection relies on the weak MD5 digest. Further, they require that user passwords be encoded in a reversible form so the server can retrieve them in the clear for use in authentication processing, which increases the risk that they will be exposed in a data breach. This primarily affects the ability to use these SASL mechanisms over an unencrypted connection for users that are required to authenticate in a secure manner (for example, if their password policy has require-secure-authentication set to true, or if their entry has a ds-auth-require-secure-authentication operational attribute with a value of true).</p> <p>These SASL mechanisms are still enabled by default for legacy backward compatibility purposes, but we discourage their use. To assist with that, we have also provided a sample dsconfig batch file that can be used to disable these SASL mechanism handlers.</p>
DS-42199	Optimized some searches commonly used by the status tool. This should improve the performance of the tool in more complex or large-scale environments.
DS-42265	Upgrade to jetty 9.4
DS-42276	Fixed an issue where using the encryption-settings tool to import definitions with the set-preferred flag could result in none of the imported definitions being set as the preferred definition.
DS-42279	Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.
DS-42298	Replaced the ldifsearch, ldifmodify, and ldif-diff command-line tools with more full-featured and robust implementations.
DS-42331	Replaced the ldapcompare tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).
DS-42347	Updated the server to use /dev/urandom (on non-Windows systems where that path exists and is readable) instead of /dev/random as the primary source for secure random data. Attempts to read from /dev/random can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from /dev/urandom will not block, and the data that it provides is no less secure than data from /dev/random in any way that matters for the server.
DS-42349, DS-43209, DS-43210, DS-43323, DS-43324	<p>Added support for JSON-formatted audit loggers, which complement the existing file-based LDIF-formatted error logger. The JSON-formatted audit log messages provide a record of changes to data in the server and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server.</p> <p>Added support for JSON-formatted HTTP operation loggers, which complement the existing file-based loggers using the W3C common log format and a proprietary space-delimited text format. The JSON-formatted HTTP operation log messages provide a record of interaction with HTTP clients and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server.</p> <p>Fixed an issue that caused JSON-formatted loggers to use a timestamp format that was not strictly compliant with the ISO 8601 format described in RFC 3339. Timestamps incorrectly omitted the colon between the hour and minute components of the time zone offset.</p>

Ticket ID	Description
DS-42381	Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.
DS-42447	Fixed an issue where PingDirectoryProxy Server sometimes logged a null pointer exception if search requests across multiple load-balanced backend servers resulted in a timeout.
DS-42504	Updated manage-profile replace-profile to set encryption settings definitions defined in the newer server profile as preferred in the encryption settings db.
DS-42527	Fixed an issue that could cause an exception when creating a resource in SCIM 1.1 using certain types of DNTemplate.
DS-42547	Fixed an issue where manage-profile generate-profile would print "null" as the generated profile directory when writing to an existing directory.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42609	Fixed an issue in which the Consent API could fail to decode certain credentials when using basic authentication.
DS-42632	Added support for creating or importing a key pair configuration object using an elliptic curve (EC) key algorithm. You can use this to designate the encryption key pair for a JWT access token validator that handles EC-encrypted access tokens.
DS-42634	The JWT Access Token Validator can now validate JWT access tokens signed using the elliptic curve digital signature algorithms ES256, ES384, and ES512.
DS-42635	<p>The JWT Access Token Validator can now validate JWT access tokens encrypted using elliptic curve cryptographic algorithms. The following key encryption algorithms are now supported in addition to RSA-OAEP: ECDH-ES, ECDH-ES+A128KW, ECDH-ES+A192KW, and ECDH-ES+A256KW.</p> <p>To support best practices for JWT security, you must now also configure the JWT Access Token Validator with explicit allow lists for key encryption and content encryption algorithms. For backward compatibility, the key encryption allow list defaults to RSA-OAEP, while the content encryption allow list defaults to A128CBC-HS256, A192CBC-HS384, and A256CBC-HS512. We recommend setting both allow lists to the strict minimum set of algorithms needed by the Access Token Validator.</p>
DS-42651	Updated the manage-profile replace-profile subcommand to better support updating the server's keystore and truststore files. When using the --generateSelfSignedCertificate argument in a server profile's setup-arguments.txt file, the server will maintain the original keystore and truststore files during replace-profile. Otherwise, replace-profile will use the keystore and truststore specified in the profile's setup-arguments.txt file.
DS-42667	Updated the server to set a unique cluster name when started for the first time.
DS-42669, DS-42748	<p>Updated the online dsconfig step of the manage-profile replace-profile subcommand to support getting LDAP connection arguments from a tools.properties file on the server being updated.</p> <p>Fixed an issue where boolean LDAP connection arguments like --useSSL and --trustAll would cause manage-profile replace-profile to fail when applying dsconfig online.</p>

Ticket ID	Description
DS-42673	Updated the manage-profile setup subcommand to fail if the start-server command has a non-zero exit code.
DS-42681, DS-42684	Performance statistics generated by the Sideband API can now be published by the Periodic Stats Logger. To enable this, use the "included-http-servlet-stat" property of the Periodic Stats Logger.
DS-42687	Upgrade to Jetty 9.4.30
DS-42740	Fixed an issue where the <code>dsconfig list</code> subcommand would not display requested properties.
DS-42749	To support best practices for JWT security, you must now configure the JWT Access Token Validator with an explicit list of the JWT signing algorithms that it accepts. For backward compatibility, this list defaults to the RSA signing algorithms RS256, RS384, and RS512, but we recommend setting this list to the strict minimum set of signing algorithms needed by the Access Token Validator.
DS-42751	Added new <code>override-status-code</code> and <code>additional-response-contents</code> attributes to the Availability State HTTP Servlet Extension. These new attributes can be used to customize the response code and JSON response body of the servlet.
DS-42850	Fixed a typo in the password-expiring template that caused "password_expiration_time_of_day" to be printed instead of the password expiration time.
DS-42861	Updated the manage-profile tool logs to include the duration of each step the tool takes. The new <code>--verbose</code> argument can also be used to display timing information in the tool's console output.
DS-42872	Added a JSON-formatted stats logger to the server's default configuration. The stats logger is disabled by default.
DS-42886	Updated non-interactive setup (including manage-profile setup) to allow the password for the initial root user to be provided in pre-encoded form using the PBKDF2, SSHA256, SSHA384, or SSHA512 password storage scheme. This eliminates the need to have access to the clear-text password when setting up the server.
DS-42926	Fixed an issue where Ping Directory products configured to run as Microsoft Windows services were sometimes unable to automatically restart following an unplanned reboot, due to errors reading a corrupted server status file.
DS-42939	The Administrative Console configuration settings have been updated to account for the new SSO functionality.
DS-42952	For Windows only, there can be a hang on start when global configuration property <code>startup-error-logger-output-location</code> is set to values that contain <code>standard-error</code> . For Windows only, <code>standard-error</code> values are silently mapped to equivalent <code>standard-output</code> values.
DS-42963	Updated the manage-profile <code>generate-profile</code> subcommand to ignore files larger than 100 megabytes when generating a server profile. Fixed an issue where many large files in the server root could cause the tool to run out of memory.

Ticket ID	Description
DS-43027	Added a new --adminPasswordFile argument to the manage-topology add-server command, to allow specifying the administrator password with a file rather than with the command line.
DS-43073, DS-43198	Added support for ID Token Validators, which validate the integrity and content of ID tokens issued by OpenID Connect providers. Use these validators with the OAuth Bearer SASL Mechanism Handler to enable single sign-on (SSO) for the Administrative Console using an OpenID Connect provider such as PingOne. Currently, only PingOne is supported for SSO.
DS-43074	Added three built-in identity mappers that you can use to look up administrative accounts stored in the server configuration: Root DN Users, Topology Admin Users, and All Admin Users.
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"> <li>* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.</li> <li>* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.</li> <li>* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li> </ul>
DS-43305	Increased the maximum number of RDN components that a DN may have from 50 to 100.
DS-43376	Updated log publisher logic to reduce the amount of CPU that the server consumes when it is idle.
DS-43466	Updated PingDirectoryProxy so that in entry balanced environments, the JoinRequestControl on a search operation is passed through to the directory server instance in more scenarios. This enables more efficient processing, which leads to faster response times.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43517	Updated the jose4j library used for JWT signing and encryption to version 0.7.2.
DS-43651	The Security Guide is now available online at pingidentity.com. The guide has been removed from the server packaging.

## Critical fixes

### Critical Fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are

unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow

a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
  - Fixed in: 4.5.0.0
  - Introduced in: 4.1.0.7
  - Support identifiers: DS-9726
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Update the PingDirectory Server to apply access controls when processing the `GetAuthorizationEntryRequestControl`.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854

### **PingDirectoryProxy Server 8.1.0.6 release notes**

The release notes for the 8.1.0.6 release of PingDirectoryProxy Server.

#### Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## **PingDirectoryProxy Server 8.1.0.5 release notes**

### Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"> <li>* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.</li> <li>* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.</li> <li>* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li> </ul>

Ticket ID	Description
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

### PingDirectoryProxy Server 8.1.0.2 Release Notes

#### Critical Fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the directory server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a `mirrored-subtree-manager-connection-asymmetry` alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are

unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow

a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
  - Fixed in: 4.5.0.0
  - Introduced in: 4.1.0.7
  - Support identifiers: DS-9726
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Update PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854

#### Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-42687	Upgrade to Jetty 9.4.30

#### PingDirectoryProxy Server 8.1 Release Notes

##### Critical Fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.0.0.1
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.0.0.1
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a `mirrored-subtree-manager-connection-asymmetry` alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

## Upgrade Considerations

Important considerations for upgrading to this version of PingDirectoryProxy Server:

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the

new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

- Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.

## What's New

These are new features for this release of PingDirectoryProxy Server:

- The SCIM v2 REST API was added to PingDirectory Server in version 8.0. PingDirectoryProxy Server now supports the SCIMv2 REST API to create, read, update and delete (CRUD) users and other resources using JSON over HTTP. PingDirectoryProxy Server supports all the same endpoints and HTTP methods that PingDirectory Server supports.
- In an ongoing effort to improve the use of containers for PingDirectory Server, several features have been implemented:
  - The `--outputFile` option has been added to the `collect-support-data` tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the `collect-support-data` tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
  - The `collect-support-data` tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
  - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the `collect-support-data` tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the `--remoteServer` added to the `collect-support-data` tool can be used to send the request to another server. In other words, you can now run `collect-support-data` on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectoryProxy Server has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party.
- Updated PingDirectoryProxy Server to improve support for the PLAIN, UNBOUNDID-DELIVERED-OTP, UNBOUNDID-TOTP, and UNBOUNDID-YUBIKEY-OTP SASL mechanisms. Previously, PingDirectoryProxy Server itself performed all of the processing for those SASL mechanisms, and it would only work if PingDirectoryProxy Server could retrieve the appropriate encoded credentials from the backend PingDirectory Server. It will now forward the bind request to the backend server for processing, which allows it to work in deployments in which the backend server prevents PingDirectoryProxy Server from accessing the stored credentials.
- Added a new `validate-ldap-schema` tool that can be used to examine schema definitions in a set of LDIF files and report any issues that it detects.

## Known Issues/Workarounds

The following are known issues in the current version of the PingDirectoryProxy Server:

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the `create-systemd-script` tool to create a forking `systemd` service, the service is stopped by the `"systemctl stop ping-directory.service"` command. At that time, you can see the status using the `"systemctl status ping-directory.service"` command. That status might contain an indication of failure: `"Active: failed (Result: exit-code)"`. This error has to do with the way the service exits. It is harmless.

## Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.
DS-10216	Updated the GSSAPI SASL mechanism handler to support integrity and confidentiality protection for client communication.
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.
DS-38008,DS-41192	<p>Updated PingDirectoryProxy Server to improve its support for retrying operations that fail in a manner that suggests they may succeed if attempted in a different server or on a newly established connection.</p> <p>Previously, PingDirectoryProxy Server would automatically enable retry support for all types of operations except add. At the time this retry support was initially implemented, retrying an add operation on a different server had the potential to result in a replication conflict if the entry was ultimately created on multiple servers. The Directory Server's replication logic has since been updated to detect and automatically resolve conflicts that result from attempts to add the same entry concurrently on multiple servers. As it is safe to enable automatic retry support for add operations (along with all other types of operations), that is now the default configuration.</p> <p>PingDirectoryProxy Server has also been updated to improve its retry support for the case in which connections to multiple backend servers have become invalidated in a manner that it cannot immediately detect (for example, as the result of an issue with a network switch or hardware load-balancer). As a result of this change, if all of the PingDirectoryProxy Server's usual attempts to process an operation fail in a manner that could indicate that connections are no longer valid, it may now attempt to establish a new connection to a backend server for one additional retry attempt.</p>

Ticket ID	Description
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.

Ticket ID	Description
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40817	PATCH operations on SCIM 2 for PingDirectory Server now require that the value of the <b>schemas</b> attribute in the request body to be "urn:ietf:params:scim:api:messages:2.0:PatchOp", in accordance with RFC 7644.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-40953	Added detection for buffer issues that could cause connections to get stuck during TLS handshake.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41136	Enabled SCIM 2 API for PingDirectoryProxy Server.
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on PingDirectory Server.

Ticket ID	Description
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41299	Fixed an issue where the Ping Directory Proxy could incorrectly return duplicate entries after timing out on an unindexed search.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41622	The use-administrative-operation-request-control property is now hidden on unsupported products.

Ticket ID	Description
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41818	Added the <code>--zip</code> argument to the <code>manage-profile generate-profile</code> subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to <code>/instance-root</code> by authenticated users with the <code>file-servlet-access</code> privilege will be granted access to files within the server instance root.
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has <code>memory.swappiness</code> set to a nonzero value.
DS-41851	Enabled Correlated LDAP Data Views for SCIM 2 resource types on PingDirectory Server and Nokia8661DirectoryProxyServerAdministrationGuid.
DS-41987	Updated the PUT request in the consent service to reject requests that have duplicate collaborators to make it consistent with POST and PATCH requests.
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a <code>NullPointerException</code> if a server was configured with a custom global result code map.
DS-42387	Updated the <code>manage-profile generate-profile</code> subcommand to exclude files in the <code>ldif/</code> and <code>bak/</code> directories by default when generating a server profile. If necessary, you can manually include those directories using the <code>--includePath</code> argument.

## PingDirectoryProxy Server 8.0.0.5 release notes

### Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.

## PingDirectoryProxy Server 8.0.0.4 release notes

### Critical fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
  - Fixed in: 8.0.0.4
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-41762 SF#00675207 SF#00683777

### Resolved Issues

The following issues have been resolved with this release of the Directory Server:

Ticket ID	Description
DS-38008,DS-41192	<p>Updated the Directory Server to improve its support for retrying operations that fail in a manner that suggests they may succeed if attempted in a different server or on a newly established connection.</p> <p>Previously, the Directory Server would automatically enable retry support for all types of operations except add. At the time this retry support was initially implemented, retrying an add operation on a different server had the potential to result in a replication conflict if the entry was ultimately created on multiple servers. The Directory Server's replication logic has since been updated to detect and automatically resolve conflicts that result from attempts to add the same entry concurrently on multiple servers. As it is safe to enable automatic retry support for add operations (along with all other types of operations), that is now the default configuration.</p> <p>The Directory Server has also been updated to improve its retry support for the case in which connections to multiple backend servers have become invalidated in a manner that it cannot immediately detect (for example, as the result of an issue with a network switch or hardware load-balancer). As a result of this change, if all of the Directory Server's usual attempts to process an operation fail in a manner that could indicate that connections are no longer valid, it may now attempt to establish a new connection to a backend server for one additional retry attempt.</p>
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-42381	Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.
DS-43908	Fixed an issue that caused the Directory Server to return error code 81 (server down) instead of 52 (unavailable) when adding an entry while a dataset was unavailable.
DS-43939	Fixed an issue where Directory Server sometimes returns incorrect result code 80 ("Other") or 81 ("Server down") instead of 32 ("No Such Entry") when adding child entries with missing parents to an entry-balanced set with only one backend server.

## PingDirectoryProxy Server 8.0.0.3 release notes

### Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

### No critical issues have been identified

### Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"> <li>* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.</li> <li>* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.</li> <li>* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li> </ul>

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at <a href="https://pingidentity.com">pingidentity.com</a> and has been removed from the server packaging.

### PingDirectoryProxy Server 8.0.0.2 Release Notes

#### Critical Fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

#### No critical issues have been identified

#### Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41054	Fixed an issue that stopped new extensions from being installed.

Ticket ID	Description
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41299	Fixed an issue where PingDirectoryProxy Server could incorrectly return duplicate entries after timing out on an unindexed search.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42812	Upgrade to jetty 9.4.30

## PingDirectoryProxy Server 8.0.0.1 Release Notes

### Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.0.0.1
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - \* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-

lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-

NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
  - Fixed in: 4.5.0.0
  - Introduced in: 4.1.0.7
  - Support identifiers: DS-9726
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
  - Fixed in: 3.5.0.0
  - Introduced in: 3.2.0.0
  - Support identifiers: DS-6054
- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
  - Fixed in: 3.5.0.0
  - Introduced in: 2.0.0.0
  - Support identifiers: DS-854

#### Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.

Ticket ID	Description
DS-41206	Fixed a memory leak when performing SCIM queries on the PingDirectory Server.

## PingDirectoryProxy Server 8.0.0.0 Release Notes

### Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

### What's New

These are new features for this release of the PingDirectoryProxy Server:

- Better insight to server health and the performance of connected applications. Administrators can now push metrics to application insight and monitoring applications such as Splunk using two new methods. A new StatsD monitoring endpoint pushes metrics to StatsD-compatible services. Also, the periodic stats logger has been updated to use JSON-format log files, greatly simplifying the use of log forwarding tools like Splunk's Universal Forwarder or Elastic's FileBeats.
- Better support by Directory Proxy Server for orchestrated Directory Server clusters in automated environments like Kubernetes or AWS EC2 Auto Scaling. Administrators can connect the topology of a PingDirectoryProxy Server cluster to the topology of a PingDirectory Server cluster in order to automatically adapt to cluster changes within the PingDirectory Server cluster. This greatly simplifies the configuration management of PingDirectoryProxy Server when PingDirectory Server clusters are being added, removed, or replaced by automated infrastructure orchestrators.
- Use Server Profiles to reduce risk and improve consistency following the DevOps principle of infrastructure-as-code. Administrators can export the configuration of the PingDirectoryProxy Server server to a directory of text files called a Server Profile, track changes to these files in version control like Git, and install new instances of PingDirectoryProxy Server or update existing instances of Directory Proxy Server from a Server Profile. Server Profiles support variable substitution in order to remove the settings unique to each pre-production or production environment from the Server Profile that is stored in version control.

### Known Issues/Workarounds

The following are known issues in the current version of the PingDirectoryProxy Server:

- The following are suggested solutions for problems with slow DNS:
  - Maintain a connection pool in the client app rather than opening new connections for each bind.
  - Add appropriate records, including PTR records, to DNS.
  - Add `options timeout:1` in the `/etc/resolv.conf` file and/or `options single-request`
  - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in Directory Server's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.
 

**Workaround:** Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.
- The working directory value used by exec tasks is not implemented for recurring exec tasks.

- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
  - `groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2`
  - `groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2`

**Workaround:** Deploy the Console in an external container using JDK 8.

#### Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-17278	Added a <code>cn=Server Status Timeline,cn=monitor monitor</code> entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, <code>endpoint-cache-refresh</code> , has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the <code>Resource</code> column in the output of <code>status</code> . This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.
DS-38560	Updated <code>manage-profile replace-profile</code> to apply configuration changes directly, when possible. If the new server profile used by <code>replace-profile</code> has changed only the <code>dsconfig</code> batch files from the original profile, then only the <code>dsconfig</code> files are applied. If no changes are detected between profiles, <code>replace-profile</code> takes no action. If changes other than <code>dsconfig</code> are detected, the full <code>replace-profile</code> process is followed.
DS-38777	Added support for updating the server version during <code>manage-profile replace-profile</code> . The server must have been originally set up with a server profile.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.

Ticket ID	Description
DS-38863	Updated the <code>manage-profile setup</code> subcommand to set a server's cluster name to match its instance name by default. This prevents servers in the same replication topology from being in the same cluster, reducing the risk of unintentionally overwriting parts of an existing server's configuration in a DevOps environment. The <code>--useDefaultClusterName</code> argument can be used to leave the cluster name unchanged.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions.  Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the <code>remove-defunct-server</code> tool's <code>--ignoreOnline</code> option. When using <code>--ignoreOnline</code> in a mixed-version environment, all servers must support the option.
DS-39155	Updated the default value for <code>maximum-degraded-missing-changes</code> to 1000000, and for <code>minimum-unavailable-missing-changes</code> to 100000. Servers that used the previous default values became unavailable prematurely, leading to outages.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit <a href="http://groovy-lang.org">groovy-lang.org</a> and view the Groovy 2.5 release notes.  As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code> , download the appropriate jar file from <a href="http://groovy-lang.org">groovy-lang.org</a> and place it in the server's <code>lib/extensions</code> directory.
DS-39253	Added a <code>replace-certificate</code> tool, which can help an administrator replace the listener or inter-server certificate for a server instance.
DS-39321	Added support for PingDirectoryProxy Server to the <code>manage-profile</code> tool and its subcommands.

Ticket ID	Description
DS-39325	<p>Removed the legacy product-specific scripts for starting and stopping the server. These include:</p> <ul style="list-style-type: none"> <li>▪ <code>start-ds</code> and <code>stop-ds</code> for Directory Server</li> <li>▪ <code>start-proxy</code> and <code>stop-proxy</code> for Directory Proxy Server</li> <li>▪ <code>start-sync</code> and <code>stop-sync</code> for Data Sync Server</li> <li>▪ <code>start-metrics-engine</code> and <code>stop-metrics-engine</code> for Data Metrics Server</li> </ul> <p>These legacy scripts had been deprecated for several releases in favor of the more general <code>start-server</code> and <code>stop-server</code> scripts, and they displayed a warning message about their upcoming removal if they were invoked.</p> <p>If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general <code>start-server</code> and <code>stop-server</code> scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point at the <code>start-server</code> and <code>stop-server</code> scripts.</p>
DS-39347	Fixed an issue where Delegated Admin would not work properly if the name of the REST Resource Type was not the same as the resource endpoint.
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as <code>X-VALUE-REGEX</code> ), this could cause unexpected or incorrect behavior.
DS-39525, DS-39526	<p>Delegated Admin enhancements for constructed attributes.</p> <ul style="list-style-type: none"> <li>▪ Allow a required attribute to be read-only if it is constructed.</li> <li>▪ Add a configured list of "Update Constructed Attributes" on the REST resource type, similar to the "Post Create Constructed Attributes", so that constructed attributes can be updated when dependent attributes change.</li> <li>▪ Handle constructed attributes which reference other constructed attributes.</li> </ul>
DS-39592	HTTP External Servers have a new attribute, <code>ssl-cert-nickname</code> , which defines the alias of a specific certificate within their keystore to be used as a client certificate.
DS-39603	Fixed an issue where Server SDK extensions could not be configured by <code>dsconfig</code> batch files in the <code>manage-profile</code> tool.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.
DS-39654	Added support for the <code>--topologyFilePath</code> argument to the <code>manage-topology add-server</code> subcommand.
DS-39671	Updated the <code>manage-topology add-server</code> subcommand to require being run from the older server in a mixed-version environment.

Ticket ID	Description
DS-39693	Fixed an issue where Delegated Admin search results were truncated and invalid upon encountering a Directory entry containing a Boolean or Integer syntax attribute whose values were invalid because they did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results and a warning message is logged to the server errors log.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39762	Added support for a "generate password" extended operation that can be used to request that the server generate one or more passwords that may be suggested as possible values when creating a new user or changing the password for an existing user.
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40114	Added a new <code>cn=Status Health Summary,cn=monitor</code> monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.
DS-40249	Fixed an issue where an LDAP search across entry-balanced server sets sometimes returned 0 (success) even though all servers in one of the sets failed with a timeout. The search should return 52 (unavailable) in this situation.
DS-40252	Update the PingDirectoryProxy Server setup process to support joining an existing PingData Platform topology.
DS-40255, DS-40256, DS-40257	Updated the fewest operations and failover load-balancing algorithms to support automatically discovering the set of backend Directory Server instances from the topology registry.
DS-40274	Updated the proxy to check if the proxy's backend has been sufficiently initialized prior to performing a health check.
DS-40354	Fixed a problem with <code>config-diff</code> when writing properties that span multiple lines using the <code>--prettyPrint</code> argument.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40543	Updated <code>manage-profile</code> <code>replace-profile</code> to copy the tool log file to the server being updated.

Ticket ID	Description
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40730	Updated the <code>encrypt-file</code> tool to prevent using the same path for both the input file and the output file.
DS-40771	Added a <code>--duration</code> argument to <code>collect-support-data</code> . When used, only the log files covering the specified duration before the current time will be collected.

## PingDataMetrics Server Release Notes

---

### PingDataMetrics Server 8.3.0.9 release notes

The release notes for the 8.3.0.9 release of the PingDataMetrics Server.

#### Critical Fixes

This release of the PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### PingDataMetrics Server 8.3.0.8 release notes

The release notes for the 8.3.0.8 release of the PingDataMetrics Server.

#### Critical Fixes

This release of the PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

### PingDataMetrics Server 8.3.0.7 release notes

The release notes for the 8.3.0.7 release of the PingDataMetrics Server.

#### Critical Fixes

This release of the PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### PingDataMetrics Server 8.3.0.6 release notes

The release notes for the 8.3.0.6 release of PingDataMetrics Server.

#### Critical fixes

This release of the DataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of PingDataMetrics Server.

Ticket ID	Description
DS-41468	Fixed an issue that prevented the server from refreshing the monitor data used to detect and warn about an upcoming certificate expiration. This could cause the server to continue to warn about an expiring certificate even after that certificate had been replaced.
DS-45162	Added support for new extended operations that can be used to help manage the server's listener and inter-server certificates. Updated the <b>replace-certificate</b> tool to add support for replacing and purging certificates in a remote instance, and to allow skipping validation for the new certificate chain.

Ticket ID	Description
DS-45480, DS-45636	<ul style="list-style-type: none"> <li>▪ Updated the topology registry to allow using issuer certificates when determining whether to trust the certificate chain presented by another server in the topology. Previously, a server's certificate chain would only be trusted if the server certificate itself was found in the topology registry. Now, a certificate chain may be trusted if either the peer certificate or any of its issuers is found in the topology registry.</li> <li>▪ Updated the <code>replace-certificate</code> tool to add new <code>list-topology-registry-listener-certificates</code> and <code>list-topology-registry-inter-server-certificates</code> subcommands that can be used to display a list of the listener or inter-server certificates for a specified server instance in the topology registry.</li> <li>▪ Updated the <code>replace-certificate</code> tool to add a new <code>add-topology-registry-listener-certificate</code> subcommand that can be used to add one or more certificates to the set of listener certificates for an instance in the topology registry. This subcommand does not alter the contents of any key store, and it may be used to add an issuer certificate to the topology registry or to add a new peer listener certificate in advance of actually activating that certificate on the server.</li> <li>▪ Updated the <code>replace-certificate</code> <code>replace-listener-certificate</code> subcommand to add <code>--topology-registry-update-type</code> and <code>--trust-store-update-type</code> arguments that allow indicating which types of certificates to include in the topology registry and trust store, respectively. Available options include suppressing the update, only adding the listener certificate itself, only adding the listener certificate's issuers, or adding both the listener certificate and its issuers.</li> <li>▪ Updated the <code>replace-certificate</code> <code>replace-listener-certificate</code> subcommand to add an <code>--ignore-current-listener-certificate-validity-window</code> argument that will allow the tool to establish a connection to the server even if its certificate has expired or is not yet valid so that a non-valid certificate can be replaced.</li> </ul>
DS-45815	Updated PingDirectory products to use Kafka v2.8.1 which resolves CVE-2021-38153.

## PingDataMetrics Server 8.3.0.5 release notes

The release notes for the 8.3.0.5 release of PingDataMetrics Server.

The 8.3.0.4 release contained internal code improvements that are included in 8.3.0.5.

### Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Data Metrics Server.

Ticket ID	Description
DS-45124	Removed <code>-XX:RefDiscoveryPolicy=1</code> from the default <code>start-server</code> Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.
DS-45190	Added support for the use of Java Development Kits (JDKs) obtained through BellSoft.

## PingDataMetrics Server 8.3.0.3 release notes

The release notes for the 8.3.0.3 release of PingDataMetrics Server.

### Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## PingDataMetrics Server 8.3.0.2 release notes

The release notes for the 8.3.0.2 release of PingDataMetrics Server.

### Critical fixes

This release of the DataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## PingDataMetrics Server 8.3.0.1 release notes

### Critical Fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or `remove-`

`defunct-server` tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

**Note:**

Since this change only applies to the most recent version of `dsreplication disable` or `remove-defunct-server`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past `dsreplication disable` or `remove-defunct-server` could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you may lose access to secret keys from servers that are removed from the topology.

- Fixed in: 8.3.0.1
- Introduced in: 7.0.0.0
- Support identifiers: DS-44591

Resolved Issues

The following issues have been resolved with this release of the DataMetrics Server.

Ticket ID	Description
DS-44224	Addressed an issue where icons on the dashboards were not properly displayed.

Ticket ID	Description
DS-44591	<p>Fixed an issue where secret keys under <code>cn=Topology,cn=config</code> could be lost when removing a server from the topology. When a server is removed via the <code>dsreplication disable</code> or <code>remove-defunct-server</code> tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.</p> <p>The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you run the tool from an older server, it will not include this fix, and you may lose access to secret keys from servers that are removed from the topology.</p> </div>

## PingDataMetrics Server 8.3.0.0 release notes

### Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue in which adding or modifying a server group would result in a 404.
  - DS-41436
  - Fixed in 8.3.0.0
  - Introduced in 7.0.1.4
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301

- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-41762 SF#00675207 SF#00683777
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - \* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that

were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-

lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition,

if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782

#### Known issues and limitations

- The option to download `collect-support-data` or to generate a server profile using the admin console will not work when logged in with single sign-on.

#### Resolved issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-8	The Administrative Console now shows a <code>dsconfig</code> command to create the current object from scratch on the edit page.
DS-15746	<p>Added a passphrase provider mechanism, which can be used to obtain clear-text passphrases, API keys, or other types of secrets that are needed by server components like those that interact with external servers or certificate key stores. Available passphrase provider implementations include:</p> <ul style="list-style-type: none"> <li>* A provider that stores an obscured representation of the passphrase directly in the server configuration.</li> <li>* A provider that reads the passphrase from a file on the server filesystem. The file may optionally be encrypted with a key from the server's encryption settings database.</li> <li>* A provider that can obtain the passphrase from an environment variable set in the server's process.</li> <li>* A provider that can obtain the passphrase from a HashiCorp Vault instance.</li> </ul> <p>Components of the server that have been updated to support using passphrase providers include:</p> <ul style="list-style-type: none"> <li>* LDAP, JDBC, SCIM, and SMTP external servers.</li> <li>* File-based key and trust manager providers.</li> <li>* The PKCS #11 key manager provider.</li> <li>* The changelog password encryption plugin.</li> <li>* The Twilio alert handler and OTP delivery mechanism.</li> <li>* The UNBOUNDID-YUBIKEY-OTP SASL mechanism handler.</li> </ul> <p>The Server SDK has been updated to provide support for creating custom passphrase provider implementations and to allow extensions to retrieve secrets from passphrase providers configured in the server.</p>

Ticket ID	Description
DS-39157,DS-39158,DS-43848	<p>The Server SDK ServerContext class has been updated to provide a new set of methods for writing messages to the server's trace log publishers using various log severity levels. These methods replace an existing API that only supported recording debug messages, which should not be enabled in production environments.</p> <p>Administrators can configure the server's trace log publishers to enable or disable message types on a per-severity basis using a trace log publisher's extension-message-type property.</p>
DS-41815	Fixed an issue with the copy/paste functionality in the Administrative Console.
DS-41911	<p>In order to reduce the time it takes for "setup" to run the testing of Java options that "setup" does will now be cached and stored in a directory. By default the directory is "logs/option-cache" relative to the server root, but an alternative directory can be specified via setup option "--optionCacheDirectory". If a directory is specified it must be created prior to running setup.</p>
DS-41951, DS-41326	<p>The Administrative Console can now download either a collect-support-data file or a server profile from the managed server. This can be done through the Status page. These operations require that a 'csd-files/' and a 'profile-files/' directory be present in the server root by default, but this can be customized through the ldap.csd-destination-folder and ldap.profile-destination-folder settings, which can be found in the Console's application.yml configuration file.</p> <p>Downloading collect-support-data files is disabled by default when using the PingDataConsole Docker image. It also strongly recommended to avoid downloading collect-support-data files from servers that are running in a container.</p>
DS-42401,DS-43754	Updated the manage-profile replace-profile subcommand to detect changes to files referenced in setup-arguments.txt when those files are outside of the server profile

Ticket ID	Description
DS-42937	The Administrative Console now allows users to specify the LDAP server they wish to bind to using the query parameters 'ldap-hostname' and 'ldaps-port' when the console is configured for SSO. This allows a single console instance to administer multiple PingData servers. Note that an LDAPS scheme is always assumed because an encrypted connection is always required for SSO.
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.
DS-43435	Fix a bug that prevented offline changes to mirrored configuration with manage-profile replace-profile.
DS-43441	Fixed "Reverse DNS resolution" warning during setup. This warning was a result of performing a reverse DNS lookup on link local addresses, which is now avoided. This is mostly only relevant to IPv6.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43817	Fixed an issue where Directory Server sometimes reports erroneous warnings about duplicate jar files.
DS-43890	Fixed an issue with dsjavaproperties --initialize that prevented changing the JVM tuning parameter using the --jvmTuningParameter command line argument.
DS-43916	Added cipher stream provider and passphrase provider implementations with support for the Amazon AWS Secrets Manager service. The Amazon Secrets Manager cipher stream provider can be used to protect the contents of the encryption settings with a key derived from a secret retrieved from the Secrets Manager service. The Amazon Secrets Manager passphrase provider can be used to obtain clear-text secrets needed for processing within the server from the Secrets Manager service.
DS-43935	Updated manage-profile replace-profile to run a shorter process when applying dsconfig changes that require administrative actions.

Ticket ID	Description
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the <code>oidc-trust-store-file</code> and <code>oidc-trust-store-type</code> settings. Also, you can set the console to skip hostname and/or certification verification through the <code>oidc-strict-hostname-verification</code> and <code>oidc-trust-all</code> configuration settings.
DS-43950	Fixed an issue where Directory Server failed to install on JDKs that lack support for AES-256 encryption.
DS-44010	Updated the server to allow obtaining client secrets from a passphrase provider as an alternative to storing an obscured representation of the secret directly in the configuration. Updated components include: <ul style="list-style-type: none"><li>* The OpenID Connect client secret needed for single sign-on to the admin console</li><li>* The OAuth client secret needed to connect to the PingOne service</li><li>* The client secret needed in conjunction with the PingFederate access token validator</li></ul>
DS-44025	Addressed an issue where the server was incorrectly displaying an "Unknown vendor" warning when using JDKs obtained on Red Hat and Ubuntu systems.

Ticket ID	Description
DS-44057	<p>Improved the behavior that the server exhibits for attempts to configure it with an invalid set of TLS cipher suites.</p> <p>Previously, if a connection handler was configured with an explicit set of TLS cipher suites, and if none of those cipher suites was supported by the underlying JVM, the server would log a message for each unsupported suite and would fall back to using a default set of suites. This could lead to cases in which the server ran with a different set of cipher suites than expected, and the warning log messages might be overlooked.</p> <p>The server will now reject an attempted configuration change that would leave it without any valid cipher suites. For the sake of preserving backward compatibility, and helping to avoid issues around upgrading the server or JVM version, it will still allow attempts to configure the set of cipher suites using one or more invalid suite names as long as the server would still be able to offer at least one valid suite, and it will still log a warning message about each invalid cipher suite referenced in the configuration.</p>
DS-44061	Fixed a NullPointerException that could occur when using manage-profile replace-profile with a server profile that configured a StatsD monitoring endpoint.
DS-44106	Updated the StatsD Monitoring Endpoint to support sending custom tags with each metric message. Custom tags will be appended at the end of each StatsD message as comma-separated key-value pairs.
DS-44122	Fixed an issue that caused cipher stream provider configuration options to be hidden.
DS-44187	Included the Bouncy Castle library with the server, which is needed to support certain cryptographic functionality, like the Argon2, bcrypt, and scrypt password storage schemes. It was not previously included with the server over concerns around compliance with U.S. export control regulations around strong encryption, but those concerns have been alleviated. You no longer need to obtain the library for yourself if you wish to use any of the functionality that requires it, and the Argon2, bcrypt, and scrypt password storage schemes are now enabled by default in the out-of-the-box configuration.

Ticket ID	Description
DS-44192	<p>Updated the default set of TLS protocols and cipher suites that the server will support. As TLSv1 and TLSv1.1 are no longer considered secure (see RFC 8996 for additional information), the server will only support TLSv1.2 and TLSv1.3 (if supported by the JVM) by default. The server will also no longer enable support for TLS cipher suites that use the SHA-1 digest algorithm (which is also no longer considered secure and is not needed for TLSv1.2 or TLSv1.3) or that use the RSA key exchange algorithm (which does not support forward secrecy).</p> <p>If you need to enable support for legacy TLS protocols or cipher suites, you may do so through the server configuration. This can be enabled on a per-connection-handler basis using the <code>ssl-protocol</code> and <code>ssl-cipher-suite</code> configuration properties. Alternatively, you may use the <code>ssl-protocol</code> and <code>ssl-cipher-suite</code> properties in the crypto manager configuration to set default values that will be used by connection handlers that do not explicitly specify values for those properties.</p>
DS-44316	<p>Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.</p>
DS-44390	<p>Fixed an issue where logs from setting up a new server could be lost when running the <code>manage-profile replace-profile</code> subcommand.</p>
DS-44410	<p>When deployed to a web application server such as Apache Tomcat, the Administrative Console will now write log messages to the application server's console output by default.</p>
DS-44436	<p>Addressed an issue in which attempting to add a member that already existed in a non-default server group would cause an error. Adds of duplicate members are now ignored and no errors are thrown.</p>

Ticket ID	Description
DS-44531	Updated the manage-profile replace-profile command to avoid printing warnings for offline config changes from the new server profile.

## PingDataMetrics Server previous releases

Release notes for previous versions of Ping Data Metrics Server are included for reference.

### PingDataMetrics 8.2.0.8 release notes

The release notes for the 8.2.0.8 release of PingDataMetrics.

#### Critical fixes

This release of PingDataMetrics addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of PingDataMetrics.

Ticket ID	Description
DS-45164	Updated Jetty Server to version 9.4.44.
DS-45813	Updated PingDirectory products to use Kafka v2.8.1.

### PingDataMetrics Server 8.2.0.7 release notes

The release notes for the 8.2.0.7 release of PingDataMetrics Server.

#### Critical fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or `remove-defunct-server` tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

#### Note:

Since this change only applies to the most recent version of `remove-defunct-server` and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past `dsreplication` and `remove-defunct-server` could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an

older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

- Fixed in: 8.2.0.7
- Introduced in: 7.0.0.0
- Support identifiers: DS-44591

## Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server.

Ticket ID	Description
DS-44591	<p>Fixed an issue where secret keys under <code>cn=Topology,cn=config</code> could be lost when removing a server from the topology. When a server is removed via the <code>dsreplication disable</code> or <code>remove-defunct-server</code> tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.</p> <p>The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.</p> <p> <b>Note:</b></p> <p>Since this change only applies to the most recent version of <code>remove-defunct-server</code> and <code>dsreplication disable</code>, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past <code>dsreplication</code> and <code>remove-defunct-server</code> could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.</p>
DS-45124	<p>Removed <code>-XX:RefDiscoveryPolicy=1</code> from the default start-server Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.</p>

Ticket ID	Description
DS-45190	Added support for the use of JDKs obtained through BellSoft.

### PingDataMetrics Server 8.2.0.6 release notes

#### Critical fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the DataMetrics Server.

Ticket ID	Description
DS-43632	Fixed an issue where the <code>format</code> field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-44224	Addressed an issue where icons on the dashboards were not properly displayed.

### PingDataMetrics 8.2.0.5 release notes

#### Critical fixes

This release of the PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the PingDataMetrics Server.

Ticket ID	Description
DS-44025	Fixed an issue where the server was incorrectly displaying an <code>Unknown vendor</code> warning when using JDKs obtained on Red Hat and Ubuntu systems.

### PingDataMetrics Server 8.2.0.2 release notes

#### Critical Fixes

This release of the PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

**No critical issues have been identified**

## Resolved Issues

The following issues have been resolved with this release of the PingDataMetrics Server:

Ticket ID	Description
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the <code>oidc-trust-store-file</code> and <code>oidc-trust-store-type</code> settings. Also, you can set the console to skip hostname and/or certification verification through the <code>oidc-strict-hostname-verification</code> and <code>oidc-trust-all</code> configuration settings.

## PingDataMetrics Server 8.2.0.1 release notes

### Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

**No critical issues have been identified**

### Data Metrics Server 8.2.0.0 Release Notes

### Upgrade Considerations

Important considerations for upgrading to this version of the Data Metrics Server

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

### What's New

These are new features for this release of the Data Metrics Server

- In an ongoing effort to improve the use of containers for PingDirectory, several features have been implemented:
  - The `--outputFile` option has been added to the `collect-support-data` tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the `collect-support-data` tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
  - The `collect-support-data` tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
  - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the `collect-support-data` tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the `--remoteServer` added to the `collect-support-data` tool can be used to send the request to another server. In other words, you can now run `collect-support-data` on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectory has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party.

#### Known Issues/Workarounds

The following are known issues in the current version of the Data Metrics Server

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the `create-systemd-script` tool to create a forking systemd service, the service is stopped by the `"systemctl stop ping-directory.service"` command. At that time, you can see the status using the `"systemctl status ping-directory.service"` command. That status might contain an indication of failure: `"Active: failed (Result: exit-code)"`. This error has to do with the way the service exits. It is harmless.

#### Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-5143, DS-11035	<p>Updated support for logging access and error log messages to a syslog server. While the server previously supported logging these messages to a syslog server (through the "syslog-based access log publisher" and "syslog-based error log publisher" logger implementations), these loggers used an older version of the syslog protocol (described in RFC 3164) and only offered support for communicating over UDP.</p> <p>These loggers are still available for legacy backward compatibility, but we now also offer new "syslog text access log publisher" and "syslog text error log publisher" implementations that use a newer version of the syslog protocol (syslog version 1, described in RFC 5424) and support communicating over UDP or the more reliable TCP. When using TCP, it is also possible to encrypt communication with TLS and to configure multiple servers for better redundancy. These loggers use the same space-delimited text format as the former loggers.</p> <p>We also offer new "syslog JSON access log publisher" and "syslog JSON error log publisher" implementations that offer the same set of capabilities, but that format the message text as JSON objects, which can be more easily parsed by third-party software.</p>

Ticket ID	Description
DS-10320, DS-12550, DS-12551, DS-12552, DS-42116, DS-42162, DS-42179, DS-42222, DS-42223, DS-42224, DS-42225, DS-42416, DS-42437	Added a config/sample-dsconfig-batch-files directory with set of well commented dsconfig batch files that may be useful in enabling or configuring a variety of features in the server.
DS-10775	<p>Updated the dictionary password validator to support additional options:</p> <ul style="list-style-type: none"> <li>▪ It can now ignore non-alphabetic characters that appear at the beginning or end of the password before checking the dictionary.</li> <li>▪ It can strip characters of diacritical marks, including accents, cedillas, circumflexes, diaereses, tildes, and umlauts, before checking the dictionary. If this option is used, then any character with such a mark will be replaced with a base version of the character without that mark (for example, a lowercase letter n with a tilde over it would be replaced with just a lowercase letter n).</li> <li>▪ You can define maps with information about character substitutions to use for checking alternative versions of the provided password. For example, if you indicate that "0" might map to "o", "1" or "!" might map to "i", "7" might map to "t", and "3" might map to "e", then the validator can reject a proposed password of "pr0h1b!73d" if the dictionary contains the word "prohibited".</li> <li>▪ It can reject a proposed password if a value from the provided dictionary makes up more than a specified percentage of that password.</li> </ul>
DS-11524, DS-41860, DS-42112	<p>Added support for new administrative alert types.</p> <ul style="list-style-type: none"> <li>▪ We have added a new admin alert account status notification handler, which can generate administrative alerts whenever an applicable account status notification is generated within the server. For example, this account status notification handler can be added to the root password policy to generate an alert whenever a root user's password is updated or their account is locked as a result of too many failed authentication attempts. A separate alert type has been defined for each account status notification type.</li> <li>▪ We have added a new "privilege-assigned" administrative alert that can be raised whenever a new entry is added or an existing entry is updated to include one or more privileges.</li> <li>▪ We have added a new "insecure-request-rejected" administrative alert that can be raised whenever the server rejects a request as a result of the reject-insecure-requests global configuration property.</li> </ul>
DS-13853	Added support for the OAUTHBEARER SASL mechanism (as described in RFC 7628) to allow LDAP clients to authenticate with OAuth 2.0 bearer tokens.
DS-15848, DS-42360	Added support for invoking a specified set of password validators during bind operations. If the password used to authenticate fails to satisfy one or more of the configured validators, the bind attempt can be rejected, the user can be forced to change their password, or the server can generate an account status notification to take some alternative action (for example, notifying the end user or server administrators).

Ticket ID	Description
DS-15864	Replaced the ldappasswordmodify tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.
DS-17903	Updated setup to provide a --populateToolPropertiesFile argument that will allow it to populate the config/tools.properties file with default values for command-line tool arguments. If requested, properties will be provided for the server address, port, and communication security, and may also include a default bind DN and optionally a bind password. When running setup interactively, it will now prompt to determine which properties (if any) should be populated in the properties file.
DS-38110	Updated the System Information monitor with an "isDocker" attribute to identify if the server is running in a Docker container.
DS-38118, DS-42495	<p>Made several updates related to the server's handling of data written to standard output and standard error:</p> <ul style="list-style-type: none"> <li>▪ The server can now be configured to rotate the logs/server.out file once it reaches a given size, and it will retain a configurable number of those log files. By default, the server will rotate the file once it reaches 100 megabytes and will keep up to ten files.</li> <li>▪ To better facilitate capturing log data in containerized environments, the server now supports writing JSON-formatted access and error log messages to the JVM's original standard output and error streams (which will be separate from the server.out file when the server is started with the --nodetach argument).</li> <li>▪ It is now possible to prevent the server from logging messages during startup in non-JSON format. It is also possible to prevent messages about administrative alerts from being written to standard error, or to write those messages in JSON format. These options are especially useful when using JSON-based logging to the console in no-detach mode, as they can help ensure that everything written to standard output and standard error will be formatted as JSON objects.</li> </ul>
DS-38868	Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.
DS-39789	Updated the JVM memory usage monitor provider to fix an issue that could prevent the monitor from reporting the total amount of memory held by all memory consumers. Also, fixed an issue that could cause the memory-consumer attribute to use an incomplete message for consumers without a defined maximum size and added an additional memory-consumer-json attribute whose values are JSON objects with data that can be more easily extracted by automated processes.
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.

Ticket ID	Description
DS-40967	Eliminated a misleading error message that could be logged at startup if the server was configured with one or more ACIs that only apply when using specific SASL mechanisms.
DS-41989	Fixed an issue that could result in duplicate column headers being produced by the Periodic Stats Logger, even when the header-prefix-per-column attribute was set to true.
DS-42045	Updated the Stats Collector Plugin with a new generate-collector-files configuration property. When using this plugin with the Data Metrics Server, leave this property at its default value of true. When using the plugin exclusively for providing metrics to one or more StatsD Monitoring Endpoints, set this property to false to prevent unnecessary I/O.
DS-42059, DS-42060	<p>Updated setup to add options for improving communication security:</p> <ul style="list-style-type: none"> <li>▪ Non-interactive setup now offers a --rejectInsecureRequests argument that will configure the server to reject any request received over a connection that is not encrypted with SSL or StartTLS.</li> <li>▪ Non-interactive setup now offers a --rejectUnauthenticatedRequests argument that will configure the server to reject any request received over a connection that is not authenticated (or that is authenticated as the anonymous user).</li> <li>▪ Interactive setup now allows you to configure the server with the LDAP connection handler disabled (which was already an option when using non-interactive setup), or enabled but only for communication encrypted with StartTLS.</li> </ul> <p>The --rejectInsecureRequests and --rejectUnauthenticatedRequests arguments can also be used with manage-profile by including them in the setup-arguments.txt file of the server profile.</p>
DS-42061	Updated the interactive command-line tool framework to prefer establishing secure LDAP connections over insecure connections. Previously, when prompting for the information needed to establish a connection, the default option was to create an unencrypted LDAP connection. Now, tools default to creating an SSL-encrypted connection if the server supports it, or to creating a StartTLS-encrypted connection if that is available but SSL is not. Tools also default to using streamlined settings when establishing secure connections. Previously, they would always prompt about how to determine whether the server's certificate chain should be trusted. When using the streamlined settings, the tools only prompt about certificates that cannot automatically be considered trusted using information in the JVM's default trust store, the server's default trust store (config/truststore), or the server's topology registry.
DS-42062	Updated the root password policy so that LDAP bind responses for root users and topology administrators will be delayed by one second after five consecutive failed authentication attempts.
DS-42063	Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non-LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.

Ticket ID	Description
DS-42115	Updated the server's command-line tool framework to make it easier and more convenient to communicate with the server over a secure connection when no trust-related arguments are provided. Most non-interactive tools will now check the server's default trust store, the topology registry, and the JVM's default trust store to see if the presented certificate chain can be automatically trusted without the need to prompt the user. If the presented chain cannot be automatically trusted, the user may be interactively prompted to determine whether it should be trusted.
DS-42279	Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.
DS-42298	Replaced the <code>ldifsearch</code> , <code>ldifmodify</code> , and <code>ldif-diff</code> command-line tools with more full-featured and robust implementations.
DS-42331	Replaced the <code>ldapcompare</code> tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).
DS-42347	Updated the server to use <code>/dev/urandom</code> (on non-Windows systems where that path exists and is readable) instead of <code>/dev/random</code> as the primary source for secure random data. Attempts to read from <code>/dev/random</code> can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from <code>/dev/urandom</code> will not block, and the data that it provides is no less secure than data from <code>/dev/random</code> in any way that matters for the server.
DS-42504	Updated <code>manage-profile</code> <code>replace-profile</code> to set encryption settings definitions defined in the newer server profile as preferred in the encryption settings db.
DS-42547	Fixed an issue where <code>manage-profile generate-profile</code> would print <code>null</code> as the generated profile directory when writing to an existing directory.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42632	Added support for creating or importing a key pair configuration object using an elliptic curve (EC) key algorithm. You can use this to designate the encryption key pair for a JWT access token validator that handles EC-encrypted access tokens.
DS-42634	The JWT Access Token Validator can now validate JWT access tokens signed using the elliptic curve digital signature algorithms ES256, ES384, and ES512.
DS-42635	<p>The JWT Access Token Validator can now validate JWT access tokens encrypted using elliptic curve cryptographic algorithms. The following key encryption algorithms are now supported in addition to RSA-OAEP: ECDH-ES, ECDH-ES+A128KW, ECDH-ES+A192KW, and ECDH-ES+A256KW.</p> <p>To support best practices for JWT security, you must now also configure the JWT Access Token Validator with explicit allow lists for key encryption and content encryption algorithms. For backward compatibility, the key encryption allow list defaults to RSA-OAEP, while the content encryption allow list defaults to A128CBC-HS256, A192CBC-HS384, and A256CBC-HS512. We recommend setting both allow lists to the strict minimum set of algorithms needed by the Access Token Validator.</p>

Ticket ID	Description
DS-42651	Updated the <code>manage-profile replace-profile</code> subcommand to better support updating the server's keystore and truststore files. When using the <code>--generateSelfSignedCertificate</code> argument in a server profile's <code>setup-arguments.txt</code> file, the server maintains the original keystore and truststore files during <code>replace-profile</code> . Otherwise, <code>replace-profile</code> uses the keystore and truststore specified in the profile's <code>setup-arguments.txt</code> file.
DS-42667	Updated the server to set a unique cluster name when started for the first time.
DS-42669, DS-42748	Updated the online <code>dsconfig</code> step of the <code>manage-profile replace-profile</code> subcommand to support getting LDAP connection arguments from a <code>tools.properties</code> file on the server being updated.  Fixed an issue where boolean LDAP connection arguments like <code>--useSSL</code> and <code>--trustAll</code> would cause <code>manage-profile replace-profile</code> to fail when applying <code>dsconfig</code> online.
DS-42681, DS-42684	Performance statistics generated by the Sideband API can now be published by the Periodic Stats Logger. To enable this, use the "included-http-servlet-stat" property of the Periodic Stats Logger.
DS-42673	Updated the <code>manage-profile setup</code> subcommand to fail if the <code>start-server</code> command has a non-zero exit code.
DS-42687	Upgrade to Jetty 9.4.30.
DS-42740	Fixed an issue where the <code>dsconfig list</code> subcommand would not display requested properties.
DS-42749	To support best practices for JWT security, you must now configure the JWT Access Token Validator with an explicit list of the JWT signing algorithms that it accepts. For backward compatibility, this list defaults to the RSA signing algorithms RS256, RS384, and RS512, but we recommend setting this list to the strict minimum set of signing algorithms needed by the Access Token Validator.
DS-42751	Added new <code>override-status-code</code> and <code>additional-response-contents</code> attributes to the Availability State HTTP Servlet Extension. These new attributes can be used to customize the response code and JSON response body of the servlet.
DS-42861	Updated the <code>manage-profile</code> tool logs to include the duration of each step the tool takes. The new <code>--verbose</code> argument can also be used to display timing information in the tool's console output.
DS-42886	Updated non-interactive <code>setup</code> (including <code>manage-profile setup</code> ) to allow the password for the initial root user to be provided in pre-encoded form using the PBKDF2, SSHA256, SSHA384, or SSHA512 password storage scheme. This eliminates the need to have access to the clear-text password when setting up the server.
DS-42926	Fixed an issue where Ping Directory products configured to run as Microsoft Windows services were sometimes unable to automatically restart following an unplanned reboot, due to errors reading a corrupted server status file.

Ticket ID	Description
DS-42952	For Windows only, there can be a hang on start when global configuration property <code>startup-error-logger-output-location</code> is set to values that contain <code>standard-error</code> . For Windows only, <code>standard-error</code> values are silently mapped to equivalent <code>standard-output</code> values.
DS-42963	Updated the <code>manage-profile generate-profile</code> subcommand to ignore files larger than 100 megabytes when generating a server profile. Fixed an issue where many large files in the server root could cause the tool to run out of memory.
DS-43376	Updated log publisher logic to reduce the amount of CPU that the server consumes when it is idle.
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that can be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments might include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server now only includes values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems and that are not expected to contain sensitive information.
DS-43517	Updated the <code>jose4j</code> library used for JWT signing and encryption to version 0.7.2.
DS-43651	The Security Guide is now available online at <a href="https://pingidentity.com">pingidentity.com</a> . The guide has been removed from the server packaging.

## Critical fixes

### Critical Fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed a memory leak when performing SCIM queries on PingDataMetrics Server.
  - Fixed in: 8.0.0.1
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.0.0.1
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301

- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578

- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
  - The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
    - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
    - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
      - Fixed in: 7.2.1.0
      - Introduced in: 7.0.0.0
      - Support identifiers: DS-38334 SF#00655578
  - The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38344 SF#00655578
  - The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38335 SF#00655578
  - Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

### **PingDataMetrics Server 8.1.0.6 release notes**

The release notes for the 8.1.0.6 release of PingDataMetrics Server.

#### Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the Data Metrics Server.

Ticket ID	Description
DS-44224	Addressed an issue where icons on the dashboards were not properly displayed.

### **PingDataMetrics 8.1.0.5 release notes**

#### Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the Data Metrics Server.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"> <li>* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.</li> <li>* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.</li> <li>* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li> </ul>

Ticket ID	Description
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

### Data Metrics Server 8.1.0.2 Release Notes

#### Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.0.1.3
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.
  - Fixed in: 5.0.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-11782

#### Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-42687	Upgrade to Jetty 9.4.30

## PingDataMetrics Server 8.1 Release Notes

### Critical Fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed a memory leak when performing SCIM queries on PingDataMetrics Server.
  - Fixed in: 8.0.0.1
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.0.0.1
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a `mirrored-subtree-manager-connection-asymmetry` alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are

unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - \* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

## Upgrade Considerations

Important considerations for upgrading to this version of the Data Metrics Server

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

## What's New

These are new features for this release of the Data Metrics Server

- In an ongoing effort to improve the use of containers for PingDirectory, several features have been implemented:
  - The --outputFile option has been added to the collect-support-data tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the collect-support-data tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
  - The collect-support-data tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
  - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the --remoteServer added to the collect-support-data tool can be used to send the request to another server. In other words, you can now run collect-support-data on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectory has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party.

## Known Issues/Workarounds

The following are known issues in the current version of the Data Metrics Server

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

### Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.

Ticket ID	Description
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.

Ticket ID	Description
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41818	Added the <code>--zip</code> argument to the <code>manage-profile generate-profile</code> subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to <code>/instance-root</code> by authenticated users with the <code>file-servlet-access</code> privilege will be granted access to files within the server instance root.
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has <code>memory.swappiness</code> set to a nonzero value.
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a <code>NullPointerException</code> if a server was configured with a custom global result code map.
DS-42387	Updated the <code>manage-profile generate-profile</code> subcommand to exclude files in the <code>ldif/</code> and <code>bak/</code> directories by default when generating a server profile. If necessary, you can manually include those directories using the <code>--includePath</code> argument.

### PingDataMetrics 8.0.0.5 release notes

#### Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Ping Data Metrics Server 8.0.0.4 release notes

#### Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
  - Fixed in: 8.0.0.4
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-41762 SF#00675207 SF#00683777

#### Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.

### PingDataMetrics Server 8.0.0.3 release notes

#### Critical Fixes

This release of the PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

#### No critical issues have been identified

#### Resolved Issues

The following issues have been resolved with this release of the PoingDataMetrics Server:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"><li>* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.</li><li>* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.</li><li>* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li></ul>

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at <a href="https://pingidentity.com">pingidentity.com</a> and has been removed from the server packaging.

### Ping Data Metrics Server 8.0.0.2 Release Notes

#### Critical Fixes

This release of the Ping Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

#### No critical issues have been identified

#### Resolved Issues

The following issues have been resolved with this release of the Ping Data Metrics Server :

Ticket ID	Description
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.

Ticket ID	Description
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42812	Upgrade to jetty 9.4.30

### PingDataMetrics Server 8.0.0.1 Release Notes

#### Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on PingDataMetrics Server.
  - Fixed in: 8.0.0.1
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - \* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that

were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
  - \* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-

lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition,

if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782

#### Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.

### PingDataMetrics Server 8.0.0.0 Release Notes

#### Critical Fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

#### No critical issues have been identified

#### Known Issues and Workarounds

The following are known issues in the current version of PingDataMetrics Server:

- The following are suggested solutions for problems with slow DNS:
  - Maintain a connection pool in the client app rather than opening new connections for each bind.
  - Add appropriate records, including PTR records, to DNS.
  - Add `options timeout:1` in the `/etc/resolv.conf` file and/or `options single-request`.
  - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.
  - **Workaround:** Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.
- The working directory value used by exec tasks is not implemented for recurring exec tasks.

## Resolved Issues

The following issues have been resolved with this release of PingDataMetrics Server:

Ticket ID	Description
DS-17278	Added a <code>cn=Server Status Timeline,cn=monitor</code> monitor entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, <code>endpoint-cache-refresh</code> , has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the <code>Resource</code> column in the output of <code>status</code> . This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions.  Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the <code>remove-defunct-server</code> tool's <code>--ignoreOnline</code> option. When using <code>--ignoreOnline</code> in a mixed-version environment, all servers must support the option.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit <a href="http://groovy-lang.org">groovy-lang.org</a> and view the Groovy 2.5 release notes.  As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code> , download the appropriate jar file from <a href="http://groovy-lang.org">groovy-lang.org</a> and place it in the server's <code>lib/extensions</code> directory.
DS-39253	Added a <code>replace-certificate</code> tool, which can help an administrator replace the listener or inter-server certificate for a server instance.

Ticket ID	Description
DS-39325	<p>Removed the legacy product-specific scripts for starting and stopping the server. These include:</p> <ul style="list-style-type: none"> <li>▪ <code>start-ds</code> and <code>stop-ds</code> for Directory Server</li> <li>▪ <code>start-proxy</code> and <code>stop-proxy</code> for Directory Proxy Server</li> <li>▪ <code>start-sync</code> and <code>stop-sync</code> for Data Sync Server</li> <li>▪ <code>start-metrics-engine</code> and <code>stop-metrics-engine</code> for PingDataMetrics Server</li> </ul> <p>These legacy scripts had been deprecated for several releases in favor of the more general <code>start-server</code> and <code>stop-server</code> scripts, and they displayed a warning message about their upcoming removal if they were invoked.</p> <p>If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general <code>start-server</code> and <code>stop-server</code> scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point at the <code>start-server</code> and <code>stop-server</code> scripts.</p>
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as <code>X-VALUE-REGEX</code> ), this could cause unexpected or incorrect behavior.
DS-39592	HTTP External Servers have a new attribute, <code>ssl-cert-nickname</code> , which defines the alias of a specific certificate within their keystore to be used as a client certificate.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.
DS-39654	Added support for the <code>--topologyFilePath</code> argument to the <code>manage-topology add-server</code> subcommand.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40114	Added a new <code>cn=Status Health Summary,cn=monitor</code> monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.

Ticket ID	Description
DS-40354	Fixed a problem with <code>config-diff</code> when writing properties that span multiple lines using the <code>--prettyPrint</code> argument.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40730	Updated the <code>encrypt-file</code> tool to prevent using the same path for both the input file and the output file.
DS-40771	Added a <code>--duration</code> argument to <code>collect-support-data</code> . When used, only the log files covering the specified duration before the current time will be collected.

## Delegated Admin Release Notes

---

### Delegated Admin 4.6 release notes

The following are enhancements, known issues, and limitations for this release of Delegated Admin.

#### Enhancements

These are new features for this release of the Delegated Administration application:

- The Delegated Administration application is designed so that delegated administrative users don't need to understand the underlying technology supporting the account management features, i.e., LDAP. The Delegated Administration application allows for resource types to be configured to link to other entries within the system. These links can now be used to view and modify referenced entry allowing for a simpler interface to manage the entire entry.
- Delegated administrative users need the ability to assist users with account and password issues. This version of the Delegated Administration application improves account management by allowing administrators to view specific information about an account, such as the last time the password was changed, the assigned password policy, and the history of recent login attempts. The configuration of the assigned password policy determines what information is available.
- Many businesses have developed precise processes to handle password changes for their users. Delegated administrative users can now trigger a password reset process for a user. This process would trigger the existing process that would invoke the self service password reset process defined by the business.

#### Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in [Upgrade considerations](#) on page 1554.

#### Known issues and limitations

The following are known issues and limitations of this release:

- Unable to Download User Report within PingCloud or when DA is deployed on a separate server. This issue is corrected by exposing the `Content-Disposition` header in the Delegated Admin servlet's CORS policy. To apply this change, run the following `dsconfig` command.

```
dsconfig set-http-servlet-cross-origin-policy-prop \
  --policy-name "Delegated Admin Cross-Origin Policy" \
  --set cors-exposed-headers:Content-Disposition
```

- Delegated Admin ACIs are deleted via replication. You can work around this issue by waiting for the server to finish rebooting, or by making a configuration change within delegated admin that would trigger the regeneration of the ACIs from a server that is still up.
- There is an issue triggering the Self Service Password Reset in Delegated Admin when deployed on Proxy server. This can be corrected by adding the password reset privilege to the user requiring the privilege. The following is an example `ldif` command that would make the correction.

```
bin/ldapmodify <<+
dn: uid=YourUser,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset
+
```

- For resource types that use a reference attribute to another entry, regardless of whether the target entry is of the same resource type, if the distinguished name (DN) of the targeted entry is modified, entries that reference the targeted entry will no longer have a valid link to the entry.

#### Resolved issues

The following issues have been resolved with this release of Delegated Admin 4.6.

Ticket ID	Description
DS-42793	Fixed an issue where Delegated Admin 4.2.0 had an intermittent, infinite spinner issue when signing on.
DS-43746	Fixed an issue where in versions 4.2.0-4.4.0, Delegated Admin produced an error on edit or create of resource types that contained an attribute with an unrecognized data type. For supported data types, see <a href="#">Configuring attributes and attribute search on PingDirectory Server</a> on page 1566. Delegated Admin 4.4.1 addresses this error.
DS-44328	Fixed an issue where a locked user account showed as locked in the search view, but the DA UI was showing it as unlocked (or enabled in the UI) when editing that user account.

## Delegated Admin previous releases

Release Notes for earlier versions of Delegated Admin are included for reference.

### Delegated Admin 4.5.0 - April 2021

The following enhancements and resolved issues are included in this release.

#### Enhancements

These are new features for this release of the Delegated Administration application:

- The Delegated Administration application is designed so that delegated administrative users don't need to understand the underlying technology supporting the account management features, such as LDAP. The Delegated Administration application allows for resource types to be configured to link to

other entries within the system. You can now use these links to view and modify a referenced entry allowing for a simpler interface to manage the entire entry.

- Delegated administrative users need the ability to assist users with account and password issues. This version of the Delegated Administration application improves account management by allowing administrators to view specific information about an account such as the last time the password was changed, the assigned password policy, and the history of recent login attempts. The configuration of the assigned password policy determines what information is available.

#### Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in [Upgrade considerations](#) on page 1554.

#### Known issues and limitations

- For resource types that use a reference attribute to another entry, regardless of whether the target entry is of the same resource type, if the `dn` of the targeted entry is modified, entries that reference the targeted entry will no longer have a valid link to the entry.
- Delegated Admin 4.2.0 has an intermittent, infinite spinner issue when signing on. To address the issue and continue using PingDirectory 8.1.0.0, install Delegated Admin 4.2.1. Alternatively, you can upgrade to Delegated Admin 4.4.0 to address the issue; however, that upgrade requires upgrading to PingDirectory 8.2.0.0.
- For versions 4.2.0-4.4.0, Delegated Admin produces an error on edit or create of resource types that contain an attribute with an unrecognized data type. For supported data types, see [Configuring attributes and attribute search on PingDirectory Server](#) on page 1566. Delegated Admin 4.4.1 addresses this error.

#### Delegated Admin 4.4.0 - December 2020

The following enhancements and resolved issues are included in this release.

#### Enhancements

These are new features for this release of the Delegated Administration application:

- Delegated administrative users can now create a user account without setting a password if the password is not required by the server. This is only true for user creation. Resetting a password still requires a valid value for the password.
- Previously, users could download a full report of users and group membership. Now the administrative user can preview the report and apply filters to limit either the entries themselves or to filter which columns are displayed. The user can also sort the report by columns. The user can then download the resulting report with all the filters applied.
- The Delegated Administrator user interface now allows you to move and display the password field anywhere on the **Create User** form. Specify this in the configuration of the REST Resource Type with the Password Attribute Category and Password Display Order Index properties. If you do not specify a category, the password field appears at the top of the page.
- The Delegated Administration application does not require delegated administrative users to understand the underlying technology supporting the account management features, such as LDAP. PingDirectory is an LDAP server and, therefore, uses Distinguished Names (DNs) to identify entries in the directory. The Delegated Administration application allows the user to select a user entry based on its DN without displaying the actual value of the DN.
- Account management improvements allow administrators to view information about account and password state, such as password expiration date, account lockout status, and last login date and time.
- Administrative users can now bulk upload user entries from a CSV file. The users need the proper rights for the resource types on which they wish to create user entries. The information in the file to upload must be based on the attributes configured for the resource type. The upload creates user

entries if they do not exist, and optionally adds the entries to a group. If a user entry exists, the upload updates the entry. You can also upload generic entries.

- Previously, administrative users could create, preview, and download reports of users, group membership, or other generic resources to a CSV file. With this release, you can choose to not present the download and/or upload options to certain administrative users.
- Completing the basic entry management functionality, administrative users with the proper rights for the resource type can now delete user, group, and generic entries.

#### Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in [Upgrade considerations](#) on page 1554.

#### Resolved issues

The following table identifies issues that have been resolved with this release of Delegated Admin.

Ticket ID	Description
DS-42793	Fixed an issue where an infinite spinner would intermittently appear when signing on.
DS-41913	Added the ability to move the Password field on the <b>Create User</b> form.

### Delegated Admin 4.2.0 Release Notes

#### Upgrade Considerations

If you are running Delegated Administration application version 3.5 or older, you will need to upgrade it to the latest version if you want to use PingDirectory 8.0 or newer.

#### What's New

These are new features for this release of PingDirectory Delegated Admin:

- Delegated Admin 4.1
  - For Delegated Admin, administrators can be assigned rights to manage different types of resources such as users and groups. Previously, administrators who can only manage users in specified groups could not create users to put them in the one of the groups they managed. Now, administrators with the ability to manage and create groups can create users within the group(s) they manage.
  - REST resource types define the types of objects that can be managed by delegated administrators. Typical REST resource types include users and groups which can be configured based on the sub-tree and a predefined search filter. A new include-filter property has been added to REST resource types to differentiate different resource types that are within the same subtree and have the same objectclass.
- Delegated Admin 4.2
  - Administrative users can now create and download reports of users, group membership or other generic resource to a CSV file. The users need the proper rights for the resource types on which they wish to report. The information stored in the downloaded file will be based on the attributes configured for the resource type. For group resource types, each report generated will be for a single group.
  - Added a new reference permission to Delegated Admin resource rights configuration which allows the administrator to reference resources when selecting a parent for a new resource. This

permission differs from read permission in that the app will not show an option to manage the parent resource type in the Delegated Administrator app.

- In many circumstances, LDAP attributes within an entry contain multiple values. The application can now display multi-valued attributes which are not handled by custom UI form fields.
- A privileged administrator for a hosting company can onboard a new tenant administrator to manage resources for the tenant's own organization without requiring additional configuration from the Administrative Console or command line.

#### Known Issues/Workarounds

The following are known issues in the current version of PingDirectory Delegated Admin:

- PingDirectory Delegated Admin does not always show the account locked status correctly if the server password policy is configured to require the user to reset their password after the password has been administratively reset. This can be corrected by enabling the Password Policy State JSON virtual attribute for the user object class. For example:

```
dsconfig set-virtual-attribute-prop --name "Password Policy State JSON" \
--set enabled:true --set require-explicit-request-by-name:true \
--set "filter:(objectClass=person)"
```

#### Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin:

Ticket ID	Description
DS-41819	Fixed an issue where a Delegated Administrator was unable to add or remove themselves to or from a group to which they had rights to manage group membership.
DS-41848	Fixed an issue where edits modifying only the case or capitalization of an attribute value did not take effect.
DS-42387	Updated the <b>manage-profile generate-profile</b> subcommand to exclude files in the <code>ldif/</code> and <code>bak/</code> directories by default when generating a server profile. If necessary, you can manually include those directories using the <code>--includePath</code> argument.

#### Delegated Admin 4.1.0 Release Notes

##### Upgrade Considerations

Upgrade directly to this release from versions prior to 7.0 is not supported. As a workaround, upgrade from a pre-7.0 version to 8.0, and then upgrade to this version.

##### What's New

These are new features for this release of PingDirectory Delegated Admin:

- Administrators can be assigned rights to manage different types of resources such as users and groups. Previously, administrators who can only manage users in specified groups could not create

users to put them in the one of the groups they managed. Now, administrators with the ability to manage and create groups can create users within the group(s) they manage.

- When the Delegated admin rights for a User REST resource type have admin scope resources-in-specific-groups, a user is added to one of the configured groups when the user is created.
- An example file for JSON attributes, example-json.html, has been added and can be located alongside other existing example files for custom UI form fields. This example file supports a single value and uses the expected JSON structure of ubidEmailJSON, an available JSON attribute type for Ping Directory. Multiple values are also supported, please see the example-multivalue.html for an example of how to handle that use-case. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.
- Multivalue attributes may now be handled as part of custom UI form fields. Contrary to single value attributes, an array of values will need to be sent up to the form when building out the custom field. An example file, example-multivalue.html, has been provided to demonstrate a string-based, multivalue attribute as a custom UI form field and can be located alongside other existing example files. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.

#### Known Issues/Workarounds

The following are known issues in this version of Delegated Admin:

- In environments with Proxy and multiple backend servers, there is a known issue using the fewest-operation load-balancing algorithm with the Delegated Admin app. Constructed attributes sometimes do not get updated when the attributes they reference are edited. Using a failover load-balancing algorithm is a workaround for this issue. (DS-40977)

#### Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin:

Ticket ID	Description
DS-40938	Fixed an issue when Delegated Admin is installed on the Directory Proxy Server where a constructed attribute that is set to be read-only may not update in the app immediately after one of the attributes it references is updated.
DS-41066	Fixed an issue where JSON object values for attributes caused an application error when attempting to display them in the UI.
DS-41275	It is now a configuration error to enable two REST resource types with the same endpoint (ignoring differences in case) at the same time. It is allowed to have two resource types with the same endpoint if one or both of them are not enabled.

Ticket ID	Description
DS-41669	An example file for JSON attributes, <code>example-json.html</code> , has been added and can be located alongside other existing example files for custom UI form fields. This example file supports a single value and uses the expected JSON structure of <code>ubidEmailJSON</code> , an available JSON attribute type for Ping Directory. Multiple values are also supported, please see the <code>example-multivalue.html</code> for an example of how to handle that use-case. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.
DS-41715	Multivalue attributes may now be handled as part of custom UI form fields. Contrary to single value attributes, an array of values will need to be sent up to the form when building out the custom field. An example file, <code>example-multivalue.html</code> , has been provided to demonstrate a string-based, multivalue attribute as a custom UI form field and can be located alongside other existing example files. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.

## Delegated Admin 4.0.0 Release Notes

### Upgrade Considerations

Important considerations for upgrading to this version of Delegated Admin:

PingDirectory 8.0.0.0 is now the minimum required version to use with Delegated Admin 4.0.0. If you are on an older version of PingDirectory, it will be necessary to upgrade to PingDirectory 8.0.0.0 to maintain compatibility.

Delegated Admin 3.5.1 is compatible with PingDirectory Server 8.0.0.0. However, versions of Delegated Admin that are earlier than 4.0.0 will not be compatible with versions of PingDirectory Server that are later than 8.0.0.0.

By default, the display name for the logged in delegated admin will no longer display. To re-configure this functionality, please see the section on enabling the `name` attribute to be returned with the OIDC id token. See the Delegated Admin Guide for more information.

The `delegated-admin-template.dsconfig` file has been updated to allow for `generate-password` extended requests and password validation details request controls. This change is not applied during an update. You must run the following two `dsconfig` commands when updating PingDirectory Delegated Admin:

```
dsconfig set-access-control-handler-prop --add \
'global-aci:(extop="1.3.6.1.4.1.30221.2.6.62")(version 3.0; \
acl "Authenticated access to the generate-password extended \
request for the Delegated Admin API"; allow (read) userdn="ldap:///all");'
```

```
dsconfig set-access-control-handler-prop \
--add 'global-aci:(targetcontrol="1.3.6.1.4.1.30221.2.5.40")\
(version 3.0;acl "Authenticated access to the password validation details \
request \
```

```
control for the Delegated Admin API"; allow (read) userdn="ldap:///all");'
```

## What's New

These are new features for this release of PingDirectory Delegated Admin:

- Invite new users via e-mail: Taking advantage of the new e-mail notification capabilities of PingDirectory Server 8.0.0.0, now administrators can configure the service so that when a delegated admin creates a new user, the server can send an HTML e-mail to tell the new user their password and invite them to use their new account. Combine this with PingFederate self-service profile management to invite the new user to complete their profile.
- When creating users or resetting passwords, delegated admins now have the option to type in the new password or have the server generate a password. Previously the application only supported server-generated passwords.
- More flexibility in delegating the management of user profiles: Now administrators can configure the service so that delegated admins of one type, such as Employee, can create and manage users of other types, such as Customers or Members. Previously delegated admins could only create and manage users of their own type.

## Known Issues/Workarounds

The following are known issues in this version of Delegated Admin:

- 
- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
  - `groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2`
  - `groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2`

**Workaround:** Deploy the Console in an external container using JDK 8.

## Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin:

Ticket ID	Description
DS-39352	When adding a user to groups and there were no non-member groups to display, the notice text did not use proper context to reflect this state.
DS-39782	Constructed attributes were not updated in the application after their associated attributes were edited. A page refresh or subsequent data request was required to reflect the change for the constructed attribute in the application.
DS-40690	This scenario occurred when a delegated admin only had permission to edit users in certain groups. If the delegated admin then went to a user's profile and removed them from the group which governed permission over that user, this action resulted in an application error.

Ticket ID	Description
DS-41715	Multivalue attributes may now be handled as part of custom UI form fields. Contrary to single value attributes, an array of values will need to be sent up to the form when building out the custom field. An example file, <code>example-multivalue.html</code> , has been provided to demonstrate a string-based, multivalue attribute as a custom UI form field and can be located alongside other existing example files. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.

### Delegated Admin 3.5.1 Release Notes

#### Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin.

Ticket ID	Description
DS-38745, DS-39639	Previously, when port 443 was used but not specified in the PingFederate Base URL, the system returned an <code>Invalid issuer in token</code> message. With this fix, the value for <code>window.PF_PORT</code> can be left blank in <code>config.js</code> to match the expected Base URL that the PingFederate token supplies.

### Delegated Admin 3.5.0 Release Notes

#### Upgrade Considerations

Important considerations for upgrading to this version of Delegated Admin:

The file `remove-sample-directory-data-aci.ldif`, which is provided with the Delegated Admin installation package, was updated to reinstate permissions for users to change their own passwords (self-service password reset). If you have used an earlier version of this LDIF file, consider manually adding the following ACI from the updated version:

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr="userPassword")(version 3.0; acl "Allow users to update their own password"; allow (write) userdn="ldap:///self");)
```

#### What's New

The following features are new with this release of Delegated Admin:

- Added the ability for developers to customize attribute form fields and form behaviors. Previously, Delegated User Admin did not support attributes whose types were neither strings nor numbers, like JSON attribute types. With the ability to override the form fields for any attribute type, developers can now extend Delegated User Admin to handle these attribute types and more. Requires PingDirectory Server 7.3.0.0 or later.
- Added more capabilities for attributes that are constructed from other attributes. The *constructed attribute* feature can now be used for attributes that the LDAP schema requires. Further,

administrators can configure constructed attributes to update automatically when their referenced attributes change. For example, if `displayName` is constructed from `givenName` and `sn`, the `displayName` attribute updates whenever the delegated administrator updates either `givenName` or `sn`. Requires PingDirectory Server 7.3.0.1 or later.

### Known Issues and Workarounds

The following issues are known in this release of Delegated Admin:

- Changes to custom form field HTML files are not displayed.

This issue relates to the browser and server. Because PingDirectory Server does not send the appropriate cache headers for static files, some browsers might cache them aggressively.

**Workaround:** Refer to the "Next steps" section in [Customizing UI form fields](#) on page 1581.

- Constructed attributes do not update automatically when editing a resource.

This issue relates to the user interface (UI). When a constructed attribute is computed and saved in PingDirectory Server, the UI does not immediately display the new value.

**Workaround:** To verify the changes visually, try one or both of the following suggestions:

- Refresh the browser.
- Visit another page, and then navigate back to the edited resource.

### Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin.

Ticket ID	Description
DS-39347	Fixed an issue in which Delegated Admin did not work properly if the name of the REST resource type was not the same as the resource endpoint.
DS-39693	Fixed an issue in which Delegated Admin search results were truncated and invalid upon encountering a Directory entry that contained a Boolean or Integer syntax attribute whose values did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results, and a warning message is logged to the server errors log.

## PingDataSync Server Release Notes

---

### PingDataSync Server 8.3.0.9 release notes

The release notes for the 8.3.0.9 release of the PingDataSync Server.

#### Critical Fixes

This release of the PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## PingDataSync Server 8.3.0.8 release notes

The release notes for the 8.3.0.8 release of the PingDataSync Server.

### Critical Fixes

This release of the PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

**No critical issues have been identified**

### Resolved Issues

The following issue has been resolved with this release of the PingDataSync Server:

Ticket ID	Description
DS-46695	Fixed an issue that caused missing IntraSync User operational attributes after running the manage-profile replace-profile subcommand.

## PingDataSync Server 8.3.0.7 release notes

The release notes for the 8.3.0.7 release of the PingDataSync Server.

### Critical Fixes

This release of the PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## PingDataSync Server 8.3.0.6 release notes

The release notes for the 8.3.0.6 release of PingDataSync Server.

### Critical fixes

This release of the DataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of PingDataSync Server.

Ticket ID	Description
DS-41468	Fixed an issue that prevented the server from refreshing the monitor data used to detect and warn about an upcoming certificate expiration. This could cause the server to continue to warn about an expiring certificate even after that certificate had been replaced.

Ticket ID	Description
DS-45162	Added support for new extended operations that can be used to help manage the server's listener and inter-server certificates. Updated the <b>replace-certificate</b> tool to add support for replacing and purging certificates in a remote instance, and to allow skipping validation for the new certificate chain.

Ticket ID	Description
DS-45480, DS-45636	<ul style="list-style-type: none"> <li>▪ Updated the topology registry to allow using issuer certificates when determining whether to trust the certificate chain presented by another server in the topology. Previously, a server's certificate chain would only be trusted if the server certificate itself was found in the topology registry. Now, a certificate chain may be trusted if either the peer certificate or any of its issuers is found in the topology registry.</li> <li>▪ Updated the <code>replace-certificate</code> tool to add new <code>list-topology-registry-listener-certificates</code> and <code>list-topology-registry-inter-server-certificates</code> subcommands that can be used to display a list of the listener or inter-server certificates for a specified server instance in the topology registry.</li> <li>▪ Updated the <code>replace-certificate</code> tool to add a new <code>add-topology-registry-listener-certificate</code> subcommand that can be used to add one or more certificates to the set of listener certificates for an instance in the topology registry. This subcommand does not alter the contents of any key store, and it may be used to add an issuer certificate to the topology registry or to add a new peer listener certificate in advance of actually activating that certificate on the server.</li> <li>▪ Updated the <code>replace-certificate</code> <code>replace-listener-certificate</code> subcommand to add <code>--topology-registry-update-type</code> and <code>--trust-store-update-type</code> arguments that allow indicating which types of certificates to include in the topology registry and trust store, respectively. Available options include suppressing the update, only adding the listener certificate itself, only adding the listener certificate's issuers, or adding both the listener certificate and its issuers.</li> <li>▪ Updated the <code>replace-certificate</code> <code>replace-listener-certificate</code> subcommand to add an <code>--ignore-current-listener-certificate-validity-window</code> argument that will allow the tool to establish a connection to the server even if its certificate has expired or is not yet valid so that a non-valid certificate can be replaced.</li> </ul>
DS-45815	Updated PingDirectory products to use Kafka v2.8.1 which resolves CVE-2021-38153.

## PingDataSync Server 8.3.0.5 release notes

The release notes for the 8.3.0.5 release of PingDataSync Server.

The 8.3.0.4 release contained internal code improvements that are included in 8.3.0.5.

### Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
DS-45124	Removed <code>-XX:RefDiscoveryPolicy=1</code> from the default <code>start-server</code> Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.
DS-45134	Addressed an issue where PingDataSync was not syncing entries to PingOne environments due to rate-limiting responses from PingOne.
DS-45190	Added support for the use of Java Development Kits (JDKs) obtained through BellSoft.

## PingDataSync Server 8.3.0.3 release notes

The release notes for the 8.3.0.3 release of PingDataSync Server.

### Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### Resolved issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
<ul style="list-style-type: none"> <li>▪ DS-44280</li> <li>▪ DS-45027</li> <li>▪ DS-45037</li> </ul>	Fixed an issue where <code>manage-profile</code> <code>replace-profile</code> did not correctly handle keystore files with a <code>.bcfks</code> extension while in FIPS-140-2-compliant mode.

## PingDataSync Server 8.3.0.2 release notes

The release notes for the 8.3.0.2 release of PingDataSync Server.

### Critical fixes

This release of the DataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## PingDataSync Server 8.3.0.1 release notes

### Critical Fixes

This release of PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or `remove-defunct-server` tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

#### Note:

Since this change only applies to the most recent version of `dsreplication disable` or `remove-defunct-server`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past `dsreplication disable` or `remove-defunct-server` could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you may lose access to secret keys from servers that are removed from the topology.

- Fixed in: 8.3.0.1
- Introduced in: 7.0.0.0
- Support identifiers: DS-44591

### Resolved Issues

The following issues have been resolved with this release of the DataSync Server.

Ticket ID	Description
DS-44513	Synchronize from Active Directory attribute <code>lockoutTime</code> source systems to PingDirectory attribute <code>pwdAccountLockedTime</code> . Since <code>pwdAccountLockedTime</code> can not be written to directly an extended operation is used. This synchronization depends on a direct attribute mapping that maps from <code>pwdAccountLockedTimeFromAD</code> to <code>pwdAccountLockedTime</code> .

Ticket ID	Description
DS-44591	<p>Fixed an issue where secret keys under <code>cn=Topology,cn=config</code> could be lost when removing a server from the topology. When a server is removed via the <code>dsreplication disable</code> or <code>remove-defunct-server</code> tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.</p> <p>The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.</p> <div data-bbox="852 835 1468 1350">  <b>Note:</b> <p>Since this change only applies to the most recent version of <code>dsreplication disable</code> or <code>remove-defunct-server</code>, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. If you run the tool from an older server, it will not include this fix, and you may lose access to secret keys from servers that are removed from the topology.</p> </div>

## PingDataSync 8.3.0.0 release notes

### Enhancements

These are new features for this release of PingDataSync Server:

- The Administrative consoles are extensively used to view and modify the configuration of an existing instance. The console now can display the associated `dsconfig` command needed to create the current object being viewed.
- In the previous release, the ability to single sign-on from the the PingOne administration console portal was implemented. Rounding out this functionality, the administrative console can now accept bearer tokens from other OpenID Connect applications or IdPs such as PingFederate.

### Critical fixes

This release of the PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue in which adding or modifying a server group would result in a 404.
  - DS-41436
  - Fixed in 8.3.0.0
  - Introduced in 7.0.1.4
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-41762 SF#00675207 SF#00683777
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow

a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.

The Sync Server has a specialized mutex that ensures that changes to the same entry are processed serially. The primary reason for this mutex is to ensure that the server can safely process changes in parallel to achieve high throughput. However, we also use this mutex to ensure that two Sync Pipes don't process the same entry at the same time for deployments that synchronize changes bi-directionally. A consequence of this locking is that if one Sync Pipe is failing (because the destination is unavailable) then it retains the lock on an entry, and when other Sync Pipes try to process changes to that entry they will block that change and all changes that follow it while they wait on the lock.

This change turns off using a shared mutex by default, but adds a new advanced configuration option on the Sync Pipe, `shared-mutex-name`, that specifies the name of a mutex that is shared by other Sync Pipes. This gives greater control over the locking so that two Sync Pipes that share end points can ensure that two changes to the same logical user are not processed concurrently, while not impacting other Sync Pipes.

See the `shared-mutex-name` property for more information.

This property is subject to change in a future release.

- Fixed in: 3.2.0.0
- Introduced in: 3.0.0.0
- Support identifiers: DS-4202 SF#1527

#### Known issues and limitations

- The option to download `collect-support-data` or to generate a server profile using the admin console will not work when logged in with single sign-on.

## Resolved issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-8	The Administrative Console now shows a dsconfig command to create the current object from scratch on the edit page.
DS-15746	<p>Added a passphrase provider mechanism, which can be used to obtain clear-text passphrases, API keys, or other types of secrets that are needed by server components like those that interact with external servers or certificate key stores. Available passphrase provider implementations include:</p> <ul style="list-style-type: none"> <li>* A provider that stores an obscured representation of the passphrase directly in the server configuration.</li> <li>* A provider that reads the passphrase from a file on the server filesystem. The file may optionally be encrypted with a key from the server's encryption settings database.</li> <li>* A provider that can obtain the passphrase from an environment variable set in the server's process.</li> <li>* A provider that can obtain the passphrase from a HashiCorp Vault instance.</li> </ul> <p>Components of the server that have been updated to support using passphrase providers include:</p> <ul style="list-style-type: none"> <li>* LDAP, JDBC, SCIM, and SMTP external servers.</li> <li>* File-based key and trust manager providers.</li> <li>* The PKCS #11 key manager provider. * The changelog password encryption plugin. * The Twilio alert handler and OTP delivery mechanism. * The UNBOUNDID-YUBIKEY-OTP SASL mechanism handler.</li> </ul> <p>The Server SDK has been updated to provide support for creating custom passphrase provider implementations and to allow extensions to retrieve secrets from passphrase providers configured in the server.</p>

Ticket ID	Description
DS-39157,DS-39158,DS-43848	<p>The Server SDK ServerContext class has been updated to provide a new set of methods for writing messages to the server's trace log publishers using various log severity levels. These methods replace an existing API that only supported recording debug messages, which should not be enabled in production environments.</p> <p>Administrators can configure the server's trace log publishers to enable or disable message types on a per-severity basis using a trace log publisher's extension-message-type property.</p>
DS-41815	Fixed an issue with the copy/paste functionality in the Administrative Console.
DS-41911	<p>In order to reduce the time it takes for "setup" to run the testing of Java options that "setup" does will now be cached and stored in a directory. By default the directory is "logs/option-cache" relative to the server root, but an alternative directory can be specified via setup option "--optionCacheDirectory". If a directory is specified it must be created prior to running setup.</p>
DS-41951, DS-41326	<p>The Administrative Console can now download either a collect-support-data file or a server profile from the managed server. This can be done through the Status page. These operations require that a 'csd-files/' and a 'profile-files/' directory be present in the server root by default, but this can be customized through the ldap.csd-destination-folder and ldap.profile-destination-folder settings, which can be found in the Console's application.yml configuration file.</p> <p>Downloading collect-support-data files is disabled by default when using the PingDataConsole Docker image. It also strongly recommended to avoid downloading collect-support-data files from servers that are running in a container.</p>
DS-42401,DS-43754	Updated the manage-profile replace-profile subcommand to detect changes to files referenced in setup-arguments.txt when those files are outside of the server profile

Ticket ID	Description
DS-42937	The Administrative Console now allows users to specify the LDAP server they wish to bind to using the query parameters 'ldap-hostname' and 'ldaps-port' when the console is configured for SSO. This allows a single console instance to administer multiple PingData servers. Note that an LDAPS scheme is always assumed because an encrypted connection is always required for SSO.
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.
DS-43435	Fix a bug that prevented offline changes to mirrored configuration with manage-profile replace-profile.
DS-43441	Fixed "Reverse DNS resolution" warning during setup. This warning was a result of performing a reverse DNS lookup on link local addresses, which is now avoided. This is mostly only relevant to IPv6.
DS-43627	Fixed an issue that could prevent Sync loggers from being properly closed during the server shutdown process.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43719	Added the capability to filter JSON field values in constructed values. Including a JSON object filter in parentheses after a JSON field name will indicate that for each attribute value, the named field value will only be extracted if the attribute value matches the provided filter. This allows, for example, when used in a Constructed Attribute Mapping's value-pattern property, for a given field value to only be mapped for values that match a given filter. For information about the syntax and use of this capability, see the config reference guide for Constructed Attribute Mappings.
DS-43817	Fixed an issue where Directory Server sometimes reports erroneous warnings about duplicate jar files.
DS-43890	Fixed an issue with dsjavaproperties --initialize that prevented changing the JVM tuning parameter using the --jvmTuningParameter command line argument.

Ticket ID	Description
DS-43916	Added cipher stream provider and passphrase provider implementations with support for the Amazon AWS Secrets Manager service. The Amazon Secrets Manager cipher stream provider can be used to protect the contents of the encryption settings with a key derived from a secret retrieved from the Secrets Manager service. The Amazon Secrets Manager passphrase provider can be used to obtain clear-text secrets needed for processing within the server from the Secrets Manager service.
DS-43935	Updated manage-profile replace-profile to run a shorter process when applying dsconfig changes that require administrative actions.
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the oidc-trust-store-file and oidc-trust-store-type settings. Also, you can set the console to skip hostname and/or certification verification through the oidc-strict-hostname-verification and oidc-trust-all configuration settings.
DS-43950	Fixed an issue where Directory Server failed to install on JDKs that lack support for AES-256 encryption.
DS-44010	<p>Updated the server to allow obtaining client secrets from a passphrase provider as an alternative to storing an obscured representation of the secret directly in the configuration. Updated components include:</p> <ul style="list-style-type: none"> <li>* The OpenID Connect client secret needed for single sign-on to the admin console</li> <li>* The OAuth client secret needed to connect to the PingOne service</li> <li>* The client secret needed in conjunction with the PingFederate access token validator</li> </ul>
DS-44025	Addressed an issue where the server was incorrectly displaying an "Unknown vendor" warning when using JDKs obtained on Red Hat and Ubuntu systems.

Ticket ID	Description
DS-44054,DS-44091,DS-44100,DS-44104,DS-44135,DS-44239	<p>Added a FIPS 140-2-compliant mode to the server. This mode may be enabled by running setup with the --fips argument, or by including the --fips argument in the setup-arguments.txt file when using manage-profile setup.</p> <p>Servers running in FIPS 140-2-compliant mode are not compatible with those running in non-compliant mode. FIPS 140-2-compliant mode cannot be enabled after setup (including when upgrading an existing instance, whether using update or manage-profile replace-profile). It can only be enabled when the instance is initially configured. Further, servers running in FIPS 140-2-compliant mode cannot replicate with or participate in the same topology as servers not running in FIPS-compliant mode. If you wish to migrate an existing deployment to use FIPS 140-2-compliant mode, you must install create a new topology of servers running in FIPS-compliant mode and migrate the data into it.</p> <p>In addition, servers running in FIPS 140-2-compliant mode will not be allowed to use the Argon2, bcrypt, or scrypt password storage schemes, as they rely on non-FIPS-approved algorithms. The PBKDF2 password storage scheme is approved and may be used in FIPS-compliant mode, but it requires passwords to have a minimum length of 14 bytes.</p> <p>Setup has also been updated to make it possible to initialize the certificate key and trust stores with certificate data read from PEM files. These options are available in both FIPS 140-2-compliant and non-FIPS-compliant modes, and can help make it easier to set up the server with existing certificates that are not available in a key or trust store that setup supports.</p>

Ticket ID	Description
DS-44057	<p>Improved the behavior that the server exhibits for attempts to configure it with an invalid set of TLS cipher suites.</p> <p>Previously, if a connection handler was configured with an explicit set of TLS cipher suites, and if none of those cipher suites was supported by the underlying JVM, the server would log a message for each unsupported suite and would fall back to using a default set of suites. This could lead to cases in which the server ran with a different set of cipher suites than expected, and the warning log messages might be overlooked.</p> <p>The server will now reject an attempted configuration change that would leave it without any valid cipher suites. For the sake of preserving backward compatibility, and helping to avoid issues around upgrading the server or JVM version, it will still allow attempts to configure the set of cipher suites using one or more invalid suite names as long as the server would still be able to offer at least one valid suite, and it will still log a warning message about each invalid cipher suite referenced in the configuration.</p>
DS-44061	Fixed a NullPointerException that could occur when using manage-profile replace-profile with a server profile that configured a StatsD monitoring endpoint.
DS-44106	Updated the StatsD Monitoring Endpoint to support sending custom tags with each metric message. Custom tags will be appended at the end of each StatsD message as comma-separated key-value pairs.
DS-44120	Fixed an issue in which Sync Failed Ops log publishers could not be deleted.
DS-44122	Fixed an issue that caused cipher stream provider configuration options to be hidden.

Ticket ID	Description
DS-44187	<p>Included the Bouncy Castle library with the server, which is needed to support certain cryptographic functionality, like the Argon2, bcrypt, and scrypt password storage schemes. It was not previously included with the server over concerns around compliance with U.S. export control regulations around strong encryption, but those concerns have been alleviated. You no longer need to obtain the library for yourself if you wish to use any of the functionality that requires it, and the Argon2, bcrypt, and scrypt password storage schemes are now enabled by default in the out-of-the-box configuration.</p>
DS-44192	<p>Updated the default set of TLS protocols and cipher suites that the server will support. As TLSv1 and TLSv1.1 are no longer considered secure (see RFC 8996 for additional information), the server will only support TLSv1.2 and TLSv1.3 (if supported by the JVM) by default. The server will also no longer enable support for TLS cipher suites that use the SHA-1 digest algorithm (which is also no longer considered secure and is not needed for TLSv1.2 or TLSv1.3) or that use the RSA key exchange algorithm (which does not support forward secrecy).</p> <p>If you need to enable support for legacy TLS protocols or cipher suites, you may do so through the server configuration. This can be enabled on a per-connection-handler basis using the <code>ssl-protocol</code> and <code>ssl-cipher-suite</code> configuration properties. Alternatively, you may use the <code>ssl-protocol</code> and <code>ssl-cipher-suite</code> properties in the crypto manager configuration to set default values that will be used by connection handlers that do not explicitly specify values for those properties.</p>
DS-44316	<p>Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.</p>
DS-44390	<p>Fixed an issue where logs from setting up a new server could be lost when running the <code>manage-profile replace-profile</code> subcommand.</p>

Ticket ID	Description
DS-44410	When deployed to a web application server such as Apache Tomcat, the Administrative Console will now write log messages to the application server's console output by default.
DS-44436	Addressed an issue in which attempting to add a member that already existed in a non-default server group would cause an error. Adds of duplicate members are now ignored and no errors are thrown.
DS-44531	Updated the manage-profile replace-profile command to avoid printing warnings for offline config changes from the new server profile.

## PingDataSync Server previous releases

Release Notes for earlier versions of PingDataSync Server are included for reference.

### PingDataSync 8.2.0.8 release notes

The release notes for the 8.2.0.8 release of the PingDataSync server.

#### Critical fixes

This release of the PingDataSync server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the PingDataSync server.

Ticket ID	Description
DS-45164	Updated Jetty Server to version 9.4.44.
DS-45813	Updated PingDirectory products to use Kafka v2.8.1.

### PingDataSync Server 8.2.0.7 release notes

The release notes for the 8.2.0.7 release of PingDataSync Server.

#### Critical fixes

This release of PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology. When a server is removed via the `dsreplication disable` or `remove-defunct-server` tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose

access to keys that had been used for reversible password encryption when removing servers from the topology.

**Note:**

Since this change only applies to the most recent version of `remove-defunct-server` and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past `dsreplication` and `remove-defunct-server` could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

- Fixed in: 8.2.0.7
- Introduced in: 7.0.0.0
- Support identifiers: DS-44591

### Resolved Issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
DS-44591	<p>Fixed an issue where secret keys under <code>cn=Topology,cn=config</code> could be lost when removing a server from the topology. When a server is removed via the <code>dsreplication disable</code> or <code>remove-defunct-server</code> tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.</p> <p>The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.</p> <p> <b>Note:</b></p> <p>Since this change only applies to the most recent version of <code>remove-defunct-server</code> and <code>dsreplication disable</code>, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past <code>dsreplication</code> and <code>remove-defunct-server</code> could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.</p>
DS-45124	<p>Removed <code>-XX:RefDiscoveryPolicy=1</code> from the default start-server Java arguments. In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.</p>
DS-45190	<p>Added support for the use of JDKs obtained through BellSoft.</p>

### PingDataSync Server 8.2.0.6 release notes

#### Critical fixes

This release of PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## Resolved issues

The following issues have been resolved with this release of the DataSync Server.

Ticket ID	Description
DS-43632	Fixed an issue where the <code>format</code> field is omitted from the list of operational attribute schemas in the Directory REST API.

**PingDataSync Server 8.2.0.5 release notes**

## Critical Fixes

This release of the PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

## Resolved issues

The following issues have been resolved with this release of the PingDataSync Server.

Ticket ID	Description
DS-44025	Fixed an issue where the server was incorrectly displaying an <code>Unknown vendor</code> warning when using JDKs obtained on Red Hat and Ubuntu systems.

**PingDataSync 8.2.0.2 release notes**

## Critical Fixes

This release of PingDataSync addresses critical issues from earlier versions. Update all affected servers appropriately.

**No critical issues have been identified**

## Resolved Issues

The following issues have been resolved with this release of PingDataSync:

Ticket ID	Description
DS-43224	Made a generic OpenID Connect ID token validator available. This change allows single sign-on to the Administrative Console with OIDC providers other than just PingOne.
DS-43941	You can now specify that the Administrative Console use a custom truststore when evaluating OIDC provider certificates by using the <code>oidc-trust-store-file</code> and <code>oidc-trust-store-type</code> settings. Also, you can set the console to skip hostname and/or certification verification through the <code>oidc-strict-hostname-verification</code> and <code>oidc-trust-all</code> configuration settings.

## PingDataSync 8.2 release notes

### Enhancements

The new feature for this release is:

- The Administrative Console now supports using OpenID Connect for admin SSO, allowing you to set up the PingOne administration console to have one-click SSO access without typing a password.

### Upgrade considerations

Upgrade considerations are no longer part of the release notes. That information is now in [Upgrade overview and considerations](#) on page 1612.

### Known issues and limitations

The following are known issues in the current version of Data Sync Server:

When signing on to the Administrative Console, you must specify an LDAPS port in the **Server** field. For example, to use port 636, you would specify pingdirectory:636. If you do not specify a port, you get a

```
"Server
  unavailable"
```

message.

### Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-5040	Improved the <code>dsframework</code> tool to support multivalued server properties.
DS-5143, DS-11035	<p>Updated support for logging access and error log messages to a syslog server. While the server previously supported logging these messages to a syslog server (through the "syslog-based access log publisher" and "syslog-based error log publisher" logger implementations), these loggers used an older version of the syslog protocol (described in RFC 3164) and only offered support for communicating over UDP.</p> <p>These loggers are still available for legacy backward compatibility, but we now also offer new "syslog text access log publisher" and "syslog text error log publisher" implementations that use a newer version of the syslog protocol (syslog version 1, described in RFC 5424) and support communicating over UDP or the more reliable TCP. When using TCP, it is also possible to encrypt communication with TLS, and it is possible to configure multiple servers for better redundancy. These loggers use the same space-delimited text format as the former loggers.</p> <p>We also offer new "syslog JSON access log publisher" and "syslog JSON error log publisher" implementations that offer the same set of capabilities, but that format the message text as JSON objects, which can be more easily parsed by third-party software.</p>

Ticket ID	Description
DS-10320, DS-12550, DS-12551, DS-12552, DS-42116, DS-42162, DS-42179, DS-42222, DS-42223, DS-42224, DS-42225, DS-42416, DS-42437	Added a config/sample-dsconfig-batch-files directory with set of well commented dsconfig batch files that may be useful in enabling or configuring a variety of features in the server.
DS-10775	<p>Updated the dictionary password validator to support additional options:</p> <ul style="list-style-type: none"> <li>* It can now ignore non-alphabetic characters that appear at the beginning or end of the password before checking the dictionary.</li> <li>* It can strip characters of diacritical marks, including accents, cedillas, circumflexes, diaereses, tildes, and umlauts, before checking the dictionary. If this option is used, then any character with such a mark will be replaced with a base version of the character without that mark (for example, a lowercase letter n with a tilde over it would be replaced with just a lowercase letter n).</li> <li>* You can define maps with information about character substitutions to use for checking alternative versions of the provided password. For example, if you indicate that "0" might map to "o", "1" or "!" might map to "i", "7" might map to "t", and "3" might map to "e", then the validator can reject a proposed password of "pr0h1b!73d" if the dictionary contains the word "prohibited".</li> <li>* It can reject a proposed password if a value from the provided dictionary makes up more than a specified percentage of that password.</li> </ul>
DS-11524, DS-41860, DS-42112	<p>Added support for new administrative alert types:</p> <ul style="list-style-type: none"> <li>* We have added a new admin alert account status notification handler, which can generate administrative alerts whenever an applicable account status notification is generated within the server. For example, this account status notification handler can be added to the root password policy to generate an alert whenever a root user's password is updated or their account is locked as a result of too many failed authentication attempts. A separate alert type has been defined for each account status notification type.</li> <li>* We have added a new "privilege-assigned" administrative alert that can be raised whenever a new entry is added or an existing entry is updated to include one or more privileges.</li> <li>* We have added a new "insecure-request-rejected" administrative alert that can be raised whenever the server rejects a request as a result of the reject-insecure-requests global configuration property.</li> </ul>
DS-13853	Added support for the OAUTHBEARER SASL mechanism (as described in RFC 7628) to allow LDAP clients to authenticate with OAuth 2.0 bearer tokens.
DS-15848, DS-42360	Added support for invoking a specified set of password validators during bind operations. If the password used to authenticate fails to satisfy one or more of the configured validators, the bind attempt can be rejected, the user can be forced to change their password, or the server can generate an account status notification to take some alternative action (for example, notifying the end user or server administrators).

Ticket ID	Description
DS-15864	Replaced the ldappasswordmodify tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.
DS-16228	Added support for JSON-formatted Sync loggers and Sync Failed Ops loggers, which complement the existing file-based Sync logger and file-based Sync Failed Ops logger, respectively. The JSON-formatted Sync log messages provide information about synchronization events the server has processed, and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server.
DS-17903	Updated setup to provide a --populateToolPropertiesFile argument that will allow it to populate the config/tools.properties file with default values for command-line tool arguments. If requested, properties will be provided for the server address, port, and communication security, and may also include a default bind DN and optionally a bind password. When running setup interactively, it will now prompt to determine which properties (if any) should be populated in the properties file.
DS-36088	Updated the crypto manager to make it possible to augment the set of enabled TLS cipher suites with specific suites to add to or remove from the default set of enabled suites. To enable one or more suites in addition to those in the default set, prefix the names of those suites with the "+" symbol. To disable one or more suites in the default set of enabled suites, prefix the names of those suites with the "-" symbol. This was already possible when configuring cipher suites for the LDAP and HTTP connection handlers, but it was not an option for the crypto manager.
DS-37890	Added a new property to sync classes called replace-all-attr-values-limit. The property is only used when replace-all-attr-values is true and the sync destination is an LDAP server. If a modification would replace more values of the same attribute than the value of replace-all-attr-values-limit, then the modification will use ADD or DELETE operations rather than a REPLACE operation.
DS-38110	Updated the System Information monitor with an "isDocker" attribute to identify if the server is running in a Docker container.
DS-38118, DS-42495	<p>Made several updates related to the server's handling of data written to standard output and standard error:</p> <ul style="list-style-type: none"> <li>* The server can now be configured to rotate the logs/server.out file once it reaches a given size, and it will retain a configurable number of those log files. By default, the server will rotate the file once it reaches 100 megabytes and will keep up to ten files.</li> <li>* To better facilitate capturing log data in containerized environments, the server now supports writing JSON-formatted access and error log messages to the JVM's original standard output and error streams (which will be separate from the server.out file when the server is started with the --nodetach argument).</li> <li>* It is now possible to prevent the server from logging messages during startup in non-JSON format. It is also possible to prevent messages about administrative alerts from being written to standard error, or to write those messages in JSON format. These options are especially useful when using JSON-based logging to the console in no-detach mode, as they can help ensure that everything written to standard output and standard error will be formatted as JSON objects.</li> </ul>

Ticket ID	Description
DS-38868	Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.
DS-39646	Updated the manage-topology add-server command to configure failover for Data Sync servers when they are added to a topology.
DS-39789	Updated the JVM memory usage monitor provider to fix an issue that could prevent the monitor from reporting the total amount of memory held by all memory consumers. Also, fixed an issue that could cause the memory-consumer attribute to use an incomplete message for consumers without a defined maximum size and added an additional memory-consumer-json attribute whose values are JSON objects with data that can be more easily extracted by automated processes.
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-40967	Eliminated a misleading error message that could be logged at startup if the server was configured with one or more ACIs that only apply when using specific SASL mechanisms.
DS-41350	Fixed an issue where disabling certain backends (such as 'alarms') caused an internal monitor to log unnecessary error messages every few seconds, about not being able to gather data from that backend.  Note that deliberately disabling the 'alarms' backend is not recommended in normal operation, but may occur during backup/restore operations.
DS-41807	Fixed an issue where LDAP DELETE operations were sometimes not synchronized from an Oracle Unified Directory sync source, due to variations in the format of the 'targetUniqueID' attribute obtained from the Oracle changelog.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-41989	Fixed an issue that could result in duplicate column headers being produced by the Periodic Stats Logger, even when the header-prefix-per-column attribute was set to true.
DS-42004	Added a new configuration property, changes-queue-size, that controls the size of the changes queue on a Sync Pipe. This was previously only configurable via a system property, and it would change the queue size of all Sync Pipes. DataSync will continue to accept the system property, but it is encouraged to migrate the setting into the configuration.

Ticket ID	Description
DS-42045	Updated the Stats Collector Plugin with a new generate-collector-files configuration property. When using the plugin exclusively for providing metrics to one or more StatsD Monitoring Endpoints, set this property to false to prevent unnecessary I/O.
DS-42049	Fixed an issue with Sync server where retry ops could get the server stuck and unable to process changes at the source.
DS-42059, DS-42060	<p>Updated setup to add options for improving communication security:</p> <ul style="list-style-type: none"> <li>* Non-interactive setup now offers a --rejectInsecureRequests argument that will configure the server to reject any request received over a connection that is not encrypted with SSL or StartTLS.</li> <li>* Non-interactive setup now offers a --rejectUnauthenticatedRequests argument that will configure the server to reject any request received over a connection that is not authenticated (or that is authenticated as the anonymous user).</li> <li>* Interactive setup now allows you to configure the server with the LDAP connection handler disabled (which was already an option when using non-interactive setup), or enabled but only for communication encrypted with StartTLS.</li> </ul> <p>The --rejectInsecureRequests and --rejectUnauthenticatedRequests arguments can also be used with manage-profile by including them in the setup-arguments.txt file of the server profile.</p>
DS-42061	Updated the interactive command-line tool framework to prefer establishing secure LDAP connections over insecure connections. Previously, when prompting for the information needed to establish a connection, the default option was to create an unencrypted LDAP connection. Now, tools will default to creating an SSL-encrypted connection if the server supports it, or to creating a StartTLS-encrypted connection if that is available but SSL is not. Tools will also default to using streamlined settings when establishing secure connections. Previously, they would always prompt about how to determine whether the server's certificate chain should be trusted. When using the streamlined settings, the tools will only prompt about certificates that cannot automatically be considered trusted using information in the JVM's default trust store, the server's default trust store (config/truststore), or the server's topology registry.
DS-42062	Updated the root password policy so that LDAP bind responses for root users and topology administrators will be delayed by one second after five consecutive failed authentication attempts.
DS-42063	Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non-LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
DS-42115	Updated the server's command-line tool framework to make it easier and more convenient to communicate with the server over a secure connection when no trust-related arguments are provided. Most non-interactive tools will now check the server's default trust store, the topology registry, and the JVM's default trust store to see if the presented certificate chain can be automatically trusted without the need to prompt the user. If the presented chain cannot be automatically trusted, the user may be interactively prompted to determine whether it should be trusted.

Ticket ID	Description
DS-42199	Optimized some searches commonly used by the status tool. This should improve the performance of the tool in more complex or large-scale environments.
DS-42265	Upgrade to jetty 9.4
DS-42276	Fixed an issue where using the encryption-settings tool to import definitions with the set-preferred flag could result in none of the imported definitions being set as the preferred definition.
DS-42279	Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.
DS-42298	Replaced the ldifsearch, ldifmodify, and ldif-diff command-line tools with more full-featured and robust implementations.
DS-42331	Replaced the ldapcompare tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).
DS-42347	Updated the server to use /dev/urandom (on non-Windows systems where that path exists and is readable) instead of /dev/random as the primary source for secure random data. Attempts to read from /dev/random can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from /dev/urandom will not block, and the data that it provides is no less secure than data from /dev/random in any way that matters for the server.
DS-42349, DS-43209, DS-43210, DS-43323, DS-43324	<p>Added support for JSON-formatted audit loggers, which complement the existing file-based LDIF-formatted error logger. The JSON-formatted audit log messages provide a record of changes to data in the server and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server.</p> <p>Added support for JSON-formatted HTTP operation loggers, which complement the existing file-based loggers using the W3C common log format and a proprietary space-delimited text format. The JSON-formatted HTTP operation log messages provide a record of interaction with HTTP clients and can be written to files on the local filesystem, written to the JVM's standard output or standard error stream, or sent to a syslog server.</p> <p>Fixed an issue that caused JSON-formatted loggers to use a timestamp format that was not strictly compliant with the ISO 8601 format described in RFC 3339. Timestamps incorrectly omitted the colon between the hour and minute components of the time zone offset.</p>
DS-42504	Updated manage-profile replace-profile to set encryption settings definitions defined in the newer server profile as preferred in the encryption settings db.
DS-42547	Fixed an issue where manage-profile generate-profile would print "null" as the generated profile directory when writing to an existing directory.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42632	Added support for creating or importing a key pair configuration object using an elliptic curve (EC) key algorithm. You can use this to designate the encryption key pair for a JWT access token validator that handles EC-encrypted access tokens.

Ticket ID	Description
DS-42634	The JWT Access Token Validator can now validate JWT access tokens signed using the elliptic curve digital signature algorithms ES256, ES384, and ES512.
DS-42635	<p>The JWT Access Token Validator can now validate JWT access tokens encrypted using elliptic curve cryptographic algorithms. The following key encryption algorithms are now supported in addition to RSA-OAEP: ECDH-ES, ECDH-ES+A128KW, ECDH-ES+A192KW, and ECDH-ES+A256KW.</p> <p>To support best practices for JWT security, you must now also configure the JWT Access Token Validator with explicit allow lists for key encryption and content encryption algorithms. For backward compatibility, the key encryption allow list defaults to RSA-OAEP, while the content encryption allow list defaults to A128CBC-HS256, A192CBC-HS384, and A256CBC-HS512. We recommend setting both allow lists to the strict minimum set of algorithms needed by the Access Token Validator.</p>
DS-42651	Updated the manage-profile replace-profile subcommand to better support updating the server's keystore and truststore files. When using the --generateSelfSignedCertificate argument in a server profile's setup-arguments.txt file, the server will maintain the original keystore and truststore files during replace-profile. Otherwise, replace-profile will use the keystore and truststore specified in the profile's setup-arguments.txt file.
DS-42665	Fixed an issue that caused the resync tool to not take the attribute-comparison-method of the sync class into account. This caused resync to ignore when byte-for-byte comparison was configured.
DS-42667	Updated the server to set a unique cluster name when started for the first time.
DS-42669, DS-42748	<p>Updated the online dsconfig step of the manage-profile replace-profile subcommand to support getting LDAP connection arguments from a tools.properties file on the server being updated.</p> <p>Fixed an issue where boolean LDAP connection arguments like --useSSL and --trustAll would cause manage-profile replace-profile to fail when applying dsconfig online.</p>
DS-42673	Updated the manage-profile setup subcommand to fail if the start-server command has a non-zero exit code.
DS-42681, DS-42684	Performance statistics generated by the Sideband API can now be published by the Periodic Stats Logger. To enable this, use the "included-http-servlet-stat" property of the Periodic Stats Logger.
DS-42687	Upgrade to Jetty 9.4.30
DS-42740	Fixed an issue where the <code>dsconfig list</code> subcommand would not display requested properties.
DS-42749	To support best practices for JWT security, you must now configure the JWT Access Token Validator with an explicit list of the JWT signing algorithms that it accepts. For backward compatibility, this list defaults to the RSA signing algorithms RS256, RS384, and RS512, but we recommend setting this list to the strict minimum set of signing algorithms needed by the Access Token Validator.

Ticket ID	Description
DS-42751	Added new <code>override-status-code</code> and <code>additional-response-contents</code> attributes to the Availability State HTTP Servlet Extension. These new attributes can be used to customize the response code and JSON response body of the servlet.
DS-42850	Fixed a typo in the password-expiring template that caused <code>"password_expiration_time_of_day"</code> to be printed instead of the password expiration time.
DS-42861	Updated the <code>manage-profile</code> tool logs to include the duration of each step the tool takes. The new <code>--verbose</code> argument can also be used to display timing information in the tool's console output.
DS-42872	Added a JSON-formatted stats logger to the server's default configuration. The stats logger is disabled by default.
DS-42886	Updated non-interactive setup (including <code>manage-profile</code> setup) to allow the password for the initial root user to be provided in pre-encoded form using the PBKDF2, SSHA256, SSHA384, or SSHA512 password storage scheme. This eliminates the need to have access to the clear-text password when setting up the server.
DS-42926	Fixed an issue where Ping Directory products configured to run as Microsoft Windows services were sometimes unable to automatically restart following an unplanned reboot, due to errors reading a corrupted server status file.
DS-42939	The Administrative Console configuration settings have been updated to account for the new SSO functionality.
DS-42952	For Windows only, there can be a hang on start when global configuration property <code>startup-error-logger-output-location</code> is set to values that contain <code>standard-error</code> . For Windows only, <code>standard-error</code> values are silently mapped to equivalent <code>standard-output</code> values.
DS-42963	Updated the <code>manage-profile generate-profile</code> subcommand to ignore files larger than 100 megabytes when generating a server profile. Fixed an issue where many large files in the server root could cause the tool to run out of memory.
DS-43027	Added a new <code>--adminPasswordFile</code> argument to the <code>manage-topology add-server</code> command, to allow specifying the administrator password with a file rather than with the command line.
DS-43073, DS-43198	Added support for ID Token Validators, which validate the integrity and content of ID tokens issued by OpenID Connect providers. Use these validators with the OAuth Bearer SASL Mechanism Handler to enable single sign-on (SSO) for the Administrative Console using an OpenID Connect provider such as PingOne. Currently, only PingOne is supported for SSO.
DS-43074	Added three built-in identity mappers that you can use to look up administrative accounts stored in the server configuration: Root DN Users, Topology Admin Users, and All Admin Users.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"> <li>* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.</li> <li>* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.</li> <li>* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li> </ul>
DS-43305	Increased the maximum number of RDN components that a DN may have from 50 to 100.
DS-43376	Updated log publisher logic to reduce the amount of CPU that the server consumes when it is idle.
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43517	Updated the jose4j library used for JWT signing and encryption to version 0.7.2.
DS-43651	The Security Guide is now available online at pingidentity.com. The guide has been removed from the server packaging.

## Critical fixes

### Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a `mirrored-subtree-manager-connection-asymmetry` alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The `dsreplication` tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like `userRoot`), the LDAP changelog backend, or the replication database.
  - \* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include `backup`, `create-initial-config`, `create-initial-proxy-config`, `dsreplication`, `enter-lockdown-mode`, `export-ldif`, `import-ldif`, `ldappasswordmodify`, `leave-lockdown-mode`, `manage-tasks`, `manage-topology`, `migrate-ldap-schema`, `parallel-update`, `prepare-`

endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not

support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.

The Sync Server has a specialized mutex that ensures that changes to the same entry are processed serially. The primary reason for this mutex is to ensure that the server can safely process changes in parallel to achieve high throughput. However, we also use this mutex to ensure that two Sync Pipes don't process the same entry at the same time for deployments that synchronize changes bi-directionally. A consequence of this locking is that if one Sync Pipe is failing (because the destination is unavailable) then it retains the lock on an entry, and when other Sync Pipes try to process changes to that entry they will block that change and all changes that follow it while they wait on the lock.

This change turns off using a shared mutex by default, but adds a new advanced configuration option on the Sync Pipe, `shared-mutex-name`, that specifies the name of a mutex that is shared by other Sync Pipes. This gives greater control over the locking so that two Sync Pipes that share end points can ensure that two changes to the same logical user are not processed concurrently, while not impacting other Sync Pipes.

See the `shared-mutex-name` property for more information.

This property is subject to change in a future release.

- Fixed in: 3.2.0.0
- Introduced in: 3.0.0.0
- Support identifiers: DS-4202 SF#1527

### **PingDataSync Server 8.1.0.6 release notes**

The release notes for the 8.1.0.6 release of PingDataSync Server.

#### Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
DS-42049	Fixed an issue with the Data Sync server where retry operations could get the server stuck and unable to process changes at the source.

### **PingDataSync Server 8.1.0.5 release notes**

#### Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

#### Resolved issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"><li>* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li></ul>

Ticket ID	Description
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

### PingDataSync 8.1.0.2 Release Notes

#### Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

  - Support identifiers: DS-18026 SF#00616763
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow

a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.
  - Fixed in: 3.2.0.0
  - Introduced in: 3.0.0.0
  - Support identifiers: DS-4202 SF#1527

#### Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-42687	Upgrade to Jetty 9.4.30

### PingDataSync 8.1 Release Notes

#### Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.1.0.0
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
  - Fixed in: 8.1.0.0
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Fixed a memory leak when performing SCIM queries on PingDataMetrics Server.
  - Fixed in: 8.0.0.1
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395

- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
  - Fixed in: 8.0.0.1
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a `mirrored-subtree-manager-connection-asymmetry` alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The `dsreplication` tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like `userRoot`), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include `backup`, `create-initial-config`, `create-initial-proxy-config`, `dsreplication`, `enter-lockdown-mode`, `export-ldif`, `import-ldif`, `ldappasswordmodify`, `leave-lockdown-mode`, `manage-tasks`, `manage-topology`, `migrate-ldap-schema`, `parallel-update`, `prepare-endpoint-server`, `prepare-external-server`, `realtime-sync`, `rebuild-index`, `re-encode-entries`, `reload-http-connection-handler-certificates`, `reload-index`, `remove-defunct-server`, `restore`, `rotate-log`, and `stop-server`. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the `tools.properties` file, or in a file referenced from `tools.properties`, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any

other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that

were provided as command-line arguments; passwords included in the `tools.properties` file, or in a file referenced from `tools.properties`, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

## Upgrade Considerations

Important considerations for upgrading to this version of the Data Sync Server:

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

## What's New

These are new features for this release of the Data Sync Server

- In an ongoing effort to improve the use of containers for PingDirectory, several features have been implemented:
  - The `--outputFile` option has been added to the `collect-support-data` tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator

can run the collect-support-data tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.

- The collect-support-data tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
- A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the --remoteServer added to the collect-support-data tool can be used to send the request to another server. In other words, you can now run collect-support-data on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectory has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party
- Updated the server to use /dev/urandom (on non-Windows systems where that path exists and is readable) instead of /dev/random as the primary source for secure random data. Attempts to read from /dev/random can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from /dev/urandom will not block, and the data that it provides is no less secure than data from /dev/random in any way that matters for the server.
- Replaced the ldapcompare tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).
- Replaced the ldifsearch, ldifmodify, and ldifdiff command-line tools with more full-featured and robust implementations.
- Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.
- Replaced the ldappasswordmodify tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.
- Added a config/sample-dsconfig-batch-files directory with set of well commented dsconfig batch files that may be useful in enabling or configuring a variety of features in the server.

#### Known Issues/Workarounds

The following are known issues in the current version of the Data Sync Server

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

#### Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.

Ticket ID	Description
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-39862	Improved support for the PingOne Sync Source and Destination in the create-sync-pipe-config tool by adding Sync Classes tailored to the PingOne endpoint.
DS-40025,DS-42041	When using an Active Directory Sync Source, the base DN of the Sync Source can now be set to a descendant of the root directory partition of the AD instance(s). When detecting changes, the Sync Source will adjust the value to be the root directory partition if it is not already set to this value, but when synchronizing changes, the Sync Source will only consider changes that have a DN under the base DN provided to the Sync Source.
DS-40241	Updated create-sync-pipe-config to support creating a sync pipe that does not synchronize any attributes. This will be suggested as the default option when either the source or destination is Active Directory or a relational database. The previous default of synchronizing all attributes will still be used when both the source and destination are non-Active Directory LDAP servers.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.

Ticket ID	Description
DS-40413	Updated the behavior of the resync tool when an invalid DN is detected. Instead of stopping the process, the offending entry will be reported and skipped, allowing for the remaining entries to be processed. This issue only affected ActiveDirectory and Changelog Sync Sources (LDAP Sync Sources that detect changes using cn=changelog, such as PingDirectory or ODSEE).
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.

Ticket ID	Description
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41263	Updated the README for the Ping Identity Active Directory Password Sync Agent to indicate support for Windows Server 2016 and Windows Server 2019 and the removal of support for Windows Server 2008.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.

Ticket ID	Description
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41579	Fixes issue with realtime-sync Password Files and Pin Files displaying contents in clear text.
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41784	Fixed a bug that could cause the duration of a sync operation to be miscalculated.
DS-41818	Added the --zip argument to the manage-profile generate-profile subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to /instance-root by authenticated users with the file-servlet-access privilege will be granted access to files within the server instance root.
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has memory.swappiness set to a nonzero value.

Ticket ID	Description
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a NullPointerException if a server was configured with a custom global result code map.
DS-42117	Updated Constructed Attribute Mapping's exclude-value property to accept multiple values with different capitalizations.
DS-42387	Updated the <code>manage-profile generate-profile</code> subcommand to exclude files in the <code>ldif/</code> and <code>bak/</code> directories by default when generating a server profile. If necessary, you can manually include those directories using the <code>--includePath</code> argument.

### PingDataSync Server 8.0.0.5 release notes

#### Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

### PingDataSync 8.0.0.4 release notes

#### Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
  - Fixed in: 8.0.0.4
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-41762 SF#00675207 SF#00683777

#### Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.

## PingDataSync 8.0.0.3 release notes

### Critical Fixes

This release of PingDataSync addresses critical issues from earlier versions. Update all affected servers appropriately.

### No critical issues have been identified

### Resolved Issues

The following issues have been resolved with this release of PingDataSync:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-41807	Fixed an issue where LDAP DELETE operations were sometimes not synchronized from an Oracle Unified Directory sync source, due to variations in the format of the 'targetUniqueID' attribute obtained from the Oracle changelog.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none"> <li>* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.</li> <li>* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.</li> <li>* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.</li> </ul>

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at <a href="https://pingidentity.com">pingidentity.com</a> and has been removed from the server packaging.

### PingDataSync 8.0.0.2 Release Notes

#### Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

#### No critical issues have been identified

#### Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-37890	Added a new property to sync classes called <code>replace-all-attr-values-limit</code> . The property is only used when <code>replace-all-attr-values</code> is true and the sync destination is an LDAP server. If a modification would replace more values of the same attribute than the value of <code>replace-all-attr-values-limit</code> , then the modification will use ADD or DELETE operations rather than a REPLACE operation.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted <code>tools.properties</code> file.

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.

Ticket ID	Description
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42665	Fixed an issue that caused the resync tool to not take the attribute-comparison-method of the sync class into account. This caused resync to ignore when byte-for-byte comparison was configured.
DS-42812	Upgrade to jetty 9.4.30

### PingDataSync 8.0.0.1 Release Notes

#### Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on PingDataMetrics Server.
  - Fixed in: 8.0.0.1
  - Introduced in: 7.2.0.0
  - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
  - Fixed in: 8.0.0.1
  - Introduced in: 5.2.0.0
  - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.3.0.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38344 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.3.0.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
  - \* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
  - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
  - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
    - Fixed in: 7.2.1.0
    - Introduced in: 7.0.0.0
    - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are

unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
  - Fixed in: 7.2.1.0
  - Introduced in: 7.0.0.0
  - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

\* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

\* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
  - Fixed in: 6.2.0.0
  - Introduced in: 6.0.0.0
  - Support identifiers: DS-18026 SF#00616763

- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
  - Fixed in: 5.1.0.0
  - Introduced in: 2.1.0.0
  - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.

The Sync Server has a specialized mutex that ensures that changes to the same entry are processed serially. The primary reason for this mutex is to ensure that the server can safely process changes in parallel to achieve high throughput. However, we also use this mutex to ensure that two Sync Pipes don't process the same entry at the same time for deployments that synchronize changes bi-directionally. A consequence of this locking is that if one Sync Pipe is failing (because the destination is unavailable) then it retains the lock on an entry, and when other Sync Pipes try to process changes to that entry they will block that change and all changes that follow it while they wait on the lock.

This change turns off using a shared mutex by default, but adds a new advanced configuration option on the Sync Pipe, `shared-mutex-name`, that specifies the name of a mutex that is shared by other Sync Pipes. This gives greater control over the locking so that two Sync Pipes that share end points

can ensure that two changes to the same logical user are not processed concurrently, while not impacting other Sync Pipes.

See the `shared-mutex-name` property for more information.

This property is subject to change in a future release.

- Fixed in: 3.2.0.0
- Introduced in: 3.0.0.0
- Support identifiers: DS-4202 SF#1527

## Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-40532	Added a <code>logging-error-behavior</code> property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.

## PingDataSync 8.0.0.0 Release Notes

### Critical Fixes

This release of the PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

### No critical issues have been identified

### What's New

These are new features for this release of the PingDataSync Server:

- Use Server Profiles to reduce risk and improve consistency following the DevOps principle of infrastructure-as-code. Administrators can export the configuration of the PingDataSync Server server to a directory of text files called a Server Profile, track changes to these files in version control such as Git, and install new instances of PingDataSync Server or update existing instances of PingDataSync Server from a Server Profile. Server Profiles support variable substitution in order to remove the settings unique to each pre-production or production environment from the Server Profile that is stored in version control.
- Improved consistency for user passwords that are managed in PingOne. Now when PingDataSync Server recognizes a password change in the source PingOne environment, the password is removed from the destination PingDirectory. Upon the next on-prem LDAP bind, the validated password is saved in the destination PingDirectory by the pass-through authentication plugin.

## Known Issues/Workarounds

The following are known issues in the current version of the PingDataSync Server:

- The following are suggested solutions for problems with slow DNS:
  - Maintain a connection pool in the client app rather than opening new connections for each bind.
  - Add appropriate records, including PTR records, to DNS.
  - Add `options timeout:1` in the `/etc/resolv.conf` file and/or `options single-request`
  - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.

**Workaround:** Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.

- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
  - `groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2`
  - `groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2`

**Workaround:** Deploy the Console in an external container using JDK 8.

## Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-17278	Added a <code>cn=Server Status Timeline,cn=monitor</code> monitor entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, <code>endpoint-cache-refresh</code> , has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the <code>Resource</code> column in the output of <code>status</code> . This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.
DS-38493	Updated the PingOne Sync Source to remove a user's password from a destination (for example, PingDirectory) when the corresponding user's password has changed in PingOne. This behavior requires the <code>password</code> attribute in PingOne to be mapped to the <code>password</code> attribute (for example, <code>userPassword</code> ) in the destination schema.

Ticket ID	Description
DS-38560	Updated <code>manage-profile replace-profile</code> to apply configuration changes directly, when possible. If the new server profile used by <code>replace-profile</code> has changed only the <code>dsconfig</code> batch files from the original profile, then only the <code>dsconfig</code> files are applied. If no changes are detected between profiles, <code>replace-profile</code> takes no action. If changes other than <code>dsconfig</code> are detected, the full <code>replace-profile</code> process is followed.
DS-38777	Added support for updating the server version during <code>manage-profile replace-profile</code> . The server must have been originally set up with a server profile.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-38863	Updated the <code>manage-profile setup</code> subcommand to set a server's cluster name to match its instance name by default. This prevents servers in the same replication topology from being in the same cluster, reducing the risk of unintentionally overwriting parts of an existing server's configuration in a DevOps environment. The <code>--useDefaultClusterName</code> argument can be used to leave the cluster name unchanged.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions.  Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the <code>remove-defunct-server</code> tool's <code>--ignoreOnline</code> option. When using <code>--ignoreOnline</code> in a mixed-version environment, all servers must support the option.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit <a href="http://groovy-lang.org">groovy-lang.org</a> and view the Groovy 2.5 release notes.  As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code> , download the appropriate jar file from <a href="http://groovy-lang.org">groovy-lang.org</a> and place it in the server's <code>lib/extensions</code> directory.
DS-39191	Updated the <code>auto-mapped-source-attribute</code> property on Sync Class configuration objects to not have a default value since the previous default of <code>-all-</code> caused confusion. Existing <code>dsconfig</code> batch files used for automated deployments might need to be updated to provide a value for this property. A value of <code>-all-</code> is recommended when synchronizing between two systems with the same schema, such as when migrating from a legacy LDAP server to PingDirectory.
DS-39253	Added a <code>replace-certificate</code> tool, which can help an administrator replace the listener or inter-server certificate for a server instance.

Ticket ID	Description
DS-39320	Added support for PingDataSync Server to the <code>manage-profile</code> tool and its subcommands.
DS-39325	<p>Removed the legacy product-specific scripts for starting and stopping the server. These include:</p> <ul style="list-style-type: none"> <li>▪ <code>start-ds</code> and <code>stop-ds</code> for Directory Server</li> <li>▪ <code>start-proxy</code> and <code>stop-proxy</code> for Directory Proxy Server</li> <li>▪ <code>start-sync</code> and <code>stop-sync</code> for Data Sync Server</li> <li>▪ <code>start-metrics-engine</code> and <code>stop-metrics-engine</code> for Data Metrics Server</li> </ul> <p>These legacy scripts had been deprecated for several releases in favor of the more general <code>start-server</code> and <code>stop-server</code> scripts, and they displayed a warning message about their upcoming removal if they were invoked.</p> <p>If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general <code>start-server</code> and <code>stop-server</code> scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point to the <code>start-server</code> and <code>stop-server</code> scripts.</p>
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as <code>X-VALUE-REGEX</code> ), this could cause unexpected or incorrect behavior.
DS-39540	Released an updated Password Sync Agent for Active Directory that uses SSHA256 as a default for its password hashing algorithm instead of SSHA, since SSHA is soon to be deprecated in PingDirectory. If SSHA256 is not supported by a directory or if it is not wanted, a registry value was added that can be set to specify the password hashing algorithm.
DS-39592	HTTP External Servers have a new attribute, <code>ssl-cert-nickname</code> , which defines the alias of a specific certificate within their keystore to be used as a client certificate.
DS-39603	Fixed an issue where Server SDK extensions could not be configured by <code>dsconfig</code> batch files in the <code>manage-profile</code> tool.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.
DS-39654	Added support for the <code>--topologyFilePath</code> argument to the <code>manage-topology add-server</code> subcommand.
DS-39671	Updated the <code>manage-topology add-server</code> subcommand to require being run from the older server in a mixed-version environment.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39853	Added support for the PingOne Sync Source and Destination to the <code>create-sync-pipe-config</code> tool.

Ticket ID	Description
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40020	Fixed an issue in Active Directory Sync Source where the persistent state was updated before applying changes, so changes could be missed when stopping the Sync Pipe.
DS-40114	Added a new <code>cn=Status Health Summary,cn=monitor monitor</code> entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.
DS-40354	Fixed a problem with <code>config-diff</code> when writing properties that span multiple lines using the <code>--prettyPrint</code> argument.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40543	Updated <code>manage-profile replace-profile</code> to copy the tool log file to the server being updated.
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40730	Updated the <code>encrypt-file</code> tool to prevent using the same path for both the input file and the output file.
DS-40771	Added a <code>--duration</code> argument to <code>collect-support-data</code> . When used, only the log files covering the specified duration before the current time will be collected.

## PingDirectory Server Administration Guide

---

The PingDirectory server is a high-performance, extensible [MISSING glossAcronymn or glossSurfaceform for gLDAP] directory that provides seamless data management over a distributed system while meeting the constant performance demands for today's markets.

## Introduction to PingDirectory Server

---

PingDirectory Server is a high-performance, extensible directory and PingData Platform, written completely in Java.

The PingDirectory Server centralizes consumer and user identity management information, subscriber data management, application configurations, and user credentials into a network, enterprise, or virtualized database environment. It provides seamless data management over a distributed system based on a standardized solution that meets the constant performance demands for today's markets. The PingDirectory Server simplifies administration, reduces costs, and secures information in systems that scale for large numbers of users.

The following topics provide an overview of the PingDirectory Server's features and components:

- [Server features](#) on page 328
- [Administration framework](#) on page 330
- [Server tools location](#) on page 330

### Server features

The PingDirectory Server provides an extensive feature-rich set of tools to meet a variety of production needs.

#### Full LDAP version 3 implementation

The PingDirectory Server fully supports LDAPv3, which supports the Request For Comments (RFCs) specified in the protocol. The Directory Server provides a feature-rich solution that supports the core LDAPv3 protocol in addition to server-specific controls and extended operations.

#### High availability

The PingDirectory Server supports N-way multi-master replication that eliminates single points of failure and ensures high availability for a networked topology. The PingDirectory Server allows you to store data across multiple machines and disk partitions for fast replication. The PingDirectory Server supports replication in entry-balancing proxy server deployments.

#### Administration tools

The PingDirectory Server provides a full set of command-line tools, an administrative console, and a Java-based setup tool to configure, monitor, and manage any part of the server.

The PingDirectory Server has a task-based subsystem that provides automated scheduling of basic functions, such as:

- Backups
- Restores
- Imports
- Exports
- Restarts
- Shutdowns

The set of utilities includes a troubleshooting support tool that aggregates system metrics into a `.zip` file, which administrators can send to your authorized support provider for analysis.

#### Self-service account manager application

The Self Service Account Manager project, hosted at <https://github.com/pingidentity/ssam>, is a customizable web application allowing users to perform their own account registration, profile updates, and password changes. The project is for testing and development purposes only and is not a supported application.

#### Delegated admin application

A Javascript-based web application can be installed for business users to manage identities stored in the PingDirectory Server. The application provides delegated administration of identities for:

- Help desk or customer service representatives initiating a password reset and unlock
- An employee in HR updating an address stored within another employee profile
- An application administrator updating identity attributes or group membership to allow application single sign-on (SSO) access.

### Security mechanisms

The PingDirectory Server provides extensive security mechanisms to protect data and prevent unauthorized access. Access control list (ACL) instructions are available down to the attribute value level and can be stored within each entry.

The PingDirectory Server allows connections over SSL through an encrypted communication tunnel. Clients can also use the StartTLS extended operation over standard, non-encrypted ports. Other security features include:

- A privilege subsystem for fine-grained granting of rights
- A password policy subsystem that allows configurable password validators and storage schemes
- SASL authentication mechanisms to secure data integrity, such as:
  - PLAIN
  - ANONYMOUS
  - EXTERNAL
  - CRAM-MD5
  - Digest-MD
  - GSSAPI

The PingDirectory Server supports various providers and mappers for certificate-based authentication in addition to the ability to encrypt specific entries or sensitive attributes. For more information, see the PingDirectory Server Security Guide.

### Monitoring and notifications

The PingDirectory Server supports monitoring entries using:

- PingDataMetrics Server
- JConsole
- SNMP
- The Administrative Console

Administrators can track the response times for LDAP operations using a monitoring histogram as well as record performance statistics down to sub-second granularity. The PingDirectory Server supports configurable notifications, auditing, and logging subsystems with filtered logging capabilities.

### Powerful LDAP SDK

The PingDirectory Server is based on a feature-rich LDAP SDK for Java, designed by Ping Identity. The LDAP SDK is a Java API standard that overcomes the limitations of the Java Naming and Directory Interface (JNDI) model. For example, JNDI does not address the use of LDAP controls and extended operations. The LDAP SDK for Java provides support for controls and extended operations to leverage Ping Identity's extensible architecture for their applications.

 **Note:**

For more information on the LDAP SDK for Java, see <http://www.LDAP.com>.

## System for Cross-domain Identity Management (SCIM) extension

The PingDirectory Server provides a SCIM servlet extension to facilitate moving users to, from, and between cloud-based software as a service (SaaS) applications in a secure and fast manner.

## Server SDK

Ping Identity provides the Server SDK, which is a library of Java packages, classes, and build tools to help in-house or third-party developers create client extensions for:

- PingDirectory
- PingDirectoryProxy
- PingDataSync Server

The servers have a highly extensible and scalable architecture with multiple plugin points for your customization needs. The Server SDK provides APIs to alter the behavior of each server's components without affecting its code base.

## Administration framework

The PingDirectory Server provides an administration and configuration framework capable of managing stand-alone servers, server groups, and highly-available deployments that include multiple redundant server instances.

Administrators can configure changes locally or remotely:

- On a single server
- On all servers in a server group

Each server configuration is stored as a flat file (LDIF) that can be accessed under the `cn=config` branch of the directory information tree (DIT). Administrators can tune the configuration and perform maintenance functions over LDAP using a suite of command-line tools or an administrative console (for configuration and monitoring). The PingDirectory Server provides plugins to extend the functionality of its components.

## Server tools location

The PingDirectory Server stores a full set of command-line tools for maintaining your system in the `PingDirectory/bin` directory for UNIX or Linux machines and the `PingDirectory\bat` directory for Microsoft Windows machines.

Ping Identity distributes the PingDirectory Server, administrative console, and LDAP SDK for Java in `.zip` format. After extracting the file, you can access the `setup` utility in the server root directory, located at `PingDirectory`.

Before installing the PingDirectory Server, see [Prepare your environment](#) on page 331 for important information on setting up your machines. See [Installing PingDirectory Server](#) on page 330 for information on installing a server instance using the `setup` utility. You can run this utility in either interactive command-line or non-interactive command-line. For information on modifying the configuration of a server instance or a group of servers using the command-line tools and the administrative console, see [Configuring the Server](#) on page 394.

## Installing PingDirectory Server

---

After you prepare your hardware and software system, you can set up the server using PingDirectory Server's installation modes.

To install the server, see the following topics:

- [Prepare your environment](#) on page 331
- [Getting the installation packages](#) on page 340
- [Signing on to the Administrative Console](#) on page 340

- [Directory Server folder layout](#) on page 341
- [make-ldif template format](#) on page 342
- [Push-replace DS GUI installation mode](#)
- [Server installation modes](#) on page 354
- [Before you begin](#) on page 354
- [Ping license keys](#) on page 355
- [Setting up the Directory Server in interactive mode](#) on page 356
- [Installing the Directory Server in non-interactive mode](#) on page 358
- [Installing a lightweight server](#) on page 359

## Prepare your environment

PingDirectory Server offers a highly portable and scalable architecture that runs on multiple platforms and operating systems.

The Directory Server is specifically optimized for operating systems used in environments that process a large number of entries.

For information on setting up your server machines for optimal processing efficiency, see the following topics:

- [Before You Begin](#)
- [Preparing the Operating System \(Linux\)](#)
- [Running as a Non-Root User \(Linux\)](#)

### Before you begin

The Directory Server requires certain software packages for the proper operation of the server.

For optimal performance, PingDirectory Server requires Java for 64-bit architectures. To view the minimum required Java version, access the Customer Support Center portal or contact your authorized support provider for the latest supported software versions.

#### Tip:

Implement a Network Time Protocol (NTP) system so that multi-server environments are synchronized and timestamps are accurate.

### System requirements

The PingDirectory server requires certain software packages to operate properly.

Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software are suspected of causing issues.

The following system requirements are qualified and certified to be compatible with the PingDirectory server.

#### Running PingDirectory on Amazon Web Services (AWS)

To take advantage of snapshots for backing up any important files, install the PingDirectory server on an Elastic Block Store (EBS) file system. You should also move any databases, logs, and other files to a high-performance file system that is separate from the rest of the server image and create an S3 bucket for storing backups, schema, and other artifacts.

The following guidelines and considerations can help you avoid environmental constraint issues:

- PingDirectory does not support the Elastic File System (EFS) for database persistence.
- For the lowest cost, use t3.medium or t3a.medium and up.
- For the best performance, use m5dn, c5dn, or r5dn instance types (size xlarge and up) and the local SSD for PingDirectory database persistence.

- The A1 and M6g instance types, Ampere and Graviton, are not qualified by Ping at this time.
- Using network load balancers (NLBs) can lead to severed connections, which could cause issues that are difficult to diagnose.

## Platforms

The following operating systems support PingDirectory server, PingDirectoryProxy server, and PingDataSync server's installation and deployment:

- Amazon Linux 2
- Canonical Ubuntu 18.04 LTS and 20.04 LTS
- CentOS 7.7 and 8.1
- Microsoft Windows Server 2016 and 2019
- Oracle Linux 7.9 and 8.2
- Red Hat Enterprise Linux ES 7.7, 8.1, and 8.2
- SUSE Linux Enterprise 12 SP5 and 15 SP1

### Attention:

This product has been tested with the default configurations of all operating system components. Customized implementations or installed third-party plugins from your organization might affect the deployment of this product.

## Docker

The following Docker version and operating systems are a pre-installation requirement:

- Version: Docker 19.03.5
- Base image operating system: Ubuntu 18.04 LTS
- Base image operating system: Alpine Linux 3.11
- Base image operating system: Oracle Linux 7.9

For more information, view the Directory Server Docker Image on DockerHub at [pingidentity/pingdirectory](https://hub.docker.com/r/pingidentity/pingdirectory) and visit the [PingIdentity DevOps documentation](#).

### Note:

Only the Directory Server software is licensed under Ping Identity's end user license agreement, and any other software components contained within the image are licensed solely under the terms of the applicable open source/third-party license.

Ping Identity accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

## Java Runtime Environment

The following [Java Development Kit \(JDK\)](#) versions are a pre-installation requirement:

- Oracle JDK 8 64-bit
- Oracle JDK 11 LTS 64-bit
- OpenJDK 8 64-bit
- OpenJDK 11
- Corretto 8
- Corretto 11

**Note:**

The [Ping Identity Java Support Policy](#) applies to your [Java Runtime Environment \(JRE\)](#).

## Browsers

The following are the browsers supported by the PingDirectory server administrative console:

- Chrome
- Firefox
- Edge

## Installing Java

Even if your system already has Java installed, you might want to create a separate Java installation for use by the PingDirectory Server so that updates to the system-wide Java installation do not impact the Directory Server.

### About this task

PingDirectory Server requires Java. For optimized performance, use Java for 64-bit architectures. View the minimum required Java version on your Customer Support Center portal, or contact your authorized support provider for the latest software versions supported.

**Note:**

A separate Java installation requires that you download the Java Development Kit (JDK) instead of the Java Runtime Environment (JRE) for the 64-bit version.

## Steps

1. Go to the [Oracle download site](#).
2. Click JDK Download.
3. On the download page, select the download file for your operating system and accept the license agreement to start the download.

## Preparing the operating system (Linux)

Several operating system customizations can improve the performance of PingDirectory Server on Linux systems.

These customizations include:

- [Increasing the file descriptor limit on Linux systems](#)
- [Setting the file system flushes](#) on page 335
- [Editing OS-level environment variables](#)

## Configuring the file descriptor limits

Operating system default file descriptor limits restrict the number of PingDirectory Server connections. Change the descriptor limits to allow more connections.

### About this task

The Directory Server allows for an unlimited number of connections by default, but the file descriptor limit on the operating system restrict the number of connections. Many Linux distributions have a default file descriptor limit of 1024 per process, which might be too low for the server if it needs to handle a large number of concurrent connections.

If the operating system relies on `systemd`, see the Linux operating system documentation for instructions on setting the file descriptor limit.

After you set the operating system limit, you can configure the number of file descriptors that the server will use either by using a `NUM_FILE_DESCRIPTOR` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as `NUM_FILE_DESCRIPTOR=12345`. If these are not set, the operating system uses the default of 65535 descriptors. This is an optional change you can make if you want to ensure that the server shuts down safely prior to reaching the file descriptor limit.

## Steps

1. Display the current `fs.file-max` limit of the system.

```
sysctl fs.file-max
```

The `fs.file-max` limit is the maximum server-wide file limit you can set without tuning the kernel parameters in the `proc` file system.

2. Edit the `/etc/sysctl.conf` file.

If there is a line that sets the value of the `fs.file-max` property, make sure that its value is set to at least 1.5 times the per-process limit.

If there is no line that sets a value for this property, add the following to the end of the file:

```
fs.file-max = 100000
```

### Note:

100000 is just an example here. Specify a value of at least 1.5 times the per-process limit.

3. Display the current hard limit of the system.

```
ulimit -aH
```

The `open files (-n)` value is the maximum number of open files per process limit.

The value should be set to at least 65535.

4. Edit the `/etc/security/limits.conf` file.

If the file has lines that set the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines before `#End of file`, making certain to insert a tab between the columns.

```
* soft nofile 65535
* hard nofile 65535
```

### Note:

The number of open file descriptors is limited by the physical memory available to the host. You can determine this limit with the following command.

```
cat /proc/sys/fs/file-max
```

If the `file-max` value is significantly higher than the 65535 limit, consider increasing the file descriptor limit to between 10% and 15% of the system-wide file descriptor limit. For example, if the `file-max` value is 810752, you could set the file descriptor limit to 100000. If the `file-max` value is lower than 65535, the host is likely not sized appropriately.

5. Reboot your system, and then use the `ulimit` command to verify that the file descriptor limit is set to 65535.

```
# ulimit -n
```

## Result

### Note:

For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits.

```
/etc/security/limits.d/20-nproc.conf

Add or edit the following lines if they do not already exist:

*          soft    nproc    65536
*          soft    nofile   65536
*          hard    nproc    65536
*          hard    nofile   65536
root      soft    nproc    unlimited
```

## Tuning the file system

Administrators can tune ext3 and ext4 file systems by setting the file system flushes and noatime to improve server performance.

Newer ext4 systems use delayed allocation to improve performance. This delays block allocation until it writes data to disk. Delayed allocation improves performance and reduces fragmentation by using the actual file size to improve block allocation.

This feature might increase the risk of data loss in cases where a system loses power before all of the data has been written to disk. This can occur if a program is replacing the contents of a file without forcing a write to the disk with `fsync`. To reduce this risk, make sure the default `auto_da_alloc` option is enabled on ext4 file systems.

The following changes can be made in the `/etc/fstab` file.

### Setting the file system flushes

Improve Directory Server performance by reducing the span between file system flushes.

### About this task

By default, Linux servers running the ext3 file system flush the data to disk every five seconds.

### Steps

1. If the Directory Server is running on a Linux server using the ext3 file system, consider editing the mount options for that file system to include the following command.

```
commit=1
```

This variable changes the flush frequency from five seconds to one second.

2. You should also set the flush frequency in the `/etc/fstab` file.  
Changing the mount command alone does not survive across reboots.

### Setting `noatime` on `ext3` and `ext4` Systems

If your Linux server uses an `ext3` or `ext4` file system, set `noatime` to improve performance by turning off any `atime` updates during read access.

#### About this task

Additionally, set the flush frequency to the `/etc/fstab` file. Performing the change through the `mount` command alone does not survive across reboots.

#### Steps

- Run the `mount` command for the relevant system.

Choose from:

- `ext3` system:

```
# mount -t ext3 -o noatime /dev/fs1
```

- `ext4` system:

```
# mount -t ext4 -o noatime /dev/fs1
```

### Setting the maximum user processes

To address memory problems when running multiple servers, increase the default maximum user process limit.

#### About this task

Some Linux distributions, such as Redhat Enterprise Linux Server and CentOS 6.0 or later, set the default maximum number of user processes to 1024. This is considerably lower than the same parameter on older distributions. The default value of 1024 leads to some Java virtual machine memory errors when running multiple servers on a machine because each Linux thread counts as a user process.

At startup, the Directory Server and its tools automatically attempt to raise the maximum user processes limit to 16,383 if the value reported by `ulimit` is less than that. If, for any reason, the server is unable to automatically set the maximum processes limit to 16,383, it displays an error message.

There are several ways to set the maximum user process limit.

#### Steps

- Set the limit in `/etc/security/limits.conf`.

Replace the (\*) with the name of the user under which the software will run.

Example:

```
* soft nproc 65535
* hard nproc 65535
```

- Set the `NUM_USER_PROCESSES` environment variable to 16383.
- In the `config/num-user-processes` file, set the `NUM_USER_PROCESSES` to 16383.

### About editing OS-level environment variables

Certain environment variables might affect the Directory Server in unexpected ways. This is particularly true for environment variables that are used by the underlying operating system to control how it uses non-default libraries.

For this reason, the Directory Server explicitly overrides the values of key environment variables like `<PATH>`, `<LD_LIBRARY_PATH>`, and `<LD_PRELOAD>` to ensure that environment settings used to start the server do not inadvertently impact its behavior.

If you need to edit any of these environment variables, set the values of those variables by manually editing the `<set_environment_vars>` function of the `lib/_script-util.sh` script.

You must stop (`bin/stop-server`) and re-start (`bin/start-server`) the server for the change to take effect.

### Installing `sysstat` and `pstack` (Red Hat)

If you plan to run PingDirectory on a Red Hat Linux system, install a couple of packages, `sysstat` and `pstack`, that are disabled by default, but are useful for troubleshooting.

About this task

The troubleshooting tool `collect-support-data` uses the `iostat`, `mpstat`, and `pstack` utilities to collect monitoring, performance, and stack trace information on the server's processes.

Steps

- To install `sysstat` on your Red Hat system, run the following command.

```
$ sudo yum install sysstat gdb dstat -y
```

### Installing `dstat` (SUSE Linux)

`dstat` is a system monitoring tool that can help you troubleshoot PingDirectory servers on SUSE distributions.

About this task

The `collect-support-data` tool uses the `dstat` utility for system monitoring. `dstat` can be obtained from the OpenSUSE project website. The following process shows how to install the `dstat` utility on SUSE Enterprise Linux 11 SP2:

Steps

1. Sign on as the root user.
2. Add the appropriate repository using the `zypper` tool.
3. Install the `dstat` utility.

```
$ zypper install dstat
```

### Disabling file system swapping

Because file system swapping can interfere with PingDirectory, disable performance tuning tools like `tuned`.

About this task

Steps

1. Sign on as the root user.
2. Add the line `vm.swappiness = 0` to the file `/etc/sysctl.conf`.

3. Restart the system to apply the change.
4. Optional: If you need to tune performance after disabling file system swapping, do the following:
  - a. Clone the existing performance profile.
  - b. Run `tuned`.
  - c. Add the line `vm.swappiness = 0` to the file `/usr/lib/tuned/profile-name/tuned.conf`.
  - d. To select the updated profile, run `tuned-adm profile customized_profile`.
  - e. Restart the system to apply the changes.

### Omitting `vm.overcommit_memory`

An improperly configured value for the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file might cause the `setup` or `start-server` tool to fail.

#### About this task

For Linux systems, the `vm.overcommit_memory` property sets the kernel policy for memory allocations. The default value of 0 indicates that the kernel determines the amount of free memory to grant a `malloc` call from an application. If the property is set to a value other than zero, the operating system might grab too much memory, reducing the amount of available memory for the `setup` or `start-server` tools.

#### Steps

Omit the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file to ensure that enough memory is available for these tools.

### Managing system entropy

Linux uses entropy to calculate random data that is used by the system in cryptographic operations.

#### About this task

Some environments with low entropy might have intermittent performance issues with SSL-based communication. This is more typical on virtual machines but can occur in physical instances as well.

#### Steps

- Monitor the `kernel.random.entropy_avail` in `sysctl` value for best results.

### Setting file system event monitoring (`inotify`)

An event monitoring tool such as `inotify` can be configured for notifying processes about file system events, including file creation, deletion, and updates.

#### About this task

Linux limits the number of `inotify` watches a user can receive.

#### Steps

- To increase the limit, edit `etc/sysctl.conf` to add the following line.

```
fs.inotify.max_user_watches = 524288
```

- Run the following command.

```
$ sudo sysctl -w fs.inotify.max_user_watches=524288
```

## Tuning the I/O scheduler

Using the correct I/O scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load.

About this task

For file systems running on an SSD or in a virtualized environment, use the recommended `noop` scheduler. For all other systems, use the `deadline` scheduler.

The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

Steps

1. To determine which scheduler is configured on your system, run the following command.

```
$ cat /sys/block/<block-device>/queue/scheduler
```

2. To change the scheduler on a running system, run the following command.

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

3. To apply the change, restart the system.

## Running as a non-root user (Linux)

You have two options to run as a non-root user but still allow connections on a privileged port.

Use a load balancer or directory proxy server

Many environments can run the server on a non-privileged port but be hidden by a hardware load balancer or LDAP directory proxy server.

Use `netfilter`

Use the `netfilter` mechanism, exposed through the `iptables` command, to automatically redirect any requests from a privileged port to the unprivileged port on which the server is listening.

## Enabling the server to listen on privileged ports (Linux)

For your convenience, enable the server to listen on privileged ports while running as a non-root user.

About this task

Linux systems have a mechanism called capabilities that is used to grant specific commands the ability to do things that are normally only allowed for a root account:

- The `setcap` command assigns capabilities to an application.
- The `cap_net_bind_service` capability enables a service to bind a socket to privileged ports (port numbers less than 1024).

Steps

1. If Java is installed in `/ds/java` (and the Java command to run the server is `/ds/java/bin/java`), you can grant the `cap_net_bind_service` capability to the Java binary with the following command.

```
$ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
```

2. Create the file `/etc/ld.so.conf.d/libjli.conf` with the path to the directory that contains the `libjli.so` file.

The java binary needs an additional shared library (`libjli.so`) as part of the Java installation. Because this process imposes stricter limits on where the operating system looks for shared libraries

to load for commands that have capabilities assigned, it is also necessary to tell the operating system where to look for this library.

Example: For example, if the Java installation is in `/ds/java`, the contents of that file should be:

```
/ds/java/lib/amd64/jli
```

3. To apply the changes, run the following command.

```
$ sudo ldconfig -v
```

## Getting the installation packages

Obtain the latest `.zip` release bundle from Ping Identity and extract it to a folder of your choice to begin the installation process.

About this task

The release bundle contains the Directory Server code, tools, and package documentation.

Complete the following steps to unpack the build distribution.

Steps

1. Download the latest `.zip` distribution of the Directory Server software.
2. Extract the compressed `.zip` archive file to a directory of your choice.

Example:

```
$ unzip PingDirectory-<version>.zip
```

Result:

You can set up the Directory Server.

## Signing on to the Administrative Console

After the server is installed, access the Administrative Console, <https://<host>/console/login>, to verify the configuration and manage the server. The root user DN or the common name of a root user DN is required to log into the Administrative Console. For example, if the DN created when the server was installed is `cn=Directory Manager, directory manager` can be used to log into the Administrative Console.

If the Administrative Console needs to run in an external container, such as Tomcat, a separate package can be installed according to that container's documentation. Contact Ping Identity Customer Support for the package location and instructions.

### Note:

The session timeout for the console is 24 hours by default. When this duration is exceeded, all inactive users are logged off automatically.

To set a different timeout value, configure the `server.sessionTimeout` application parameter, which specifies the timeout duration in seconds. You can set the value as an init parameter either in the console or on the command line, as shown below.

- Console

Select **Web Application Extensions # Console** and then use the **Init Parameter** field.

- Command line

The following example uses a value of 1800 seconds (30 minutes).

```
dsconfig set-web-application-extension-prop --no-prompt \
--extension-name Console \
--add init-parameter:server.sessionTimeout=1800
```

For the change to take effect, restart the HTTP(S) Connection Handler or the server itself.

## Directory Server folder layout

After extracting the Directory Server distribution file, you see the following folders and command-line utilities.

### Layout of the Directory Server Folders

Directories/Files/Tools	Description
License.txt	Licensing agreement for the Directory Server.
README	README file that describes the steps to set up and start the Directory Server.
bak	Stores the physical backup files used with the <b>backup</b> command-line tool.
bat	Stores Windows-based command-line tools for the Directory Server.
bin	Stores UNIX/Linux-based command-line tools for the Directory Server.
classes	Stores any external classes for server extensions.
collector	Used by the server to make monitored statistics available to PingDataMetrics Server.
config	Stores the configuration files for the backends (admin, config) as well as the directories for messages, schema, tools, and updates .
db	Stores the Oracle Berkeley Java Edition database files for the Directory Server.
docs	Provides the product documentation.
import-tmp	Stores temporary imported items.
ldif	Stores any LDIF files that you might have created or imported.
legal-notice	Stores any legal notices for dependent software used with the Directory Server.
lib	Stores any scripts, jar, and library files needed for the server and its extensions.
locks	Stores any lock files in the backends.

Directories/Files/Tools	Description
logs	Stores log files for the Directory Server.
metrics	Stores the metrics that can be gathered for this server and surfaced in PingDataMetrics Server.
resource	Stores the MIB files for SNMP and can include ldif files, make-ldif templates, schema files, dsconfig batch files, and other items for configuring or managing the server.
revert-update	The <b>revert-update</b> tool for UNIX/Linux systems.
revert-update.bat	The <b>revert-update</b> tool for Windows systems.
setup	The <b>setup</b> tool for UNIX/Linux systems.
setup.bat	The <b>setup</b> tool for Windows systems.
scim-data-tmp	Used to create temporary files containing System for Cross-domain Identity Management (SCIM) request data.
uninstall	The <b>uninstall</b> tool for UNIX/Linux systems.
uninstall.bat	The <b>uninstall</b> tool for Windows systems.
update	The <b>update</b> tool for UNIX/Linux systems.
update.bat	The <b>update</b> tool for Windows systems.
Velocity	Stores any customized Velocity templates and other artifacts (CSS, Javascript, images), or Velocity applications hosted by the server.

## make-ldif template format

The `make-ldif` template demonstrates the use of all supported tags.

`make-ldif` template

### Note:

Because this file contains elements that are not defined in the schema, do not import it into a directory.

```
# Copyright 2012-2020 Ping Identity Corporation
# All Rights Reserved.
#
# This file provides a make-ldif template whose primary purpose is to
# demonstrate the use of all variations of all supported tags. It is not
# intended to result in an LDIF file that should be imported into a
# directory,
# since it includes elements that aren't defined in the schema.
# Nevertheless,
# this file may be useful to individuals looking to create their own
# make-ldif templates or to customize an existing template.
```

```

# Any global replacement tokens defined at the top of the template file will
# be replaced with their corresponding value later in the template anywhere
# the token name appears in square brackets.
define basedn=dc=example,dc=com

# A branch is a special kind of entry with a fixed, non-dynamically
# generated
# DN (although the DN may be based partially or entirely on a global
# replacement token). Some kinds of tags may be used in branch definitions
# (as
# indicated below through the "allowed-in-branch" attribute. Also, the
# "subordinateTemplate" element specifies the type and number of entries to
# create immediately below each branch.

# The template definitions come after the branch definitions, and define
# entries that will be dynamically generated, including their DNs. Entries
# generated from a template may be either created directly below a branch,
# or
# they may be created below other template-generated entries (i.e., a
# template
# may include a "subordinateTemplate" element indicating that one or more
# entries of a different type should appear below each of the initial
# template
# entries. In this template file, each template below will demonstrate the
# use of exactly one tag, and exactly one variation of that tag (so tags
# with
# multiple variations may be illustrated through multiple templates).

template: attribute-value-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: attribute value tag with name
syntax: open-curly-brace attribute-name close-curly-brace
example: {cn}
allowed-in-branch: true
description: This tag will be replaced with the first value of the indicated
attribute. The specified attribute must have already been assigned at
least one value earlier in the template.

template: attribute-value-tag-with-name-and-max-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: attribute value tag with name and max length
syntax: open-curly-brace attribute-name colon max-length close-curly-brace
example: {cn:5}
allowed-in-branch: true
description: This tag will be replaced with at most the specified number
of characters from the beginning of the first value of the indicated
attribute. The specified attribute must have already been assigned at
least one value earlier in the template.

template: dn-tag-full
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: dn tag with full dn
syntax: less-than "dn" greater-than
example: <dn>
allowed-in-branch: true
description: This tag will be replaced with the full DN of the entry
currently being generated. All RDN attributes must be assigned values
earlier in the template.

template: dn-tag-partial
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: dn tag with partial dn
syntax: less-than "dn" colon num-components greater-than
example: <dn:1>
allowed-in-branch: true
description: This tag will be replaced with at most the specified number of
components from the entry currently being generated, as counted from left

```

to right (e.g., a value of 1 will cause only the RDN to be used, a value of 2 will cause both the current entry's RDN and the parent entry's RDN to be used, etc.). All RDN attributes must be assigned values earlier in the template.

```
template: escaped-characters
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: An example of escaping special characters
syntax: backslash-character character-to-escape
example: \{ "this" : "is JSON" \}
allowed-in-branch: true
description: The following characters need to be escaped with a backslash in
  order to be taken literally by make-ldif: \{ \} \< \> \[ \]
```

```
template: file-tag-path
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: file tag with path
syntax: less-than "file" colon file-path greater-than
example: <file:cities>
allowed-in-branch: true
description: This tag will be replaced with a randomly-selected line from
  the specified file. The file may be specified using a full path, but if no
  path information is provided, then it will be assumed to be in the config/
  MakeLDIF directory below the server root.
```

```
template: file-tag-path-sequential
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: file tag with path and sequential
syntax: less-than "file" colon file-path colon "sequential" greater-than
example: <file:cities:sequential>
allowed-in-branch: true
description: Each subsequent use of this tag will be replaced with the next
  line from the specified file. Once all lines of the file have been used,
  then subsequent uses will start over from the beginning of the file.
```

```
template: first-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: first tag
syntax: less-than "first" greater-than
example: <first>
allowed-in-branch: false
description: This tag will be replaced with a first name value (taken
  from the first.names file). The algorithm that the make-ldif tool uses
  guarantees that the combination of the first and last name values will
  always be unique, no matter how many entries are generated (although it may
  need to append a number to the last name value in LDIF files with extremely
  large numbers of values).
```

```
template: guid-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: GUID tag
syntax: less-than "guid" greater-than
example: <guid>
allowed-in-branch: true
```

description: This tag will be replaced with a randomly-generated globally-unique identifier (GUID), also known as a universally-unique identifier (UUID).

```
template: ifabsent-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifabsent tag with name
syntax: less-than "ifabsent" colon attribute-name greater-than
example: <ifabsent:cn>This value will only appear if the resulting entry
  doesn't have a cn attribute.
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
  always be replaced with the empty string. However, it may cause any in
  which this tag is used to be completely suppressed from the resulting entry
  if the specified attribute already exists in the generated entry. This is
  primarily useful for attributes whose inclusion in generated entries is not
  guaranteed (e.g., randomly determined via the presence tag).
```

```
template: ifabsent-tag-with-name-and-value
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifabsent tag with name
syntax: less-than "ifabsent" colon attribute-name colon attribute-value
  greater-than
example: <ifabsent:cn:value>This value will only appear if the resulting
  entry doesn't have a cn attribute with a value of "value".
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
  always be replaced with the empty string. However, it may cause any in
  which this tag is used to be completely suppressed from the resulting entry
  if the specified attribute value already exists in the generated entry.
  This is primarily useful for attributes whose inclusion in generated
  entries is not guaranteed (e.g., randomly determined via the presence tag).
```

```
template: ifpresent-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifpresent tag with name
syntax: less-than "ifpresent" colon attribute-name greater-than
example: <ifpresent:cn>This value will only appear if the resulting entry
  includes a cn attribute.
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
  always be replaced with the empty string. However, it may cause any in
  which this tag is used to be completely suppressed from the resulting entry
  if the specified attribute is missing from the generated entry. This is
  primarily useful for attributes whose inclusion in generated entries is not
  guaranteed (e.g., randomly determined via the presence tag).
```

```
template: ifpresent-tag-with-name-and-value
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifpresent tag with name
syntax: less-than "ifpresent" colon attribute-name colon attribute-value
  greater-than
example: <ifpresent:cn:value>This value will only appear if the resulting
  entry includes a cn attribute with a value of "value".
allowed-in-branch: true
```

**description:** This tag is not intended to generate replacement text, and will always be replaced with the empty string. However, it may cause any in which this tag is used to be completely suppressed from the resulting entry if the specified attribute value is missing from the generated entry. This is primarily useful for attributes whose inclusion in generated entries is not guaranteed (e.g., randomly determined via the presence tag).

```
template: last-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: last tag
syntax: less-than "last" greater-than
example: <last>
allowed-in-branch: false
description: This tag will be replaced with a last name value (taken from the last.names file). The algorithm that the make-ldif tool uses guarantees that the combination of the first and last name values will always be unique, no matter how many entries are generated (although it may need to append a number to the last name value in LDIF files with extremely large numbers of values).
```

```
template: list-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: list tag
syntax: less-than "list" colon value1 colon value2 ... colon valueN greater-than
example: <list:first:second:third>
allowed-in-branch: true
description: This tag will be replaced with one of the values in the given list. The value will be selected at random, with each possibility having the same chance of being selected.
```

```
template: list-tag-with-weights
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: list tag with weights
syntax: less-than "list" colon value1 semicolon weight1 colon value2 semicolon weight2 ... colon valueN semicolon weightN greater-than
example: <list:first;50:second;30:third;20>
allowed-in-branch: true
description: This tag will be replaced with one of the values in the given list. The value will be selected at random, with the relative weight for each value used to determine its likelihood of being selected. The weight values do not need to add up to 100, but if they do add up to 100 then the weights will be treated as percentages.
```

```
template: local-value-line
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: local value definition line
syntax: local name=tags
local streetAddress=<random:numeric:5> <file:streets> Street
local locality=<file:cities>
local region=<file:states>
local postalCode=<random:numeric:5>
examplePostalAddressJSON: \{"formatted": "{streetAddress}, {locality}, {region}, {postalCode}, US", "streetAddress": "{streetAddress}", "locality": "{locality}", "region": "{region}", "postalCode": "{postalCode}"\}
allowed-in-branch: true
```

```

description: This line will define a local value that can be accessed using
  \{name\} just like attribute accesses. The local is evaluated strictly on
  each template entry creation.

template: multiple-tag-with-fixed-number-of-values
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: multiple tag with fixed number of values
syntax: less-than "multiple" colon num-values greater-than
example: <multiple:5><random:alpha:10>
allowed-in-branch: true
description: This tag will cause make-ldif to attempt to generate the
  specified number of different values for this attribute. Any line
  including this tag must have a value that includes some variable content so
  that all of the values will be different.

template: multiple-tag-with-range-of-values
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: multiple tag with range of values
syntax: less-than "multiple" colon min-values colon max-values greater-than
example: <multiple:1:5><random:alpha:10>
allowed-in-branch: true
description: This tag will cause make-ldif to attempt to generate a number
  of different values for this attribute, with the number of values to
  generate selected at random between the specified minimum and maximum
  bounds. Any line including this tag must have a value that includes some
  variable content so that all of the values will be different.

template: multiple-tag-with-number-of-values-determined-from-attribute
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: multiple tag with fixed number of values
syntax: less-than "multiple" colon open-curly-brace attribute-name close-
  curly-brace greater-than
random-integer: <random:numeric:1:5>
example: <multiple:{random-integer}><random:alpha:10>
allowed-in-branch: true
description: This tag will cause make-ldif to attempt to generate a number
  of different values for this attribute, with the number of values to
  generate determined from another attribute already defined in the entry
  (which may itself be dynamically-generated). Any line including this tag
  must have a value that includes some variable content so that all of the
  values will be different.

template: parentdn-tag
rdnAttr: cn
objectClass: top

objectClass: make-ldif-example
cn: random tag hex variable length
syntax: less-than "random" colon "hex" colon min-length colon max-length
       greater-than
example: <random:hex:5:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing a number
            of randomly-selected hexadecimal digits. The length of the string will be
            selected at random between the specified minimum and maximum length.

template: random-tag-base64-fixed-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag base64 fixed length
syntax: less-than "random" colon "base64" colon length greater-than
example: <random:base64:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing the
            specified number of randomly-selected characters from the base64 character
            set.

template: random-tag-base64-variable-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag base64 variable length
syntax: less-than "random" colon "base64" colon min-length colon max-length
       greater-than
example: <random:base64:5:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing a number of
            randomly-selected characters from the base64 character set. The length of
            the string will be selected at random between the specified minimum and
            maximum length.

template: random-tag-month
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag month

```

```

syntax: less-than "random" colon "month" greater-than
example: <random:month>
allowed-in-branch: true
description: This tag will be replaced with a string containing the name of
  a randomly-selected month of the year. The American English name of the
  month will be used, with the first letter capitalized.

template: random-tag-month-with-max-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag month with max length
syntax: less-than "random" colon "month" colon max-length greater-than
example: <random:month:3>
allowed-in-branch: true
description: This tag will be replaced with a string containing at most
  the specified number of characters from the beginning of the name of a
  randomly-selected month of the year. The American English name of the
  month will be used, with the first letter capitalized.

template: random-tag-telephone
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag telephone
syntax: less-than "random" colon "telephone" greater-than
example: <random:telephone>
allowed-in-branch: true
description: This tag will be replaced with a string containing a randomly-
  generated telephone number, using the international representation of a
  U.S. telephone number in the format "+1 xxx xxx xxxx" (in which each x
  represents a randomly-selected numeric digit).

template: random-tag-timestamp
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag timestamp
syntax: less-than "random" colon "timestamp" greater-than
example: <random:timestamp>
allowed-in-branch: true
description: This tag will be replaced with a string containing a
  generalized time representation of a randomly-selected time within the last
  ten years.

template: random-tag-timestamp-range
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag timestamp range
syntax: less-than "random" colon "timestamp" colon min-timestamp colon max-
  timestamp greater-than
example: <random:timestamp:20000101000000.000Z:20091231235959.999Z>
allowed-in-branch: true
description: This tag will be replaced with a string containing a
  generalized time representation of a randomly-selected time within the
  specified time range (in which the minimum and maximum values should also
  be specified using the generalized time format).

template: sequential-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: sequential tag

```

```

syntax: less-than "sequential" greater-than
example: <sequential>
allowed-in-branch: true
description: This tag will be replaced with a sequentially-incrementing
  value such that each subsequent entry will have a value that is greater
  than the one in the entry before it. The first value generated will be
  zero.

template: sequential-tag-with-starting-point
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: sequential tag with starting point
syntax: less-than "sequential" colon initial-value greater-than
example: <sequential:1>
allowed-in-branch: true
description: This tag will be replaced with a sequentially-incrementing
  value such that each subsequent entry will have a value that is greater
  than the one in the entry before it. The first value generated will be the
  specified initial value.

template: sequential-tag-with-starting-point-and-reset-below-new-parent
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: sequential tag with starting point and reset below new parent
syntax: less-than "sequential" colon initial-value colon "true" greater-than
example: <sequential:1:true>
allowed-in-branch: true
description: This tag will be replaced with a sequentially-incrementing
  value such that each subsequent entry will have a value that is greater
  than the one in the entry before it. The first value generated will be the
  specified initial value. If this template is used below multiple parents,
  then the counter will be reset to the initial value for the first entry
  below each new parent.

template: underscore-dn-tag-full
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: underscore dn tag with full dn
syntax: less-than "_dn" greater-than
example: <_dn>
allowed-in-branch: true
description: This tag will be replaced with the full DN of the entry
  currently being generated, except with commas replaced with underscores.
  All RDN attributes must be assigned values earlier in the template.

template: underscore-dn-tag-partial
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: underscore dn tag with partial dn
syntax: less-than "_dn" colon num-components greater-than
example: <_dn:1>
allowed-in-branch: true
description: This tag will be replaced with at most the specified number of
  componenets from the entry currently being generated, as counted from left
  to right (e.g., a value of 1 will cause only the RDN to be used, a value
  of 2 will cause both the current entry's RDN and the parent entry's RDN
  to be used, etc.), except with commas replaced with underscores. All RDN
  attributes must be assigned values earlier in the template.

template: underscore-parentdn-tag

```

```

rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: underscore-parentdn tag
syntax: less-than "_parentdn" greater-than
example: <_parentdn>
allowed-in-branch: false
description: This tag will be replaced with the full DN of the entry
            immediately superior to the entry being generated, except with commas
            replaced with underscores.

```

## Server installation modes

One of the strengths of the PingDirectory Server is the ease with which you can install a server instance using the `setup` tool. The `setup` tool allows you to quickly install and configure a stand-alone Directory Server instance.

To install a server instance, run the `setup` tool in one of the following modes: interactive command-line, or non-interactive command-line mode.

- **Interactive Command-Line Mode.** Interactive command-line mode prompts for information during the installation process. To run the installation in this mode, use the `setup --cli` command.
- **Non-Interactive Command-Line Mode.** Non-interactive command-line mode is designed for setup scripts to automate installations or for command-line usage. To run the installation in this mode, `setup` must be run with the `--no-prompt` option as well as the other arguments required to define the appropriate initial configuration.

All installation and configuration steps should be performed while logged on to the system as the user or role under which the Directory Server will run.

## Before you begin

After you have unzipped the Directory Server ZIP file, you may want to carry out the following functions depending on your deployment requirements:

- **Custom Schema Elements.** If your deployment uses custom schema elements in a custom schema file (for example, `98-schema.ldif`), you may do one of the following:
  - Copy your custom schema file to the `config/schema` directory before running `setup`.
  - Copy your custom schema file to the `config/schema` directory after `setup` and re-start the server. If replication is enabled, the restart will result in the schema replicating to other servers in the replication topology.
  - Use the **Schema Editor** after `setup`. If replication is enabled, schema definitions added through the **Schema Editor** will replicate to all servers in the replication topology without the need for a server restart.
- **Certificates.** If you are setting up a new machine instance, copy your keystore and truststore files to the `<server-root>/config` directory prior to running `setup`. The keystore and truststore passwords can be placed, in clear text, in corresponding `keystore.pin` and `truststore.pin` files in `<server-root>/config`.
- **Encryption Passphrase.** Encryption for directory data, backups, LDIF exports, and log files can be enabled during `setup` by providing or generating an encryption key with a passphrase.
- **Locations.** Location names are used to define a grouping of PingDirectory Server products based on physical proximity. For example, a location is most often associated with a single datacenter location. During the installation, assign a location to each server for optimal inter-server behavior. The location assigned to a server within Global Configuration can be referenced by components within the server as well as processes external to the server to satisfy "local" versus "remote" decisions used in replication, load balancing, and failover.
- **Validate AClS.** Many directory servers allow for less restrictive application of its access control instructions (AclS), so that they accept invalid AclS. For example, if a Sun/Oracle server encounters

an access control rule that it cannot parse, then it will simply ignore it without any warning, and the server may not offer the intended access protection. Rather than unexpectedly exposing sensitive data, PingDirectory Server rejects any ACIs that it cannot interpret, which ensures data access is properly limited as intended, but it can cause problems when migrating data with existing access control rules to a PingDirectory Server. If you are migrating from a Sun/Oracle deployment to a PingDirectory Server, PingDirectory Server provides a `validate-acis` tool in the `bin` directory (UNIX or Linux systems) or `bat` directory (Windows systems) that identifies any ACI syntax problems before migrating data. For more information, see [Validating ACIs Before Migrating Data](#).

### Important:

Each server deployment requires an execution of `setup`. Duplicating a server-root is not supported. The installation of the server doesn't write or require any data outside of the server-root directory.

After you run the `setup` tool, do not copy the server-root to another location or system to duplicate the installation because this isn't a supported method of deployment. If a host or file system change is needed, you can move the server-root to another host or disk location.

## Ping license keys

License keys are required to install, update, and renew all Ping products.

How to obtain a license

To obtain a license key, contact your account representative or use the [Ping Identity licensing portal](#).

When do you need a license

A license is required for setting up a new single server instance and can be used site-wide for all servers in an environment. Additionally, you must obtain a new license when updating a server to a new major version, such as when upgrading from 7.3 to 8.0. When cloning a server instance with a valid license, you do not need a new license.

### Note:

The update process displays a prompt for a new license.

How to specify a license

- Specify a license at setup

You have these options:

- Use the `--licenseKeyFile <path-to-license>` option with `setup`.
- Copy the license file to the server root directory and then run the `setup` tool. The tool discovers the license file.

- Specify a license after setup

Use the Administrative Console or `dsconfig` (in the Topology section, select License).

### Note:

Placing the new license file in the server root directory does not work in this case.

How to view the license status

To view the details of a license, including its expiration, you have these options:

- The server's `status` tool
- The Administrative Console's **Status** page (On the **Monitors** tab, search for License.)

### License expiration

The server provides a notification as the expiration date approaches.

Before a license expires, obtain a new one and install it by using `dsconfig` or the Administrative Console.

#### Note:

An expiring license causes alerts and alarms but does not affect the functionality of the product.

## Setting up the Directory Server in interactive mode

The `setup` tool also provides an interactive text-based command-line interface to set up a Directory Server instance.

### About this task

Complete the following steps to install the Directory Server in interactive mode.

### Steps

1. Extract the distribution `.zip` file, review [Before You Begin](#), and then go to the server root directory.

Example:

```
$ ./setup
```

If the `JAVA_HOME` environment variable is set to an older version of Java, explicitly specify the path to the Java Development Kit (JDK) installation during the setup process. Either set the `<JAVA_HOME>` environment variable with the JDK path or execute the `setup` command in a modified Java environment using the `env` command.

Example:

```
$ env JAVA_HOME=/ds/java ./setup
```

2. Read the Ping Identity End-User License Agreement, and type `yes` to continue.
3. Enter the fully qualified host name or IP address of the local host, or press Enter to accept the default.
4. Enter the distinguished name (DN) for the initial root user, or press Enter to accept the default (`cn=Directory Manager`).
5. Enter and confirm the root user password.
6. Press Enter to enable the Ping Identity services (Configuration, Consent, Delegated Admin, Documentation, and Directory REST API) and Administrative Console over HTTPS.

After setup, you can enable or disable individual services and applications by configuring the HTTPS Connection Handler.

7. Enter the port on which the Directory Server will accept connections from HTTPS clients, or press Enter to accept the default.
8. Enter the port on which the Directory Server will accept connections from LDAP clients, or press Enter to accept the default.
9. Enter `no` to use a standard LDAP connection, or accept the default (`yes`) to enable both LDAPS and StartTLS.

Enabling LDAPS configures the LDAPS Connection Handler to allow SSL over its client connections. Enabling StartTLS configures the LDAP Connection Handler to allow StartTLS.

10. Select the certificate option for this server:  
Choose from:
  - Generate a self-signed certificate for testing purposes only.
  - Enter the keystore path and keystore PIN to use an existing certificate using a Java Keystore, .
  - Enter the keystore path and the keystore PIN to use an existing certificate using use a PKCS#12 keystore.
  - Enter only the keystore PIN ro use the PKCS#11 token.
11. Choose the desired encryption for the directory data, backups, and log files from the choices provided:  
Choose from:
  - Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments. Use the same encryption passphrase when setting up each server in the topology.
  - Encrypt data with a key generated from a passphrase read from a file.
  - Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
  - Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
  - Do not encrypt server data.
12. Type the base DN for the data, or accept the default base DN of `dc=example,dc=com`.
13. To choose an option to generate and import sample data, type the desired number of entries, or press Enter to accept the default number (10000).  
  
This option is used for quick evaluation of the Directory Server. See [Initializing Data onto the Server](#) if you want to use other options to initialize the server.
14. Choose the option to tune the amount of memory that will be consumed by the Directory Server and its tools.
15. Press Enter to prime or preload the database cache at startup prior to accepting client connections.  
  
Priming the cache can increase the startup time for the Directory Server but provides optimum performance after startup has completed. This option is best used for strict throughput or response time performance requirements, or if other replicas in a replication topology can accept traffic while this Directory Server instance is starting. Priming the cache also helps determine the recommended JVM option, `CMSInitiatingOccupancyFraction`, when a Java garbage collection pause occurs. See [JVM Garbage Collection Using CMS](#).
16. Enter a location name for this server.
17. Enter a unique instance name for this server.  
  
You cannot change the name after you set it.
18. Press Enter to accept the default (yes) to start the Directory Server after the configuration has completed.  
  
To configure additional settings or import data, enter `no` to keep the server in shutdown mode.
19. Choose an option to continue server set up.
20. In the **Setup Summary** window, confirm the configuration. , or  
Choose from:
  - Press Enter to accept the default (set up with the parameters given), enter the option to repeat the installation process.
  - Enter the option to cancel the setup completely.

## Installing the Directory Server in non-interactive mode

Run the `setup` command in non-interactive mode to automate the installation process using a script or to run the command directly from the command line.

Non-interactive mode is useful when setting up production or QA servers with specific configuration requirements.

The non-interactive command-line mode requires that all mandatory options be present for each command call. If there are missing or incorrect arguments, the `setup` tool fails and aborts the process. You must also use a `--no-prompt` option to suppress interactive output, except for errors, when running in non-interactive mode. Additionally, you must also use the `--acceptLicense` option and specify the port using the `--ldapPort` or `--ldapsPort` option. If neither option is specified, an error message is displayed. To view the license, run the `bin/review-license` command.

To automatically tune the Java virtual machine (JVM) to use maximum memory, use the `--aggressiveJVMtuning` and `--maxHeapSize {memory}` options. To preload the database at startup, use the `--primeDB` option.

To configure a deployment using a truststore, see [Installing the Directory Server in Non-Interactive Mode with a Truststore](#).

To see a description of the available command-line options for the `setup` tool, use `setup --help`.

### Installing the Directory Server in non-interactive mode

Install a Directory Server in a production or QA environment with no security enabled.

#### Steps

- Extract the distribution `.zip` file, review “Before You Begin”, and then use `setup` with the `--cli` and `--no-prompt` options for non-interactive mode from the `<server-root>` directory.

The following command uses the default root user distinguished name (DN) (`cn=Directory Manager`) with the specified `--rootUserPassword` option. You must include the `--acceptLicense` option or the setup generates an error message. The `--instancename` option specifies the name for the server instance and should be unique across all instances in the topology. The `--location` option specifies the name of the location in which the instance will be installed. You should generally configure your topology with a separate location for each data center to allow inter-server communication to prioritize servers in the same location over those in remote locations.

Example:

```
$ ./setup --cli --no-prompt --rootUserPassword "password" \
  --baseDN "dc=example,dc=com" --acceptLicense --ldapPort 389 \
  --instancename Instance1 --location Location1
```

### Installing the Directory Server in non-interactive mode with a truststore

#### About this task

You can set up the Directory Server using an existing truststore for secure communication. This section assumes that you have an existing keystore and truststore with trusted certificates.

#### Steps

- Unzip the distribution ZIP file, review [Before You Begin](#), and then, from the server root directory, use `setup` with the `--cli` and `--no-prompt` options for non-interactive mode. The following example enables security using both SSL and StartTLS. It also specifies a JKS keystore and truststore that

define the server certificate and trusted CA. The `userRoot` database contents will remain empty and the base DN entry will not be created.

Example:

```
$ ./setup --cli --no-prompt --rootUserPassword "password" \
--baseDN "dc=example,dc=com" --ldapPort 389 --enableStartTLS \
--ldapsPort 636 --useJavaKeystore config/keystore.jks \
--keyStorePasswordFile config/keystore.pin \
--certNickName server-cert --useJavaTrustStore config/truststore.jks \
--acceptLicense --instancename Instance1 --location Location1
```

The password to the private key with the keystore is expected to be the same as the password to the keystore. If this is not the case, the private key password can be defined with the Administrative Console or the `dsconfig` tool by editing the Trust Manager Provider standard configuration object.

## Installing a lightweight server

Users who want to demo or test a lightweight version of the Directory Server on a memory-restricted machine can do so by removing all unused or unneeded configuration objects.

All configuration entries, whether enabled or not, take up some amount of memory to hold the definition and listeners that are notified of changes to those objects.

The configuration framework does not allow you to remove objects that are referenced, and in some cases if you have one configuration object referencing another but really do not need it, then you must first remove the reference to it. If you try to remove a configuration object that is referenced, both `dsconfig` and the administrative console should prevent you from removing it and tell you what still references it.

Depending on your test configuration, some example configuration changes that can be made are as follows:

### Reduce the number of worker threads

Each thread has a stack associated with it, and that consumes memory. If you're running a bare-bones server, then you probably do not have enough load to require a lot of worker threads.

```
$ bin/dsconfig set-work-queue-prop \
--set num-worker-threads:8 \
--set num-administrative-session-worker-threads:4 \
--set max-work-queue-capacity:100
```

### Reduce the percentage of JVM memory used for the JE database cache

When you have a memory-constrained environment, you want to ensure that as much of the memory that is there is available for use during processing and not tied up caching database contents.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set db-cache-
percent:5
```

### Disable the Dictionary Password Validator

The Dictionary Password Validator takes a lot of memory to hold its dictionary. Disabling it frees up some memory. You can delete the other password validators if not needed, such as Attribute Value, Character Set, Length-based, Repeated Characters, Similarity-based, or Unique Characters Password Validator.

```
$ bin/dsconfig delete-password-validator --validator-name Dictionary
```

### Remove non-essential schema files

Although not recommended for production deployments, some candidates that you can remove are the following: `03-rfc2713.ldif`, `03-rfc2714.ldif`, `03-rfc2739.ldif`, `03-rfc2926.ldif`, `03-rfc2985.ldif`, `03-rfc3712.ldif`, `03-uddiv3.ldif`.

There are other items that can be removed, depending on your desired configuration. Contact your authorized support provider for assistance.

## Uninstalling the Server

---

The Directory Server provides an `uninstall` command-line utility for quick removal of the code base.

To uninstall a server instance, run the `setup` tool in interactive command-line, or non-interactive command-line mode.

### Interactive command-line mode

Interactive command-line mode is a text-based interface that prompts the user for input. To run this mode, use the `bin/uninstall` command with the `--cli` option.

### Non-interactive command-line mode

Non-interactive command-line mode suppresses progress information from being written to standard output during processing, except for fatal errors. To run this mode, use the `bin/uninstall` command with the `--no-prompt` option.

### Note:

For standalone installations with a single Directory Server instance, you can also manually remove the Directory Server by stopping the server and recursively deleting the directory and subdirectories, as in the following example.

```
$ rm -rf /ds/PingDirectory
```

## Uninstalling the server in interactive mode

Interactive mode uses a text-based, command-line interface to help you remove your instance.

### About this task

If `uninstall` cannot remove all of the Directory Server files, the `uninstall` tool generates a message with a list of the files and directories that must be manually deleted. The `uninstall` command must be run as either the root user or the same user (or role) that installed the Directory Server.

### Steps

1. From the server root directory, run the `uninstall` command.

Example:

```
$ ./uninstall --cli
```

2. Select the components to be removed.

Choose from:

- Remove all components - If you want to remove all components, press **Enter** to accept the default (remove all).
- Select the components to be removed - If you do not want to remove all components, enter the option to specify the removal of only specific components.

For each type of server component, press **Enter** to remove it or enter `no` to keep it.

3. If the Directory Server is part of a replication topology, enter `yes` to provide your authentication credentials (Global Administrator ID and password). If you are uninstalling a standalone server, continue to step 7.
4. Enter the Global Administrator ID and password to remove the references to this server in other replicated servers, and then enter or verify the host name or IP address for the server that you are uninstalling.
5. Select how you want to trust the server certificate if you have set up SSL or StartTLS. Press **Enter** to accept the default.

Example:

```
How do you want to trust the server certificate for the Directory Server
on server.example.com:389?

1) Automatically trust
2) Use a trust store
3) Manually validate

Enter choice [3]:
```

6. View the logs for any remaining files and manually remove any remaining files or directories.

If your Directory Server is running, the server shuts down before continuing the uninstall process. The uninstall action processes the removal requests before completing.

## Uninstalling the server in non-interactive mode

The `uninstall` utility provides a non-interactive method to enter the command with the `--no-prompt` option.

### About this task

Another useful argument is the `--forceOnError` option that continues the uninstall process when an error is encountered. If an option is incorrectly entered or if a required option is omitted and the `--forceOnError` option is not used, the command fails and aborts.

### Steps

1. From the server root directory, run `uninstall` tool with the `--remove-all` option to remove all of the Directory Server's libraries.

The optional `--quiet` option suppresses output information.

Example:

The following command assumes that the Directory Server is standalone and not part of a replication topology.

```
$ ./uninstall --cli --remove-all --no-prompt --quiet --forceOnError
```

2. If any files or directories remain, manually remove them.

## Uninstalling selected components in non-interactive mode

### Steps

1. From the server root directory, run `uninstall` with the `--backup-files` option to remove the Directory Server's backup files.

Example:

```
$ ./uninstall --cli --backup-files --no-prompt --quiet --forceOnError
```

2. To view the other options available to remove specific components, use the `--help` or `-H` option.

## Upgrading the Server

---

This section presents multiple update scenarios and their implications to consider when upgrading your server code.

Ping Identity issues software release builds periodically with new features, enhancements, and fixes for improved server performance. Use the Directory Server's update utility to upgrade the current server code version.

### Upgrade overview and considerations

The following content provides a brief description of the upgrade process and considerations that might affect your upgrade decisions.

#### Overview

For the upgrade process, you must download and extract a new version of the Directory Server `.zip` file on the server that will be updated. In addition, you must run the `update` utility with the `--serverRoot` or `-R` option value from the new root server pointing to the installation that will be upgraded.

#### Considerations

Consider the following when planning for and upgrading replicating servers:

- The upgrading process affects only the server being upgraded. The process does not alter the configuration of other servers.
- The `update` tool verifies that the Java version installed meets the new server requirements. Before running the tool, install the Java version that is supported by the new server.
- For precautionary measures, backup the user data `userRoot` before an upgrade. Restoring from a backup might be necessary if all other servers in the replication topology have been upgraded and a database or encoding change in the new server version prevents the database from being used with the older server version. The `update` and `revert-update` utilities issue a warning when this is the case.
- Temporarily raise the replication purge delay for all servers in the topology to cover the expected downtime for maintenance. This results in a temporary increase in disk usage for the replicationChanges database stored in `<server-root>/changelogDb`.
- Replication does not need to be disabled on a server before an upgrade.
- Make sure upgraded servers are working as expected before upgrading the last server in the topology.
- After all replicating servers are upgraded, enable new features.

#### Tip:

For additional considerations, see the [Planning your upgrade guide](#).

## Considerations when upgrading to 8.3.0.0

### Important:

If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

RFC 8996 has just been released, which officially deprecates the TLSv1 and TLSv.1.1 protocols and explicitly states that these MUST NOT be used. Per this specification, only TLSv1.2 and TLSv1.3 are considered acceptable for use. Therefore, for this release, TLSv1 and TLSv.1.1 are disabled by default. Disabling support for TLSv1 and TLSv.1.1 does not prevent these protocols from being used, it only disables them by default. Support for these legacy protocols can be re-enabled in the configuration if necessary. Also, support for TLS cipher suites that use the SHA-1 message digest is being deprecated, as SHA-1 is no longer considered secure. We are also deprecating support for TLS cipher suites that use RSA key exchange because these do not provide forward secrecy.

Changes to entries made by the clients using the SCIMv2 API will now have the actual user ID, making the request stored in the access and audit logs. By default, the server will continue to use the "SCIM2 Servlet" user as the authorization identity for all SCIM2 requests, and the DN of this user will be recorded in the access log and in the `creatorsName` and `modifiersName` attributes. If you want to change this behavior, change the value of the `map-access-tokens-to-local-users` property from `disabled` to either `optional` or `required`. This will cause the server to map the token to a local user, and if the mapping is successful, the mapped user's DN will be used as the authorization identity for the operations.

## Upgrading servers in a topology

An update to the current PingDirectory Server release includes the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts.

Before you begin

Before you can update and migrate the admin backend, the following conditions must be satisfied:

- Run the update tool and provide LDAP authentication options to the peer servers of the server being updated. The `update` tool connects to the peer servers of the server being updated to obtain the necessary information to populate the topology registry.
- On every server in the topology, configure the encryption protocol requested, either plain, TLS, StartTLS, or SASL, for an LDAP connection.
- Ensure the LDAP credentials are present on every server in the topology.
- Ensure the users related to the LDAP credentials have permissions to read from the admin backend and the config backend of every server in the topology. For example, you can use a root DN user that has `inherit-default-privileges` set to true, such as the `cn=Directory Manager` user, that exists on every server.
- The instance name is set on every server and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been

updated, each server is uniquely identified by its instance name. After the name is set, it cannot be changed.

**Tip:**

If needed, use the following command to set the instance name of a server prior to the update.

```
$ bin/dsconfig set-global-configuration-prop \
  --set instance-name:uniqueName
```

**Important:**

This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than a 7.x to a 7.x version and is not applicable to any updates to a server version of 8.x or later.

About this task

Upgrade to a server that uses a topology registry to store network configuration, administrator user accounts, and keys information, as well as migrate the information from the previous server version. The following requirements must be met:

- When the first server is being updated, all other servers in the topology are online.
- When updating additional servers, all topology information was obtained from one of the servers that has already been updated.
- The users related to the provided LDAP credentials have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server and is unique across all servers in the topology.

Steps

1. To make clustered configuration changes in a mixed-version cluster, choose one of the following options:

Choose from:

- Update each server to the same version.
- Temporarily split up the cluster by changing the `cluster-name` property on the server instance configuration objects.

**Note:**

Changes to clustered configurations are not allowed in mixed-version clusters. This applies to configuration in the `cn=Cluster, cn=config` subtree and only applies to servers with matching cluster names.

2. Make clustered configuration changes again to mirror these changes across the topology.

Result:

When all of these conditions are met, the cluster-wide configuration is synchronized on all servers in the topology.

**Note:**

Older versions have some topology configuration under the `cn=cluster, cn=config` JSON attribute and field constraints. These items do not support mirrored cluster-wide configuration data. In an

update, avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree master. If additional configuration steps are needed, see step 4.

3. To synchronize the cluster-wide configuration data across all servers in the topology, run the **config-diff** tool on each pair of servers to determine the differences, and use **dsconfig** to update each instance using the **config-diff** output.

Example:

```
$ bin/config-diff --sourceHost hostName \  
  --sourcePort port \  
  --sourceBindDN bindDN \  
  --sourceBindPassword password \  
  --targetHost hostName \  
  --targetPort port \  
  --targetBindDN bindDN \  
  --targetBindPassword password
```

### Restoring a mixed topology to a clean state

Perform the following steps to restore a mixed-version 6.2 - 7.x topology with replication problems to a clean state with all servers at the same level and with replication functioning normally.

About this task

#### Note:

This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than 7.x to a 7.x version and is not applicable to any updates to server version 8.x or later.

If you are upgrading a Directory Server version prior to 7.3 to 7.3 or later and at least one server was previously removed from the topology, you might receive an error message similar to one of the following:

```
[09/Dec/2019:18:37:56.927 -0700] instanceName="[INSTANCE_NAME]" \  
  threadID=438 category=REPLICATION severity=NOTICE msgID=118947975 \  
  msg="The \  
  replication total backlog count is 163364"
```

Or:

```
[09/Dec/2019:17:15:10.108 -0700] category=REPLICATION \  
  severity=SEVERE_ERROR msgID=14942295 msg="While clearing the database 997 \  
 \  
  o=mycompany, the following error happened: (JE 7.5.12) Attempted to \  
  remove \  
  non-existent database 997 o=mycompany DatabaseNotFoundException: (JE \  
  7.5.12) \  
  Attempted to remove non-existent database 997 o=pingone (DbTree.java:922 \  
 \  
  DbTree.java:1183 DbTree.java:1235 Environment.java:1001 \  
  Environment.java:1221 \  
  Environment.java:1204 Environment.java:1009 ReplicationDbEnv.java:1186 \  
  DomainDbEnv.java:995 ReplicationDB.java:1002 DbHandler.java:1324 \  
  DbHandler.java:1064 \  
  DbHandler.java:1042 DbHandler.java:798 DbHandler.java:723 \  
  DirectoryThread.java:352 \  
  (7.3.0.4-20191127203417.000Z-83a75e2a) "
```

### Steps

1. To export a safe copy of the data, run `bin/export-ldif` on the primary server.
2. Start the down-level primary server and stop the upgraded replica server.
3. Run `bin/remove-defunct-server` on the upgraded replica server and do the following when prompted:
  - a. Select the replica server itself.
  - b. Supply the credentials for the primary server when prompted.
  - c. Select **[c]** to continue.
  - d. Enter the path to the local `changelogDB` when prompted.
4. Leave the upgraded replica server stopped and stop the down-level primary server.
5. Run `bin/dsreplication` on the primary server and do the following:
  - a. Select **2) Manage the topology (add and remove servers)**.
  - b. Select **4) Cleanup Server**.
  - c. Select **[c]** to continue.
  - d. Enter the path to the local `changelogDB` when prompted.
6. Start the down-level primary server and the upgraded replica server.
7. Run `bin/status` on both servers and verify that status of **Replication: disabled** in **Data Sources**.
8. Upgrade the replica server to version 7.3.0.5 or later, which contains fixes for issues 00668265 and DS-40955.
9. Upgrade the primary server to the same level as the replica server.
10. To re-enable replication between the primary and replica server, run the `bin/dsreplication` tool.
11. Re-initialize the replica server data from the primary server.
12. Run `bin/status` on both servers to verify that replication is enabled in **Data Sources** and that both servers show the same number of entries.

## Upgrading the Directory Server

Perform an upgrade to the Directory Server with the following steps.

### Steps

1. Download and extract the new version of the Directory Server in a location outside the existing server's installation.  
 For these steps, assume the existing server installation is located in `/prod/PingDirectory` and the new server version is extracted in the `/home/stage/PingDirectory` location.
2. Run the `update` tool provided with the new server package to update the existing Directory Server.

#### Note:

The update tool might prompt for confirmation of the server configuration changes if it detects customization and display the following code.

```
$ /home/staging/PingDirectory/update --serverRoot /prod/PingDirectory
```

## Reverting an update

After PingDirectory Server has been updated, you can revert to the last version or one level back using the **revert-update** tool.

### About this task

The **revert-update** tool accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the **revert-update** tool multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing PingDirectory Server, you can run the **revert-update** command to revert to its previous state, then run the **revert-update** command again to return to its original state. The following steps detail reverting from 7.x to a version prior to 7.0.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server displays warnings about "offline configuration changes," but they are not critical and do not appear on subsequent start ups.

To revert to the most recent server version:

### Steps

- Use **revert-update** in the server root directory to revert back to the most recent version of the server.

Example:

```
$ PingDirectory-old/revert-update
```

### Next steps

Reverting from the 7.0 version or later to a version earlier than 7.0 using the **revert-update** command might require extra steps. This is also the case when updating or reverting from a version earlier than 6.2.0.2 to a 6.2.0.2 version or later. These steps are listed when the **update** and **revert-update** tool are run as well. Depending on your installation and configuration, you might need to perform one or more of the following tasks:

- When updating or reverting from 6.2.0.2 or later to a version earlier than 6.2.0.2, indexes might need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and rebuild the indexes using the **rebuild-index** tool. The command for recreating an index is in the **Undo** portion of the `logs/config-audit.log` file. To later revert to an older version, delete and recreate those composite indexes again after the revert process completes.
- When updating to 7.x for the first time, instance names must be set for each server in the topology if they were not previously set. This is done with the following **dsconfig** command.

```
$ bin/dsconfig --bindDN "cn=Directory Manager" \
--bindPassword secret \
--no-prompt set-global-configuration-prop \
--set instance-name:<name>
```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the **admin** backend. As long as new servers are not added to the topology after this update, you can use the **revert-update** command to return to the previous version. However, if new servers are added, then the restored **admin** backend of this server does not contain information about the new servers, and the local server cannot communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.

- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a version earlier than 7.x, any servers in the topology using the topology portion of the configuration rather than the `admin` backend must know that the reverted server was downgraded to the `admin` backend. To do this, run the following `dsconfig` command on one of the servers that has not been reverted.

```
$ bin/dsconfig set-server-instance-prop \
  --instance-name <Reverted server instance name> \
  --set server-version:<Version to which server is reverted>
```

- If the topology does not have a master server when this command is run, the `revert-update` will not succeed. In this case, you must make one of the remaining updated servers in the topology the master with the following command. This enables the chosen instance to run the `revert-update` command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
  --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions, such as 6.x or earlier. To later revert to an older version, you must export the data to LDIF before performing the reversion. Then, re-import the data after the revert process completes. In addition, you must delete the `changelogDb/` and `db/changelog/` directories in the reverted server root after the revert process completes.

## Getting Started with Directory Server

After you have set up your Directory Server instance, you can configure any specific server settings, import your user database, or run initial performance tests to optimize your server's throughput.

### Note:

The URL is based on the host name and HTTPS port specified during installation, such as `https://hostname.com:443/console`.

### Apply Server Configurations

Apply your server configuration changes individually or using a `dsconfig` batch file. The batch file defines the Directory Server configuration tool, `dsconfig`, commands necessary to configure your server instance. For more information on using batch files, see [Using dsconfig in Batch Mode](#).

If you are migrating from a Sun Java System 5.x, 6.x, 7.x directory server, you can use the `bin/migrate-sun-ds-config` command to migrate your configuration settings to this new server instance.

### Import Data

Import user data using the `import-ldif` tool. The import serves as an initial test of the schema settings.

```
$ bin/import-ldif --backendID userRoot --ldifFile ../user-data.ldif
```

### Install and Configure the Delegated Admin Application

Install a Javascript-based web application for business users to manage identities stored in the Directory Server. The application provides delegated administration of identities for help desk or customer service representatives initiating a password reset and unlock, an employee in HR

updating an address stored within another employee profile, or an application administrator updating identity attributes or group membership to allow application single sign-on (SSO) access.

### Run Performance Tests

The Directory Server provides two tools for functional performance testing using in-house LDAP clients that access the server directly: **searchrate** to test search performance and **modrate** to test modification performance.

```
$ bin/searchrate --baseDN "dc=example,dc=com" --scope sub \
  --filter "(uid=user.[0-1999])" --attribute givenName --attribute sn
  \
  --attribute mail --numThreads 10

$ bin/modrate --entryDN "uid=user.[0-1999],ou=People,dc=example,dc=com"
  \
  --attribute description --valueLength 12 --numThreads 10
```

## Multiple backends

You can create multiple local database backends, each containing one or more different base distinguished names (DNs).

There should be at most one replicating domain on each local database backend. The replication domain should not span multiple local database backends.

The typical entry-balancing configuration involves two local database backends:

- One backend serves the global domain data that resides above the entry-balancing point.
- One backend is defined with the entry-balancing point as the base DN, such as `ou=people,dc=example,dc=com`.

With multiple local database backends configured, you can manage the data existing with each backend independently. Separate index settings are applied to each local database backend.

When creating multiple database backends, consider the following:

- No two backends can have the same base DN.
- If any base DN for a given backend is subordinate to a base DN on another backend, then all base DN on that backend must be subordinate to the base DN of the other backend.
- The total of all **db-cache-percent** values should be no more than 65-70% in most cases and should never exceed 100%.

## Importing data

After installing the database, such as `userRoot`, import data into the database.

### Steps

- To add a server to a replicating set:
  - a. Perform a **dsreplication enable** operation.
  - b. Import the database through the **dsreplication initialize** operation.
- To add a server to a non-replicating set or to add the first server of a future replicating set, import the data with the `bin/import-ldif` tool.

For more information about the `bin/import-ldif` tool, see [Importing and exporting data](#) on page 571.

## Generating sample data

PingDirectory Server provides LDIF templates to generate sample entries for initializing your server. You can generate the sample data with the `make-ldif` utility together with template files that come bundled with the `.zip` build, or you can use template files that you create yourself.

### About this task

The templates create sequential entries for testing PingDirectory Server with a range of dataset sizes. The Directory Server templates are located in the `config/MakeLDIF`.

The sample data templates generate a dataset with basic access control privileges that grants anonymous read access to anyone, grants users the ability to modify their own accounts, and grants the admin account full privileges. The templates also include the `uid=admin` and `ou=People` entries.

### Steps

- To generate randomized sample data, use the `--randomSeed` option with the `make-ldif` command.

Example:

```
$ bin/make-ldif --templateFile config/MakeLDIF/example-10k.template \
  --ldifFile /path/to/data.ldif --randomSeed 0
```

#### Note:

If the `--randomSeed` option is used with the same seed value, the template always generates the same `.ldif` file.

Result: The command generates 10,000 sample entries and writes them to an output file, `data.ldif`. The random seed generator is set to 0.

- To bypass the `make-ldif` command, use the `--templateFile` option with the `import-ldif` tool.

## Importing data on the Directory Server using offline import

### Steps

- Create a `.ldif` file that contains entries or locate an existing file.  
The `import-ldif` tool requires a `.ldif` file, which conforms to standard LDIF syntax without change records. The `changeType` attribute is not allowed in the input LDIF. For information on adding entries to , see [Managing Entries](#).
- Stop the Directory Server.
- To import data from an LDIF file to the Directory Server, use the `import-ldif` command.

#### Tip:

For assistance with the list of options, run `import-ldif --help`.

In the following example, the data is imported from the `data.ldif` file to the `userRoot` backend. Entries rejected due to schema violation are written with the rejection reason to the `rejects.ldif` file. Skipped entries, written to `skipped.ldif`, occur if an entry cannot be placed under a branch node in the directory information tree (DIT) or if exclusion filters, such as `--excludeBranch`, `--excludeAttribute`, or `--excludeFilter` are used. The `--overwrite` option instructs `import-ldif` to overwrite existing skipped and rejected files. The `--overwriteExistingEntries` option indicates that any existing data in the backend should be overwritten, and the `--`

`stripTrailingSpaces` option strips trailing spaces on attributes that would otherwise result in an LDIF parsing error.

Example:

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif --
rejectFile
  rejects.ldif --skipFile skipped.ldif --overwrite --
overwriteExistingEntries --stripTrailingSpaces
```

4. Restart the Directory Server.

## Running the server

Run the server as a background or foreground process.

Steps

1. To start the Directory Server, run the `bin/start-server` command on UNIX or Linux systems.

An analogous command is in the `bat` folder on Microsoft Windows systems.

### Note:

The `bin/start-server` command starts the Directory Server as a background process when no options are specified.

2. Optional: To run the Directory Server as a foreground process, use the `bin/start-server` command with the `--nodetach` option.

## Starting the Directory Server

Start the directory server using the terminal.

Steps

- To start the server, on the terminal run `bin/start-server`.

Example:

```
$ bin/start-server
```

## Running the server as a foreground process

Use the terminal to run the PingDirectory service as a foreground process.

Steps

1. To launch the Directory Server as a foreground process, open the terminal and enter `bin/start-server` with the `--nodetach` option.

Example:

```
$ bin/start-server --nodetach
```

2. To stop the Directory Server:

Choose from:

- Press **CTRL+C** in the terminal window where the server is running.
- Run the `bin/stop-server` command from another terminal window.

## Starting the server at boot time

By default, PingDirectory Server does not start automatically when the system is booted. Instead, you must manually start it with the `bin/start-server` command.

### About this task

To configure the Directory Server to start automatically when the system boots, use the `create-systemd-script` utility to create a script, or create the script manually.

### Steps

1. Create the service unit configuration file in a temporary location, where "ds" is the user running PingDirectory.

Example:

```
$ bin/create-systemd-script \
  --outputFile /tmp/ping-directory.service \
  --userName ds
```

2. As a root user, copy the `ping-directory.service` configuration file into the `/etc/systemd/system` directory.
3. To read the new configuration file, reload `systemd`.

Example:

```
$ systemctl daemon-reload
```

4. To start the PingDirectory, run the `start` command.

Example:

```
$ systemctl start ping-directory.service
```

5. To configure the PingDirectory to start automatically when the system boots, run the `enable` command.

Example:

```
$ systemctl enable ping-directory.service
```

6. Log out as root.

To perform this task on an RC system, create the startup script with `bin/create-rc-script` and move it to the `/etc/init.d` directory.

#### Note:

Create symlinks to this script from the `/etc/rc3.d` directory (starting with an "S" to ensure that the server is started) and `/etc/rc0.d` directory (starting with a "K" to ensure that the server is stopped).

## Signing on to the Administrative Console

After the server is installed, access the administrative console, `https://hostname:HTTPport/console/login`, to verify the configuration and manage the server.

To sign on to the administrative console, use the initial root user DN specified during setup (by default `cn=Directory Manager`).

You can use the `dsconfig` command or the administrative console to create additional root DN users in `cn=Root DNs`, `cn=config`. These new users require the fully qualified DN as the username, such as `cn=new-admin`, `cn=Root DNs`, `cn=config`. To use a simple username (without the `cn=` prefix) for

signing on to the administrative console, the root DN user must have the `alternate-bind-dn` attribute configured with an alternate name, such as "admin."

The default link to the administrative console is `https://hostname:HTTPport/console/login`.

If you need to run the administrative console in an external container, such as Tomcat, you can install a separate package (`/server-root/resource/admin-console.zip`) according to that container's documentation.

#### Note:

The default session timeout for the console is 24 hours. When this duration is exceeded, all inactive users are signed off automatically.

To set a different timeout value, configure the `server.sessionTimeout` application parameter, which specifies the timeout duration in seconds. You can set the value as an init parameter either in the console or on the command line, as shown below.

For changes to take effect, restart the HTTP(S) Connection Handler or the server.

#### Console

1. Go to **Web Application Extensions # Console**.
2. Use the **Init Parameter** field.

#### Command line

- The following example uses a value of 1800 seconds (30 minutes).

```
dsconfig set-web-application-extension-prop --no-prompt \
--extension-name Console \
--add init-parameter:server.sessionTimeout=1800
```

## Stopping the Directory Server

The Directory Server provides a simple shutdown script, `bin/stop-server`, to stop the server. Run it manually from the command line or within a script.

#### About this task

If the Directory Server has been configured to use a large amount of memory, then it might take several seconds for the operating system to fully release the memory and make it available again. If you try to start the server too quickly after shutting it down, then the server might fail because the system does not yet have enough free memory. On UNIX systems, run the `vmstat` command and watch the values in the "free" column increase until all memory held by the Directory Server is released back to the system.

You can also set a configuration option that specifies the maximum shutdown time a process might take.

#### Steps

- Use the `bin/stop-server` tool to shut down the server.

Example:

```
$ bin/stop-server
```

## Scheduling a server shutdown

Schedule a server shutdown.

### Steps

- To schedule a server shutdown, use the `bin/stop-server` tool with the `--stopTime` `YYYYMMDDhhmmss` option .

The Directory Server schedules the shutdown and sends a notification to the `server.out` log file. The following example sets up a shutdown task that is scheduled to be processed on June 6, 2012 at 8:45 A.M. CDT. The server uses the UTC time format if the provided timestamp includes a trailing "Z", for example, 20120606134500Z. The command also uses the `--stopReason` option that writes the reason for the shut down to the logs.

Example:

```
$ bin/stop-server --stopTime 20120606134500Z --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --stopReason "Scheduled offline maintenance"
```

## Restarting the server

Restart the Directory Server.

### About this task

Running the command is equivalent to shutting down the server, exiting the Java Virtual Machine (JVM) session, and then starting up again.

### Steps

- Go to the server root directory, and run the `bin/stop-server` command with the `-R` or `--restart` options.

Example:

```
$ bin/stop-server --restart
```

## Running the server as a Microsoft Windows service

The server can run as a Windows service on Windows Server 2012 R2 and Windows Server 2016. This enables signing-out of a machine without stopping the server.

### Registering the server as a Windows service

Register the server as a Windows service using the Windows command prompt.

### About this task

Perform the following steps to register the server as a service:

### Steps

1. Stop the server with `bin/stop-server`.  
You cannot register a server while it is running.
2. To register the server as a service, from a Windows command prompt, run `bat/register-windows-service.bat`.

3. After registration, start the server from the Windows Services Control Panel or with the `bat/start-server.bat` command.

Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

### Running multiple service instances

Only one instance of a particular service can run at one time.

#### About this task

Services are distinguished by the `wrapper.name` property in the `<server-root>/config/wrapper-product.conf` file.

#### Steps

1. To run additional service instances, change the `wrapper.name` property on each additional instance.
2. Add or change descriptions of the service in the `wrapper-product.conf` file.

### Deregistering and uninstalling services

To uninstall a service, you must first deregister it.

#### About this task

While a server is registered as a service, it cannot run as a non-service process or be uninstalled.

#### Steps

1. To remove the service from the Windows registry, use the `bat/deregister-windows-service.bat` file.
2. To uninstall the server, run the `uninstall.bat` script.

### Configuring log files for services

#### About this task

The log files are stored in `<server-root>/logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or the file reaches its maximum size. Only the last three log files are retained.

#### Steps

These configurations can be changed in the `<server-root>/config/wrapper.conf` file.

### Running the status tool

The Directory Server provides a `status` tool that outputs the current state of the server as well as other information, such as server version, java runtime environment statistics, operation processing times, work queue, and administrative alerts.

#### About this task

The `status` tool is located in the `bin` directory for UNIX and Linux or the `bat` directory for Windows.

## Steps

1. Run the `status` command on the command line.

The following code displays an example of the current Directory Server status and limits the number of viewable alerts in the last 48 hours. It provides the current state of each connection handler, data sources, JE environment statistics, processing times by operation type, and the current state of the work queue.

Example:

```
$ bin/status --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret

      --- Server Status ---
Server Run Status:   Started 28/Mar/2012:10:47:17.000 -0500
Operational Status: Available
Open Connections:   13
Max Connections:    13
Total Connections:  50

      --- Server Details ---
Host Name:          server1.example.com
Administrative Users: cn=Directory Manager
Installation Path:  PingDirectory
Server Version:     PingDirectory Server
                   8.1.0.0
Java Version:       jdk-7u9

      --- Connection Handlers ---
Address:Port : Protocol : State

-----:-----:-----:-----
Info     : 28/Mar/2012 10:47:17 -0500 : The Directory Server has started
      successfully
Info     : 28/Mar/2012 10:47:14 -0500 : The Directory Server is starting
Info     : 28/Mar/2012 10:44:22 -0500 : The Directory Server has started
      successfully
Info     : 28/Mar/2012 10:44:18 -0500 : The Directory Server is starting

Shown are alerts of type [Info,Warning,Error,Fatal] from the past 48
hours Use the
--maxAlerts and/or --severity options to filter this list

```

#### Note:

By default, the `status` command displays the alerts generated in the last 48 hours. To change this default setting, see step 2.

- To limit the number of viewable alerts from the default 48 hours, use the `--maxAlerts` option.

## Tuning the Server

---

PingDirectory Server's installation process automatically determines the optimal Java Virtual Machine (JVM) settings based on calculations of the machine running setup.

The default configuration and JVM settings are suitable for most deployments, but it is not uncommon in high-performance environments to make slight changes to the Directory Server's JVM settings as well as performance and resource-related configuration changes with the `dsconfig` tool. For these high-performance environments, tuning can achieve optimum throughput performance and disk space usage for PingDirectory Server and its tools.

### About minimizing disk access

Minimizing disk access is critical to the directory server performance.

Defining a Java Virtual Machine (JVM) heap size that can contain the entire contents of the database cache in memory minimizes read operations from disk and achieves optimal performance. The database on-disk is comprised of transaction log files, which are only appended to. After an initial database import, the size on-disk will grow by a factor of at least 25% as inactive records accumulate in the transaction logs. During normal operation, the on-disk size of the database transaction logs does not represent the memory needed to cache the database.

Consider minimizing the size of the database based on the known characteristics of your data. Doing so reduces hard disk requirements and the memory requirements for the database cache. An example of this is the Directory Server automatically compacting common parent distinguished names (DN).

Finally, consider the write load on your server and its effect on the database. Write operations will always require an associated write-to-disk, but an environment that sustains a high load of write operations might consider tuning the background database cleaner to minimize the size of the database on disk.

## Memory allocation and database cache

Memory allocation and database cache comprise the basic components of the Directory Server footprint and logic behind the automated tuning of the `setup` tool.

The Directory Server's optimal performance is dependent on:

- The proper allocation of memory to the Java Virtual Machine (JVM) heap
- The number of processor cores in the system
- The correct combination of JVM options for optimized garbage collection

The `setup` tool for Directory Server automatically assigns the JVM options and determines the memory allocation based on the total amount of memory on the system; however, in most production deployments, additional tuning might be required to meet the performance objectives for your system.

Often directory server performance tuning can be accomplished by adjusting a few settings. Tuning these settings, which include both JVM and configuration options, require an understanding of the JVM heap structure and the expected database usage.

### Directory Server process memory

The Directory Server consists mainly of a Java Virtual Machine (JVM) heap and a marginal amount of memory allocated by the JVM's execution of native code.

While we frequently refer to the JVM Heap as the maximum memory consumed by the Directory Server, the actual process size is slightly larger than the `Xmx` value because of accumulation of small chunks of native code that Java requires for things, such as SSL sockets.

### Java Development Kit (JDK) Heap Structure

Within the JVM Heap, the principal memory components are the new and old generations. The new generation is a smaller area of memory where all data is initially allocated and is cleaned of garbage often. Any data that is present long enough is promoted to the old generation for the longer term. The old generation is where the database cache eventually resides. The old generation size is computed from the leftover heap after defining the `MaxHeapSize` and new generation sizes. It is not explicitly stated in the JVM options. A typical set of generation definitions for the JVM is as follows, where `mx` and `ms` values represent the heap size.

```
-Xmx16g -Xms16g -XX:MaxNewSize=2g -XX-NewSize=2g
```

#### Note:

The `mx` and `ms` values should always be the same, and the `MaxNewSize` and `NewSize` values should be the same. This helps avoid negative changes in performance.

The `MaxNewSize` and `NewSize` values should never need to exceed 2g. The `setup` and `dsjavaproperties` tools set `MaxNewSize` and `NewSize` values based on the results of extensive performance testing and should not need to be changed.

## Determining heap and database cache size

Define proper memory allocation of the directory server components using the Directory Server `setup` command.

About this task

To define the proper memory allocation of the directory server components:

Steps

1. Run the Directory Server `setup` command.

### Note:

This must be done on hardware that represents the target production platform, especially with regard to process and memory, and the largest heap size that the `setup` tool allows.

2. To define schema and production database settings for the database import, use the `import-ldif` tool.

### Note:

After running `import-ldif`, the database is at its most optimized state on-disk with no inactive records. Over time, the on-disk representation of the database grows up to 25-50% as inactive records accumulate before being removed by the server's cleaner thread.

3. After the database is imported, start the server and make any needed configuration changes.

Example: Set the `prime-method` to `preload` on the `userRoot` backend configuration.

4. Restart the Directory Server and watch for a successful preload message.

Choose from:

- If preloading completes, proceed to step 6.
- If preloading does not complete, proceed to step 5.

5. If preloading does not complete, troubleshoot with the following steps:

- a. In the `config/java.properties` file, in the `start-server.java-args` entry, edit the entry to use larger values for `-Xmx` and `-Xms` arguments.
- b. Run the following command.

```
bin/dsjavaproperties
```

- c. Restart the server and proceed to step 6.

6. After preload completes, run the `status` command to review the database cache utilization.

### Note:

A fully loaded database needs at least 10-20% cache headroom available for future growth, as in the following example.

Example:

```

--- JE Environment ---
ID      : Cache Full : Cache   : On-Disk : Alert
-----:-----:-----:-----:-----
userRoot : 30%          : 1.1 gb : 868.6mb : None

```

- Optional: To see the state of the database cache in more detail, run an `ldapsearch` on the backend monitor.

**Note:**

In addition to the user configured backends, there might be backends for replication and changelog. The heap is shared among all backends. For information on how the heap amount allocated to each backend is calculated, see [Automatic DB cache percentages](#) on page 380.

**Automatic DB cache percentages**

Adjust the allocation of the DB cache percentage when setting up the server.

**About this task**

The setup process automatically tunes the percentage of the `db-cache-percent` property for the `userRoot` backend based on the maximum configured Java Virtual Machine (JVM) heap size. This is only done for the `userRoot` backend during setup. Other backends created by the user are allocated 10%. Change the allocation if needed. When setting up the server:

**Steps**

1. Install the server with the necessary memory.

**Note:**

The server autotunes the size of the cache.

2. Set the autotuned cache size to the limit for the combined cache sizes of all of the backends.
3. Divide the server cache based on the expected size of the data in each backend.

**Automatic memory allocation**

If the Memory Tuning feature is enabled during setup, the `setup` algorithm determines the maximum Java Virtual Machine (JVM) heap size based on the total amount of available system memory. Otherwise, the server allocates a maximum JVM heap of 384 MB.

**About this task**

Directory Server also allows you to specify the maximum heap size during the setup process. For more information, see [JVM Properties for Server and Command-Line Tools](#).

## Steps

- To enable Memory Tuning during the setup process:  
Choose from:
  - Select the feature in interactive command-line mode.
  - Add the `--jvmTuningParameter` option using the `setup` tool in non-interactive command-line mode.
  - Regenerate the Java properties file with `bin/dsjavaproperties` and the `--jvmTuningParameter` options.

### Note:

If Memory Tuning is selected, the server allocates the maximum JVM heap depending on the total system memory. The following table displays the automatically allocated maximum JVM heap memory based on available system memory.

### Allocated Max JVM Memory if Tuning is Enabled

Available Memory	Allocated JVM Memory
16 GB or more using a 64-bit JVM	The maximum JVM heap size is set to 70% of total system memory. If the maximum JVM heap size is less than or equal to 128GB of memory, which should be the case for systems with up to 160 GB of memory, then the initial heap size is set to equal the maximum heap size.
6 GB#16 GB using a 64-bit JVM	Total system memory - 4 GB
4 GB–6 GB using a 64-bit JVM	2 GB
2 GB–4 GB	512 MB
1 GB–2 GB	384 MB

### Automatic memory allocation for the command-line tools

At setup, the Directory Server automatically allocates memory to each command-line utility based on the maximum Java Virtual Machine (JVM) heap size.

The server sets each command-line utility in the `config/java.properties` file with `-Xmx/Xms` values, depending on the expected memory needs of the tools.

Because some tools can be invoked as a server task while the server is online, there are two definitions of the tool in the `config/java.properties` file:

`.Online`

Typically requires minimal memory because the task is performed within the Directory Server's JVM.

`.Offline`

Can require the same amount of memory needed by the Directory Server. Examples include `import-ldif.offline` and `rebuild-index.offline`.

With large databases, some tools, such as `ldap-diff` and `verify-index`, might need more than the minimal memory. The following table lists the tools that are expected to have more than the minimal memory needs along with the rules for defining the default heap size.

## Default Memory Allocation to the Command-Line Tools

Command-Line Tools	Allocated JVM Memory
start-server, import-ldif (offline), rebuild-index (offline)	MaxHeapSize
backup (offline), dbtest export-ldif (offline), ldap-diff, restore (offline), scramble-ldif, summarize-access-log, verify-index	If Max System Memory is: <ul style="list-style-type: none"> <li>▪ Greater than or equal to 16 GB: set heap to 3 GB</li> <li>▪ Greater than or equal to 8 GB: set heap to 1 GB</li> <li>▪ Greater than or equal to 4 GB: set heap to 512 MB</li> <li>▪ Under 4 GB: set heap to 256 MB</li> </ul>

## Database preloading

The ability to maintain the database contents in the database cache within the Java Virtual Machine (JVM) memory is key to the Directory Server performance.

With a properly sized database cache, a priming method of preload directs the server to load the database contents into memory at server startup before accepting the first client connection. The time needed to preload the database is proportional to the database size. To avoid priming, you can start the server with the `start-server --skipPrime` command. If the priming method is `none`, or the `--skipPrime` option is specified at startup, the database cache slowly builds as entries are accessed. This can take several days to reach optimal performance.

The preload priming method is suitable for nearly all Directory Server deployments. If the size of the database precludes storing the whole database in memory, there are priming alternatives for optimizing server performance. This type of deployment is considered disk-bound since the disk is accessed when processing most operations. See the section Disk-Bound Deployments for more information. The remaining priming options are applicable to these environments.

The Directory Server database `prime-method` property configures how the caches get primed, what gets primed, such as data, internal nodes, system indexes, and where it gets primed, for example a database cache, file system cache, or both. The `prime-method` property is a multi-valued option that enables preloading the internal nodes into the database cache before the server starts and then primes the values in the background by cursoring across the database. For more details, see the PingDirectory Server Configuration Reference.

The following is a summary of the priming methods:

### Preload All Data

Prime the contents of the backend into the database cache.

### Preload Internal Nodes Only

Prime only internal database structure information into the database cache, but do not prime any actual data. This corresponds to the `cache-keys-only` cache-mode.

### Cursor Across Indexes

Use the `cursor-across-indexes` property to iterate through backend contents. This is similar to and might be slower than using the preload mechanism, but it enables priming to happen in the background after the server has started. This is used when shorter start up times are desired, and the slower performance of an uncached database is acceptable until the database is primed.

### Configuring database preloading

Use the `dsconfig` tool to set the database priming method.

If multiple prime methods are used, the order in which they are specified in the configuration is the order in which they are performed. Changing the preloading option requires restarting the Directory Server. The following procedures shows how to configure database preloading.

### Configuring database preloading

Configure database preloading.

#### Steps

1. To load the database contents from disk into memory when the server starts up, set the prime method to preload.

This eliminates the need for the server to gradually prime the database cache using client traffic and ensures that the server has optimal performance when it starts to receive client connections.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set prime-method:preload
```

2. To apply the changes, restart the Directory Server.
  - a. Run `bin/stop-server`.
  - b. Run `bin/start-server`.

### Configuring multiple preloading methods

Configure multiple preloading methods.

#### Steps

1. To achieve the benefits of preloading without delaying server startup, set `prime-method` to `preload-internal-nodes-only`, which caches all of the keys within the database, but not the values.

The database values themselves can be cached in the background once the server has been started with the `cursor-across-indexes` option.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --add prime-method:preload-internal-nodes-only \
  --add prime-method:cursor-across-indexes \
  --set background-prime:true
```

2. To apply the changes, restart the Directory Server.
  - a. Run `bin/stop-server`.
  - b. Run `bin/start-server`.

### Configuring system index preloading

Configure system index preloading.

#### About this task

Some environments have many indexes configured though only a few are used for performance-sensitive traffic.

## Steps

1. To reduce server start up time, preload only the necessary indexes into the database at startup.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --set prime-method:preload \
  --set prime-all-indexes:false \
  --set system-index-to-prime:dn2id \
  --set system-index-to-prime:id2entry
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name mail \
  --set prime-index:true
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name uid \
  --set prime-index:true
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name entryUUID \
  --set prime-index:true
```

2. To apply the changes, restart the Directory Server.
  - a. Run `bin/stop-server`.
  - b. Run `bin/start-server`.

## Databases on storage area networks, network-attached storage, or running in virtualized environments

There are several considerations when using network-based storage or storage abstracted by virtualization that are not issues when databases are stored on local disks.

A data durability problem occurs when remote storage or the virtualization environment experiences service interruptions, ranging from connectivity loss to total failure from power loss. Data corruption can occur when the storage layer accepts data for writing that is not made durable before a crash occurs. In these cases, a database property can be set that reduces the likelihood of data loss and data corruption. The database property `database-on-virtualized-or-network-storage` can be set on a per-backend environment basis to request all database writes to be written durably to the underlying storage.

There is a performance penalty when enabling this property and, in most cases, is not recommended except where network storage is unreliable. For network file systems, the benefits of faster recovery and less likelihood of data loss from unplanned events might outweigh the penalty. The exact overhead of enabling `database-on-virtualized-or-network-storage` depends on the characteristics of the database, the host file system, storage array configuration, and network and virtualization input and output parameters. The write overhead penalty might be substantial for SAN environments. Incremental and full backup strategies should be used instead if performance is unacceptable.

To enable `database-on-virtualized-or-network-storage` for each applicable backend, use the following command as an example, which references the configuration for the userRoot backend.

```
$ bin/dsconfig set-global-configuration-prop \
  --set database-on-virtualized-or-network-storage:true
```

This should be set to `false` if the database is on a local disk.

## Database cleaner

Production environments that have a high volume of write operations might require cleaner thread tuning to control the on-disk database size as log files with inactive nodes wait to be cleaned and deleted.

The Directory Server stores its Oracle Berkeley DB Java Edition (JE) database files on-disk in the `db` directory. Each JE database log file is labeled `nnnnnnnnn.jdb`, where `nnnnnnnnn` is an 8-digit hexadecimal number that starts at 00000000 and is increased by 1 for each file written to disk. JE only appends data to the end of each file and does not overwrite any existing data. JE uses one or more cleaner threads that run in the background to compact the number of JE database (`db`) files.

The cleaner threads begin by scanning the records in each `db` file, starting with the file that contains the smallest number of active records. Next, the cleaner threads append any active records to the most recent database file. If a record is no longer active due to modifications or deletions, the cleaner threads leave it untouched. After the `db` file no longer has active records, the cleaner threads can either delete the file or rename the discarded file.

### Note:

Because of this approach to cleaning, the database size on-disk can temporarily increase when cleaning is being performed and files are waiting to be removed.

The local DB backend configuration object has two properties that control database cleaning: `db-cleaner-min-utilization` and `db-num-cleaner-threads`. The `db-cleaner-min-utilization` property determines, by percentage, when to begin cleaning out inactive records from the database files. By default, the property is set to 75, which indicates that database cleaning ensures that at least 75% of the total log file space is devoted to live data.

### Note:

This property only affects the on-disk representation of the database and not the in-memory database cache—only live data is ever cached in memory.

The `db-num-cleaner-threads` property determines how many threads are configured for `db` cleaning. The default single cleaner thread is normally sufficient. However, environments with a high volume of write traffic might need to increase this value to ensure that database cleaning can keep up.

If the number of database files grow beyond your expected guidelines or if the Directory Server is experiencing an increased number of update requests, you can increase the number of cleaner threads using the `dsconfig` tool by going to **Backend # Select Advanced Properties # db-num-cleaner-threads**.

## Compacting common parent DNs

PingDirectory Server compacts entry distinguished names (DNs) by tokenizing common parent DNs.

About this task

Tokenizing the common parent DNs allows you to increase space usage efficiency when encoding entries for storage.

By default, PingDirectory generates tokens for the following:

- Base DNs for the backend, such as `dc=example,dc=com`
- Any `compact-common-parent-dn` values defined in the server configuration
- `ou=People,<base dn>`
- `ou=Groups,<base dn>`

The tokens are generated in this order. You can also define additional common base DNs to be tokenized.

## Steps

- Use the following configuration to tokenize two branches: `ou=people,dc=example,dc=com` and `ou=customers,dc=example,dc=com`.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --add "compact-common-parent-dn:ou=people,dc=example,dc=com" \
  --add "compact-common-parent-dn:ou=customers,dc=example,dc=com"
```

## Setting the import thread count

For most systems, the default setting of 16 threads is sufficient and provides good import performance. On some systems, increasing the import thread count can lead to improved import performance while selecting a value that is too large can actually cause import performance to degrade.

### About this task

If minimizing LDIF import time is crucial to your deployment, you must determine the optimal number of import threads for your system, which is dependent on both the underlying system and the data set being imported.

## Steps

- Use the `dsconfig` command to set the number of import threads.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set import-
thread-count:24
```

## JVM properties for server and command-line tools

The Directory Server and tools refer to the `config/java.properties` file for Java Virtual Machine (JVM) options that include important memory settings.

The `java.properties` file sets the default Java arguments for the Directory Server and each command-line utility includes the default `<JAVA_HOME>` path.

The `java.properties` is generated at server setup time and defines memory-related JVM settings based on the user-provided value for max heap size if you selected the aggressive memory tuning option at setup. Most of the JVM options specified for both server and tools do not need customization after setup. The exception is the `-Xmx/Xms` options, which specify the maximum and initial JVM heap size. See the section on [Memory Allocation and Database Cache](#) for advice on tailoring the `-Xmx/Xms` values.

Other than altering the heap size of the server process (`start-server`) or command-line tools, the most common change required to `java.properties` is when you want to update the JVM version. A single edit applies the new JVM to all server and tool use.

### Applying changes using `dsjavaproperties`

To apply the changes to the `config/java.properties` file, edit the file manually, and then run the `bin/dsjavaproperties` utility.

The `dsjavaproperties` tool uses the information contained in the `config/java.properties` file to generate a `lib/set-java-home` script, or `lib\set-java-home.bat` on Microsoft Windows systems, which is used by the Directory Server and all of its supporting tools to identify the Java environment and its JVM settings. During the process, `dsjavaproperties` calculates an MD5 digest of the contents of the `config/java.properties` file and stores the digest in the generated `set-java-home` script.

The `dsjavaproperties` utility also performs some minimal validation whenever the property references a valid Java installation by verifying that `$(java-home)/bin/java` exists and is executable.

If you make any changes to the `config/java.properties` file but forget to run `bin/dsjavaproperties`, the Directory Server compares the MD5 digest with the version stored in `set-java-home` and sends a message to standard error if the digests differ.

```
WARNING -- File /ds/PingDirectory
         /config/java.properties has been edited without
         running dsjavaproperties to apply the changes
```

### Updating the Java version in the properties file

To change the version of Java that is used by the server and tools, edit the `config/java.properties` file and apply the change by invoking `bin/dsjavaproperties` with no command line options.

#### About this task

You must restart the server for the change to take affect.

#### Steps

- Inside `config/java.properties`, alter the value of `default.java-home` to point to the Java correct Java Runtime Environment (JRE).

Any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration.

Example:

```
$ bin/dsjavaproperties
```

### Regenerating the Java properties file

The `dsjavaproperties` command provides an `--initialize` option that allows you to regenerate the Java properties file specifically if you set up the Directory Server using standard memory usage but opt for aggressive memory tuning after setup.

#### About this task

Rather than reconfigure the Java properties file by re-running `setup` or manually editing the `java.properties` file, you can regenerate the properties file for aggressive memory tuning. Any existing file is renamed with a `.old` suffix.

#### Steps

- Run the `dsjavaproperties` command to regenerate the java properties file for aggressive memory tuning.

Example:

```
$ bin/dsjavaproperties --initialize --jvmTuningParameter AGGRESSIVE
```

## Tuning for disk-bound deployments

Configure the server for a disk-bound configuration.

#### About this task

For best performance, configure the Directory Server to fully cache the DIT in the backend database cache. Directory Server configuration assumes this scenario. For databases too large to fit in memory, other options are available:

- Configure the server for a disk-bound data set. When the database is stored on an SSD, this configuration yields server performance that is comparable to a fully-cached scenario.

- Use uncached attributes or entries as described in the following section.
- Use a Directory Proxy Server in an entry-balancing deployment, which allows all data to be cached in a partitioned environment.

### Steps

1. When installing the server, choose the **Aggressive** option for JVM memory configuration and to preload the data when the server starts.
2. Set the `default-cache-mode` of the `userRoot` backend to `cache-keys-only`.
3. Set operating system `vm.swappiness` to 0 to protect the Directory Server JVM process from an overly aggressive file system cache.
4. When the data set is imported with the above settings, verify in the `import-ldif` output that the cached portions of the data set fit comfortably within the database cache.

## Uncached attributes and entries

Although achieving optimal Directory Server performance requires that the entire data set be fully cached, there can be deployments in which fully caching the data set is not possible due to hardware or financial constraints, or in which acceptable performance can be achieved by only caching a portion of the data.

The Directory Server already provides support for controlling caching on a per-database basis, such as to cache only certain indexes and system databases, but these features might not provide sufficient control over how memory is used, particularly with regard to which entries are included in the cache, and they do not provide any degree of control over caching only a portion of attributes.

To better address the needs of environments that require partial caching, the Directory Server provides two new options: the ability to exclude certain entries from the cache, and the ability to exclude certain attributes from the cache. The Directory Server uses an `uncached-id2entry` database container, which is similar to the `id2entry` database that maps an entry's unique identifier and its encoded representation. The `uncached-id2entry` database contains either complete or partial representations of entries that are intended to receive less memory for caching. For example, if an entry has a large attribute and the system has hardware constraints on memory, then you can configure the system to not cache this particular attribute or entry. This functionality is only available for the local DB backend, which uses the Berkeley DB Java Edition database.

The `uncached-id2entry` database can be included in the set of databases to prime, but if priming is to be performed, it only includes internal nodes and not leaf nodes. For example, the internal nodes of the `uncached-id2entry` database are included in the preload if the `prime-all-indexes` option is set to "true," or if the `system-index-to-prime-internal-nodes-only` option has a value of `uncached-id2entry`.

### Backup and Restore

There are no special considerations for backup and restore with regard to uncached entries and attributes. Backup successfully saves your database contents, including uncached entries and attributes. Because of the way the server deals with changes to uncached entry and uncached attribute configuration, there is no problem with restoring a backup that was taken with a different uncached entry configuration than is currently in place for the server. Any entries encoded in a manner that is inconsistent with the current uncached entry or uncached attribute configuration are properly re-encoded whenever they are updated, or whenever the re-encode entries task is invoked.

### Replication

Replication does not propagate information about which portions of entries might have been cached or uncached, nor does it require that different replicas have the same uncached attribute or uncached entry configuration.

## LDIF Import and Export

When LDIF content is imported into the server, the `uncached` attribute and `uncached` entry configuration is used to determine on a per-entry basis whether some or all of the content for that entry should be written into the `uncached-id2entry` database. The determination is based on the current configuration and is completely independent of and unaware of the configuration that might have been in place when the LDIF data was initially exported. Neither the LDIF import nor export tools provide any options that specifically target only cached or only uncached content, but these tools do provide the ability to include or exclude entries using search filters or to include or exclude specific attributes.

## Server Access Log

Server access log messages can include `uncachedDataAccessed=true` in the result message for any operation in which it was necessary to access uncached data in the course of processing the associated request. For add, delete, modify, or modify DN result messages, `uncachedDataAccessed=true` indicates that at least a portion of the new or updated entry was written into the `uncached-id2entry` database or that at least a portion of the updated entry was formerly contained in the `uncached-id2entry` database. For compare result messages, it indicates that at least a portion of the target entry was contained in the `uncached-id2entry` database and that data from the uncached portion of the entry was required to evaluate the assertion. For search result messages, it indicates that one or more of the entries evaluated as potential matches contained uncached data and that data from the uncached portion of at least one entry was needed in determining what data should be returned to the client.

## Uncached Entry and Attribute Properties

The Directory Server provides three new advanced properties on the local DB backend to control the caching mode for the `uncached-id2entry` database:

### `uncached-id2entry-cache-mode`

Specifies the cache mode that is used when accessing the records in the `uncached-id2entry` database. If the system has enough memory available to fully cache the internal nodes for this database, then `cache-keys-only` is recommended. Otherwise it is better to select `no-caching` to minimize the amount of memory required for interacting with the `uncached-id2entry` database. For more information, see the PingDirectory Server Configuration Reference.

### `uncached-attribute-criteria`

Specifies the criteria used to identify attributes that are written into the `uncached-id2entry` database, rather than the `id2entry` database. This property is only used for entries in which the associated `uncached-entry-criteria` does not indicate that the entire entry should be uncached. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all attributes are written into the `id2entry` database.

### `uncached-entry-criteria`

Specifies the criteria used to identify entries that are written into the `uncached-id2entry` database, rather than the `id2entry` database. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all entries are written into the `id2entry` database.

## Configuring uncached attributes and entries

Configure uncached attributes and entries.

### About this task

The following procedure assumes that the `uncached-id2entry-cache-mode` property is set to the default value, `cache-keys-only`. For more information on the `uncached-id2entry` cache modes, see the PingDirectory Server Configuration Reference.

### Steps

1. Run `dsconfig` to uncache entries that match the criteria.

Example:

```
$ bin/dsconfig create-uncached-entry-criteria \
  --criteria-name "Fully Uncached l=austin" --type filter-based \
  --set enabled:true --set "filter:(l=austin)"
```

The filter uncaches all entries that have its location set to "austin", such as `l=austin`.

2. Run `dsconfig` to uncache attributes that match the criteria.

The `--type simple` option indicates that the simple uncached attribute criteria be used to specify the attribute-type that should be uncached. For those entries that are fully stored in the `uncached-id2entry` database container, the uncached attribute is ignored.

Example:

In this example, the attribute-type criteria that should be uncached is `jpegPhoto`.

```
$ bin/dsconfig create-uncached-attribute-criteria \
  --criteria-name "Uncached jpegPhoto" --type simple \
  --set enabled:true --set attribute-type:jpegPhoto
```

3. Set the uncached properties for the `userRoot` backend.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set "uncached-entry-criteria:Fully Uncached l=austin" \
  --set "uncached-attribute-criteria:Uncached jpegPhoto"
```

4. Run the `re-encode-entries` tool to initiate a task that causes a local DB `userRoot` backend to re-encode all or a specified subset of the entries that it contains.

The tool does not alter the entries themselves but provides a useful mechanism for applying significant changes to the way that entries are stored in the backend.

Example:

The following example initiates a task that re-encodes all fully-cached entries in the `userRoot` backend, rate-limited to no more than 100 entries per second.

```
$ bin/re-encode-entries --hostname directory.example.com --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --backendID userRoot --skipFullyUncachedEntries \
  --skipPartiallyUncachedEntries --ratePerSecond 100
```

## JVM garbage collection using CMS

To ensure reliable server performance with Java, the Directory Server depends on Java's Concurrent Mark and Sweep process (CMS) for background garbage collection.

Out of several garbage collection options, CMS is the ideal choice for consistent system availability. For the most part, the CMS collector runs as one or more background threads within the Java virtual machine (JVM), freeing up space in JVM Heap from an area called the old generation. One of the criteria used by CMS to determine when to start background garbage collection is a parameter called `CMSInitiatingOccupancyFraction`. This percentage value, which applies to the Old Generation, is recommended for the JVM to initiate CMS when data occupancy in Old Generation reaches the threshold.

Ideally, the database cache takes less than 70% of the space available in the Old Generation, and the `CMSInitiatingOccupancyFraction` value of 80 leaves plenty of headroom to prevent the JVM from running out of space in Old Generation because of an inability for CMS to keep up. Because CMS takes processing resources away from the Directory Server, do not set the `CMSInitiatingOccupancyFraction` at or below the expected database cache size, which would result in the constant running of CMS in the background. For a description of determining Old Generation size, see the section on [Memory Footprint and Database Cache](#).

When the CMS collection process cannot keep pace with memory demands in the Old Generation, the JVM resorts to pausing all application processing to allow a full garbage collection. This event, called a "stop-the-world pause", does not break existing TCP connections or alter the execution of the Directory Server requests. The goal in tuning CMS is to prevent the occurrence of these pauses. When one does occur, the Directory Server generates an alert after the pause and records the pause time in the error log.

Because determining an ideal `CMSInitiatingOccupancyFraction` can be difficult, we warn if the Directory Server detects a garbage collection pause by generating a recommended value for the occupancy threshold based on the current amount of memory being consumed by the backend caches. Unfortunately, an administrator cannot determine the ideal occupancy threshold value in advance. To warn of any impending garbage collection pauses, the Directory Server calculates a recommended value for the `CMSInitiatingOccupancyFraction` property and exposes it in the JVM Memory Usage monitor entry in the following attribute:

```
recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

Also, when you start the server, an administrative alert indicates the current state of the `CMSInitiatingOccupancyFraction` and its recommended value.

```
$ bin/start-server [20/April/2012:10:35:25 -0500] category=CORE
  severity=NOTICE msgID=458886
msg="PingDirectory Server
      8.1.0.0 (build 20120418135933Z, R6226) starting up"

... (more output) ...

[20/April/2012:10:35:53 -0500] category=UBID_EXTENSIONS severity=NOTICE
msgID=1880555580 msg="Memory-intensive Directory Server
components are configured to consume 71750382 bytes of memory:
['userRoot local DB backend' currently consumes 26991632 bytes and
can grow to a maximum of 64323584 bytes, 'changelog cn=changelog backend'
currently consumes 232204 bytes and can grow to a maximum of 2426798 bytes,
'Replication Changelog Database' currently consumes 376661 bytes and can
grow to a maximum of 5000000 bytes]. The configured value of
CMSInitiatingOccupancyFraction is 36 which is less than the minimum
recommended value (43) for the server's current configuration. Having
this value too low can cause the Concurrent Mark and Sweep garbage
collector to run too often, which can cause a degradation of throughput
and response time. Consider increasing the CMSInitiatingOccupancyFraction
value to at least the minimum value, preferably setting it to the
recommended value of 43 by editing the config/java.properties file,
```

```
running dsjavaproperties, and restarting the Directory Server.
If the server later detects that this setting actually leads to a
performance degradation, a separate warning message will be logged.
If this server has not yet been fully loaded with data, then you
can disregard this message"
```

```
[20/April/2012:10:35:53 -0500] category=CORE severity=NOTICE msgID=458887
msg="The Directory Server has started successfully"
```

The Directory Server only makes a recommendation if all of the backends are preloaded and the **CMSInitiatingOccupancyFraction** JVM property is explicitly set, which is done automatically. For example, if you installed the Directory Server and specified that the database be preloaded (or "primed") at startup, then the Directory Server can make a good recommendation for the Directory Server when a pause occurs. If the backend database cache is not full and has not been preloaded, then the recommended value might be an inaccurately low value.

#### Note:

The generated value for the Directory Server property could change over time with each Directory Server build, Java release, or changes in data set. If the current value is close to the recommended value, then you do not need to change the property unless the server experiences a JVM pause.

If the Directory Server experiences a JVM garbage collection pause, you can retrieve the recommended value from the server, reset the Directory Server property, run **dsjavaproperties**, and restart the server.

### Determining the CMSInitiatingOccupancyFraction

Use the terminal to determine the **CMSInitiatingOccupancyFraction** value.

#### Steps

1. Retrieve the `prime-method` property for the backend.

Example:

```
$ bin/dsconfig get-backend-prop --backend-name userRoot \
  --property prime-method
```

#### Note:

If you set the `Preload Database at startup` option during the installation, then skip to step 3.

2. If the `prime-method` property was not configured, run **bin/dsconfig** to set the property to `PRELOAD`, and then restart the Directory Server to preload the database cache.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --set prime-method:preload

$ bin/stop-server
```

```
$ bin/start-server
```

**Result:** At startup, you see an administrative message if the current **CMSInitiatingOccupancyFraction** property is below the recommended value.

 **Note:**

You can get the recommended value from this message and change it in the `config/java.properties` file in step 5.

3. If you were unable to see the recommended **CMSInitiatingOccupancyFraction** property at startup presented in the previous step, pre-tune the value of the **CMSInitiatingOccupancyFraction** property to ensure that all of the data is imported into the server and preloading is enabled in the backend.
  - a. Retrieve the recommended **CMSInitiatingOccupancyFraction** value by issuing the following search.

**Example:**

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectclass=ds-memory-usage-monitor-entry)" \
  cms-initiating-occupancy-fraction \
  recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

 **Note:**

If the `recommended-cms-initiating-occupancy-fraction-for-current-data-set` is not present, then make sure that the server has been restarted since enabling preload for the backends.

**Result:**

```
dn: cn=JVM Memory Usage,cn=monitor
cms-initiating-occupancy-fraction:80
recommended-cms-initiating-occupancy-fraction-for-current-data-set:55
```

4. Open the `config/java.properties` file using a text editor and manually edit the **CMSInitiatingOccupancyFraction** (or any other property) to its recommended value in the `start-server.java-args` property.
5. Save the file.

The following arguments are recommended for a Sun 5440 server. Contact your authorized support provider for specific assistance.

**Example:**

```
start-server.java-args=-d64 -server -Xmx20g -Xms20g -XX:MaxNewSize=1g
-XX:NewSize=1g -XX:ParallelGCThreads=16 -XX:+UseConcMarkSweepGC
-XX:+CMSConcurrentMTEnabled -XX:+CMSParallelRemarkEnabled
-XX:+CMSParallelSurvivorRemarkEnabled -XX:ParallelCMSThreads=8
-XX:CMSMaxAbortablePrecleanTime=3600000
-XX:+CMSScavengeBeforeRemark -XX:RefDiscoveryPolicy=1
-XX:CMSInitiatingOccupancyFraction=55 -XX:+UseParNewGC
-XX:+UseBiasedLocking -XX:+UseLargePages
-XX:+HeapDumpOnOutOfMemoryError
```

The `-XX:ParallelGCThreads` should be limited to 16 (default) or to 8 for smaller systems. The `-XX:ParallelCMSThreads` should be limited to 8.

- To apply the changes, run the `bin/dsjavaproperties` command.

Example:

```
$ bin/dsjavaproperties
```

- Restart the Directory Server.

## Configuring the Server

---

Configure the server to meet the performance, hardware, operating system, and memory requirements for your production environment.

The out-of-the-box, initial configuration settings for the PingDirectory Server provide an excellent starting point for most general-purpose Directory Server applications. However, additional tuning might be necessary to meet the needs of your production environment.

The Directory Server stores its configuration settings in an LDIF file, `config/config.ldif`. Rather than editing the file directly, the Directory Server provides command-line options and an administrative console to configure the server. The Directory Server also includes tools to create server groups to apply configuration changes to multiple servers at one time

### About the configuration tools

Use the administrative console or the `dsconfig` command-line tool to modify the PingDirectory Server.

You can access and modify the PingDirectory Server configuration in the following ways:

- Use the Administrative Console. The PingDirectory Server provides an administrative console for graphical server management and monitoring. The console provides equivalent functionality to the `dsconfig` command for viewing or editing configurations. All configuration changes using this tool are recorded in `logs/config-audit.log`, which also has the equivalent reversion commands that let you back out of a configuration.
- Use the `dsconfig` command-line tool. The `dsconfig` tool is a text-based menu-driven interface to the underlying configuration. The tool runs the configuration using three operational modes: interactive command-line mode, non-interactive command-line mode, and batch mode. All configuration changes made using this tool are recorded in `logs/config-audit.log`.

### About the dsconfig configuration tool

The `dsconfig` tool is the text-based management tool used to configure the underlying Directory Server configuration.

The `dsconfig` tool has three operational modes: interactive mode, non-interactive mode, and batch mode.

The `dsconfig` tool offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, you should keep the server running when you access the configuration for the server to give the user feedback about the validity of the configuration.

### Using dsconfig in interactive command-line mode

In interactive mode, the `dsconfig` tool offers a filtering mechanism that only displays the most common configuration elements.

About this task

The user can specify that more expert level objects and configuration properties be shown using the menu system.

Running `dsconfig` in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the PingDirectory Server.

## Steps

1. To start `dsconfig` in interactive command-line mode, invoke the `dsconfig` script without any arguments.  
Result: You are prompted for connection and authentication information to the Directory Server, and then a menu displays the available operation types.
2. To accept the default values, press **Enter**.

### Note:

In some cases, a default value is provided in square brackets. For example, `[389]` indicates that the default value for that field is port 389.

3. To skip the connection and authentication prompts, provide the connection and authentication information using the command-line options of `dsconfig`.

## Configuring the Server using `dsconfig` interactive mode

Configure the PingDirectory Server using the `dsconfig` command-line tool in interactive mode.

## Steps

1. Launch the `dsconfig` tool in interactive command-line mode.

Example:

```
$ bin/dsconfig
```

2. Enter the LDAP connection parameters.  
Choose from:
  - Enter the Directory Server host name or IP address.
  - Press **Enter** to accept the default.
3. Enter the number corresponding to the type of LDAP connection that you are using on the Directory Server, or press **Enter** to accept the default.

The numbers for the LDAP connection type are 1 for LDAP, 2 for SSL, and 3 for StartTLS. The default entry is 1.

4. Enter the LDAP listener port number, or accept the default port.

The default port is the port number of the server local to the tool.

5. Enter the user bind DN and the bind DN password.

The default is `cn=Directory Manager`.

6. On the **Directory Server Configuration Console** main menu, enter a number corresponding to the configuration that you want to change.

### Note:

The number might change between releases or within the same release, depending on the options selected, such as in cases where more expert level objects and properties are displayed.

7. In this example, select the number for Backend.
8. Set the `db-cache-percent` to 40%.  
The optimal cache percentage depends on your system performance objectives and must be tuned as determined through analysis. In many cases, the default value chosen by the `setup` utility is sufficient.
9. On the **Backend management** menu, enter the number corresponding to view and edit an existing backend.

10. Select the backend to work with or press **Enter** to accept the default.

In this example, using the basic object menu, only one backend that can be viewed in the directory, `userRoot`.

11. From the **Local DB Backend** properties menu, type the number corresponding to the `db-cache-percent` property.
12. Enter the option to change the value, and then type the value for the `db-cache-percent` property.  
In this example, type `40` for 40 %.
13. To apply the changes, enter `f`.

#### Note:

Before you apply the change, the `dsconfig` interactive command-line mode provides an option to view the equivalent non-interactive command based on your menu selections. This is useful in building `dsconfig` script files for configuring servers in non-interactive or batch mode. If you want to view the equivalent `dsconfig` non-interactive command, type `d`. For more information, see [Getting the Equivalent dsconfig Non-Interactive Mode Command](#).

14. In the **Backend management** menu, to quit the `dsconfig` tool, enter `q`.

### Viewing dsconfig advanced properties

Configure `dsconfig` interactive mode to hide or display additional advanced properties.

About this task

#### Note:

For most configuration settings, some properties are more likely to be modified than others.

### Steps

1. Repeat steps 1–9 in [Configuring the Server using dsconfig interactive mode](#) on page 395.
2. To display the advanced properties, from the **Local DB Backend properties** menu, enter `a`.  
Result: This toggles any hidden properties.

### Changing the dsconfig object menu

The purpose of object levels is to present only those properties that an administrator will likely use.

About this task

Because some configuration objects are more likely to be modified than others, the PingDirectory Server provides four different object menus that hide or expose configuration objects to the user. The `object` type is a convenience feature designed to improve menu readability.

The following object menus are available:

#### Basic

Only includes the components that are configured most frequently.

#### Standard

Includes all components in the Basic menu plus other components that might occasionally need to be altered in many environments.

#### Advanced

Includes all components in the Basic and Standard menus plus other components that might require configuration under special circumstances or that might be harmful if configured incorrectly.

#### Expert

Includes all components in the Basic, Standard, and Advanced menus plus other components that almost never require configuration, or that could seriously impact the functionality of the server if not properly configured.

To change the `dsconfig` object menu:

#### Steps

1. Using `dsconfig`, repeat steps 1–6 in [To Install the Directory Server in Interactive Mode](#).
2. On the **PingDirectory Server configuration** main menu, enter the letter `o` to change the object level.

Basic objects are displayed by default.

3. Enter a number corresponding to an object level of your choice.  
Choose from:

- Enter 1 for Basic.
- Enter 2 for Standard.
- Enter 3 for Advanced.
- Enter 4 for Expert.

4. Review the menu at the new object level.

Additional configuration options for the Directory Server components are displayed.

#### **dsconfig interactive administrative alerts**

The `dsconfig` tool and the administrative console provide a feature that displays notifications for certain operations that require further administrative action to complete the process.

If you change a certain backend configuration property, the admin action appears in two places during a `dsconfig` interactive session:

- When configuring the property
- Before you apply the change

For example, if you change the `db-directory` property on the `userRoot` backend, such as specifying the path to the file system path that holds the Oracle Berkeley DB Java Edition backend files, an admin action reminder displays during one of the steps.

The admin action alert also appears as a final confirmation step. The alert allows you to continue and apply the change or back out of the configuration if the resulting action cannot be conducted at the present time. For example, after you type the letter `f` to apply the `db-directory` property change, the admin alert message appears:

```
Enter choice [b]: f One or more configuration property changes require
administrative action or confirmation/notification. Those properties
include: * db-directory: Modification requires that the Directory Server be
stopped, the database directory manually relocated, and then the Directory
Server restarted. While the Directory Server is stopped, the directory
and files pertaining to this backend in the old database directory must
be manually moved or copied to the new location. Continue? Choose 'no' to
return to the previous step (yes / no) [yes]:
```

```
Enter choice [b]: f One or more configuration property changes require
administrative action or confirmation/notification. Those properties include:
* db-directory: Modification requires that the Directory Server be stopped,
the database directory manually relocated, and then the Directory Server
restarted. While the Directory Server is stopped, the directory and files
```

pertaining to this backend in the old database directory must be manually moved or copied to the new location. Continue? Choose 'no' to return to the previous step (yes / no) [yes]:

Currently, only a small set of properties that display an admin action alert appear in **dsconfig** interactive mode and the administrative console. For more information on the properties, see the *PingDirectory Server Configuration Reference*, located in the server's `docs/config-guide` directory.

## Using dsconfig in non-interactive mode

The **dsconfig** non-interactive command-line mode provides a simple way to make arbitrary changes to the Directory Server by invoking it from the command line.

### Steps

1. To use administrative scripts to automate configuration changes, run the **dsconfig** command in non-interactive mode.

Non-interactive mode is convenient for scripting applications.

#### Note:

If you plan to make changes to multiple configuration objects at the same time, then the batch mode might be more appropriate.

2. Use the **dsconfig** tool to update a single configuration object using command-line arguments to provide all of the necessary information.

Example:

The following shows the general format for the non-interactive command line.

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

#### Note:

The `--no-prompt` argument indicates that you want to use non-interactive mode. The `{subcommand}` is used to indicate which general action to perform. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the Directory Server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on your setup. For example, using standard LDAP connections, you can invoke the **dsconfig** tool, as shown.

```
$ bin/dsconfig --no-prompt list-backends \  
  --hostname server.example.com \  
  --port 389 \  
  --bindDN uid=admin,dc=example,dc=com \  
  --bindPassword password
```

3. If your system uses SASL GSSAPI (Kerberos), invoke **dsconfig** as shown.

```
$ bin/dsconfig --no-prompt list-backends \  
  --saslOption mech=GSSAPI \  
  --saslOption authid=admin@example.com \  
  --saslOption ticketcache=/tmp/krb5cc_1313 \  
  --saslOption useticketcache=true
```

- To always display the advanced properties, use the `--advanced` command-line option.

**Note:**

The `{subcommandArgs}` argument contains a set of arguments specific to the particular subcommand that you want to invoke.

Global arguments can appear anywhere on the command line, including before the subcommand and after or intermingled with subcommand-specific arguments. The subcommand-specific arguments can appear anywhere after the subcommand.

### Configuring the Server using `dsconfig non-interactive mode`

Use `dsconfig non-interactive mode` to modify memory and specify parent distinguished names (DNs).

#### Steps

- To change the amount of memory used for caching database contents and to specify common parent DN's that should be compacted in the underlying database, use the `dsconfig` command in non-interactive mode.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set db-cache-percent:40 \
  --add "compact-common-parent-dn:ou=accts,dc=example,dc=com" \
  --add "compact-common-parent-dn:ou=subs,dc=example,dc=com"
```

### Viewing a list of `dsconfig` properties

Run `dsconfig` commands to view a list of properties, objects, property descriptions, and property information.

#### Steps

- To view the list of all `dsconfig` properties, run the `dsconfig` command with the `list-properties` option.

**Note:**

Remember to add the LDAP connection parameters.

Example:

```
$ bin/dsconfig list-properties
```

- To view objects at and below the menu object level, use the `dsconfig` command with the `list-properties` option and the `--complexity <menu level>` option.

Example:

```
$ bin/dsconfig list-properties --complexity advanced --includeDescription
```

**Note:**

You can also add the `--includeDescription` argument that includes a synopsis and description of each property in the output. Remember to add the LDAP connection parameters.

3. If the server is offline, you can run the command with the `--offline` option without needing to enter the LDAP connection parameters.

Example:

```
$ bin/dsconfig list-properties --offline --complexity advanced --includeDescription
```

4. To review the property information provided with the server, view the `<server-root>/docs/config-properties.txt` file.

## Getting the equivalent dsconfig non-interactive mode command

Although the `dsconfig` non-interactive command-line mode is convenient for scripting and automating processes, obtaining the correct arguments and properties for each configuration change can be time-consuming.

About this task

For quick and easy configuration, use an option to display the equivalent non-interactive command using `dsconfig` interactive mode. The command displays the equivalent `dsconfig` command to recreate the configuration in a scripted configuration or to enter any pending changes on the command line for another server instance more quickly.

### Note:

There are two other ways to get the equivalent `dsconfig` command. One way is by looking at the `logs/config-audit.log` file. It might be more convenient to configure the Directory Server the way you want and then get the `dsconfig` arguments from the log. Another way is to configure an option using the Administrative Console. The console shows the equivalent `dsconfig` command prior to applying the change.

To get the equivalent `dsconfig` non-interactive mode command:

Steps

1. Use `dsconfig` in interactive mode to make changes to a configuration, but do not enter the letter `f` to apply the changes.
2. To view the equivalent non-interactive command, enter `d`.
3. View the equivalent command, and then press `Enter` to continue.

Result:

Based on an example in the previous section, changes made to the `db-cache-percent` returns the following message.

```
Command line to apply pending changes to this Local DB Backend: dsconfig set-backend-prop --backend-name userRoot --set db-cache-percent:40
```

The command does not contain the LDAP connection parameters required for the tool to connect to the host because the command is presumed to be used to connect to a different remote host.

## Using dsconfig batch mode

Configure the Directory Server in `dsconfig` batch mode.

About this task

The PingDirectory Server provides a `dsconfig` batching mechanism that reads multiple `dsconfig` invocations from a file and executes them sequentially.

The batch file provides advantages over standard scripting by minimizing LDAP connections and Java virtual machine (JVM) invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

If a `dsconfig` command has a missing or incorrect argument, the command fails and aborts the batch process without applying any changes to the Directory Server. The `dsconfig` command supports a `--batch-continue-on-error` option that instructs `dsconfig` to apply all changes and skip any errors.

You can view the `logs/config-audit.log` file to review the configuration changes made to the Directory Server and use them in the batch file. The batch file can have blank lines for spacing and lines starting with a pound sign (`#`) for comments. The batch file also supports a `\` line continuation character for long commands that require multiple lines.

The Directory Server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Oracle to PingDirectory Server machines.

### Steps

1. Create a text file that lists each `dsconfig` command with the complete set of properties that you want to apply to the Directory Server.

#### Note:

The items in this file should be in the same format as those accepted by the `dsconfig` command. The batch file can have blank lines for spacing and lines starting with a pound sign (`#`) for comments. The batch file also supports a `\` line continuation character for long commands that require multiple lines.

#### Example:

```
# This dsconfig operation creates the exAccountNumber global attribute
index.
dsconfig create-global-attribute-index
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--index-name exAccountNumber --set prime-index:true

# Here we create the entry-count placement algorithm with the
# default behavior of adding entries to the smallest backend
# dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name example_com_entry_count
--type entry-counter
--set enabled:true
--set "poll-interval:1 m"

# Note that once the entry-count placement algorithm is created
# and enabled, we can delete the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then delete the
# original round-robin algorithm created during the setup
# procedure.

dsconfig delete-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin
```

2. To read and execute the commands, run `dsconfig` with the `--batch-file` option.

## Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth tokens

Configure an access token validator to use PingFederate OAuth tokens with PingDirectory.

Before you begin

You need the following information:

- The runtime engine service port of the PingFederate server, usually 9031
- The client ID of an OAuth 2.0 client configured on the PingFederate server
- The client secret of the OAuth 2.0 client
- The IP address of the PingFederate server

About this task

After you configure a PingFederate server to issue OAuth 2 tokens, you must make these tokens compatible with SCIM 2.0 operations on PingDirectory Server or PingDirectoryProxy.

This section explains how to set up an access token validator to handle this task.

Steps

1. Register the PingFederate server using the following command.

```
dsconfig create-external-server \
  --server-name PingFederateInstance \
  --type http \
  --set base-url:https://<PingFed IP address>:<PingFed port> \
  --set hostname-verification-method:allow-all \
  --set "trust-manager-provider:Blind Trust"
```

### Note:

In this example, the hostname verification method is set to `allow-all` and the Blind Trust manager provider is used for the sake of simplicity. You should not use these settings for production environments.

2. Create the access token validator using the following command.

```
dsconfig create-access-token-validator \
  --validator-name PingFederateValidator \
  --type ping-federate \
  --set enabled:true \
  --set authorization-server:PingFederateInstance \
  --set client-id:<client-id> \
  --set client-secret:<client-secret>
```

### Note:

Take the `client-id` and `client-secret` values from the PingFederate OAuth 2 client that will be used with the PingDirectory Server or PingDirectoryProxy.

3. Add the access token validator to the SCIM 2 HTTP Servlet configuration with the following command.

```
dsconfig set-http-servlet-extension-prop \
```

```
--extension-name SCIM2 \
--set access-token-validator:PingFederateValidator
```

4. Test the validator by sending a GET request to `/scim/v2/ServiceProviderConfig`.

This endpoint does not require any scopes to access, just a valid bearer token. The sever should return a response similar to the following.

```
{
  "schemas": [
    "urn:ietf:params:scim:schemas:core:2.0:ServiceProviderConfig"
  ],
  "patch": {
    "supported": true
  },
  "bulk": {
    "supported": false,
    "maxOperations": 0,
    "maxPayloadSize": 0
  },
  "filter": {
    "supported": true,
    "maxResults": 0
  },
  "changePassword": {
    "supported": true
  },
  "sort": {
    "supported": false
  },
  "etag": {
    "supported": false
  },
  "authenticationSchemes": [
    {
      "name": "OAuth 2.0 Bearer Token",
      "description": "The OAuth 2.0 Bearer Token Authentication
scheme. OAuth enables clients to access protected resources by obtaining
an access token, which is defined in RFC 6750 as \"a string representing
an access authorization issued to the client\", rather than using the
resource owner's credentials directly.",
      "specUri": "http://tools.ietf.org/html/rfc6750",
      "type": "oauthbearertoken",
      "primary": true
    }
  ],
  "meta": {
    "resourceType": "ServiceProviderConfig",
    "location": "https://localhost:8443/scim/v2/
ServiceProviderConfig"
  }
}
```

## About recurring tasks and task chains

You can use the `dsconfig create-recurring-task` command to create recurring tasks and task chains to perform regular maintenance tasks for PingDirectory Server. These tasks can perform regular backups, LDIF exports, enter and exit lockdown mode, or other static operations.

Because this process is owned by the server, tasks do not require special privileges or credentials, and they can be run when the server is offline.

Create tasks and then add them to a recurring task chain for scheduling. The task chain ensures that invocations of a task or set of tasks run in a specified order and do not overlap.

A recurring task includes:

- The task-specific object classes to include in the task entry
- The task-specific attributes to include in the task entry, if any
- Whether to alert on task start, success, or failure
- Any addresses to email on task start, success, or failure
- Whether to cancel an instance of the task if it is dependent upon another task and that task does not complete successfully

After you create a task, add one or more tasks to a task chain and schedule the chain using the **dsconfig create-recurring-task-chain** command.

A recurring task chain includes:

- An ordered list of the tasks to invoke
- The months, days, times, and time zones in which each task can be scheduled to start
- The behavior to exhibit if any of the tasks are interrupted by a server shutdown
- The behavior to exhibit if the server is offline when the start time occurs

#### Note:

Changing the schedule for an existing recurring task chain only takes effect the next time an instance of the chain needs to be scheduled. It does not affect any existing instances of the chain that are already scheduled. Existing scheduled instances still run at the originally scheduled time. When that run is complete, the server schedules the next iteration according to the then-current schedule logic.

Also, you cannot simply cancel the existing scheduled instance to make the next instance run earlier. When you cancel an instance of a recurring task chain, the server automatically schedules the next instance for the next time that matches the scheduling criteria. It never schedules a new instance for earlier than or the same time as one that you manually canceled.

### Creating a recurring task and task chain

Use **dsconfig** to create one or more tasks and then add them to a task chain for scheduling.

#### Steps

1. To create a task, use **dsconfig create-recurring-task**.

Example:

The following creates a backup task.

```
$ bin/dsconfig create-recurring-task \
  --task-name backup-1 \
  --type backup \
  --set 'email-on-failure:admin1@company.com' \
  --set 'email-on-failure:admin2@company.com' \
  --set compress:true \
  --set encrypt:true \
  --set "retain-previous-full-backup-age:4 w" \
  --set retain-previous-full-backup-count:10
```

2. To create a task chain to schedule and run recurring tasks, use **dsconfig create-recurring-task-chain**.

Example:

```
$ bin/dsconfig create-recurring-task-chain \
  --chain-name "backup chain" \
```

```
--set recurring-task:backup-1 \
--set scheduled-date-selection-type:selected-days-of-the-month \
--set scheduled-day-of-the-month:last-day-of-the-month \
--set scheduled-time-of-day:02:00
```

### LDIF export as a recurring task

You can create a recurring task to schedule the export of LDIF data.

For new installations, the server exports LDIF data by default every day at 1:05 a.m. in the default time zone for the Java virtual machine (JVM), which is generally the time zone configured for the underlying system. At the scheduled time, the server exports the contents of each public backend to a file in the server root `ldif` directory.

#### Note:

Public backends are non-administrative backends containing user-supplied data.

The server compresses and encrypts the LDIF exports if the global configuration is set to encrypt LDIF exports by default, which is enabled if encryption is configured during setup. The LDIF exports are rate limited to ten megabytes per second to minimize the impact on server performance, and exports are retained for seven days.

The recurring task chain is created in instances that are updated to this release. However, the task chain is not enabled by default.

LDIF export can export multiple backends in the same recurring task. You can use the `backend-id` property to include multiple backends. You can use the `exclude-backend-id` property to exclude one or more backends. These optional properties are mutually exclusive:

- If the `backend-id` property has one or more values, only the backends with those IDs are exported.
- If the `exclude-backend-id` property has one or more values, all public backends except those listed are exported.
- If neither the `backend-id` property nor the `exclude-backend-id` property supply values, all public backends are exported.

### Lockdown mode as a recurring task

You can create recurring tasks to move a server in and out of lockdown mode. Moving a server in and out of lockdown mode is useful for scheduling other tasks while the server is mostly idle and not accepting connections from clients.

While in lockdown mode, the server reports itself as unavailable and also rejects requests from any user that doesn't have the `lockdown-mode` privilege.

The recommended flow for a recurring task chain that uses lockdown mode would be:

1. Enter lockdown mode task.
2. Delay task that waits for the work queue to report that the server is idle.
3. Run desired tasks to perform while the server is in lockdown mode.
4. Leave lockdown mode task.

The enter lockdown mode and leave lockdown mode tasks each allow one optional property that you can use to supply a description for why that the server is being moved into this mode.

### File retention recurring task

You can configure a recurring task to remove files in a specified directory that match a given pattern.

You can exclude files that match count-based, time-based, or space-based retention criteria. If any files are to be removed, the oldest files are removed before the most recent file.

If the file name pattern includes a `"${timestamp}"` element, the timestamp is used to identify the file's age. If the file name pattern does not include a timestamp, then the file's age is determined by using the

file's creation time, if available, or the last modified time, if the creation time is not available. If a file's age cannot be determined, the file is not removed.

If multiple files have the same age, the server uses lexicographic ordering to differentiate between them. Lexicographic ordering is applicable only for files with no `retain-file-age` property configured or for files that are older than that age. If multiple files do not share the same age, but that age is younger than the `retain-file-age` value, then those files are retained.

When configuring a file removal task, you must specify at least one of the following properties:

- `retain-file-count`
- `retain-file-age`
- `retain-aggregate-file-size`

## Using exec tasks

Exec tasks allow administrators and external users to execute a specified command on the server once or as recurring tasks.

About this task

The server restricts the kinds of commands that can be executed, and the access level of users who can execute them.

These safeguards and requirements include:

- The absolute path to the command to execute must be listed in the `<server-root>/config/exec-command-whitelist.txt` file.
- The global configuration must be updated to allow the exec task. The server does not permit it by default. The following command enables this.

```
$ bin/dsconfig set-global-configuration-prop \
  --add allowed-task:com.unboundid.directory.server.tasks.ExecTask
```

- The user scheduling the task must have the `exec-task` privilege. The server does not grant permission to run this task to any user by default, including root users.

The following configuration changes grant the `exec-task` privilege to a single root user, all root users, or a single non-root user:

Steps

- To grant the `exec-task` privilege to a single root user, run the following.

```
$ bin/dsconfig set-root-dn-user-prop --user-name "<username>" \
  --add privilege:exec-task
```

- To grant the `exec-task` privilege to all root users, run the following.

```
$ bin/dsconfig set-root-dn-prop \
  --add default-root-privilege-name:exec-task
```

- To grant the `exec-task` privilege to a single non-root user, run the following.

```
dn: <userdn>
changetype: modify
add: ds-privilege-name
ds-privilege-name: exec-task
```

- Use the `schedule-exec-task` tool to create an exec task from the command line.

Example:

The following command schedules an exec task to run the `verify-index` tool to check the integrity of the `cn` index in the backend that hosts "`dc=example,dc=com`", assuming that the server is installed in `/ds`.

```
$ bin/schedule-exec-task --hostname directory.example.com \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --promptForBindPassword \
  --waitForCompletion \
  --logCommandOutput \
  /ds/bin/verify-index --baseDN dc=example,dc=com --index cn
```

## Topology configuration

Topology configuration enables automatic server grouping and configuration change mirroring. It uses a master and slave architecture for mirroring shared data across the topology.

All writes and updates are forwarded to the master, which forwards them to all other servers. Reads can be served by any server in the group, and servers can be added to an existing topology at installation.

### Note:

To remove a server from the topology, you must uninstall it with the `uninstall` tool.

### Topology master requirements and selection

A topology master server receives configuration changes from other servers in the topology, verifies the changes, and then makes the changes available to all connected servers.

When updating, the master sends a digest of its subtree contents. If the node's digest differs from the master's, the server node knows it is not synchronized. The servers pull the entire subtree from the master if they detect that they are not synchronized.

A server detects it is not synchronized with the master under the following conditions:

- The server's subtree digest differs from the master's digest at the end of its periodic polling interval.
- One or more servers have been added to or removed from the topology.

The master of the topology is selected by prioritizing servers based on:

- Minimum supported product version
- Availability
- Server version
- Earliest start time
- Startup UUID (smaller is preferred)

After determining a master, the topology data is reviewed from all available servers, every five seconds by default, to determine if any new information identifies a better server master. If a new server can be the master and no other servers have indicated that they should be the master, it will communicate its eligibility to the other servers. This ensures that all servers accept the same master at approximately the same time, within a few milliseconds of each other. If there is no better master, the initial master maintains the role.

After the best master has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that master.
  - The master server itself is considered while determining this majority.
- There is only a single master in the entire topology.

If either of these conditions is not met, the topology is without a master and the peer polling frequency is reduced to 100 milliseconds to find a new master as quickly as possible. If there is no master in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as master with the `force-as-master-for-mirrored-data` option in the Global Configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as masters, then a `multiple-servers-forced-as-masters` alarm is raised.

### Topology components

When you install a server, you can add it to an existing topology, cloning the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

#### Server configuration settings

Configuration settings for the topology are configured in the global configuration and in the config file handler backend. They are topology settings, but they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The global configuration object contains a single topology setting, `force-as-master-for-mirrored-data`. This should be set to `true` on only one of the servers in the topology, and is used only if the topology cannot determine a master because most of the servers are not available. A server with this setting enabled is assigned the role of master if no suitable master can be determined.

The config file handler backend defines three topology `mirrored-subtree` settings:

#### `mirrored-subtree-peer-polling-interval`

Specifies the frequency at which the server polls its topology peers to identify any changes warranting a new master selection. A lower value ensures a faster failover, but it also causes more traffic among the peers. The default value is 5 seconds. If no suitable master is found, the polling frequency adjusts to 100 milliseconds until a new master is selected.

#### `mirrored-subtree-entry-update-timeout`

Specifies the maximum length of time to wait for an entry update operation, such as add, delete, modify or modify-dn, to be applied by the master on all of the servers in the topology. The default is 10 seconds, but updates can take up to twice as long if master selection is in progress at the time the update operation is received.

#### `mirrored-subtree-search-timeout`

Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

#### Topology settings

Topology metadata is stored under the `cn=topology,cn=config` subtree and cluster data is stored under the `cn=cluster,cn=config` subtree. The only setting that can be changed is the cluster name.

### Monitor data for the topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to identify changes in the topology.

Topology data includes the following:

- The server ID of the current master, if the master is not known
- The instance name of the current master or if a master is not set, a description stating why a master is not set
- A flag indicating which server thinks that it should be the master
- A flag indicating which server is the current master

- A flag indicating a server that was forced as master
- The total number of configured peers in the topology group
- The peers connected to this server
- The current availability of this server
- A flag indicating that a server is not synchronized with its master or another node in the topology if the master is unknown
- The amount of time in milliseconds that multiple masters were detected by this server
- The amount of time in milliseconds that no suitable server is found to act as master
- A SHA-256 digest encoded as a base-64 string for the current subtree contents

The following metrics are included if this server has processed any operations as master:

- The number of operations processed by this server as master
- The number of successful operations processed by this server as master
- The number of operations processed by this server as master that failed to validate
- The number of operations processed by this server as master that failed to apply
- The average amount of time taken in milliseconds by this server to process operations as the master
- The maximum amount of time taken in milliseconds by this server to process an operation as the master

## Servers and certificates

The following provides a detailed description of PingDirectory Server certificate types.

PingDirectory Server uses two main types of certificates:

### Listener certificates

Used to secure communication through TLS.

### Inter-server certificates

Used to authenticate between server instances in a topology.

### Listener certificates

When a client initiates TLS negotiation with the server, the server presents a certificate chain to the client and the certificate at the head of the chain functions as a listener certificate.

Because the client decides whether to trust the certificate chain, it is recommended that the chain be signed by an issuer whom the client is likely to trust or that the client can be easily configured to trust.

You can create self-signed certificates with long lifespans, but a certificate that a certification authority signs is likely to have a relatively short lifespan. Commercial authorities typically issue certificates that are valid for only one or two years, but some authorities use shorter validity windows.

Short certificate lifespans offer some security benefits. In particular, because most clients do not verify whether a certificate has been revoked, a shorter validity window minimizes the timeframe that a compromised certificate can be used. If the process for replacing certificates is streamlined or automated, administrative inconvenience can be kept to a minimum.

Listener certificates are stored in key stores that are referenced by key manager providers, which in turn provide the logic and configuration for accessing the key stores. If a server component, like a connection handler, requires access to a certificate that it presents to a peer during the TLS negotiation process, that component must reference the key manager provider that points to the key store containing the appropriate certificate. If the key store contains multiple certificates, and if the component referencing the key store includes a property specifying the certificate's nickname, the certificate with that alias is selected. Otherwise, the server lets the Java virtual machine (JVM) select a certificate that might not be well-defined.

The server also provides trust manager providers, which determine whether to trust the certificate chains with which it is presented. A trust manager provider can reference a specified trust store file, but other options include the JVM default trust store, which uses the Java installation's default set of trusted issuers,

and the blind trust manager provider, which automatically trusts every certificate chain that is presented to it.

**Note:**

Never use a blind trust manager in a production environment because it leaves the server vulnerable to impersonation and man-in-the-middle attacks. However, a blind trust manager can be convenient in test environments when troubleshooting certain types of problems.

**Replacing listener certificates**

Certificate authorities typically restrict the lifespans of the certificates that they sign. If you use a certification authority to issue listener certificates, you are likely replacing the certificates on a regular basis.

About this task

The **replace-certificate** tool performs the following steps:

1. Obtain a new certificate chain.
2. Make necessary updates to the key manager provider and the connection handler configurations
3. Update the server instance listener configuration with the new certificate.

The **replace-certificate** tool offers the following modes of operation:

Interactive mode

Walks you through the process of obtaining a new certificate and installing it in the server. Interactive mode also displays the non-interactive commands that are required to achieve the same result.

Non-interactive mode

Useful when scripting the process of replacing a certificate.

## Steps

- To replace a listener certificate, run the `replace-listener-certificate` subcommand of the `replace-certificate` tool.

**Note:**

You can replace certificates manually, but the `replace-certificate` tool automates the process. The `replace-certificate` tool provides information about multiple listener certificates during the transitional phase that occurs when you install them.

The `replace-listener-certificate` subcommand takes arguments that provide the following information:

- Arguments required to authenticate to PingDirectory Server, such as `--bindDN` and `--bindPasswordFile`
- Details about the key store that contains the new certificate
- Updates that must be made to the key and trust manager providers
- Whether to signal the HTTP connection handler to reload its certificates after the update is complete

The following arguments are available:

Argument	Description
<code>--source-key-store-file {path}</code>	Path to the Java KeyStore (JKS) or PKCS #12 file that contains the private key entry with the new certificate chain. This argument is required.
<code>--source-key-store-password {password}</code>	Clear-text password that is needed to access the contents of the source key store.
<code>--source-key-store-password-file {path}</code>	Path to the file that contains the password necessary to access the contents of the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database.
<code>--source-certificate-alias {alias}</code>	Password that is required to access the appropriate private key in the source key store. If neither the <code>--source-private-key-password</code> nor the <code>--source-private-key-password-file</code> argument is provided, the key store password is used as the private key password.
<code>--source-private-key-password-file {path}</code>	Path to the file that contains the password needed to access the appropriate private key in the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database. If neither the <code>--source-private-key-password</code> nor the <code>--source-private-key-password-file</code> argument is provided, the key store password is used as the private key password.
<code>--key-manager-provider {name}</code>	Name of the key manager provider that is updated to use the new certificate chain. The

Argument	Description
	value must identify a file-based key manager provider, and the new certificate chain must be enabled. Defaults to <code>JKS</code> if a value is not specified.
<code>--trust-manager-provider {name}</code>	Name of the trust manager provider that is updated with the information required to trust the new certificate chain. The value must identify a file-based trust manager provider, and the new certificate chain must be enabled. If neither this argument nor the <code>--use-jvm-default-trust-manager-provider</code> argument is provided, the tool assumes that the name of the trust manager provider is identical to the name of the key manager provider.
<code>--use-jvm-default-trust-manager-provider</code>	Indicates that the server must be configured to use the JVM-default trust manager provider, which trusts certificates signed by issuers in the <code>cacerts</code> trust store provided with the Java virtual machine (JVM), rather than updating an existing trust manager provider.
<code>--target-certificate-alias {alias}</code>	<p>Alias to use for the new certificate in the key manager provider's key store, and for appropriate updates in the trust manager provider's trust store. Defaults to an alias of <code>server-cert</code> if a value is not specified.</p> <div data-bbox="867 1073 1468 1318" style="border: 1px solid black; padding: 5px;"> <p> <b>Note:</b></p> <p>If the key manager provider's key store, or the trust manager provider's trust store, already contains an entry with the given alias, the existing entry is renamed.</p> </div>
<code>--reload-http-connection-handler-certificates</code>	<p>Indicates that the tool is requesting that the server cause any HTTPS-based connection handlers to reload their certificates, so that the connection handlers can use the updated certificate.</p> <p>LDAP connection handlers react to the change immediately and start presenting the new certificate chain during subsequent TLS negotiations. HTTPS connection handlers continue using the former certificate until the connection handler is restarted or until the connection handler is asked specifically to reload its certificates.</p> <div data-bbox="867 1787 1468 1837" style="border: 1px solid black; padding: 5px;"> <p> <b>Note:</b></p> </div>

Argument	Description
	This option might prevent clients with existing TLS sessions that were negotiated with the former certificate from being resumed.

- To remove earlier certificates from the server instance listener configuration, run the **purge-retired-listener-certificates** subcommand.

 **Note:**

The **purge-retired-listener-certificates** subcommand does not take arguments other than the ones that are required to authenticate to the server.

By default, the **replace-certificate** tool updates the server instance listener configuration object to include the new listener certificate, and it merges the old and new certificates residing in the configuration object.

### Inter-server certificates

Each server instance in a topology has an inter-server certificate that is generated during the setup process.

The inter-server certificate is not exposed to clients, so a trusted issuer does not need to sign it. Instead, the topology registry, representing a mirrored portion of the configuration with information about every PingDirectory Server instance in the environment, contains the information that each instance needs to trust the inter-server certificates for all other instances.

Inter-server certificates can be used to protect certain secrets that are shared among servers within the topology, like the secrets that are used to digitally sign log files, backups, and LDIF exports. Inter-server certificates include the encryption keys that reversible password-storage schemes use.

The inter-server certificate is generated with a long lifespan. Replace it only when you suspect that its private key is compromised.

### Replacing the inter-server certificate

During the installation process, the inter-server certificate is generated with a long lifespan and does not require replacement under normal circumstances. You should replace the inter-server certificate only if you suspect that its private key is compromised.

#### About this task

The inter-server certificate is intended for use only between server instances within the same topology. Because it is not exposed to regular clients, the inter-server certificate does not need to be trusted.

The **replace-certificate replace-inter-server-certificate** command performs the following steps:

- Acquires the new inter-server certificate from a provided Java KeyStore (JKS) or PKCS #12 key store
- Makes the necessary updates to the `config/ads-truststore` file in the server key store
- Updates the server instance configuration object to include the new inter-server certificate

 **Note:**

To avoid the need to replace the inter-server certificate on a regular basis, use a self-signed certificate with a long lifespan. Each server instance must possess its own, unique inter-server certificate that satisfies the following conditions:

- Uses an RSA key pair

- Has a minimum key size of 2048 bits

The following types of certificates are not allowed:

- Certificates with an elliptic curve key pair
- Certificates with an RSA key that is smaller than 2048 bits

## Steps

- To replace the inter-server certificate, run the `replace-inter-server-certificate` subcommand of the `replace-certificate`.

The `replace-inter-server-certificate` subcommand takes a subset of the arguments that are used with the `replace-listener-certificate` subcommand, including the following arguments:

- `--source-key-store-file {path}--source-key-store-password {password}`
- `--source-key-store-password-file {path}`
- `--source-certificate-alias {alias}`
- `--source-private-key-password {password}`
- `--source-private-key-password-file {path}`
- To delete earlier values that are no longer needed, run the `purge-retired-inter-server-certificates` subcommand.

### Note:

By default, the new inter-server certificate is merged with the existing values in the server instance configuration entry.

## X.509 certificates

The server supports X.509 certificates, the most common type of certificates. [RFC 5280](#) describes X.509v3, which provides the current version of the specification.

An X.509v3 certificate includes the following components:

### X.509 encoding version

Enables the differentiation between an X.509v3 certificate and one that conforms to an earlier or later version of the specification.

### Serial number of the certificate

Integer value that uniquely identifies a certificate as issued by a certification authority.

### Subject DN

Distinguished name for the certificate, which often provides details about the context in which the certificate is to be used. For more information, see [Certificate subject DNs](#) on page 415.

### Issuer DN

Distinguished name for the issuer certificate, which is the certificate used to sign the certificate. For a self-signed certificate, this value matches the subject DN.

### Validity window

Indicates the timeframe during which the certificate is considered valid. This component includes the following elements:

- **notBefore**  
Specifies the earliest time at which the certificate is considered valid.

- **notAfter**

Specifies the latest time at which the certificate is considered valid.

#### Public key

Public portion of a pair of cryptographically linked keys. For more information, see [Certificate key pairs](#) on page 416.

#### Signature

A type of cryptographic proof that the certificate truly was sent from the issuer and has remained unaltered. A self-signed certificate is signed with its own private key. Otherwise, it is signed with the issuer's private key.

An X.509v3 certificate might also include the following optional components:

#### Subject unique ID

Uniquely identifies the certificate. This component has been deprecated in favor of the subject key identifier extension, so it is generally omitted from X.509v3 certificates.

#### Issuer unique ID

Subject unique ID of the issuer certificate, if available. This component has been deprecated in favor of the authority key identifier extension.

#### Set of extensions

Provides additional context for the certificate and the manner in which it is used. For more information, see [Certificate extensions](#) on page 417.

### Certificate subject DNs

A certificate's subject distinguished name (DN) provides information about how the certificate should be used.

Like an LDAP DN, a certificate's subject DN consists of a comma-delimited series of attribute-value pairs. However, unlike an LDAP DN, the attribute names in a certificate subject DN are typically written in all uppercase characters.

A certificate's subject DN is also referred to as its subject. The following attributes commonly appear in a certificate subject.

Attribute name	Attribute description
CN	Common name   <b>Note:</b> For a listener certificate, the CN attribute typically identifies the host name that clients use to access the certificate. However, the subject alternative name extension is recommended more highly for accomplishing the same task. Most certificate subject DNs include at least the CN attribute.
E	Email address
OU	Name of the organizational unit, such as the relevant department
O	Name of the organization or company
L	Name of the locality, such as the appropriate city

Attribute name	Attribute description
ST	Full name of the state or province
C	ISO 3166 country code

A certificate subject includes at least one attribute-value pair, and the `CN` attribute is typically present. Other attributes can be omitted, although the `O` and `C` attributes are also common. For example, a listener certificate for a server with an address of `ldap.example.com`, which is run by the US-based company Example Corp, might have a subject of `CN=ldap.example.com,O=Example Corp,C=US`.

### Certificate key pairs

Each certificate contains a key pair that consists of two keys that are linked cryptographically. If you encrypt data with one key, the data can be only decrypted with the other key.

Although a key pair can be created easily when both keys are generated simultaneously, the process of deriving one key from the other is extremely difficult, a process categorized in cryptographic terms as computationally infeasible.

When generating a key pair, one key is designated as the public key, and the other key is designated the private key. The public key can be made widely available, but the private key must be kept secret and not shared with anyone.

As long as the secrecy of the private key is maintained, the key pair can be used to perform the following functions:

- Encryption, sometimes referred to as confidentiality

If someone wants to send you a secret message without anyone else viewing it, the message can be encrypted with your public key. Only you possess the private key, so only you can decrypt the message.

- Digital signatures

If you encrypt data with your private key, it can be decrypted only with your public key. Because your public key can be made widely available, this encryption method does not actually protect the content. However, digital signatures prove that a message came from you because only your private key could have generated it.

#### Note:

When generating a digital signature, the entire message is generally not encrypted. Only a hash of the message is encrypted, typically by using a digest algorithm like SHA-256.

This approach protects the integrity of a message. A decrypted signature that matches the digest of the original message guarantees that the message came from you and that it has remained unaltered since you signed it.

The following public key algorithms are used primarily in certificates that facilitate TLS communication:

- RSA, which is based on the multiplication of large prime numbers
- EC, which is based on computations that involve special types of elliptical curves

Although RSA is supported more widely than EC, it is slower and requires larger keys to achieve the same level of security. To support legacy clients, you should use an RSA certificate and choose a key size of at least 2,048 bits.

If all of your clients support EC certificates, you should use an EC certificate with a key size of at least 256 bits.

## Certificate extensions

Extensions provide additional context for a certificate.

Some of the more common extension types include the following:

### Subject key identifier

Holds a unique identifier for the certificate, which is generally derived from the certificate's public key.

### Authority key identifier

Holds the subject key identifier for the issuer certificate. This extension type helps to identify the issuer certificate, especially when presented with an incomplete certificate chain.

### Subject alternative name

Holds a list of ways that clients are expected to reference a server when establishing a connection to it.

#### Note:

Clients must take this information into account when deciding whether to trust a server's certificate.

The most common types of values include DNS names, IP addresses, and URIs. DNS names must be fully qualified, but can optionally use an asterisk in the leftmost component to match any single name in that component. For example, `*.example.com` could match `www.example.com` or `ldap.example.com`, but would not match `ldap.east.example.com` or `example.com`.

## Key usage

Provides information about the manner in which the certificate is expected to be used. The following key usages are allowed:

### `digitalSignature`

Indicates that the certificate can be used for digitally signing data, excluding certificates and certificate revocation lists (CRL).

### `nonRepudiation`

Indicates that the certificate can be used to prevent denying the authenticity of a message. `nonRepudiation` is also known as `contentCommitment`.

### `keyEncipherment`

Indicates that the certificate can be used to protect encryption keys, such as symmetric keys that are derived during TLS key agreement.

### `dataEncipherment`

Indicates that the certificate can be used for encrypting data directly.

### `keyAgreement`

Indicates that the certificate's public key can be used for key agreement, such as deriving the symmetric key that protects TLS communication.

### `keyCertSign`

Indicates that the certificate can act as a certification authority and be used for signing other certificates.

### `cRLSign`

Indicates that the certificate can be used to sign CRLs.

`encipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for encrypting data during key agreement.

`decipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for decrypting data during key agreement.

### Extended key usage

Acts as an alternative to the key usage extension and provides additional high-level functionality. The following extended key usages are allowed:

`serverAuth`

Indicates that the server can present the certificate to the client during TLS negotiation.

`clientAuth`

Indicates that the client can present the certificate to the server during TLS negotiation.

`codeSigning`

Indicates that the certificate can be used to sign source and compiled code.

`emailProtection`

Indicates that the certificate can be used to sign or encrypt email messages.

`timeStamping`

Indicates that the certificate can be used to assert the time that an event occurred.

`ocspSigning`

Indicates that the certificate can be used to sign an online certificate status protocol (OCSP) response.

### Basic constraints

Indicates whether the certificate can act as a certification authority and, if so, the maximum number of intermediate certificates that can follow it in a certificate chain.

### Certificate chains

A certificate chain is an ordered list of one or more certificates. In such a chain, each subsequent certificate is the issuer of the previous certificate.

During TLS negotiation, the server presents a certificate chain to the client, which determines whether to trust the chain and continue with the negotiation. The client can also present its own certificate chain to the server.

If a certificate is self-signed, its chain contains only that single certificate. If a certificate is signed by a self-signed certificate authority (CA) certificate, such as a root CA, the chain contains two certificates: the server certificate and the CA certificate that follows it. If a single intermediate CA (a CA certificate that is signed by a root CA) is present, the chain contains the server certificate, followed by the intermediate CA, and then the root CA.

Intermediate certificate authorities are useful for security purposes, especially in commercial authorities. If a client trusts a root CA certificate, it is likely to trust anything with that root CA certificate at the base of its chain. Consequently, the root CA certificate must be kept secure.

**Note:**

If the root CA certificate is compromised, any certificate that is directly or indirectly signed by it can no longer be trusted.

With intermediate CA certificates, the root certificate can be kept offline in secure storage and used only when a new intermediate CA certificate must be signed. The intermediate CA certificates can be used to sign end-entity certificates, but must be protected to avoid compromising any of the certificates. A compromised certificate must be revoked along with all of the certificates that it signed. In such a scenario, the root CA can be used to sign a new certificate.

**Note:**

The certificate chain that the server presents to the client, or that the client presents to the server, during TLS negotiation does not always need to be the complete chain. If the root CA at the end of the chain is widely trusted, the server can assume that the client already has that root CA in its default set of trusted certificates. The server can leave that root CA off the chain with the assumption that the client will retrieve it from its default trust store. While the same assumption could theoretically be true for intermediate CA certificates, only the root CA certificate is commonly omitted. When a client receives an incomplete chain, the client looks in its default trust store to determine whether the trust store contains the issuer certificate, which it can identify by using properties like the issuer distinguished name (DN) or an authority key identifier extension.

The certificate at the head of a certificate chain, which appears as the first one in the list, is often called the end-entity certificate. If this certificate appears at the head of the chain that a server presents during TLS negotiation, it is referred to as the server certificate. If the certificate appears at the head of a chain that a client presents, it is referred to as a client certificate. The certificate at the end of a complete chain must be a root CA certificate. In the case of a self-signed certificate, the chain contains only a single certificate that serves both roles.

**About representing certificates, private keys, and certificate signing requests**

X.509 is an encoding format that uses the ASN.1 distinguished encoding rules (DER), which exist in binary format. When writing a certificate to a file, either a raw DER format or a plaintext format called PEM can be used.

PEM encoding consists of a line that contains the text `-----BEGIN CERTIFICATE-----`, followed by a set of lines that contains the base64-encoded representation of the raw DER bytes (typically with no more than 64 characters per line), followed by a line that contains the text `-----END CERTIFICATE-----`.

The X.509 encoding contains a certificate's public key, but not its private key. The PKCS #8 specification in [RFC 5958](#) describes the encoding for private keys. This approach uses a DER encoding with a PEM variant that instead uses the following header and footer, respectively.

```
-----BEGIN PRIVATE KEY-----
-----END PRIVATE KEY-----
```

RFC 5958 also describes an encrypted representation of the private key, but that format is currently unsupported.

The PKCS #10 specification in [RFC 2986](#) describes the CSR format. This format uses a DER encoding with a PEM variant that uses the following header and footer, respectively.

```
-----BEGIN CERTIFICATE REQUEST-----
-----END CERTIFICATE REQUEST-----
```

Some implementations use the following alternate, nonstandard forms.

```
-----BEGIN NEW CERTIFICATE REQUEST-----
-----END NEW CERTIFICATE REQUEST-----
```

## Certificate trust

When a server presents its certificate chain to a client during TLS negotiation, the client decides whether to trust the certificate chain and concludes whether it is communicating with a legitimate server instead of an impostor.

If a client is tricked through DNS hijacking into communicating with a rogue application instead of with a legitimate server, the application can steal the client's credentials, or can fool the client into concluding that it has performed an action that it has not performed. If a rogue application acts as a broker between the client and the legitimate server, the client might be unable to detect the change, and the malicious application might be capable of stealing data or altering the communication. Consequently, you should avoid `trust all` or `blind trust` options in a production environment.

When determining whether to trust a server certificate chain, a client performs the following steps.

### Processing steps

1. Verifies that it has received the complete certificate chain.

If a server presents an incomplete chain, the client must ensure that it can complete the chain with information in an explicitly provided trust store or default trust store. If the client cannot complete the certificate chain, the chain is not trusted.

2. Verifies that each subsequent certificate in the chain is the issuer certificate for, and that its private key was used to sign, the certificate that precedes it.

#### Note:

If a certificate chain contains extraneous certificates, or if a subsequent certificate did not issue the certificate that precedes it, the chain is not trusted.

3. Confirms that it has a reason to trust the certificate at the root of the chain.

#### Note:

This step is generally performed by ensuring that the root certificate authority (CA) certificate can be found in either a default trust store or a trust store that is configured for use by the client. If the client has no prior knowledge of the root CA certificate, the chain is not trusted.

4. Verifies that the current time lies within the validity window for each certificate in the chain.

#### Note:

The chain is not trusted under the following conditions:

- When the `notBefore` value of any certificate in the chain is later than the current time.
- When the `notAfter` value of any certificate in the chain is earlier than the current time.

5. Verifies that the server certificate at the head of the chain is suitable for the server with which the client thinks it is communicating.

**Note:**

The client must verify that the address used to connect to the server matches one of the following values:

- The `CN` attribute of the certificate's subject.
- One of the values of any subject alternative name extension.

These steps represent a starting point. If necessary, the client can perform additional types of validation. For example, if a root or intermediate certification authority maintains a certificate revocation list (CRL) or supports the online certificate status protocol (OCSP), the client must verify that none of the certificates in the chain has been revoked. The client can also verify that the CA certificates include the basic constraints extension, and that the server certificate does not contain too many levels. Other checks, like those that use certificate policy extensions, can also be performed.

### Keystores and truststores

A keystore is a type of database that holds certificates.

The following examples represent the most common forms of keystores:

- File that uses the Java-specific Java KeyStore (JKS) format
- File that uses the standard PKCS #12 format
- Collection of files that holds certificates and private keys, typically in PEM or DER format
- Hardware security module (HSM) that makes the certificate information available through an interface like PKCS #11

The server supports file-based keystores by using the JKS and PKCS #12 formats and by using hardware security modules that are accessible through PKCS #11. The server does not currently support a keystore format that consists of individual certificate and private key files. To import these files into a JKS or PKCS #12 keystore, use the `manage-certificates` tool.

A keystore also represents a collection of entries, each of which is identified by a name that an alias calls. Keystores can have the following entry types:

#### Private key entries

Contain a certificate chain and a private key. When a server accepts a TLS-based connection, it uses a private key entry to obtain the certificate chain that it presents to the client. The server can also use the private key from the same entry to process its key agreement. Similarly, a client uses a private key entry when presenting its own certificate chain to a server.

#### Trusted certificate entries

Contain a single certificate without a private key. As the name implies, a trusted certificate entry is intended primarily for use when determining whether to trust a certificate chain that is presented during TLS negotiation.

#### Secret key entries

Contain a secret key only, without an associated certificate. These types of entries are not used for TLS processing. Instead, they hold symmetric encryption keys or other types of secrets.

A password, sometimes called a PIN, protects the contents of a keystore. In some cases, like with JKS keystores, some content might be accessible without a password, and a password might be required only when trying to access private keys or secret keys. In other cases, like with PKCS #12 keystores, you might need a password for any interaction with the keystore.

Additional passwords can further protect private keys. This approach is often the same as with the keystore password, but the password can be different. This tactic is useful when a single keystore is shared for multiple purposes, for example, and when merely having access to the keystore does not guarantee access to all of the data that it contains.

**Note:**

A truststore is another name for a keystore that is intended primarily for use when determining whether to trust a certificate chain that has been presented. Truststores generally contain primarily trusted certificate entries, but that case is not required.

Java runtime environments typically include a default truststore, often `jre/lib/security/cacerts` or `lib/security/cacerts`, that is prepopulated with several widely trusted certification authority certificates. When presented with a certificate that one of these authorities has signed, the default truststore can allow the certificate to be trusted without any additional configuration. When presented with a self-signed certificate, or when presented with a certificate that is signed by an issuer not in the default truststore, such as a private corporate certification authority, a separate truststore is required.

**Transport Layer Security (TLS)**

TLS describes a mechanism for securely communicating between two parties that might have no prior knowledge of each other.

TLS is the successor to SSL, and the two terms are often used interchangeably, even though such usage might not technically be correct.

**Note:**

SSL remains the more widely recognized term. The abbreviation TLS occasionally generates confusion with the StartTLS extended operation, particularly in LDAP.

TLS provides security in the form of the following main components:

**Certificate trust**

Is about reassuring a connection-initiating client that it is communicating with the server to which it intended to connect. To ensure that the server shares the same degree of confidence in the identity and legitimacy of the client, it can ask the client to present its own certificate chain. For more information, see [Certificate Trust](#).

**Cipher selection**

Involves choosing the cipher and the key to protect the bulk of the communication. Although a client can use a server certificate's public key to encrypt data before sending it, this approach can lead to the following issues:

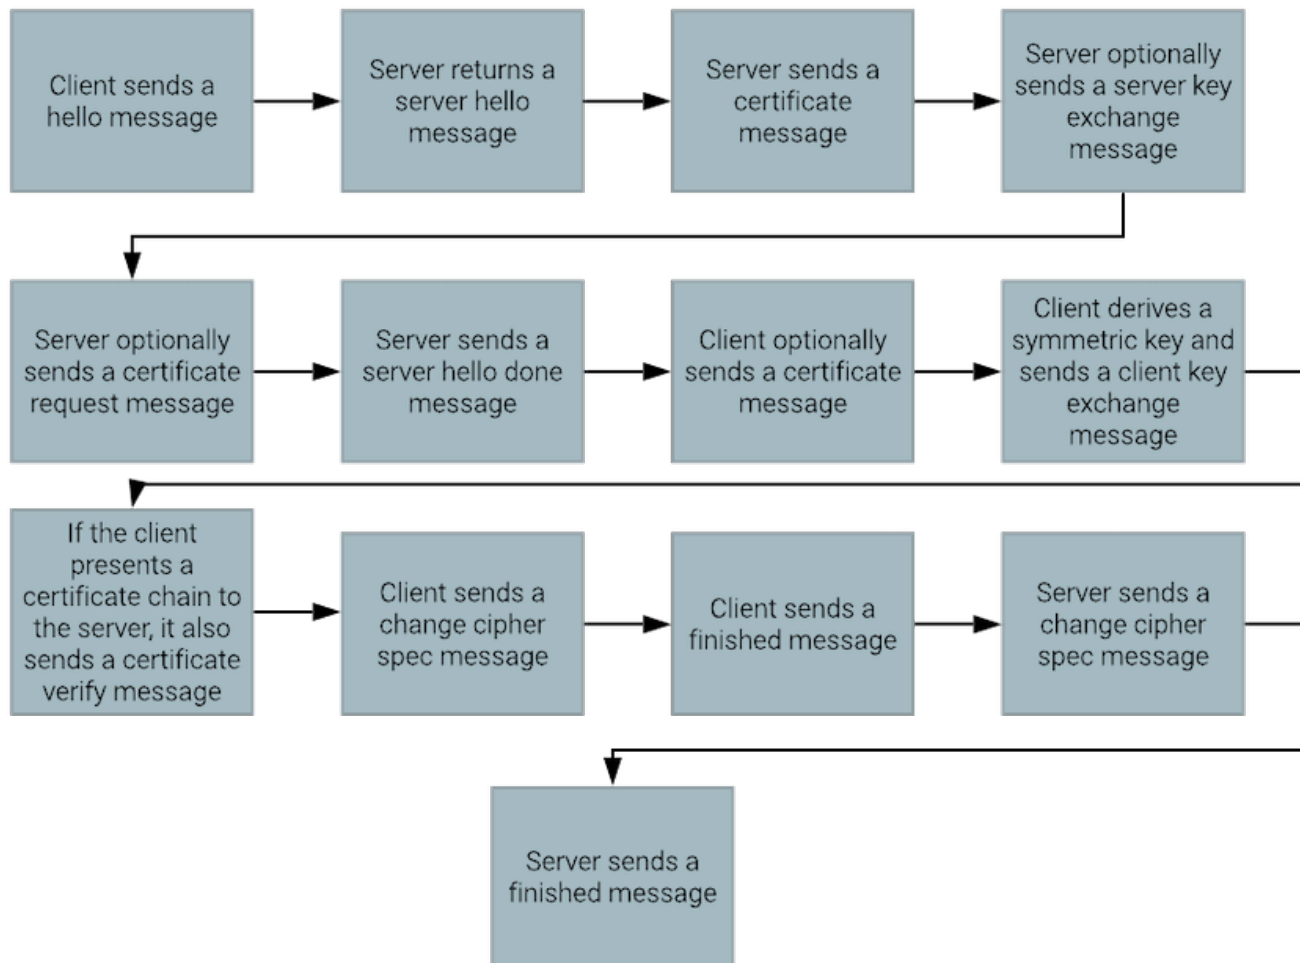

- Unless the client presents its own certificate chain to the server, the server cannot encrypt the data that it sends back to the client.
- Public key encryption is considerably slower than symmetric encryption, in which the same key is used for both encryption and decryption. Public key encryption is also called asymmetric encryption because different keys are used to encrypt and decrypt data.
- If you rely entirely on the security of a private key to ensure the secrecy of a communication, and if the private key becomes compromised, data that has been encrypted with the private key must also be considered compromised.

Rather than relying solely on public key encryption to protect communication between a client and server, the TLS negotiation process allows a client and server to agree on the type of encryption and the secret key to use after completing the negotiation process.

## TLS handshakes

The process of negotiating the TLS is referred to as the handshake.

Although the exact process depends on the TLS version that is ultimately chosen, the following steps represent the basic components of a TLS 1.2 handshake:

## TLS processing steps

1. The client sends a `hello` message that provides the server with the following information:
  - Highest supported version of the TLS protocol
  - The cipher suites that the client uses
  - Set of extensions with additional information:
    - The address that the client uses to communicate with the server
    - The signature algorithms and elliptic curves that the client supports
    - Whether the client supports secure renegotiation
2. The server returns a `server hello` message that provides the client with the following information:
  - The TLS protocol version that the server uses
  - The cipher suite that the server selects

The server can also provide its own extensions to the client.

3. The server sends a `certificate` message that provides its certificate chain to the client.
4. The server can optionally send a `server key exchange` message with additional information that the client might need to securely derive the same symmetric encryption key that the server generates.
5. The server can optionally send a `certificate request` message that asks the client to present its own certificate chain to the server.
6. The server sends a `server hello done` message to inform the client that it has completed its `hello` sequence.
7. The client can optionally send a `certificate` message to the server with its own certificate chain.

**Note:**

The client sends a `certificate` message only when the server initially sends a certificate request. If the client receives such a request, it can refuse to, and probably will not, send a certificate chain. The server decides whether to require a client certificate chain. In LDAP, the server commonly asks the client to present a certificate, but continues with TLS negotiation even if the client does not present one. This approach supports authentication methods like SASL EXTERNAL, in which a client uses the certificate chain that it presents during TLS negotiation as proof of its identity.

8. The client derives a symmetric key to use for the remainder of the encrypted processing, and sends a `client key exchange` message to the server. The `client key exchange` message includes the information that the server needs to generate the same key. Only the client and server know the value of the key, even if another entity can observe the communication that passes between the client and the server.
9. If the client presents a certificate chain to the server, it also sends a `certificate verify` message to prove that the private key for the certificate is included at the head of the chain.
10. The client sends a `change cipher spec` message to the server, which informs the server that the client will use the agreed-upon symmetric key to encrypt everything else that it sends to the server.
11. The client sends a `finished` message to the server to indicate that it has completed its portion of the handshake.
12. The server sends a `change cipher spec` message to the client, which informs the client that the server will use the agreed-upon symmetric key to encrypt everything else that it sends to the client.
13. The server sends a `finished` message to the client to indicate that it has completed its portion of the handshake.

TLS 1.3 uses a different handshake sequence that can require only a single round-trip to exchange the necessary information between the client and the server. TLS 1.2 requires two round-trips. To accomplish this task, TLS 1.3 tries to guess the type of key agreement that the server wants to use, and sends the relevant information to the server up front instead of waiting to hear from the server.

Because an extra round of communication between the client and server is eliminated, the server finishes its portion of the negotiation before the client. The server must assume that the client trusts its certificate chain. Because the server might log a successful negotiation only to discover late, through a TLS alert, that the client rejected the certificate, this approach might complicate certain types of troubleshooting.

### Key agreement

Key agreement processing provides a critical component of TLS negotiation.

It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

#### RSA key exchange

The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.

#### Diffie-Hellman (DH) key exchange

The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, use ECHDE over DHE, and either of those options over RSA. The DH algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. The use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

### LDAP StartTLS extended operation

In most scenarios, a client that uses TLS establishes a connection to a port that is dedicated to its use, like 636 (LDAPS) or 443 (HTTPS).

The client begins the TLS-negotiation process by sending a `client hello` message over the connection. In some scenarios, the client establishes a non-secure connection and later converts it to a secure one. In LDAP, this task is accomplished by using the `StartTLS` extended operation.

The `StartTLS` extended operation provides the following advantages over a dedicated LDAPS connection:

- To enable secure as well as insecure communication, only one port needs to be opened through a firewall.
- A client can use opportunistic encryption, in which the client performs the following steps:
  1. Queries the root DSE to determine whether the server supports StartTLS.
  2. Secures the connection, if possible.

Opportunistic encryption is useful in scenarios like following referrals because LDAP URLs do not officially support LDAPS as a scheme.

To ensure that a communication is always secure, use LDAPS instead of establishing an insecure connection that you secure later with the `StartTLS` extended operation. If you enable support for unencrypted LDAP communication, as `StartTLS` requires, a client might send a password-containing bind request or other sensitive data over an unencrypted connection. A server can be configured to reject unencrypted communication, but it cannot prevent a client from sending an unencrypted request.

#### Note:

Although you can use `StartTLS` to temporarily secure a connection before falling back on an unencrypted LDAP communication, the server does not support this strategy.

### About the `manage-certificates` tool

PingDirectory Server offers a `manage-certificates` tool that enables interaction with Java KeyStore (JKS) and PKCS #12 key stores.

Although it behaves similarly to the `keytool` utility that accompanies most Java distributions, `manage-certificates` is easier to use, provides improved usage information, and offers additional functionality.

### Available subcommands

The `manage-certificates` tool uses the following subcommands to indicate which function to invoke:

Subcommand	Function
<code>list-certificates</code>	Lists the certificates in a keystore.
<code>import-certificate</code>	Imports a certificate into a trusted certificate entry or imports a certificate chain and private key into a private key entry.
<code>export-certificate</code>	Exports a certificate from a keystore.
<code>export-private-key</code>	Exports a private key from a keystore.
<code>generate-self-signed-certificate</code>	Generates a self-signed certificate.
<code>generate-certificate-signing-request</code>	Generates a certificate-signing request that can be provided to a certification authority.
<code>sign-certificate-signing-request</code>	Signs a certificate-signing request with a specified issuer certificate.
<code>check-certificate-usability</code>	Checks a specified certificate in a keystore to verify whether it is suitable for use as a listener certificate.
<code>trust-server-certificate</code>	Initiates the TLS-negotiation process with a specified server to obtain its certificate chain so that a truststore can be updated with the necessary information to trust the chain.
<code>display-certificate-file</code>	Displays the contents of a file that contains one or more PEM-encoded or DER-encoded X.509 certificates.
<code>display-certificate-signing-request-file</code>	Displays the contents of a file that contains a PEM-encoded or DER-encoded PKCS #10 certificate-signing request (CSR).
<code>change-certificate-alias</code>	Changes the alias for an entry in a keystore.
<code>change-keystore-password</code>	Changes the password for a keystore.
<code>change-private-key-password</code>	Changes the password that protects the private key for a specified entry in a keystore.

### Common arguments

Most of the `manage-certificates` subcommands require access to a Java KeyStore (JKS) or PKCS #12 keystore. In such instances, use the `--keystore` argument to specify the path to the keystore.

If the keystore already exists, the tool detects automatically whether it is a JKS or PKCS #12 keystore. If the operation creates a new keystore, you can specify the type explicitly by using the `--keystore-type` argument, followed by a value of `JKS` or `PKCS12`. If you do not specify the keystore type, a default value of `JKS` is used.

Some situations require you to provide the password that is needed to access the keystore. For a JKS keystore, you might need to provide a keystore password only for operations that involve creating

a keystore or accessing a private key. However, you will likely need to provide the password for all operations that involve a PKCS #12 keystore.

To provide a keystore password, use one of the following arguments:

- `--keystore-password`, followed by the clear-text password for the keystore.
- `--keystore-password-file`, followed by the path to a file that contains the password for the keystore. The file might contain the password in the clear, or it might be encrypted with a definition from the server's encryption-settings database.
- `--prompt-for-keystore-password`. If this argument is provided, the tool prompts you interactively to provide the password.

If a private key is protected with a different password than the keystore itself, specify one of the following arguments to provide the private key password:

- `--private-key-password`, followed by the plaintext password.
- `--private-key-password-file`, followed by the path to a file that contains the clear-text or encrypted password.
- `--prompt-for-private-key-password`, which causes the tool to prompt interactively for the password.

Several operations require you to specify the keystore entry to target. In such scenarios, provide the `--alias` argument, followed by the name of the alias for that entry.

### Listing the certificates in a keystore

List the certificates available in a keystore.

#### Steps

- To list the certificates in a keystore, use the `list-certificates` subcommand.

This subcommand requires you to specify the path to the keystore file, and possibly the password that is needed to access the keystore. The following options are also available:

Option	Description
<code>--alias {alias}</code>	Specifies the alias of the certificate to display. If this value is not provided, all certificates are displayed. To list more than one specific certificate, specify this value multiple times.
<code>--display-pem-certificate</code>	Includes a PEM-encoded representation of each certificate as part of the output.
<code>--verbose</code>	Includes details about each certificate.

#### Example:

The following command demonstrates the basic listing of a keystore that contains a single certificate chain.

```
$ bin/manage-certificates list-certificates \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin

Alias: server-cert (Certificate 1 of 2 in a chain)
Subject DN: CN=ds1.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Certification Authority,O=Example Corp,C=US
Validity Start Time: Saturday, November 9, 2019 at 11:26:09 AM CST
                    (8 minutes, 15 seconds ago)
Validity End Time: Sunday, November 8, 2020 at 11:26:09 AM CST
                   (364 days, 23 hours, 51 minutes, 44 seconds from now)
Validity State: The certificate is currently within the validity window.
```

```

Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint:  42:f8:85:97:bf:88:bc:74:4b:5b:ce:0c:54:43:9b:44:6b:

### Generating self-signed certificates

The process of creating a self-signed certificate is straightforward because a self-signed certificate claims itself as its own issuer.

Although self-signed certificates are convenient for testing environments, clients do not trust them by default. Consequently, you should not use them as listener certificates in production environments.

The **manage-certificates** tool offers a **generate-self-signed-certificate** subcommand that can create a self-signed certificate. In addition to the arguments that provide information about the keystore, certificate alias, and optional private key password, the following arguments are available.

Argument	Description
<code>--subject-dn {subject}</code>	Subject DN for the certificate to create. This value is required.
<code>--days-valid {number}</code>	Number of days that the certificate remains valid. Defaults to <b>365</b> if no value is specified.
<code>--validity-start-time {timestamp}</code>	Indicates the time at which the certificate begins its validity window. This value is assumed to reflect the local time zone, and must be expressed in the form <b>YYYYMMDDhhmmss</b> , where a value of <b>20190102030405</b> indicates January 2, 2019, at 3:04:05 AM.  Defaults to the current time if no value is specified.

Argument	Description
<pre>--key-algorithm {name}</pre>	<p>Name of the algorithm to use when generating the key pair. For a listener certificate, this value is typically <b>RSA</b> or <b>EC</b>.</p> <p>Defaults to <b>RSA</b> if no value is specified.</p> <p> <b>Note:</b></p> <p>This argument cannot be used in conjunction with the <code>--replace-existing-certificate</code> argument.</p>
<pre>--key-size-bits {number}</pre>	<p>Length of the key, in bits, to generate. If the <code>--key-algorithm</code> argument is given, then <code>--key-size-bits {number}</code> must also be specified. Conversely, if the <code>--replace-existing-certificate</code> argument is given, then <code>--key-size-bits {number}</code> must not be specified.</p> <p>Typical key sizes are:</p> <ul style="list-style-type: none"> <li>▪ RSA key – 2048 or 4096 bits</li> </ul> <p style="padding-left: 20px;">If a default RSA key is used but this argument is not provided, a default key size of 2048 bits is used.</p> <ul style="list-style-type: none"> <li>▪ Elliptic curve key – 256 or 384 bits</li> </ul>
<pre>--signature-algorithm {name}</pre>	<p>Name of the algorithm to use to sign the certificate. If the <code>--key-algorithm</code> argument is used to specify an algorithm other than <b>RSA</b>, then <code>--signature-algorithm {name}</code> must also be specified.</p> <p>If the <code>--replace-existing-certificate</code> argument is used, then <code>--signature-algorithm {name}</code> must not be specified.</p> <p>Typical signature algorithms include <b>SHA256withRSA</b> for certificates with RSA keys, and <b>SHA256withECDSA</b> for certificates with elliptic curve keys. If a default key algorithm is used but the <code>--signature-algorithm {name}</code> argument is not provided, a default value of <b>SHA256withRSA</b> is used.</p>
<pre>--replace-existing-certificate</pre>	<p>Uses the new certificate to replace an existing certificate in the key store (within the same alias), and reuses the key for that certificate.</p>

Argument	Description
<code>--inherit-extensions</code>	Indicates that, when replacing an existing certificate, the new certificate contains the same set of extensions as the existing certificate. If the <code>--replace-existing-certificate</code> argument is provided, but the <code>--inherit-extensions</code> argument is omitted, the new certificate contains only arguments that are provided explicitly.
<code>--subject-alternative-name-dns {name}</code>	Indicates that the certificate is expected to have a subject alternative name extension with the provided DNS name. The given name must be fully qualified, although it can contain an asterisk (*) as a wildcard in the leftmost component.  To include multiple DNS names in the subject alternative name extension, specify the <code>--subject-alternative-name-dns {name}</code> argument multiple times.
<code>--subject-alternative-name-ip-address {address}</code>	Indicates that the certificate is expected to have a subject alternative name extension with the provided IP address. The given address must be a valid IPv4 or IPv6 address. No wildcards are allowed.  To include multiple IP addresses in the subject alternative name extension, specify the <code>--subject-alternative-name-ip-address {address}</code> argument multiple times.
<code>--subject-alternative-name-email-address {address}</code>	Indicates that the certificate is expected to have a subject alternative name extension with the provided email address.  To include multiple email addresses in the subject alternative name extension, specify the <code>--subject-alternative-name-email-address {address}</code> argument multiple times.
<code>--subject-alternative-name-uri {uri}</code>	Indicates that the certificate is expected to have a subject alternative name extension with the provided URI.  To include multiple URIs in the subject alternative name extension, specify the <code>--subject-alternative-name-uri {uri}</code> argument multiple times.

Argument	Description
<pre>--subject-alternative-name-oid {oid}</pre>	<p>Indicates that the certificate is expected to have a subject alternative name extension with the provided object identifier (OID). The given value must be a valid OID.</p> <p>To include multiple OIDs in the subject alternative name extension, specify the <code>--subject-alternative-name-oid {oid}</code> argument multiple times.</p>
<pre>--basic-constraints-is-ca {value}</pre>	<p>Indicates that the certificate is expected to have a basic constraints extension, with a specified value of <b>true</b> or <b>false</b>, for the flag indicating whether to consider the certificate a certification authority that can be used to sign other certificates.</p> <ul style="list-style-type: none"> <li>▪ For root and intermediate certificate authority (CA) certificates, the <code>--basic-constraints-is-ca {value}</code> argument must be present with a value of <b>true</b>.</li> <li>▪ For end-entity certificates, the <code>--basic-constraints-is-ca {value}</code> argument can optionally be present with a value of <b>false</b>.</li> <li>▪ For a self-signed certificate, specify the <code>--basic-constraints-is-ca {value}</code> argument with a value of <b>false</b> to indicate that the certificate is not considered a CA certificate.</li> </ul>
<pre>--basic-constraints-maximum-path-length {number}</pre>	<p>Indicates that the basic constraints extension is expected to include a path length constraint element with the specified value. Use this argument only if <code>--basic-constraints-is-ca</code> is provided with a value of <b>true</b>.</p> <p>A path length constraint value of <b>0</b> indicates that the certificate can be used to issue only end-entity certificates. A path length constraint value of <b>1</b> indicates that the certificate can be used to sign end-entity certificates or intermediate CA certificates, the latter of which can be used to sign only end-entity certificates.</p> <p>A value greater than <b>1</b> indicates the presence of several intermediate CA certificates between it and the end-entity certificate at the head of the chain.</p>

Argument	Description
<code>--key-usage {value}</code>	<p>Indicates that the certificate is expected to have a key usage extension with the specified value. The following values are allowed:</p> <ul style="list-style-type: none"> <li>▪ <b>digital-signature</b></li> <li>▪ <b>non-repudiation</b></li> <li>▪ <b>key-encipherment</b></li> <li>▪ <b>data-encipherment</b></li> <li>▪ <b>key-agreement</b></li> <li>▪ <b>key-cert-sign</b></li> <li>▪ <b>crl-sign</b></li> <li>▪ <b>encipher-only</b></li> <li>▪ <b>decipher-only</b></li> </ul> <p>To include multiple key usages, specify the <code>--key-usage {value}</code> argument multiple times.</p>
<code>--extended-key-usage {value}</code>	<p>Indicates that the certificate is expected to have an extended key usage extension with the specified value. The following values are allowed:</p> <ul style="list-style-type: none"> <li>▪ <b>server-auth</b></li> <li>▪ <b>client-auth</b></li> <li>▪ <b>code-signing</b></li> <li>▪ <b>email-protection</b></li> <li>▪ <b>time-stamping</b></li> <li>▪ <b>ocsp-signing</b></li> </ul>

### Example

For example, the following command can be used to generate a self-signed server certificate.

```
bin/manage-certificates generate-self-signed-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --keystore-type JKS \
  --alias server-cert \
  --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
  --key-algorithm EC \
  --key-length-bits 256 \
  --signature-algorithm SHA256withECDSA \
  --subject-alternative-name-dns ds.example.com \
  --subject-alternative-name-dns dsl.example.com \
  --subject-alternative-name-dns localhost \
  --subject-alternative-name-ip-address 1.2.3.4 \
  --subject-alternative-name-ip-address 127.0.0.1 \
  --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
  --key-usage digital-signature \
  --key-usage key-encipherment \
  --key-usage key-agreement \
  --extended-key-usage server-auth \
  --extended-key-usage client-auth
```

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:

```

Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=ds.example.com,O=Example Corp,C=US
Validity Start Time: Monday, January 27, 2020 at 03:40:13 PM CST
                    (0 seconds ago)
Validity End Time: Tuesday, January 26, 2021 at 03:40:13 PM CST
                  (364 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
SHA-1 Fingerprint:
  4f:41:82:7f:08:e9:d8:05:8c:19:8b:3e:5b:bc:59:98:d3:15:71:3a
SHA-256 Fingerprint:
  76:e6:8e:c5:c8:8d:27:ce:2b:85:b9:8c:9d:49:3c:06:f4:40:f1:d0:70:67:39:24:fc:
  31:bc:f8:51:83:f2:42

```

### Generating certificate signing requests

A certificate signing request (CSR) contains all of the information that a certification authority requires to issue a certificate.

[RFC 2986](#) defines the request format, also known as PKCS #10, and includes the following elements:

- Certificate signing request version
- Requested subject distinguished name (DN) for the certificate
- Public key for the requested certificate
- Requested set of extensions for the certificate
- Signature that proves the requester has the private key for the given public key

To create a certificate signing request, use the `manage-certificates generate-certificate-signing-request` command, which performs the following steps:

1. Generated a public and private key pair.
2. Stores the key pair in a key store with a given alias.
3. Outputs the certificate signing request to the terminal.
4. Optionally writes the certificate signing request to a file.

Because a certificate signing request contains many of the same elements as a certificate, the command to generate one takes most of the same arguments as for generating a self-signed certificate. The following arguments are unavailable when generating a CSR:

- `--replace-existing-certificate`
- `--days-valid {number}`
- `--validity-start-time {timestamp}`

The following arguments are available when generating a certificate signing request but not when generating a self-signed certificate:

`--output-file {path}`

Path to a file to which the certificate signing request is written. If this value is not provided, the request is written only to the terminal in PEM form.

`--output-format {value}`

Format to use when writing the certificate signing request. This value can be **PEM** or **DER**, but the DER format is used only in conjunction with the `--output-file` argument. Defaults to **PEM** if the `--output-format {value}` argument is not provided.

`--use-existing-key-pair`

Indicates that the CSR uses a key pair that already exists in the key store with the given alias, rather than generating a new key pair, in which case the specified alias must not already be in use in the key store.

The following example command creates a CSR.

```
bin/manage-certificates generate-certificate-signing-request \
  --output-file dsl-cert.csr \
  --output-format PEM \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --keystore-type JKS \
  --alias server-cert \
  --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
  --key-algorithm EC \
  --key-length-bits 256 \
  --signature-algorithm SHA256withECDSA \
  --subject-alternative-name-dns ds.example.com \
  --subject-alternative-name-dns dsl.example.com \
  --subject-alternative-name-dns localhost \
  --subject-alternative-name-ip-address 1.2.3.4 \
  --subject-alternative-name-ip-address 127.0.0.1 \
  --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
  --key-usage digital-signature \
  --key-usage key-encipherment \
  --key-usage key-agreement \
  --extended-key-usage server-auth \
  --extended-key-usage client-auth
```

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing request.

Successfully wrote the certificate signing request to file  
'/ds/build/package/PingDirectory/dsl-cert.csr'.

If the contents of the resulting CSR file are made available to a certification authority to be signed, the resulting signed certificate can be imported into the key store.

To print the contents of a certificate signing request file, use the **display-certificate-signing-request-file** subcommand, which supports the following arguments:

```
--certificate-signing-request-file {path}
```

Path to the file that contains the certificate signing request to display.

```
--verbose
```

Indicates that the command is expected to display verbose information about the request, rather than a basic information set.

The following example demonstrates the basic output from the command.

```
$ bin/manage-certificates display-certificate-signing-request-file \
  --certificate-signing-request-file dsl-cert.csr

PKCS #10 Certificate Signing Request Version:  v1
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
```

The following example demonstrates the verbose output.

```
$ bin/manage-certificates display-certificate-signing-request-file \
  --certificate-signing-request-file dsl-cert.csr \
```

```

--verbose

```

### Importing signed and trusted certificates

Use the `manage-certificates import-certificate` command to import certificates into a keystore.

This command is used to accomplish the following tasks:

- Import a certificate that a certification authority has signed into the keystore in which the key pair was generated. In this scenario, the certificate is imported into a private key entry and must be imported as a certificate chain rather than an end-entity certificate.
- Import a trusted issuer certificate into a trust store. In this scenario, the certificate is imported into a trusted certificate entry as a single certificate instead of as a chain.
- Import a certificate chain, along with the private key for the end-entity certificate. This approach imports certificates that were generated through another library, like OpenSSL.

In addition to the arguments that provide information about the key store and the alias into which the certificate or certificate chain is imported, the `manage-certificates import-certificate` command accepts the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to import. The certificate can be in PEM or DER format and can be a single certificate or a certificate chain. If the certificates in the chain reside in separate files, specify the `--certificate-file {path}` argument multiple times when you import a certificate chain.

`--private-key-file {path}`

Path to the file containing the private key that corresponds to the certificate at the head of the imported chain. The private key can be in PEM or DER format.

`--no-prompt`

Indicates that the certificate is to be imported without prompting for confirmation. By default, a summary of the certificate is displayed, and you must confirm that you want to import it.

The following example command imports a signed certificate into the key store that generates the certificate signing request.

```
$ bin/manage-certificates import-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --certificate-file ds1-cert.pem \
  --certificate-file ca-cert.pem
```

The following certificate chain will be imported into the keystore into alias 'server-cert', preserving the existing private key associated with that alias:

```
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
                    (4 minutes, 16 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
                    (364 days, 23 hours, 55 minutes, 43 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
SHA-1 Fingerprint:
02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb
SHA-256 Fingerprint: 1d:b5:eb:3c:f5:ff:bf:79:a2:a5:86:b8:e4:33:76:4d:d7:
                    50:dc:a4:34:95:37:be:89:45:86:1f:5d:79:c3:93
```

```
Subject DN: CN=Example Root CA,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:00:07 PM CST
                    (13 minutes, 32 seconds ago)
Validity End Time: Saturday, November 5, 2039 at 10:00:07 PM CDT
                    (7299 days, 23 hours, 46 minutes, 27 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP384r1)
SHA-1 Fingerprint:
0e:5c:21:c9:a5:36:0a:24:eb:aa:55:b6:a5:94:0e:e0:56:03:22:e6
SHA-256 Fingerprint: 77:cf:66:d7:3c:8a:fd:67:2d:b7:36:fd:60:1d:ca:eb:1b:03:b1:
                    12:7b:10:1f:26:05:b7:b9:0d:02:e0:38:3e
```

Do you want to import this certificate chain into the keystore? yes

```
Successfully imported the certificate chain.
```

If you do not provide the `--no-prompt` argument, the `manage-certificates import-certificate` tool still displays information about the certificates to import. To view additional information about a certificate before you import it, use the `display-certificate-file` subcommand, which supports the following arguments:

```
--certificate-file {path}
    Path to the file that contains the certificate to view.

--verbose
    Displays verbose information about the certificate.
```

The output of the `display-certificate-file` subcommand has the same format and content as the `list-certificates` subcommand.

### Exporting certificates

Use the `export-certificate` subcommand to export a single certificate or a certificate chain from a key store to a file in PEM or DER format.

The `export-certificate` subcommand supports the normal arguments about the key store and certificate alias, in addition to the following arguments:

```
--output-file {path}
    Path to the file to which exported certificates are written. If this value is not provided, the certificates are written to standard output rather than a file.

--output-format {format}
    Format in which exported certificates are written. The value can be PEM or DER, but the DER format can be used only if the output is written to a file. Defaults to PEM if no value is specified.

--export-certificate-chain
    Indicates that a certificate chain, rather than the end-entity certificate only, is to be exported.

--separate-file-per-certificate
    Indicates the use of separate output files for each exported certificate, rather than placing all of the certificates in a single file. If this argument is provided and multiple certificates are to be exported, then .1 is appended to the path for the indicated output file for the first certificate in the chain, .2 is appended for the second certificate, and so on.
```

The following example exports a certificate chain.

```
$ bin/manage-certificates export-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --output-file server-cert.pem \
  --output-format PEM \
  --export-certificate-chain \
  --separate-file-per-certificate

Successfully exported the following certificate to '/ds/server-cert.pem.1':
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
                    (3 hours, 26 minutes, 23 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
                    (364 days, 20 hours, 33 minutes, 36 seconds from
now)
```

```

Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
SHA-1 Fingerprint:
  02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb
SHA-256 Fingerprint:
  1d:b5:eb:3c:f5:ff:bf:79:a2:a5:86:b8:e4:33:76:4d:d7:50:dc:a4:34:95:37:be:89:45:
  86:1f:5d:79:c3:93

```

```

Successfully exported the following certificate to '/ds/server-cert.pem.2':
Subject DN: CN=Example Root CA,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:00:07 PM CST
                  (3 hours, 35 minutes, 39 seconds ago)
Validity End Time: Saturday, November 5, 2039 at 10:00:07 PM CDT
                  (7299 days, 20 hours, 24 minutes, 20 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP384r1)
SHA-1 Fingerprint:
  0e:5c:21:c9:a5:36:0a:24:eb:aa:55:b6:a5:94:0e:e0:56:03:22:e6
SHA-256 Fingerprint:
  77:cf:66:d7:3c:8a:fd:67:2d:b7:36:fd:60:1d:ca:eb:1b:03:b1:12:7b:10:1f:26:
  05:b7:b9:0d:02:e0:38:3e

```

The **export-certificate** subcommand exports only the public portion of a certificate. Its private key is not included. To export the private key, use the **export-private-key** subcommand, which supports the following arguments, in addition to the usual key store and alias arguments:

```
--output-file {path}
```

Path to the file to which the exported private key is written. If this value is not provided, the key is written to standard output rather than a file.

```
--output-format {format}
```

Format in which the exported private key is written. The value can be **PEM** or **DER**, but the DER format is used only if the output is written to a file. Defaults to **PEM** if no value is specified.

The following code provides an example of the **export-private-key** subcommand .

```

$ bin/manage-certificates export-private-key \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --output-file server-cert-key.pem \
  --output-format PEM

```

```
Successfully exported the private key.
```

### Using manage-certificates as a simple certification authority

If your server instances need to support an arbitrary or unknown set of clients, configure them with certificates from a trusted issuer, such as a commercial authority or the free Let's Encrypt service.

#### About this task

If you control every client that accesses the servers, you might want to create your own internal certification authority so that you have a common issuer for all servers. In such a scenario, the clients need to trust only the certificates that the issuer signs. Commercial and open-source software packages provide full-featured certification authority functionality, but you can use the **manage-certificates** tool to create a certificate authority (CA) certificate that you can use to sign certificate-signing requests.

## Steps

### 1. Create a CA certificate.

A CA certificate is a self-signed certificate that possesses the following extensions:

- A key usage extension that includes at least the keyCertSign usage
- A basic constraints extension that identifies the certificate as a CA certificate

If you do not plan to use an intermediate CA certificate, the basic constraints extension must have a path length constraint of 0. If you plan to use an intermediate CA certificate, the path length constraint must be 1. Because certificates that the CA certificate signs are valid only for as long as all certificates in the chain remain valid, we recommend that you specify a long lifespan for the CA certificate.

Example:

The following example creates a new root CA certificate.

```
$ bin/manage-certificates generate-self-signed-certificate \
  --keystore /ca/root-ca-keystore \
  --keystore-password-file /ca/root-ca-keystore.pin \
  --keystore-type JKS \
  --alias root-ca-cert \
  --subject-dn "CN=Example Root CA,O=Example Corp,C=US" \
  --days-valid 7300 \
  --key-algorithm RSA \
  --key-size-bits 4096 \
  --signature-algorithm SHA256withRSA \
  --basic-constraints-is-ca true \
  --basic-constraints-maximum-path-length 1 \
  --key-usage key-cert-sign \
  --key-usage crl-sign

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:
Subject DN: CN=Example Root CA,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Monday, January 27, 2020 at 03:47:29 PM CST (0
seconds ago)
Validity End Time: Sunday, January 22, 2040 at 03:47:29 PM CST
(7299 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
SHA-1 Fingerprint:
bc:8e:5b:30:52:ec:03:63:b4:9a:aa:1a:45:a0:fc:84:49:dd:e8:64
SHA-256 Fingerprint:
d5:47:06:cd:a2:95:42:61:1f:c7:aa:04:16:1e:c1:70:41:c4:44:48:bf:74:20:5f:1c:
61:e2:aa:40:08:3a:ff
```

### 2. Export the public portion of the root CA certificate for future reference.

When you import a signed certificate, you can import the public portion of the root CA certificate as a standalone certificate into trust stores as well as into part of a certificate chain.

### 3. Create a new certificate signing request to create an intermediate CA certificate,

The certificate signing request uses essentially the same settings as the root CA. If you anticipate only a single intermediate CA, its basic constraints extension must have a path length constraint of

0, rather than 1, to indicate that it is used only to sign end-entity certificates and that it cannot create subordinate CA certificates by itself.

Example:

The following example command creates a certificate signing request.

```
$ bin/manage-certificates generate-certificate-signing-request \  
  --keystore /ca/intermediate-ca-keystore \  
  --keystore-password-file /ca/intermediate-ca-keystore.pin \  
  --keystore-type JKS \  
  --alias intermediate-ca-cert \  
  --subject-dn "CN=Example Intermediate CA,O=Example Corp,C=US" \  
  --key-algorithm RSA \  
  --key-size-bits 4096 \  
  --signature-algorithm SHA256withRSA \  
  --basic-constraints-is-ca true \  
  --basic-constraints-maximum-path-length 0 \  
  --key-usage key-cert-sign \  
  --key-usage crl-sign \  
  --output-file /ca/intermediate-ca-cert.csr \  
  --output-format PEM
```

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing request.

Successfully wrote the certificate signing request to file '/ca/intermediate-ca-cert.csr'.

- Use the root CA certificate to sign the certificate signing request for the intermediate CA certificate with the `sign-certificate-signing-request` subcommand.

The `sign-certificate-signing-request` subcommand takes most of the same arguments as generating a self-signed certificate. The primary differences between the argument sets are as follows:

- The key store that contains the certificate uses the provided key store arguments to sign the request. To specify the name of the certificate to use when signing the request, use the `--signing-certificate-alias` argument.
- To specify the path to the file that contains the certificate signing request file to generate, provide a `--request-input-file` argument.
- To specify the path to the file to which the signed certificate is written, provide a `--certificate-output-file` argument. If this argument is omitted, the PEM representation of the certificate is written to standard output.
- To specify the format, **PEM** or **DER**, in which the certificate is written to the output file, provide an `--output-format` argument.
- To specify the subject to use for the signed certificate, use the `--subject-dn` argument. To use the subject DN from the certificate signing request, omit this argument.
- To specify the name of the signature algorithm, use the `--signature-algorithm` argument.

**Note:**

Because the requester generated the key, you cannot specify the key algorithm or the key length.

- To indicate that the signed certificate includes every extension that is listed in the certificate signing request, use the `--include-requested-extensions` argument. If this argument is not provided, explicitly specify the set of extensions to include.

Example:

The following example command signs the certificate signing request for an intermediate CA certificate.

```
$ bin/manage-certificates sign-certificate-signing-request \
  --keystore /ca/root-ca-keystore \
  --keystore-password-file /ca/root-ca-keystore.pin \
  --signing-certificate-alias root-ca-cert \
  --days-valid 7300 \
  --include-requested-extensions \
  --request-input-file /ca/intermediate-ca-cert.csr \
  --certificate-output-file /ca/intermediate-ca-cert.pem \
  --output-format PEM
```

Read the following certificate signing request:

```
PKCS #10 Certificate Signing Request Version: v1
Subject DN: CN=Example Intermediate CA,O=Example Corp,C=US
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
```

Do you really want to sign this request? yes

```
Successfully wrote the signed certificate to file
'/ca/intermediate-ca-cert.pem'.
```

- After you obtain the intermediate CA certificate, create secure, offline backups of the root CA certificate.

- Remove the root CA certificate, or at least its private key, from all systems.

**Note:**

Make certain that all end-entity certificates are signed with the intermediate CA certificate, and that the process is identical to the previous example. Restore the root CA certificate only if you need to sign another intermediate CA certificate.

### Enabling TLS support during setup

Enable TLS support in the server.

To enable TLS support in the server, you should complete one of the following tasks during the setup procedure:

- Provide a key store that contains the certificate to use.
- Make the installer generate a self-signed certificate.

When using the `setup` tool in interactive mode, it prompts you for the information that it needs to configure secure communication, as shown in the following example.

```
Do you want to enable the Directory Server services (Available State,
Available or Degraded State, Configuration, Consent, Directory REST API,
Documentation, SCIM2, and Swagger UI) and Administrative Console over
HTTPS? After setup, you can selectively enable or disable individual
services and applications by configuring the HTTPS Connection Handler
(yes / no) [yes]: yes

On which port should the Directory Server accept connections from HTTPS
clients? [443]: 443

On which port should the Directory Server accept connections from LDAP
clients? [389]: 389

Do you want to enable LDAPS? (yes / no) [yes]: yes
On which port should the Directory Server accept connections from LDAPS
clients? [636]: 636

Do you want to enable StartTLS? (yes / no) [yes]: yes

Certificate server options:

    1) Generate self-signed certificate (recommended for testing purposes
       only)
    2) Use an existing certificate located on a Java Keystore (JKS)
    3) Use an existing certificate located on a PKCS12 keystore
    4) Use an existing certificate on a PKCS11 token

Enter option [1]: 2

Java Keystore (JKS) path: /ca/dsl-keystore
Keystore PIN: {password}

Truststore options:

    1) Generate a default JKS truststore
    2) Use an existing JKS truststore
    3) Use an existing PKCS12 truststore

Enter option [1]: 2

JKS truststore path: /ca/truststore
```

```
Truststore password (can be blank): {password}
```

When using **setup** in non-interactive mode, use the following arguments to configure TLS support.

Argument	Description
<code>--ldapsPort {port}</code>	Server enables support for LDAPS (LDAP over TLS) on the specified TCP port.
<code>--httpsPort {port}</code>	Server enables support for HTTPS for SCIM, the Directory REST API, and the web-based administration console on the specified TCP port.
<code>--enableStartTLS</code>	LDAP connection handler enables support for the StartTLS extended operation.
<code>--generateSelfSignedCertificate</code>	<b>setup</b> generates a self-signed certificate that is presented to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
<code>--useJavaKeyStore {path}</code>	Server uses the specified Java KeyStore (JKS) key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
<code>--usePKCS12KeyStore {path}</code>	Server uses the specified PKCS #12 key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
<code>--usePKCS11KeyStore</code>	Server uses a PKCS #11 key store, like a hardware security module, to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation. The Java Virtual Machine (JVM) must already be configured to access the appropriate key store through PKCS #11.
<code>--keyStorePassword {password}</code>	Password that is needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store. The <b>setup</b> tool assumes that the private key password matches the key store password.
<code>--keyStorePasswordFile {path}</code>	Path to the file that contains the password needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store.
<code>--certNickname {alias}</code>	Alias of the private key entry in the specified key store that contains the certificate chain to present to clients during TLS negotiation. This argument is optional but recommended if the key store contains multiple certificates.

Argument	Description
<code>--useJavaTrustStore {path}</code>	Server uses the specified JKS trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation.
<code>--usePKCS12TrustStore {path}</code>	Server uses the specified PKCS #12 trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation.
<code>--trustStorePassword {password}</code>	Password that is needed to interact with the specified JKS or PKCS #11 trust store.
<code>--trustStorePasswordFile {path}</code>	Path to the file that contains the password needed to interact with the specified JKS or PKCS #11 trust store.

The following example command sets up PingDirectory Server in non-interactive mode with an existing certificate.

```
$ ./setup \
  --no-prompt \
  --acceptLicense \
  --ldapPort 389 \
  --ldapsPort 636 \
  --httpsPort 443 \
  --enableStartTLS \
  --useJavaKeyStore config/keystore \
  --keyStorePasswordFile config/keystore.pin \
  --certNickname server-cert \
  --useJavaTrustStore config/truststore \
  --trustStorePasswordFile config/truststore.pin \
  --baseDN dc=example,dc=com \
  --rootUserDN "cn=Directory Manager" \
  --rootUserPasswordFile root-pw.txt \
  --maxHeapSize 10g \
  --encryptDataWithPassphraseFromFile encryption-settings-password.txt \
  --instanceName dsl \
  --location Austin \
  --noPropertiesFile
```

```
Ping Identity Directory Server 8.0.0.0
```

```

```

## Enabling TLS support after setup

If the server has been set up without support for TLS, enable TLS support later by completing the following tasks.

### Steps

1. Obtain a certificate chain.

For more information about obtaining a certificate chain, see [Certificate chains](#) on page 418. To prepare a Java KeyStore JKS or PKCS #12 key store with an appropriate certificate chain and private key, use the `manage-certificates` tool. We also recommend that you create a trust store that the server can use.

2. Configure the key and trust manager providers.

For more information, see [Configuring key and trust manager providers](#) on page 447.

3. Configure connection handlers.

For more information, see [Configuring connection handlers](#) on page 447.

### Configuring key and trust manager providers

After you have a key store, configure a key manager provider to access it.

The server is preconfigured with key manager providers, `JKS` and `PKCS12`, that you can use with JKS or PKCS #12 key stores, respectively. You can update the appropriate key manager provider in most cases to reference the key store that you plan to use. The following code provides an example.

```
dsconfig set-key-manager-provider-prop \
  --provider-name JKS \
  --set enabled:true \
  --set key-store-file:config/keystore \
  --set key-store-pin-file:config/keystore.pin
```

A similar change configures a trust manager provider to reference the appropriate trust store. The following code provides an example.

```
dsconfig set-trust-manager-provider-prop \
  --provider-name JKS \
  --set enabled:true \
  --set include-jvm-default-issuers:true \
  --set trust-store-file:config/truststore \
  --set trust-store-pin-file:config/truststore.pin
```

#### Note:

If all clients and servers use certificates that are signed by issuers and are included in the JVM's default trust store, you can use the `JVM-Default` trust manager provider to accomplish this task.

### Configuring connection handlers

After you configure the key and trust manager providers, update the connection handlers to use the key and trust manager providers.

### Steps

- For the LDAP connection handler, use the following command to enable StartTLS with a configuration change. By default, the LDAP connection handler accepts non-secure connections.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
```

```
--set allow-start-tls:true \
--set key-manager-provider:JKS \
--set trust-manager-provider:JKS \
--set ssl-cert-nickname:server-cert \
--set ssl-client-auth-policy:optional
```

- If you did not configure secure communication during setup, the LDAPS connection handler is disabled. To configure LDAPS support in this scenario, enable the connection handler and configure most of the same settings. You must set `allow-start-tls` to `false` and `use-ssl` to `true`. See the following code for an example configuration.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "LDAPS Connection Handler" \
  --set enabled:true \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert \
  --set ssl-client-auth-policy:optional
```

Example: The following example uses a similar configuration change to enable the HTTPS connection handler.

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true \
  --set listen-port:443 \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert
```

### Updating the topology registry

After the server connection handlers are updated to enable TLS, update the topology registry to provide information about the new configuration.

The topology registry holds information about server instances that are part of the environment, and it helps to facilitate inter-server communication, such as replication, mirroring portions of the configuration, and PingDirectory Server's automatic backend server-discovery functionality.

The following table details the two types of entries that require updating.

## Configuration types and their update descriptions

Configuration Type	Update description
Server instance listener configuration	<ul style="list-style-type: none"> <li>▪ Provides information that is needed to trust the TLS certificates that instances in the topology present.</li> <li>▪ The server instance listener configuration must include the server certificate, which is defined as the certificate at the head of the chain. This version must be the multi-line, PEM-formatted representation of the certificate. You can use <b>dsconfig</b> to import the certificate from a file, as shown in the following example.</li> </ul> <pre data-bbox="906 617 1446 884">bin/dsconfig set-server-instance-listener-prop \   --instance-name ds1 \   --listener-name ldap-listener-mirrored-config \   --set server-ldap-port:636 \   --set connection-security:ssl \   --set 'listener-certificate&gt;/ca/ds1-cert.pem'</pre> <div data-bbox="906 932 938 974" style="display: inline-block; vertical-align: middle;"></div> <p data-bbox="954 947 1024 974"><b>Note:</b></p> <p data-bbox="906 999 1466 1220">The less-than operator &gt; in the final line indicates that the value is read from a file rather than provided directly. In addition, you might not need to enclose the property name and path within single straight quotes to prevent the shell from interpreting the less-than symbol as an attempt to redirect input.</p>

Configuration Type	Update description
Server instance configuration	<ul style="list-style-type: none"> <li>▪ Provides information about options for communicating with those instances.</li> <li>▪ Update the server instance configuration object to reflect the new methods that are available for communication with the instance. For example, the <code>preferred-security</code> property identifies the mechanism by which other instances in the topology attempt to communicate with the instance.</li> </ul> <p>The following example code sets the LDAPS and HTTPS ports, indicates that StartTLS support is enabled, and instructs other instances to use SSL (LDAPS) when communicating with the instance.</p> <pre style="background-color: #f0f0f0; padding: 10px;">dsconfig set-server-instance-prop \   --instance-name dsl \   --set ldaps-port:636 \   --set https-port:443 \   --set preferred-security:ssl \   --set start-tls-enabled:true</pre>

### Troubleshooting TLS-related issues

Use this section for troubleshooting problems that might arise during TLS configuration, including communication and security issues that affect clients as well as PingDirectory Server.

- [Log messages](#)
- [manage-certificates check-certificate-usability](#)
- [ldapsearch](#)
- [Using low-level TLS debugging](#)

### Log messages

The following describes how to use the server's log messages to troubleshoot TLS-related issues.

To troubleshoot TLS-related issues, start by checking the server's access log. If the client can establish a TCP connection to the server, which must occur before TLS negotiation can start, the access log shows a `CONNECT` message with the following information:

- Source and destination address and port for the connection
- Protocol
- Selected client connection policy

The `CONNECT` message does not appear

If the `CONNECT` does not appear, the client might be unable to communicate with the server. The culprit can be a network problem, a firewall that is blocking attempts to communicate, or the client is trying to use an incorrect address or port.

The `CONNECT` message does appear

If the `CONNECT` message appears in the access log, it typically includes a `conn` element that specifies the connection ID. To view additional log messages for the client connection, use the `search-logs` tool. For example, if the connection ID is `12345`, the following command displays the complete set of associated log messages.

```
$ bin/search-logs --logFile logs/access conn=12345
```

If you are using LDAPS

If you are attempting to use LDAPS, one of the following log messages appears next:

- `SECURITY-NEGOTIATION` message – Indicates that the client and server successfully completed the negotiation process and that the issue likely occurred after the TLS session was established. This message also includes details about the negotiation, including the TLS protocol and the selected cipher suite.
- `DISCONNECT` message – The issue might involve a failure in the TLS-negotiation process. In such scenarios, the message usually includes a `reason` element that provides additional information about the reason for the disconnect.

If the failure occurred during TLS negotiation, the usefulness of the `DISCONNECT` message depends in part on whether the failure occurred on the client or the server. For example, if the server decided to abort the negotiation, the message ideally contains the specific reason. If the problem occurred on the client, the log message likely contains only the general category for the failure.

**Note:**

The TLS protocol does not provide a mechanism for conveying detailed error messages. Instead, it offers only a basic alert mechanism with a fixed set of alert types. For example, if a client does not trust the certificate chain that the server presents to it, the server might receive a generic alert like `certificate_unknown`, even if the client knows the precise reason for rejecting the chain. In such instances, you might need to determine whether the client can provide additional details about the issue.

If the access log does not provide useful information

If the access log does not provide useful information, check the server error log. Although the error log does not normally include information about issues that relate to client communication, it provides helpful information in certain circumstances, like when an internal error within the server interferes with communication attempts.

**manage-certificates check-certificate-usability**

The `manage-certificates` tool offers a `check-certificate-usability` subcommand to examine a specified entry in a key store and to identify potential issues that might interfere with secure communication.

The `check-certificate-usability` tool completes the following tasks:

- Ensures that a specified entry in the key store includes a private key and a complete certificate chain
- Checks whether the certificate at the root of the chain is found in the Java virtual machine's (JVM's) default set of trusted certificates
- Ensures that the current time lies within the validity window for all certificates in the chain
- Validates the signatures for all certificates in the chain
- Warns if the end-entity certificate is self-signed
- Warns if the end-entity certificate does not contain an extended key usage extension with the `serverAuth` usage
- Warns if the issuer certificates do not have a key usage extension with the `keyCertSign` usage
- Warns if the issuer certificates do not have a basic constraints extension indicating that it can operate as a certification authority

If the chain violates a path length constraint, the `check-certificate-usability` tool reports an error.

- Ensures that the signature algorithm uses a strong message digest algorithm, like SHA-256

The `check-certificate-usability` tool reports an error for weak digest algorithms like MD5 or SHA-1, and reports a warning for unrecognized digest algorithms.

- Ensures that none of the certificates that use an RSA key pair have a key size less than 2048 bits

The following example demonstrates the usage for the `manage-certificates check-certificate-usability` command and its output when no problems are identified.

```
$ bin/manage-certificates check-certificate-usability \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert

Successfully retrieved the certificate chain for alias 'server-cert':

OK: The certificate chain is complete. Each subsequent certificate is
the issuer for the previous certificate in the chain, and the chain ends
with a self-signed certificate.

OK: Certificate 'CN=ds1.example.com,O=Example Corp,C=US' has a valid
```

signature.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a valid signature.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a valid signature.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' will expire at Wednesday, November 11, 2020 at 03:52:44 PM CST (364 days, 23 hours, 54 minutes, 14 seconds from now), which is not in the near future.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' will expire at Monday, November 7, 2039 at 03:52:42 PM CST (7299 days, 23 hours, 54 minutes, 12 seconds from now), which is not in the near future.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' will expire at Monday, November 7, 2039 at 03:52:38 PM CST (7299 days, 23 hours, 54 minutes, 8 seconds from now), which is not in the near future.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' at the head of the chain includes an extended key usage extension, and that extension includes the serverAuth usage.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' includes a basic constraints extension, and the certificate chain satisfies those constraints.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' includes a key usage extension with the keyCertSign usage flag set to true.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes a basic constraints extension, and the certificate chain satisfies those constraints.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes a key usage extension with the keyCertSign usage flag set to true.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' has a 2048-bit RSA public key, which is considered strong.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a 4096-bit RSA public key, which is considered strong.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a 4096-bit RSA public key, which is considered strong.

No usability errors or warnings were identified while validating the certificate chain.

If any usability issues are identified, they might be responsible for communication problems.

## Idapsearch

The `ldapsearch` command-line utility is a powerful tool for issuing searches against an LDAP directory server. It also provides a convenient method for troubleshooting a variety of issues, including problems that are relevant to TLS communication.

The following table details arguments that are the most useful for TLS-related communication.

### TLS-related communication arguments and their descriptions

Argument	Description
<code>--hostname {address}</code>	Address of the server to which the connection is established
<code>--port {port}</code>	TCP port of the server to which the connection is established. The standard port for non-secure LDAP, or LDAP to be secured with StartTLS, is <b>389</b> , and the standard port for secure LDAPS is <b>636</b> . Many deployments use alternate ports, especially non-privileged ports above <b>1024</b> .
<code>--useSSL</code>	The tool establishes an initially insecure LDAP connection, which is secured later with the StartTLS extended operation.
<code>--trustStorePath {path}</code>	Path to the trust store that is used when determining whether to trust the certificate chain that the server presents during TLS negotiation. If neither this argument nor the <code>--trustAll</code> argument is provided, the tool prompts you interactively whether to trust server certificates that are not signed by an issuer in the Java virtual machine's (JVM's) default trust store.
<code>--trustStoreFormat {format}</code>	Format for the trust store, which is typically <b>JKS</b> or <b>PKCS12</b> .
<code>--trustStorePassword {password}</code>	Password that is required to access the contents of the trust store.
<code>--trustStorePasswordFile {path}</code>	Path to the file that contains the password that is required to access the contents of the trust store.
<code>--trustAll</code>	The tool blindly trusts all TLS certificate chains that are presented to it. Although this argument can prove useful for troubleshooting purposes, it is not recommended for general use.

Argument	Description
<code>--keyStorePath {path}</code>	<p>Path to the key store to use if a client certificate chain is presented to the server.</p> <p> <b>Note:</b></p> <p>Use this argument only when one of the following conditions is satisfied:</p> <ul style="list-style-type: none"> <li>▪ The server is configured to require clients to present a certificate.</li> <li>▪ You intend to use the certificate to authenticate through SASL EXTERNAL.</li> </ul>
<code>--keyStoreFormat {format}</code>	Format for the key store, which is typically <b>JKS</b> or <b>PKCS12</b> .
<code>--keyStorePassword {password}</code>	Password to access the key store.
<code>--keyStorePasswordFile {path}</code>	Path to the file that contains the password necessary to access the key store.
<code>--certNickname {alias}</code>	Alias of the private key entry in the key store. Use when obtaining the certificate chain to present to the server.
<code>--useSASLExternal</code>	The client authenticates with the EXTERNAL SASL mechanism, which typically identifies the client using the certificate chain that is presented during TLS negotiation.
<code>--enableSSLDebugging</code>	The tool activates the low-level TLS-debugging feature that the JVM provides.

The following command provides an example of the simplest method for testing TLS communication with PingDirectory Server.

#### Example

```
$ bin/ldapsearch \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --baseDN "" \
  --scope base \
  "(objectClass=*)"
```

The server presented the following certificate chain:

```
Subject: CN=ds1.example.com,O=Example Corp,C=US
Valid From: Tuesday, November 12, 2019 at 08:28:08 PM CST
Valid Until: Wednesday, November 11, 2020 at 08:28:08 PM CST
SHA-1 Fingerprint:
  6a:22:2a:bd:0b:1b:09:35:63:bc:12:3e:2c:9e:e7:70:bc:a4:73:de

### Trust stores and trust-related arguments

If no trust-related arguments are provided, the tool uses the JVM's default trust store to verify whether to trust the certificate chain, based on the information that it contains. If a trusted authority has signed the server certificate, the negotiation process continues without further interaction.

If the chain cannot be trusted, based on the information in the JVM-default trust store, **ldapsearch** prompts you interactively about whether to trust the certificate. If you accept the chain, the client and server complete the negotiation process, and the client sends the search request to the server. If the search succeeds, the server can communicate over TLS.

To test with a trust store instead of being prompted interactively, use the **--trustStorePath** argument that points to the appropriate trust store. If you are using a Java Keystore (JKS) trust store, you might not need to provide the trust store password. If you are using a PKCS #12 trust store, you need to provide the trust store password. The following code provides an example.

### Example

```

$ bin/ldapsearch \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --trustStorePath config/truststore.p12 \
  --trustStorePasswordFile config/truststore.pin \
  --trustStoreFormat PKCS12 \
  --baseDN "" \
  --scope base \
  "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse

```

```

startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code: 0 (success)
# Number of Entries Returned: 1

```

### Client certificate chains and key stores

To present a client certificate chain to the server, either because the server's connection handler is configured with an `ssl-client-auth-policy` value of `required` or because you plan to use the certificate to authenticate by way of the SASL EXTERNAL mechanism, provide at least the key store and its corresponding password. You can also specify the alias of the certificate chain to present, which is recommended if your client key store contains multiple certificates. The following code provides an example.

### Example

```

$ bin/ldapsearch \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --trustStorePath config/truststore.p12 \
  --trustStorePasswordFile config/truststore.pin \
  --trustStoreFormat PKCS12 \
  --keyStorePath client-keystore \
  --keyStorePasswordFile client-keystore.pin \
  --certNickname client-cert \
  --useSASLExternal \
  --baseDN "" \
  --scope base \
  "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code: 0 (success)
# Number of Entries Returned: 1

```

If you need to further troubleshoot a TLS-related issue

If you encounter a TLS-related issue that you cannot resolve by examining the `ldapsearch` output or the server logs, use the `--enableSSLDebugging` option to enable the JVM's support for low-level debugging of TLS processing. For more information, see [Using low-level TLS debugging](#) on page 457.

### Using low-level TLS debugging

Use tools other than the command-line tools that are provided with PingDirectory Server for performing low-level TLS debugging.

Before you begin

#### Note:

If you need to use low-level debugging options, enable the Java Virtual Machine (JVM)'s support for TLS debugging. Many of the command-line tools that are provided with PingDirectory Server, such as `ldapsearch`, offer an `--enableSSLDebugging` argument that simplifies this process.

## Steps

1. In the `config/java.properties` file, add the following line to the set of properties for the appropriate tool.

```
-Djavax.net.debug=all
```

2. For the changes to take effect, run the `bin/dsjavaproperties` command.

## Next steps

The next time the tool is run, an output is generated detailing the TLS-related processing that the JVM is performing. You and the Ping Identity support team can use the output to identify the issue.

## Using the Configuration API

PingDirectory Server provides a Configuration API when updating the server configuration with LDAP is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers allow the `application/json` content type.

### About this task

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP.

## Steps

- To add the extension to one of the server's HTTP Connection Handlers, run the following code.

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:Configuration
```

### Note:

By default, the extension is enabled for new installations. You can enable the extension for existing deployments.

Result: The API is made available on the HTTPS Connection Handler's host:port in the `/config` context. Due to the potentially sensitive nature of the server's configuration, use the HTTPS Connection Handler for hosting the configuration extension.

## Authentication and authorization with the Configuration API

Use this topic for how to make changes for customizing authentication and authorization access with the Configuration API.

### Authentication

Clients must use HTTP basic authentication to authenticate to the Configuration API. If the username value is not a distinguished name (DN), then it resolves to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a username. To customize this behavior, either customize the default identity mapper or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. The following code provides an example.

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Configuration \
```

```
--set "identity-mapper:Alternative Identity Mapper"
```

## Authorization

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACL.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

## The Configuration API and the `dsconfig` tool relationship

The Configuration API is designed to mirror the `dsconfig` tool, using the same names for properties and object types.

Property names are presented as hyphen case in `dsconfig` and as camel-case attributes in the API. In API requests that specify property names, case is not important. `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the `dsconfig list-connection-handlers` command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a local database backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the `dsconfig` tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the System for Cross-domain Identity Management (SCIM) specification. Request specific attributes using the `attributes` query parameter, whose value must be a comma-delimited list of properties to be returned, such as `attributes=baseDN,description`. You can exclude attributes from responses by specifying the `excludedAttributes` parameter.

## Configuration API operations supported in REST APIs

HTTP Method	Description	Related <code>dsconfig</code> Example
GET	Lists the properties of an object when used with a path representing an object, such as <code>/config/global-configuration</code> or <code>/config/backends/userRoot</code> .  Can also list objects when used with a path representing a parent relation, such as <code>/config/backends</code> .	<ul style="list-style-type: none"> <li>▪ <code>get-backend-prop</code></li> <li>▪ <code>list-backends</code></li> <li>▪ <code>get-global-configuration-prop</code></li> </ul>
POST	Creates a new instance of an object when used with a relation parent path, such as <code>/config/backends</code> .	<code>create-backend</code>
PUT	Replaces the existing properties of an object. A PUT operation is similar to a PATCH operation, except that the PATCH identifies the difference between an existing target object and a supplied source object. Only those properties in the source object are modified in the target object. The target object is specified using a path, such as <code>/config/backends/userRoot</code> .	<ul style="list-style-type: none"> <li>▪ <code>set-backend-prop</code></li> <li>▪ <code>set-global-configuration-prop</code></li> </ul>

HTTP Method	Description	Related dsconfig Example
PATCH	Updates the properties of an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .	<ul style="list-style-type: none"> <li>▪ <code>set-backend-prop</code></li> <li>▪ <code>set-global-configuration-prop</code></li> </ul>
DELETE	Deletes an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .	<code>delete-backend</code>

**Note:**

The `OPTIONS` method can also be used to determine the operations permitted for a particular path.

Object names, such as `userRoot` in the description column, must be URL-encoded for use in the path segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent, `%`, character. The following URL is for accessing the HTTP Connection Handler object.

```
/config/connection-handlers/http%20connection%20handler
```

**GET example**

This topic provides an example of a GET request and response concerning the `userRoot` backend for reference.

**GET request**

The following code example is a GET request for information about the `userRoot` backend.

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

**GET response**

The following code example is the response.

```
{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],

### GET list example

See the following example of a GET request and response for all local backends for reference.

#### GET request

The following is a code example GET request for all local backends.

```
GET /config/backends/
Host: example.com:5033
Accept: application/scim+json

```

#### GET response

The following is a code example GET response, which is shortened.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 24,
  "Resources": [
    {
      "schemas": [
        "urn:unboundid:schemas:configuration:2.0:backend:ldif"
      ],
      "id": "adminRoot",
      "meta": {
        "resourceType": "LDIF Backend",
        "location": "http://localhost:5033/config/backends/adminRoot"
      },
      "backendID": "adminRoot",
      "backupFilePermissions": "700",

      "returnUnavailableWhenDisabled": "true",
      "setDegradedAlertWhenDisabled": "false",
      "writabilityMode": "enabled"
    },
    {
      "schemas": [
        "urn:unboundid:schemas:configuration:2.0:backend:trust-store"
      ],
      "id": "ads-truststore",
      "meta": {
        "resourceType": "Trust Store Backend",
        "location": "http://localhost:5033/config/backends/ads-
truststore"
      },
      "backendID": "ads-truststore",
      "backupFilePermissions": "700",
      "baseDN": [
        "cn=ads-truststore"
      ],

```

```

    "enabled": "true",
    "javaClass":
"com.unboundid.directory.server.backends.TrustStoreBackend",
    "returnUnavailableWhenDisabled": "true",
    "setDegradedAlertWhenDisabled": "true",
    "trustStoreFile": "config/server.keystore",
    "trustStorePin": "*****",
    "trustStoreType": "JKS",
    "writabilityMode": "enabled"
  },
  {
    "schemas": [
      "urn:unboundid:schemas:configuration:2.0:backend:alarm"
    ],
    "id": "alarms",
    "meta": {
      "resourceType": "Alarm Backend",
      "location": "http://localhost:5033/config/backends/alarms"
    },
    ...
  }

```

### PATCH example

Modify the Configuration API using the HTTP PATCH method.

The PATCH request body is a JSON object formatted according to the System for Cross-domain Identity Management (SCIM) patch request. The Configuration API supports a subset of possible values for the path attribute that indicates the configuration attribute to modify.

Modify the configuration object's attributes according to the information in the following table, which details the comparable `dsconfig modify-[object]` options to each PATCH request.

## Operations and PATCH requests to modify the configuration object's attributes

Operation	PATCH request	Comparable dsconfig modify- [object] options
Set the single-valued description attribute to a new value.	<pre>{   "op" : "replace",   "path" :   "description",   "value" : "A new   backend." }</pre>	<pre>\$ dsconfig set-backend- prop --backend-name userRoot \ --set "description:A new backend"</pre>
Add a new value to the multi-valued jeProperty attribute.	<pre>{   "op" : "add",   "path" :   "jeProperty",   "value" :   "je.env.backgroundReadLimit=32" }</pre>	<pre>\$ dsconfig set- backend-prop --backend- name userRoot \ --add je- property:je.env.backgroundReadLimit=32</pre>
Remove a value from a multi-valued property. In this case, path specifies a SCIM filter identifying the value to remove.	<pre>{   "op" : "remove",   "path" :   "[jeProperty eq   \"je.cleaner.adjustUtilization=32\"   \"]" }</pre>	<pre>\$ dsconfig set-backend- prop --backend-name userRoot \ --remove je- property:je.cleaner.adjustUtilization=32</pre>
Second operation to remove a value from a multi-valued property, where the path specifies both an attribute to modify and a SCIM filter whose attribute is the following value.	<pre>{   "op" : "remove",   "path" :   "jeProperty[value eq   \"je.nodeMaxEntries=32\"   \"]" }</pre>	<pre>\$ dsconfig set-backend- prop --backend-name userRoot \ --remove je- property:je.nodeMaxEntries=32</pre>
Option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value.	<pre>{   "op" : "remove",   "path" :   "id2childrenIndexEntryLimit" }</pre>	<pre>\$ dsconfig set-backend- prop --backend-name userRoot \ --reset id2childrenIndexEntryLimit</pre>

## Example

The following is the full example request.

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json

{
  "schemas" : [ "urn:ietf:params:scim:api:messages:2.0:PatchOp" ],
  "Operations" : [ {
    "op" : "replace",
    "path" : "description",
```

```

    "value" : "A new backend."
  }, {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }, {
    "op" : "remove",
    "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
  }, {
    "op" : "remove",
    "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
  }, {
    "op" : "remove",
    "path" : "id2childrenIndexEntryLimit"
  } ]
}

```

### Example

The API responds with the entire modified configuration object, which can include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions. The following is an example response.

```

{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],
  "id": "userRoot2",
  "meta": {
    "resourceType": "Local DB Backend",
    "location": "http://example.com:5033/config/backends/userRoot2"
  },
  "backendID": "userRoot2",
  "backgroundPrime": "false",
  "backupFilePermissions": "700",
  "baseDN": [
    "dc=example2,dc=com"
  ],
  "checkpointOnCloseCount": "2",
  "cleanerThreadWaitTime": "120000",
  "compressEntries": "false",
  "continuePrimeAfterCacheFull": "false",
  "dbBackgroundSyncInterval": "1 s",
  "dbCachePercent": "10",
  "dbCacheSize": "0 b",
  "dbCheckpointIntervalBytes": "20 mb",
  "dbCheckpointIntervalHighPriority": "false",
  "dbCheckpointIntervalWakeup": "1 m",
  "dbCleanOnExplicitGC": "false",
  "dbCleanerMinUtilization": "75",
  "dbCompactKeyPrefixes": "true",
  "dbDirectory": "db",
  "dbDirectoryPermissions": "700",
  "dbEvictorCriticalPercentage": "0",
  "dbEvictorLruOnly": "false",
  "dbEvictorNodesPerScan": "10",
  "dbFileCacheSize": "1000",
  "dbImportCachePercent": "60",
  "dbLogFileMax": "50 mb",
  "dbLoggingFileHandlerOn": "true",
  "dbLoggingLevel": "CONFIG",
  "dbNumCleanerThreads": "0",

```

```

"dbNumLockTables": "0",
"dbRunCleaner": "true",
"dbTxnNoSync": "false",
"dbTxnWriteNoSync": "true",
"dbUseThreadLocalHandles": "true",

        the component must be restarted, either by disabling and
        re-enabling it, or by restarting the server"
    },
    {
      "property": "id2childrenIndexEntryLimit",
      "type": "other",
      "synopsis": "If this limit is increased, then the contents
        of the backend must be exported to LDIF and re-imported to
        allow the new limit to be used for any id2children keys
        that had already hit the previous limit."
    }
  ]
}
}
}

```

## Configuration API paths

The Configuration API and supported sub-paths are available under the `/config` path.

A full listing of supported sub-paths is available when you access the base `/config/ResourceTypes` endpoint.

```
GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json
```

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted or created. These paths can be differentiated from others by their singular, rather than plural, relation name, such as `global-configuration`.

## Example

The following sample response is abbreviated.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 520,
  "Resources": [
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "dsee-compat-access-control-handler",
      "name": "DSEE Compat Access Control Handler",
      "description": "The DSEE Compat Access Control
        Handler provides an implementation that uses syntax
        compatible with the Sun Java System Directory Server
        Enterprise Edition access control handler.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/dsee-
        compat-access-control-handler"
      }
    },
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "access-control-handler",
      "name": "Access Control Handler",
      "description": "Access Control Handlers manage the
        application-wide access control. The server's access
        control handler is defined through an extensible
        interface, so that alternate implementations can be created.
        Only one access control handler may be active in the server
        at any given time.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/access-
        control-handler"
      }
    }
  ],
}
```

```
{
  ...
}
```

The response's `endpoint` elements enumerate all available sub-paths. You can use the path `/config/access-control-handler` in the example to get a list of existing access control handlers and create new ones. You can use a path containing an object name, such as `/config/backends/{backendName}` (where `{backendName}` corresponds to an existing backend like `userRoot`) to obtain an object's properties, update the properties, or delete the object.

### Sort and filter objects

The Configuration API supports System for Cross-domain Identity Management (SCIM) parameters for filter, sorting, and pagination.

Search operations can specify a SCIM filter to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters, or paging parameters. Include or exclude attributes can be specified in both GET and list operations.

GET Parameter	Description
<b>filter</b>	Values can be simple SCIM filters, such as <code>id eq "userRoot"</code> , or compound filters like <code>meta.resourceType eq "Local DB Backend" and baseDn co "dc=example,dc=com"</code> .
<b>sortBy</b>	Specifies a property value by which to sort.
<b>sortOrder</b>	Specifies either <code>ascending</code> or <code>descending</code> alphabetical order.
<b>startIndex</b>	1-based index of the first result to return.
<b>count</b>	Indicates the number of results per page.

### Update properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH.

With PUT, the server computes the differences between the object in the request with the current version in the server and performs modifications where necessary. The server never removes attributes that are not specified in the request. The API responds with the entire modified object.

#### Example

Sample request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
  "description" : "A new description."
}
```

Sample response:

```
{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],
  "id": "userRoot",
  "meta": {
    "resourceType": "Local DB Backend",
  }
```

```

    "location": "http://example.com:5033/config/backends/userRoot"
  },
  "backendID": "userRoot",
  "backgroundPrime": "false",

"uncachedId2entryCacheMode": "cache-keys-only",
"writabilityMode": "enabled"
}

```

### Administrative actions

Updating a property might require an administrative action before changes can take effect.

If you need administrative actions to update a property, the server returns 200 Success. Any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

### Example

For example, changing the `jeProperty` of a backend results in the following:

```

"urn:unboundid:schemas:configuration:messages:2.0": {
  "required-actions": [
    {
      "property": "baseContextPath",
      "type": "componentRestart",
      "synopsis": "In order for this modification to take effect, the
component
must be restarted, either by disabling and re-enabling it,
or
by restarting the server"
    },
    {
      "property": {
        "type": "other",
        "synopsis": "If this limit is increased, then the
contents of the backend must be exported to LDIF
and re-imported to allow the new limit to be used
for any id2children keys that had already hit the
previous limit."
      }
    }
  ]
}

```

### Updating servers and server groups

You can configure servers as part of a server group so that configuration changes applied to a single server are applied to all servers in a group.

When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query attribute. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `single-server` or `server-group` can be specified.

### Example

```

http://localhost:8082/config/backends/userRoot?applyChangeTo=single-server

```

### Configuration API responses

Clients of the API should examine the HTTP response code to determine the success or failure of a request.

The following are response codes and their meanings.

Response Code	Description	Response Body
200 Success	The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the <code>urn:unboundid:schemas:configuration:messages:2.0</code> object.	List of objects, object properties, or administrative actions
204 No Content	The requested operation succeeded and no further information has been provided, as in the case of a DELETE operation.	None
400 Bad Request	The request contents are incorrectly formatted or a request is made for an invalid API version.	Error summary and optional message
401 Unauthorized	User authentication is required. Some user agents, such as browsers, might respond by prompting for credentials. If the request specified credentials in an Authorization header, they are invalid.	None
403 Forbidden	The requested operation is forbidden, either because the user does not have sufficient privileges or some other constraint, such as an object is edit-only and cannot be deleted.	None
404 Not Found	The requested path does not refer to an existing object or object relation.	Error summary and optional message
409 Conflict	The requested operation could not be performed due to the current state of the configuration. For example, an attempt was made to create an object that already exists, or an attempt was made to delete an object that is referenced by another object.	Error summary and optional message
415 Unsupported Media Type	The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.	None
500 Server Error	The server encountered an unexpected error. Report server errors to Customer Support.	Error summary and optional message

#### Note:

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages can change, and their presence can depend on server configuration. Use the HTTP return code and the context of the request to create a client error message.

## Example

The following is an example encoded error message.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": 404,
  "scimType": null,
  "detail": "The Local DB Index does not exist."
}
```

## Working with the Directory REST API

The Directory REST API is the native interface for client access to the PingDirectory Server. Instead of trying to manage directory hierarchy or require attribute mapping, the Directory REST API provides direct access to directory data in a way that is dynamic, discoverable, and efficient.

Before you begin

The Directory REST API gives developers who are more comfortable with REST than LDAP access to arbitrary directory data in a way that ensures directory data remains consistent regardless of whether it is accessed from LDAP or REST. The Directory API is enabled during server setup. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.

While both the Directory REST API and System for Cross-domain Identity Management (SCIM) provide REST access to directory data, the goals of the two protocols are different. SCIM is useful to generic, external clients that require simple, narrow access to identity data, but because it is a less common standard for identity stores, it might not offer as much functionality or be as user-friendly as the Directory REST API.

The Directory REST API can be used for the following operations.

HTTP operation	Resource endpoint	Description	Allowed query parameters
DELETE	<code>/directory/v1/{dn}</code>	Delete an entry.	
GET	<code>/directory/v1</code>	Get metadata about the API and server.	
GET	<code>/directory/v1/{dn}</code>	Retrieve a single entry.	<ul style="list-style-type: none"> <li>▪ <code>expand</code></li> <li>▪ <code>includeAttributes</code></li> <li>▪ <code>excludeAttributes</code></li> </ul>
GET	<code>/directory/v1/{dn}/subtree</code>	Search an entry's descendants.	<ul style="list-style-type: none"> <li>▪ <code>filter</code></li> <li>▪ <code>searchScope</code></li> <li>▪ <code>cursor</code></li> <li>▪ <code>limit</code></li> <li>▪ <code>includeAttributes</code></li> <li>▪ <code>excludeAttributes</code></li> </ul>
GET	<code>/directory/v1/schemas</code>	Retrieve the schemas of all available object classes.	

HTTP operation	Resource endpoint	Description	Allowed query parameters
GET	/directory/v1/schemas/{objectclass}	Retrieve schema for a specific object class.	
GET	/directory/v1/schemas/_operationalAttributes	Retrieve schema for operational attributes.	
GET	/directory/v1/me	Alias for retrieving the current user.	
PATCH	/directory/v1/{dn}	Modify an entry (add or delete values).	<b>expand</b>
POST	/directory/v1	Create a new entry.	<b>expand</b>
PUT	/directory/v1/{dn}	Modify or rename an entry.	<b>expand</b>

#### Steps

- Configure the Directory REST API with any of the following properties using **dsconfig**:

Command	Description
<b>basic-auth-enabled</b>	Specifies whether users can connect to the service with HTTP Basic authentication. If disabled, users need a bearer token. If changed, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled. Basic authentication is enabled by default.
<b>identity-mapper</b>	If HTTP Basic authentication is enabled, the identity mapper referenced by this distinguished name (DN) must be used to map the user names provided to user entries. By default, an identity mapper is provided, which maps a fully-qualified DN to an entry. For changes to take effect, the server must be restarted, or any HTTP connection handlers referencing this service disabled and re-enabled.
<b>access-token-validator</b>	Specifies the subset of this server's Access Token Validators (by DN), which can validate Bearer authentication tokens. By default, if no validators are specified, then any of the validators on the server can be used. For changes to take effect, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled.
<b>access-token-scope</b>	The scope that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, Bearer token authentication is disabled, and only Basic authentication is used. By default, no value is provided. Changes to this value take effect immediately.
<b>audience</b>	A string or URI audience that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, any

Command	Description
<code>max-page-size</code>	audience is acceptable. By default, no value is provided. Changes to this value take effect immediately.
<code>schemas-endpoint-objectclass</code>	The maximum number of entries to be returned in one page from the search endpoint. Actual results returned might be lower due to the limit query parameter on the request and the actual number of available results. The value must be an integer between 1 and 1000. The default value is 100. Changes to this value take effect immediately.
<code>schemas-endpoint-objectclass</code>	The list of object classes that will be returned by the <code>/schemas/</code> endpoint in the REST API. By default, no schemas are returned. Changes to this value take effect immediately.

Example:

The following example uses `dsconfig` to configure an `objectClass` entity.

```
dsconfig set-http-servlet-extension-props --extension-name "Directory
REST API" \
  --add schemas-endpoint-objectclass:ubidPerson
```

## Configuring the Server using the Administrative Console

The PingDirectory Server provides an administrative console for server configuration and monitoring that has the same functionality as the `dsconfig` command.

When signing on to the Administrative Console, the console does not persistently store any credentials for authenticating to the Directory Server. Instead, the console uses the credentials provided by the user when signing on.

When managing multiple directory server instances, the provided credentials must be valid for each instance.

### Signing on to the Administrative Console

About this task

To sign on to the console, enter a fully qualified distinguished name (DN), for example, `cn=admin2,cn=Topology Admin Users,cn=Topology,cn=config`. For more information, see [Configuring a global administrator](#) on page 487.

Steps

1. Start the Directory Server.  

```
$ bin/start-server
```
2. In a browser, go to <http://server-name:389/console/login>.

3. In the **Username** and **Password** fields, enter the root user DN credentials.

4. Click **Sign In**.

## Configuring the Server using the Console

### Steps

1. From the Administrative Console, go to **Configuration #**

### Backends.

2. At the top of the **Administrative Console** page, select the **Show Advanced Properties** check box.
3. Click the name of the backend you want to configure.

4. Change or enter values in the server configuration.

**PingIdentity. PingData Administrative Console** Servers directory manager

snapshot.unboundid.lab.3389 Configuration Backends Configuration Guide

### Edit Local DB Backend

The Local DB Backend uses the Berkeley DB Java Edition to store user-provided data in a local repository.

**General Configuration**

Backend ID \* userRoot ⓘ

Description

Enabled \*  Enabled ⓘ

Base DN \*  + ⓘ  
 ✕

Writability Mode \*  x ⓘ

Set Degraded Alert When Disabled  Enabled ⓘ

Return Unavailable When Disabled  Enabled ⓘ

Notification Manager  / + ⓘ

Is Private Backend  Enabled ⓘ

The following list describes the server configuration fields.

#### **Backend ID**

#### **Description**

#### **Enabled**

This check box allows you to enable or disable the local DB backend.

#### **Base DN**

#### **Writeability Mode**

This list includes the following options:

enabled

#### **Set Degraded Alert When Disabled**

When selected, this check box tells the server to create an alert...

#### **Return Unavailable When Disabled**

#### **Notification Manager**

#### **In Private Backend**

5. To apply your changes, click **Save**.

## Generating a summary of configuration components

The `config-diff` tool generates a summary of the configuration in a local or remote directory server instance.

### About this task

The `config-diff` tool is useful for comparing configuration settings on the directory server instance when troubleshooting issues or when verifying configuration settings on newly-added servers. The tool can interact with the local configuration regardless of whether the server is running.

### Steps

- To generate a summary of configuration components, run `config-diff`  
Example: `$ bin/config-diff` generates a summary of a local online server.
- To generate a comparison of the current configuration with the pre-installation configuration, run the following.

```
$ bin/config-diff --sourceLocal \  
--sourceBaseline \  
--targetLocal \  
--exclude differs-after-install \  
--outputFile configuration-steps.dsconfig
```

This comparison ignores any changes that could be made by the installer and writes the output to a file called `configuration-steps.dsconfig`.

You can use this file as the basis for a script to configure a new server identical to the local server.

- To view other available tool options, run `config-diff --help`.

## Administrator account classes

Directory Server provides three different classes of administrator accounts: root user, administrator, and global administrator.

### Root user

The root user is the LDAP-equivalent of a UNIX super-user account and inherits its privileges from the default root user privilege set. For more information on default root privileges, see [Default root privileges](#). The root user account is an entry that is stored in the server's configuration under `cn=Root` DNs, `cn=config` and bypasses access control evaluation. It can be created manually or with the `dsconfig` tool. This account has full access to the entire set of data in the directory information tree (DIT) and to the server configuration and its operations. One important difference between other vendors' servers and Directory Server's implementation is that the root user's rights are granted through a set of privileges. This allows Directory Server to have multiple root users on its system, but the normal practice is to set up administrator user entries. The root user has no resource limits by default.

### Administrator

The administrator user can have a full set of root user privileges but often has a subset of these privileges to limit the accessible functions that can be performed. The administrators' entries typically have limited access to the entire set of data in the DIT, which is controlled by access control instructions. These entries reside in the backend configuration, for example, `uid=admin,dc=example,dc=com`, and are replicated between servers in a replication topology. In some cases, administrator user accounts might be unavailable when the server enters lockdown mode unless the administrator is given the lockdown mode privilege.

## Global administrator

A global administrator is primarily responsible for managing configuration server groups. A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology where configuration changes to one server can be applied to all of the servers at one time.

Global administrator entries are stored in the `cn=Topology Admin Users,cn=Topology,cn=config` backend and are always mirrored across servers in a replication topology. These users can be assigned privileges like other administrator users but are typically used to manage the data under `cn=Topology,cn=config`.

## Using separate administrator accounts

Each administrator should have their own account with their own credentials tailored to the level of access needed.

The `setup` utility only creates a single root user. Some directory servers from other vendors only support a single root account so all administrators are required to share that account. However, this is a bad practice for a number of reasons, including:

- It's difficult to audit the actions of individual administrators. With separate accounts for each administrator, it's easy to see who did what.
- Credentials have to be shared across multiple administrators. Shared credentials are at a greater risk of being leaked or compromised. With separate accounts for each administrator, each has its own credentials that are not shared with anyone else.
- If the credentials for that single root account are leaked or compromised (or if someone with legitimate access to those credentials leaves their position and no longer needs that access), then those credentials need to be changed. The new credentials need to be communicated to all of the administrators sharing that account, which can be difficult to do securely. If the new credentials are not communicated in advance of the change, then administrators who have not received them won't be able to manage the server. If the new credentials are communicated in advance of the change, then the old, potentially compromised credentials remain in effect for longer than necessary.
- Using a single root account makes it more difficult to use strong authentication, such as a certificate or two-factor authentication, in a secure manner. With separate accounts for each administrator, it's easier to use strong authentication in a secure manner.
- If there is only a single root account, then that account must have a level of access that permits everything that any administrator might need to do, even if all administrators don't need the same level of access. With separate accounts for each administrator, each can be given precisely the level of access that they need.

It might also be beneficial to remove or disable the account for the initial root user created by `setup` once all of the administrators have their own accounts.

Using separate accounts is mentioned in the following `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file, which provides an example for creating a topology admin user with various restrictions.

```
# Although setup automatically creates an initial root user account that can
# be used to manage the server, we strongly recommend creating a separate
# account for each administrator rather than using a single shared account.
# This offers several benefits, including:
#
# * It is easier to determine which administrator performed a given action.
# * There is no need to share credentials or coordinate password changes.
# * It is easier to use strong authentication options like certificates or
#   two-factor mechanisms.
# * You can customize the level of access that each administrator has.
#
# We also recommend creating topology admin user accounts rather than root
# user accounts. If you create a root user account, then it is only created
```

```

# in that one instance. If you create a topology admin user, then that
# account will be available in all instances in the topology.
#
# Because administrative accounts are very powerful, they are high-priority
# targets for attackers to try to compromise. They should be required to
# have
# strong credentials, and you may wish to require that they use strong
# authentication mechanisms (see other dsconfig batch files for configuring
# password validators and other password policy features). You may also
# want
# to give them usernames that are not likely to be guessed by an attacker,
# even if they know information about the individuals administering the
# service. For example, you may not want to use their name in the DN or
# username, choosing instead something that is less predictable or even
# completely random like a UUID.
#
# Once each administrator has their own account, we recommend that you
# disable
# or remove the initial root user created during setup. See the
# disable-or-remove-the-initial-root-user.dsconfig batch file for more
# information about that.

#
# NOTE: Do not edit this file directly. Changing this file could prevent
# it
# from being updated during a server upgrade. If you want to alter the
# dsconfig commands below before applying the configuration changes, copy
# this
# file to another directory and edit that copy.
#

# Create a new topology administrator account. In this example, the user
# will
# be able to read the configuration but will not be allowed to update it,
# and
# will be given the bypass-read-acl privilege rather than bypass-acl, which
# only ensures they will be able to read entries but they will not be
# permitted to update them unless permitted by the server's access control
# configuration. They will also only be permitted to communicate with the
# server over a secure connection, and they will only be permitted to
# authenticate with the EXTERNAL or UNBOUNDID-TOTP mechanisms.
dsconfig create-topology-admin-user \
  --user-name "[USER_NAME]" \
  --set "password:[PASSWORD]" \
  --set "first-name:[FIRST_NAME]" \
  --set "last-name:[LAST_NAME]" \
  --set "user-id:[USER_NAME]" \
  --set inherit-default-root-privileges:true \
  --set privilege:bypass-read-acl \
  --set privilege:-bypass-acl \
  --set privilege:-config-write \
  --set search-result-entry-limit:0 \
  --set time-limit-seconds:0 \
  --set look-through-entry-limit:0 \
  --set idle-time-limit-seconds:0 \
  --set require-secure-authentication:true \
  --set require-secure-connections:true \
  --set "allowed-authentication-type:SASL EXTERNAL" \
  --set "allowed-authentication-type:SASL UNBOUNDID-TOTP"

```

## Unpredictable identifiers for server administrators

You can prevent online password guessing attacks by using unpredictable identifiers for users.

If an attacker doesn't know the name of the account, then it's another obstacle to overcome before they can authenticate as them.

An entry's DN is the most common identifier used to authenticate, as it's required for simple binds and is often used for SASL binds. For regular users, you should name accounts with the entryUUID attribute. However, this isn't feasible for root users or topology administrators because the configuration framework requires these entries to use `cn` as the naming attribute. Further, many SASL mechanisms allow identifying users with a username, which is correlated to the associated entry using an identity mapper, so using an unpredictable DN might not be enough to sufficiently interfere with an attacker's ability to target a server administrator.

The best way to obscure identifiers for root users and topology administrators is to choose unpredictable values for the `cn` attribute in their accounts and not include any predictable alternate bind DN values for those accounts. Although it is possible to use randomly generated `cn` values, it should be sufficient to use more memorable strings as long as they aren't something an attacker is likely to guess even if they know the identities of those administrators.

## Secure communication for server administrators

Requiring secure communication for server administrators is recommended to prevent unencrypted communication.

While you should only permit secure access to the server, many environments might still allow access to unencrypted communication. Unencrypted communication is potentially dangerous for any kind of client because it could be observed and altered by a malicious third party, but it's especially dangerous for administrative accounts. Even if the server is configured to allow some clients to issue insecure requests, you should ensure that administrative accounts always use secure communication.

The best way to require that a user only be permitted to communicate with the server over a secure connection is to include the `ds-auth-require-secure-connection` operational attribute in that user's entry with a value of `true`. Although the password policy configuration includes `require-secure-authentication`, and `require-secure-password` changes properties, those properties can only guarantee the safety of authentication credentials. They don't guarantee secure communication for other operations processed by that user. This is because it's possible to authenticate in a manner that the server considers secure, without exposing credentials to an observer, without using a secure connection such as using a SASL mechanism like GSSAPI.

### Note:

CRAM-MD5 and DIGEST-MD5 also currently fall into this category, but for this purpose they are no longer considered secure.

Although it's possible to enable this by default for root users and topology administrators, you shouldn't do so at the risk of affecting backward compatibility with existing deployments that expect to be able to use insecure communication for these accounts. If the server is configured to only accept secure connections, or to reject insecure requests, then this setting is not as necessary.

## Managing root user accounts

PingDirectory Server provides a default root user, `cn=Directory Manager`, that is stored in the server's configuration file, such as under `cn=Root DNs,cn=config`.

About this task

The root user is the LDAP-equivalent of a UNIX superuser account and inherits its read-write privileges from the default root privilege set.

## Steps

- To create or update root users, use the `dsconfig` tool.

Example:

```
bin/dsconfig create-root-dn-user --user-name "Joanne Smith" \
  --set last-name:Smith \
  --set first-name:Joanne \
  --set user-id:jsmith \
  --set 'email-address:jsmith@example.com' \
  --set mobile-telephone-number:8889997777 \
  --set home-telephone-number:5556667777 \
  --set work-telephone-number:4445556666
```

### Note:

Root user entries are stored in the server's configuration.

- To limit full access to all of Directory Server, create separate administrator accounts with limited privileges so that you can identify the administrator responsible for a particular change.

### Note:

Separate user accounts for each administrator make it possible to enable password policy functionality, such as password expiration, password history, and requiring secure authentication, for each administrator.

## Default root privileges

The PingDirectory Server contains a privilege subsystem that allows for a more fine-grained control of privilege assignments.

### Note:

Creating restricted root user accounts requires assigning privileges and necessary access controls for actions on specific data or backends. Access controls are determined by how the directory is configured and the structure of your data. See Chapter 16: Managing Access Controls for more information.

The following set of root privileges are available to each root user DN:

### Default Root Privileges

Privilege	Description
audit-data-security	Allows the associated user to execute data security auditing tasks.
backend-backup	Allows the user to perform backend backup operations.
backend-restore	Allows the user to perform backend restore operations.
bypass-acl	Allows the user to bypass access control evaluation.
config-read	Allows the user to read the server configuration.
config-write	Allows the user to update the server configuration.
disconnect-client	Allows the user to terminate arbitrary client connections.
ldif-export	Allows the user to perform LDIF export operations.

Privilege	Description
ldif-import	Allows the user to perform LDIF import operations.
lockdown-mode	Allows the user to request a server lockdown.
manage-topology	Allows the user to modify topology setting.
metrics-read	Allows the user to read server metrics.
modify-acl	Allows the user to modify access control rules.
password-reset	Allows the user to reset user passwords but not their own. The user must also have privileges granted by access control to write the user password to the target entry.
permit-get-password-policy-state-issues	Allows the user to access password policy state issues.
privilege-change	Allows the user to change the set of privileges for a specific user, or to change the set of privileges automatically assigned to a root user.
server-restart	Allows the user to request a server restart.
server-shutdown	Allows the user to request a server shutdown.
soft-delete-read	Allows the user access to soft-deleted entries.
stream-values	Allows the user to perform a stream values extended operation that obtains all entry DN's and/or all values for one or more attributes for a specified portion of the DIT.
third-party-task	Allows the associated user to invoke tasks created by third-party developers.
unindexed-search	Allows the user to perform an unindexed search in the Oracle Berkeley DB Java Edition backend.
update-schema	Allows the user to update the server schema.
use-admin-session	Allows the associated user to use an administrative session to request that operations be processed using a dedicated pool of worker threads.

The Directory Server provides other privileges that are not assigned to the root user DN by default but can be added using the `ldapmodify` tool (see Modifying Individual Root User Privileges) for more information.

### Other Available Privileges

Privilege	Description
bypass-pw-policy	Allows the associated user bypass password policy rules and restrictions.
bypass-read-aci	Allows the associated user to bypass access control checks performed by the server for bind, compare, and search operations. Access control evaluation may still be enforced for other types of operations.
jmx-notify	Allows the associated user to subscribe to receive JMX notifications.
jmx-read	Allows the associated user to perform JMX read operations.
jmx-write	Allows the associated user to perform JMX write operations.

Privilege	Description
permit-externally-processed-authentication	Allows the associated user accept externally processed authentication.
permit-proxied-mschapv2-details	Allows the associated user to permit MS-CHAP V2 handshake protocol.
proxied-auth	Allows the associated user to accept proxied authorization.

## Configuring administrator accounts

An administrator account is any account in the user backend that is assigned one or more privileges or is given access to read and write operations beyond that of a normal user entry.

The privilege mechanism is the same as that used for root distinguished name (DN) accounts and allows individual privileges to be assigned to an administrator entry.

Typically, administrator user entries are controlled by access control evaluation to limit access to the entire set of data in the directory information tree (DIT). You can grant fine-grained read and write access using the access control definitions available through the `aci` attribute. Administrator entries reside in the backend configuration, for example, `uid=admin,dc=example,dc=com`, and are replicated between servers in a replication topology.

The following examples show how to configure administrator accounts:

- The first procedure shows how to set up a single, generic `uid=admin,dc=example,dc=com` account with limited privileges.

### Note:

If you generated sample data at install, you can view an example `uid=admin` entry using `ldapsearch`.

- The second example shows a more realistic example where the user is part of the administrators group.

### Note:

Both examples are based on a simple DIT. Actual deployment cases depend on your schema.

## Setting up a single administrator account

About this task

To create an example of a single, generic administrator account:

Steps

1. Create an LDIF file with an example administrator entry.

Example:

```
dn: uid=admin,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
givenName: Admin
uid: admin
cn: Admin User
```

```
sn: User
userPassword: password
```

2. To add the entry, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --defaultAdd --filename admin.ldif
```

3. To add the access control instruction (ACI) to the root suffix or base DN to give full access to the new administrator, create another LDIF file.

**Note:**

The ACI grants full access to all user attributes, but not to operational attributes. To grant access to operational attributes as well as user attributes, use `(targetattr = "*"|+)` in the access control instruction.

Example:

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr = "*")
      (version 3.0; acl "Grant full access for the admin user";
       allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

4. To add the entry, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --filename admin.ldif
```

5. To verify the additions, use the `ldapsearch` tool.

Example:

In the following example, the first command searches for the entry that contains `uid=Admin` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including ACIs, associated with the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=admin)"
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base
  "(objectclass=*)" "+"
```

6. Add specific privileges to the administrator account, then to process the modify operation press **CTRL-D**.

Example:

For this example, add the `password-reset` privilege to the administrator account from the command line.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset
```

Result:

```
Processing MODIFY request for uid=admin,dc=example,dc=com
```

```
MODIFY operation successful for DN uid=admin,dc=example,dc=com
```

7. Assign a password policy for the administrator account.

Example:

Create an Admin Password Policy, then add the password policy to the account.

```
$ bin/dsconfig create-password-policy \
  --policy-name "Admin Password Policy" \
  --set "description:Password policy for administrators" \
  --set password-attribute:userpassword \
  --set "default-password-storage-scheme:Salted SHA-256" \
  --set password-change-requires-current-password:true \
  --set force-change-on-reset:true \
  --set "max-password-age:25w 5d" \
  --set grace-login-count:3 \
  --no-prompt
```

8. To apply the password policy to the account, run the `ldapmodify` command.

Example:

Execute the `ldapmodify` command with a bind DN that has sufficient rights, such as a root DN, as in the following example.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password
Policies,cn=config
```

## Changing the administrator password

About this task

Root users are governed by the root password policy and by default, their passwords never expire. To change a root user password, use the `ldappasswordmodify` tool.

Steps

1. Open a text editor and create a text file containing the new password.

Example:

For this example, name the file `rootuser.txt`.

```
$ echo password > rootuser.txt
```

2. To change the root user's password, run `ldappasswordmodify`.

Example:

```
$ bin/ldappasswordmodify --port 1389 --bindDN "cn=Directory Manager" \
  --bindPassword secret --newPasswordFile rootuser.txt
```

3. Remove the text file.

Example:

```
$ rm rootuser.txt
```

## Setting up an administrator group

### About this task

The following example shows how to set up a group of administrators that have access rights to the whole Directory Server.

#### Note:

The example uses a static group using the `GroupOfUniqueNames` object class.

### Steps

1. Create an LDIF file with an example administrator group.

#### Example:

For this example, name the file `admin-group.ldif`

```
dn: ou=Groups,dc=example,dc=com
objectClass: organizationalunit
objectClass: top
ou: Groups

dn: cn=Dir Admins,ou=Groups,dc=example,dc=com
objectClass: groupofuniqueNames
objectClass: top
uniqueMember: uid=user.0, ou=People, dc=example,dc=com
uniqueMember: uid=user.1, ou=People, dc=example,dc=com
cn: Dir Admins
ou: Groups
```

2. To add the entries, use the `ldapmodify` tool.

#### Example:

```
$ bin/ldapmodify --defaultAdd --filename admin-group.ldif
```

3. To add the ACL to the root suffix or base DN to provide full access to the Directory Server to the new administrator, create another LDIF file.

#### Example:

For this example, name the file `admin-aci.ldif`.

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (target="ldap:///dc=example,dc=com")
(targetattr != "aci")
(version 3.0; acl "allow all Admin group";
allow(all) groupdn = "ldap:///cn=Dir
Admins,ou=Groups,dc=example,dc=com";)
```

4. To add the ACL, use the `ldapmodify` tool.

#### Example:

```
$ bin/ldapmodify --filename admin-aci.ldif
```

- To verify the additions, use the `ldapsearch` tool.

Example:

In the following example, the first command searches for the entry that contains `cn=Dir Admins` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including ACIs, associated with the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(cn=Dir Admins)"
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base \
  "(objectclass=*)" "+"
```

- To add specific privileges to each administrator account, use an LDIF file.

Example:

For this example, name the file `admin-priv.ldif`.

For this example, add the `password-reset` privilege to the `user.0` administrator account from the command line. To add the privilege, use the `ldapmodify` tool. Repeat the process for the other administrators configured in the administrator group.

```
dn: uid=user.0,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset

$ bin/ldapmodify --filename admin-priv.ldif
```

Result:

```
Processing MODIFY request for uid=user.0,dc=example,dc=com
MODIFY operation successful for DN uid=user.0,dc=example,dc=com
```

- To assign a password policy for the administrator account, use an LDIF file. Save the file as `admin-pwd-policy.ldif`.

Example:

For example, create an `Admin Password Policy`, then add the password policy to the account. To apply the password policy to the account, use the `ldapmodify` tool.

```
dn: uid=user.0,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password
Policies,cn=config

$ bin/ldapmodify --filename admin-pwd-policy.ldif
```

## Configuring a global administrator

A global administrator is created when replication is enabled and is responsible for managing configuration server groups.

A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology where configuration changes to one server can be applied to all of the servers at a time.

Global administrators are stored in the topology registry. These entries are always mirrored between servers in a topology. Global administrators can be assigned privileges like other administrator users but are typically used to manage the data under `cn=topology`, `cn=config` and `cn=config`. You can create

new or remove global administrators using the **dsconfig** tool. The global administrator entries are located in the `cn=Topology Admin User, cn=topology,cn=config` branch.

## Creating a global administrator

### Steps

1. To create a new global administrator, use the `create-topology-admin-user` option with **dsconfig**.

Example:

```
$ bin/dsconfig create-topology-admin-user \
  --user-name admin2 \
  --set alternate-bind-dn:cn=admin2 \
  --set password:rootPassword
```

2. To verify the creation of the new administrator, use the `list-topology-admin-users` option with **dsconfig**.

Example:

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
-----:-----
admin               : generic
admin2              : generic
```

## Removing a global administrator

### Steps

1. To delete a global administrator, use the `delete-topology-admin-user` option with **dsconfig**.

Example:

```
$ bin/dsconfig delete-topology-admin-user --user-name admin2
```

2. To verify the deletion of the global administrator, use the `list-topology-admin-users` option with **dsconfig**.

Example:

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
-----:-----
admin               : generic
```

## Configuring server groups

The PingDirectory Server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group.

### About this task

After you have set up a server group, you can make an update on one server using **dsconfig**, then apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the **dsconfig** non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using **dsconfig** in interactive command-line mode, you are asked if you want to apply the change to a single server or to all servers in the server group.

You can create an administrative server group using the `dsconfig` tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group, as outlined in [Replication Configuration](#).

The following example procedure adds three instances into the server group labeled "group-one".

#### Steps

1. Create a group called "group-one" using `dsconfig`.

Example:

```
$ bin/dsconfig create-server-group --group-name group-one
```

2. Add any PingDirectory Server to the server group.

If you have set up replication between a set of servers, these server entries are created by the `dsreplication enable` command.

Example:

```
$ bin/dsconfig set-server-group-prop \  
  --group-name group-one --add member:server1  
  
$ bin/dsconfig set-server-group-prop \  
  --group-name group-one --add member:server2  
  
$ bin/dsconfig set-server-group-prop \  
  --group-name group-one --add member:server3
```

3. Set a global configuration property for each of the servers that should share changes in this group.

Example:

```
$ bin/dsconfig set-global-configuration-prop \  
  --set configuration-server-group:group-one
```

4. Test the server group.

In this example, enable the log publisher for each PingDirectory Server in the group "server-group" by using the `--applyChangeTo server-group` option.

Example:

```
$ bin/dsconfig set-log-publisher-prop \  
  --publisher-name "File-Based Audit Logger" \  
  --set enabled:true \  
  --applyChangeTo server-group
```

5. View the property on the first PingDirectory Server instance.

Example:

```
$ bin/dsconfig get-log-publisher-prop \  
  --publisher-name "File-Based Audit Logger" \  
  --property enabled
```

Result:

```
Property : Value(s)  
-----:-----  
enabled : true
```

6. Repeat step 5 on the second and third PingDirectory Server instances.

7. Test the server group by disabling the log publisher on the first PingDirectory Server instance by using the `--applyChangeTo single-server`.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:disabled \
  --applyChangeTo single-server
```

8. View the property on the first PingDirectory Server instance.

The first PingDirectory Server instance should be disabled.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
-----:-----
enabled : false
```

9. View the property on the second PingDirectory Server instance.

Repeat this step on the third PingDirectory Server instance to verify that the property is still enabled on that server.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
-----:-----
enabled : true
```

## Client connection policy configuration

Client connection policies help distinguish what portions of the DIT the client can access.

They enforce restrictions on what clients can do in the server. A client connection policy specifies criteria for membership based on information about the client connection, including client address, protocol, communication security, and authentication state and identity. The client connection policy, however, does not control membership based on the type of request being made.

Every client connection is associated with exactly one client connection policy at any given time, which is assigned to the client when the connection is established. The choice of which client connection policy to use is reevaluated when the client attempts a bind to change its authentication state or uses the StartTLS extended operation to convert an insecure connection to a secure one. Any changes you make to the client connection policy do not apply to existing connections. The changes only apply to new connections.

Client connections are always unauthenticated when they are first established. If you plan to configure a policy based on authentication, you must define at least one client connection policy with criteria that match unauthenticated connections.

When a client has been assigned to a policy, you can determine what operations they can perform. For example, your policy might allow only SASL bind operations. Client connection policies are associated with one or more subtree views, which determine the portions of the DIT a particular client can access. For example, you might configure a policy that prevents users connecting over the extranet from accessing configuration information. The client connection policy is evaluated in addition to access control, so even a root user connecting over the extranet would not have access to the configuration information.

### About the client connection policy

Client connection policies are based on two factors.

#### Connection criteria

The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can be used in other instances when the server needs to perform matching based on connection-level properties, such as filtered logging. A single connection can match multiple connection criteria definitions.

#### Evaluation order index

If multiple client connection policies are defined in the server, then each of them must have a unique value for the `evaluation-order-index` property. The client connection policies are evaluated in order of ascending evaluation order index. If a client connection does not match the criteria for any defined client connection policy, then that connection will be terminated.

If the connection policy matches a connection, then the connection is assigned to that policy and no further evaluation occurs. If, after evaluating all of the defined client connection policies, no match is found, the connection is terminated.

### When a client connection policy is assigned

A client connection policy can be associated with a client connection at the following times.

- When the connection is initially established. This association occurs exactly once for each client connection.
- After completing processing for a StartTLS operation. This association occurs once at most for a client connection because StartTLS cannot be used more than once on a particular connection. You can not stop using StartTLS while keeping the connection active.
- After completing processing for a bind operation. This association occurs zero or more times for a client connection because the bind request can be processed many times on a given connection.

StartTLS and bind requests are subject to whatever constraints are defined for the client connection policy that is associated with the client connection at the time that the request is received. When they have completed, then subsequent operations are subject to the constraints of the new client connection policy assigned to that client connection. This policy might not be the same client connection policy that was associated with the connection before the operation was processed. That is, any policy changes do not apply to existing connections and only apply when the client reconnects.

All other types of operations are subject to whatever constraints are defined for the client connection policy used by the client connection at the time that the request is received. The client connection policy assigned to a connection never changes as a result of processing any operation other than a bind or StartTLS. The server does not re-evaluate the client connection policy for the connection in the course of processing an operation. For example, the client connection policy is never re-evaluated for a search operation.

### Restricting the type of search filter used by clients

You can restrict the types of search filters that a given client might be allowed to use to prevent the use of potentially expensive filters, like range or substring searches.

You can use the `allowed-filter-type` property to provide a list of filter types that can be included in the search requests from clients associated with the client connection policy. This setting is only used if search is included in the set of allowed operation types. This restriction only applies to searches with a

scope other than `baseObject`, such as searches with a scope of `singleLevel`, `wholeSubtree`, or `subordinateSubtree`.

You can use the `minimum-substring-length` property to specify the minimum number of non-wildcard characters in a substring filter. Any attempt to use a substring search with an element containing fewer than this number of bytes is rejected. For example, you can configure the server to reject filters like `"(cn=a*)"` and `"(cn=ab*)"`, but to allow `"(cn=abcde*)"`. This property setting is only used if `search` is included in the set of allowed operation types and at least one of `sub-initial`, `sub-any`, or `sub-final` is included in the set of allowed filter types.

There are two primary benefits to enforcing a minimum substring length:

- Allowing short substrings can require the server to perform more expensive processing. The search requires more server effort to assemble a candidate entry list for short substrings because the server has to examine more index keys.
- Allowing short substrings makes it easier for a client to put together a series of requests to retrieve all the data from the server, a process known as "trawling". If a malicious user wants to obtain all the data from the server, then it is easier to issue 26 requests like `"(cn=a*)"`, `"(cn=b*)"`, `"(cn=c*)"`, ..., `"(cn=z*)"` than if the user is required to do something like `"(cn=aaaaa*)"`, `"(cn=aaaab*)"`, `"(cn=aaaac*)"`, ..., `"(cn=zzzzz*)"`.

### Resource limits

Client connection policies can specify resource limits, helping to ensure that no single client monopolizes server resources.

You can limit the total number of connections to a server from a particular client or from clients that match specified criteria. You can also limit the duration of the connection.

A client connection policy can only be used to enforce additional restrictions on a client connection. You cannot use it to grant a client capabilities that it would not otherwise have.

Any change to any of these new configuration properties only impacts client connections that are assigned to the client connection policy after the change is made. Any connection associated with the client connection policy before the configuration change was made continues to be subject to the configuration that was in place at the time it was associated with that policy.

### Resource Limiting Properties

Property	Description
<code>maximum-concurrent-connections</code>	<p>Specifies the maximum number of client connections that can be associated with that client connection policy at any given time. The default value of zero indicates that no limit is enforced.</p> <p>If the server already has the maximum number of connections associated with a client connection policy, then any attempt to associate another connection with that policy, such as newly-established connections or an existing connection that has done something to change its client connection policy, such as perform a bind or StartTLS operation, causes that connection to be terminated.</p>
<code>terminate-connection</code>	<p>Specifies that any client connection for which the client connection policy is selected, such as whether it is a new connection or an existing connection that is assigned to the client connection policy after performing a bind or StartTLS operation, is immediately terminated.</p> <p>This property can be used to define criteria for connections that you do not want to be allowed to communicate with the Directory Server.</p>

Property	Description
maximum-connection-duration	<p>Specifies the maximum length of time that a connection associated with the client connection policy can remain established to the Directory Server, regardless of the amount of activity on that connection.</p> <p>A value of "0 seconds" (default) indicates that no limit is enforced. If a connection associated with the client connection policy has been established for longer than this time, then it is terminated.</p>
maximum-idle-connection-duration	<p>Specifies the maximum length of time that a connection associated with the client connection policy can remain established with the Directory Server without any requests in progress.</p> <p>A value of "0 seconds" (default) indicates that no additional limit is enforced on top of whatever idle time limit might already be in effect for an associated connection. If a nonzero value is provided, then the effective idle time limit for any client connection is the smaller of the <code>maximum-idle-connection-duration</code> from the client connection policy and the idle time limit that would otherwise be in effect for that client.</p> <p>This property can be used to apply a further restriction on top of any value that might be enforced by the <code>idle-time-limit</code> global configuration property which defines a default idle time limit for client connections, or the <code>ds-rlim-idle-time-limit</code> operational attribute which might be included in a user entry to override the default idle time limit for that user.</p>
maximum-operation-count-per-connection	<p>Specifies the maximum number of operations that a client associated with the client connection policy is allowed to request. A value of zero (default) indicates that no limit is enforced. If a client attempts to request more than this number of operations on the same connection, then that connection will be terminated.</p>
maximum-concurrent-operations-per-connection	<p>Specifies the maximum number of operations that might be active at any time from the same client. This limit only applies to clients that use asynchronous operations with multiple outstanding requests at any given time.</p> <p>A value of zero (default) indicates that no limit is enforced.</p> <p>If a client already has the maximum number of outstanding requests in progress and issues a new request, then that request is delayed or rejected based on the value of the <code>maximum-concurrent-operation-wait-time-before-rejecting</code> property.</p>

Property	Description
<code>maximum-concurrent-operation-wait-time-before-rejecting</code>	<p>Specifies the maximum length of time that a client connection should allow an outstanding operation to complete if the maximum number of concurrent operations for a connection are already in progress when a new request is received on that connection.</p> <p>A value of "0 seconds" (default) indicates that any new requests received while the maximum number of outstanding requests are already in progress for that connection are immediately rejected.</p> <p>If an outstanding operation completes before this time expires, then the server might be allowed to process that operation. If the time expires, the new request is rejected.</p>
<code>maximum-ldap-join-size-limit</code>	<p>Specifies the maximum number of entries that can be directly joined with any individual search result entry. A value of zero indicates that no LDAP join size limit is enforced. The limit can be overridden on a per-user basis using the <code>ds-rlim-ldap-join-size-limit</code> operational attribute. The LDAP join size limit is also restricted by the search operation size limit. If a search result entry is joined with more entries than allowed, the join result control has a "size limit exceeded" (integer value 4) result code.</p>
<code>allowed-request-control</code>	<p>Specifies the OIDs of the request controls that clients associated with the client connection policy are allowed to use.</p> <p>If any <code>allowed-request-control</code> OIDs are specified, then any request that includes a control not in that set is rejected. If no <code>allowed-request-control</code> values are specified (default), then any control whose OID is not included in the set of <code>denied-request-control</code> values is allowed.</p>
<code>denied-request-control</code>	<p>Specifies the OIDs of the request controls that clients associated with the client connection policy are not allowed to use. If there are any <code>denied-request-control</code> values, then any request containing a control whose OID is included in that set is rejected.</p> <p>If there are no <code>denied-request-control</code> values (default), then any request control is allowed if the <code>allowed-request-control</code> property is also empty, or only those controls whose OIDs are included in the set of <code>allowed-request-control</code> values are allowed if at least one <code>allowed-request-control</code> value is provided.</p>

Property	Description
<p><code>allowed-filter-type</code></p>	<p>Specifies the types of components that might be used in filters included in search operations with a non-base scope that are requested by clients associated with the client connection policy. Any non-base scoped search request whose filter contains a component not included in this set is rejected. The set of possible filter types include:</p> <ul style="list-style-type: none"> <li>▪ <code>and</code></li> <li>▪ <code>or</code></li> <li>▪ <code>not</code></li> <li>▪ <code>equality</code></li> <li>▪ <code>sub-initial</code></li> <li>▪ <code>sub-any</code></li> <li>▪ <code>sub-final</code></li> <li>▪ <code>greater-or-equal</code></li> <li>▪ <code>less-or-equal</code></li> <li>▪ <code>approximate-match</code></li> <li>▪ <code>extensible-match</code></li> </ul> <p>By default, all filter types are allowed.</p> <p> <b>Note:</b></p> <p>No restriction is placed on the types of filters that might be used in searches with a base scope.</p>
<p><code>allow-unindexed-searches</code></p>	<p>Specifies whether clients associated with the client connection policy are allowed to request searches that cannot be efficiently processed using the configured set of indexes.</p> <p> <b>Note:</b></p> <p>Clients must still have the <code>unindexed-search</code> privilege, so this option does not grant the ability to perform unindexed searches to clients that would not have otherwise had that ability, but it might be used to prevent clients associated with the client connection policy from requesting unindexed searches when they might have otherwise been allowed to do so.</p> <p>By default, this has a value of "true", indicating that any client associated with the client connection policy that has the <code>unindexed-search</code> privilege is allowed to request unindexed searches.</p>
<p><code>minimum-substring-length</code></p>	<p>Specifies the minimum number of bytes, which might be present in any sub-Initial, subAny, or subFinal element of a substring search filter component in a search with a non-baseObject scope. A value of one (which is the default) indicates that no limit is enforced. This property might be used to prevent clients from issuing overly-vague substring searches that might require installing the Directory Server to examine too many entries over the course of processing the request.</p>

Property	Description
maximum-search-size-limit	Specifies the maximum number of entries that might be returned from any single search operation requested by a client associated with this client connection policy.
	 <b>Note:</b> This property only specifies a maximum limit and never increases any limit that might already be in effect for the client through the <code>size-limit</code> global configuration property or the <code>ds-rlim-size-limit</code> operational attribute.
	A value of zero (default) indicates that no additional limit is enforced on top of whatever size limit might already be in effect for an associated connection.  If a nonzero value is provided, then the effective maximum size limit for any search operation requested by the client is the smaller of the size limit from that search request, the <code>maximum-search-size-limit</code> from the client connection policy, and the size limit that would otherwise be in effect for that client.

### Defining the operation rate

Configure the maximum operation rate for individual client connections and collectively for all connections associated with a client connection policy.

If the operation rate limit is exceeded, the Directory Server can either reject the operation or terminate the connection. You can define multiple rate limit values, making it possible to fine tune limits for both a long term average operation rate and short term operation bursts. For example, you can define a limit of one thousand operations per second and one million operations per day, which works out to an average of fewer than twelve operations per second, but with bursts of up to one thousand operations per second.

Specify rate limit strings as a maximum count, followed by a slash and a duration. The count portion must contain an integer and can be followed by the following multipliers:

- k (to indicate that the integer should be interpreted as thousands)
- m (to indicate that the integer should be interpreted as millions)
- g (to indicate that the integer should be interpreted as billions)

The duration portion must contain a time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w) and can be preceded by an integer to specify a quantity for that unit.

For example, the following are valid rate limit strings:

- 1/s (no more than one operation over a one-second interval)
- 10K/5h (no more than ten thousand operations over a five-hour interval)
- 5m/2d (no more than five million operations over a two-day interval)

You can provide time units in many different formats. For example, a unit of seconds can be signified using s, sec, sect, second, and seconds.

### Client connection policy deployment example

In this example scenario, we assume the following:

1. Two external LDAP clients are allowed to bind to the Directory Server.
2. Client 1 should be allowed to open only one connection to the server.
3. Client 2 should be allowed to open up to five connections to the server.

For more information on this client connection policy deployment example, see the following topics:

- [Define the connection policies](#) on page 497
- [How the policy is evaluated](#) on page 497
- [Configuring a client connection policy using the console](#) on page 498
- [Configuring a client connection policy using dsconfig](#) on page 499
- [Restricting server access based on client IP address](#) on page 500

### Define the connection policies

Set a per-client connection policy limit on the number of connections that can be associated with a particular client connection policy

Define at least two client connection policies, one for each of the two clients. Each policy must have different connection criteria for selecting the policy with which a given client connection should be associated.

Because the criteria is based on authentication, you must create a third client connection policy that applies to unauthenticated clients because client connections are always unauthenticated as soon as they are established and before they have sent a bind request. Clients are not required to send a bind request as their first operation.

Define the following three client connection policies:

- Client 1 Connection Policy, which only allows client 1, with an evaluation order index of 1
- Client 2 Connection Policy, which only allows client 2, with an evaluation order index of 2
- Unauthenticated Connection Policy, which allows unauthenticated clients, with an evaluation order index of 3

Define simple connection criteria for the Client 1 Connection Policy and the Client 2 Connection Policy with the following properties:

- The `user-auth-type` must not include `none` so that it only applies to authenticated client connections.
- The `included-user-base-dn` should match the bind DN for the target user. This distinguished name (DN) can be full DN for the target user, or it can be the base DN for a branch that contains a number of users that you want treated in the same way.

#### Tip:

To create more generic criteria that match more than one user, you could list the DNs of each of the users explicitly in the `included-user-base-dn` property. If there is a group that contains all of the pertinent users, then you could instead use the `[all|any|not-all|not-any]-included-user-group-dn` property to apply to all members of that group. If the entries for all of the users match a particular filter, then you could use the `[all|any|not-all|not-any]-included-user-filter` property to match them.

### How the policy is evaluated

Whenever a connection is established, the server associates the connection with exactly one client connection policy.

The server does this by iterating over all of the defined client connection policies in ascending order of the evaluation order index. Policies with a lower evaluation order index value are examined before those with a higher evaluation order index value. The first policy that the server finds whose criteria match the client connection is associated with that connection. If no client connection policy is found with criteria matching the connection, then the connection is terminated.

So, in this example, when a new connection is established, the server first checks the connection criteria associated with the Client 1 Connection Policy because it has the lowest evaluation order index value. If it finds that the criteria do not match the new connection, the server then checks the connection criteria associated with the Client 2 Connection Policy because it has the second lowest evaluation order

index. If these criteria do not match, the server finally checks the connection criteria associated with the Unauthenticated Connection Policy because it has the third lowest evaluation order index. It finds a match, so the client connection is associated with the Unauthenticated Connection Policy.

After the client performs a bind operation to authenticate to the server, then the client connection policies are re-evaluated. If Client 2 performs the bind, then the Client 1 Connection Policy does not match, but the Client 2 Connection Policy does, so the connection is re-associated with that client connection policy. Whenever a connection is associated with a client connection policy, the server checks to see if the maximum number of client connections have already been associated with that policy. If so, then the newly-associated connection is terminated.

For example, Client 1 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. Client 1 then sends a bind request. The determination of whether the bind operation is allowed is made based on the constraints defined in the Unauthenticated Connection Policy because it is the client connection policy already assigned to the client connection. When the bind has completed, the server re-evaluates the client connection policy against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to the Client 1 Connection Policy.

Next, Client 2 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. When Client 2 sends a bind request, the operation is allowed based on the constraints defined in the Unauthenticated Connection Policy. When the bind is complete, the client connection is evaluated against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria do not match, so the Client 2 connection is evaluated against the connection criteria associated with Client 2 Connection Policy because it has the next lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to Client 2 Connection Policy.

Client 1 sends a search request. The Client 1 Connection Policy is used to determine whether the search operation should be allowed because this is the client connection policy assigned to the client connection for Client 1. The connection is not re-evaluated before or after processing the search operation.

### Configuring a client connection policy using the console

Configure a client connection policy using the PingDirectory Administrative Console.

#### Steps

1. From the Administrative Console, in the **Core Server** section, click **Client Connection Policies**.

#### Tip:

If you do not see **Client Connection Policies** on the menu, change the **Object Types** filter to **Standard**.

2. To add a new policy, click **Add New**.
3. Enter a **Policy ID**.  
If you want to base your new client connection policy on an existing policy, select it from the **Template** menu.
4. Configure the properties of the client connection policy, then to enable the policy, select **Enabled**.
5. Enter the order in which you want the new policy to be evaluated in the **Evaluation Order Index** box, and then click **Continue**.

A policy with a lower index is evaluated before a policy with a higher index. The Directory Server uses the first evaluated policy that applies to a client connection.

6. Select the connection criteria that match the client connection for this policy.
  - a. To change the criteria, click **View** and **Edit**.
  - b. To add new criteria, click **Select New**.
  - c. Select the operations allowed for clients that are members of this connection group.
  - d. To make operations available to clients, use the **Add** and **Remove** buttons.
  - e. Specify the extended operations that clients are allowed and denied to use.
7. Enter the type of authorization allowed and the SASL mechanisms that are allowed and denied in response to client requests.
8. Select the **Include Backend Subtree Views** check box if you want to automatically include the subtree views of backends configured in the Directory Server.

You can also choose to include and exclude specific base DNs using the appropriate fields.

9. Save your changes.  
Choose from:
  - To review the `dsconfig` command equivalent and save your changes, click **Confirm then Save**.
  - To save your changes without first reviewing the `dsconfig` output, click **Save Now**.

### Configuring a client connection policy using dsconfig

Configure a client connection policy using the `dsconfig` tool.

#### About this task

Configure a client connection policy using the `dsconfig` tool in interactive mode from the command line. You can access the **Client Connection Policy** menu on the **Standard objects** menu.

#### Steps

1. Use the `dsconfig` tool to create and configure a client connection policy.  
Specify the host name, connection method, port number, and bind distinguished names (DNs) described in previous procedures.
2. To change to the **Standard objects** menu, from the Directory Server main menu, enter `o`, and then enter the number for the **Standard** menu.
3. From the Directory Server main menu, enter the number associated with **Client Connection Policy**.
4. From the **Client Connection Policy management** menu, enter the number corresponding to **Create a new connection policy**.
5. To create a new client connection policy from scratch, enter `n`.
6. Enter a name for the new client connection policy.
7. To enable the connection policy, from the **Enabled Property** menu, select **True**.
8. To set the evaluation order for the policy, from the **Evaluation-Order Property** menu, enter a value between 0 and 2147483647.  
  
A client connection policy with a lower evaluation-order is evaluated before one with a higher number. For this example, enter `9999`.
9. From the **Client Connection Policy** menu, review the configuration.
  - a. If you want to make any further modifications, enter the number corresponding to the property.
  - b. To finish the creation of the client connection policy, enter `f`.

Any changes that you make to the client connection policy do not apply to existing connections. They only apply to new connections.

## Restricting server access based on client IP address

Two methods are available to limit client access to the Directory Server.

### Connection Handlers

You can limit the IP addresses using the LDAP or LDAPS connection handlers. The connection handlers provide an `allowed-client` property and a `denied-client` property. The `allowed-client` property specifies the set of allowable address masks that can establish connections to the handler. The `denied-client` property specifies the set of address masks that are not allowed to establish connections to the handler.

### Client Connection Policies

For a more fine-grained approach, restrict access by configuring a new client connection policy. Then, create a new connection criteria and associate it with the connection policy. A connection criteria defines sets of criteria for grouping and describing client connections based on a number of properties, including the protocol, client address, connection security, and authentication state for the connection. Each client connection policy can be associated with zero or more connection criteria. Server components can use connection criteria to indicate which connections to process and what kind of processing to perform, such as to select connections and operations for filtered logging or to classify connections for network groups.

#### *Restricting server access using the connection handlers*

Use `dsconfig` to set the `allowed-client` property for the LDAP connection handler.

#### Steps

- Set the `allowed-client` property for the LDAP connection handler using `dsconfig`.
- Specify the address mask for the range of allowable IP addresses that can establish connections to the Directory Server.
- To configure the server using the `dsconfig` tool on the local host, specify the loopback address to 127.0.0.1.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --set "allowed-client:10.6.1.*" \
  --set allowed-client:127.0.0.1
```

#### *Restricting server access using client connection policies*

A client-established connection to the PingDirectory server is associated with a client connection policy. Use client connection policies to restrict the kinds of requests that the client can issue and impose resource limits for that connection.

#### Steps

1. Create a simple connection criteria.

Example:

The following example uses the `dsconfig` tool in non-interactive mode. It allows only the Directory Server's IP address and loopback to have access.

```
$ bin/dsconfig set-connection-criteria-prop \
  --criteria-name allowed-ip-addr \
  --add included-client-address:10.6.1.80 \
  --add included-client-address:127.0.0.1
```

2. Assign the criteria to the client connection policy.

Example:

```
$ bin/dsconfig set-client-connection-policy-prop \
  --policy-name new-policy \
  --set connection-criteria:allowed-ip-addr
```

Result: After you have run the command, access is denied to remote IP addresses. The Directory Server does not require a restart.

3. Add a remote IP range to the criteria.

**Note:**

For the following example, add 10.6.1.\*.

Example:

```
$ bin/dsconfig set-connection-criteria-prop \
  --criteria-name allowed-ip-addr \
  --add "included-client-address:10.6.1.*"
```

Result: Access from any remote servers is allowed. The Directory Server does not require a restart.

4. To restore default behavior, remove the criteria from the connection policy.

Example:

**Tip:**

Include the LDAP or LDAPS connection parameters, such as host name, port, bindDN, bindPassword, with the **dsconfig** command.

Example:

```
$ bin/dsconfig set-client-connection-policy-prop \
  --policy-name new-policy --remove connection-criteria:allowed-ip-addr
```

Result: The Directory Server does not require a restart.

*Automatically authenticating clients that have a secure communication channel*

The Directory Server provides the option to automatically authenticate clients that have a secure communication channel, either SSL or StartTLS, and to present their own certificate.

About this task

By default, this option is disabled. When enabled, the net effect is as if the client issued a SASL EXTERNAL bind request on that connection.

**Note:**

This option is ignored if the client connection is already authenticated, such as when using StartTLS, but the client had already performed a bind before the StartTLS request. If the bind attempt fails, the connection remains unauthenticated but usable. If the client subsequently sends a bind request on the connection, it's processed as normal, and any automatic authentication is destroyed.

## Steps

- Run the following **dsconfig** command.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAPS Connection Handler" \
  --set "auto-authenticate-using-client-certificate:true"
```

## Securing the Server with lockdown mode

The Directory Server provides tools to enter and leave lockdown mode if the server requires a security lockdown.

### About this task

In lockdown mode, only users with the `lockdown-mode` privilege can perform operations. Users who do not have the privilege are rejected. By default, root users have this privilege. You can give other administrators this privilege. Users with this privilege can configure lockdown mode as a recurring task.

Some configuration problems can lead to inadvertent exposure of sensitive information, such as an access control rule that cannot be properly parsed, and cause the server to place itself in lockdown mode. This ensures that an administrator can manually correct the problem. Lockdown mode does not persist across restarts.

## Steps

- To perform some administrative operations and ensure that other client requests are not allowed to access any data in the server, manually place the Directory Server into lockdown mode.

Result:

Any client request to the Directory Server in lockdown mode receives an `Unavailable` response.

- To take the directory server out of lockdown mode, use either of the following options:
  - Use the **leave-lockdown-mode** command.
  - Restart the server.
- To start a server in lockdown mode, use the **start-server** `--lockdownMode` option.

## Entering lockdown mode manually

### Steps

- To enter lockdown mode, run **enter-lockdown-mode**.

Example:

```
$ bin/enter-lockdown-mode
```

## Leaving lockdown mode

### Steps

- To leave lockdown mode, run **leave-lockdown-mode**.

Example:

```
$ bin/leave-lockdown-mode
```

## Starting a server in lockdown mode

### Steps

- To start a server in lockdown mode, run the `start-server` command with the `--lockdownMode` option.

Example:

```
$ bin/start-server --lockdownMode
```

## Configuring maximum shutdown time

The Directory Server provides an option for administrators to set a maximum time for a shutdown process to take.

### Before you begin

During shutdown, some database checkpointing and cleaning threads might remain active even after the default time period on systems with large or busy database backends. If checkpointing or cleaning is aborted prematurely, it can lead to significantly longer startup times for the Directory Server. When a shutdown process is initiated, the server begins stopping all of its internal components and waits up to 5 minutes for all threads to complete before exiting.

### About this task

Use the `dsconfig` tool to configure the maximum shutdown time to allow database operations to complete.

### Steps

- To increase the maximum shutdown time for your system, choose from one of the following options. Choose from:
  - Run the `dsconfig` tool.

#### Note:

The following command increases the maximum shutdown time from 5 minutes to 6 minutes. The command allows time values of w (weeks), d (days), h (hours), m (minutes), s (seconds), ms (milliseconds).

Include the LDAP or LDAPS connection parameters, such as host name, port, bindDN, and bindDN password, with the `dsconfig` command.

```
$ bin/dsconfig set-global-configuration-prop --set "maximum-shutdown-time:6 m"
```

- Change the `maximum-shutdown-time` property using the `dsconfig` tool in interactive mode. From the main menu, select **Global Configuration**, and then select the option to display advanced properties.

## About working with referrals

A referral is a redirection mechanism that tells client applications that a requested entry or set of entries is not present on the Directory Server but can be accessed on another server.

Use referrals when entries are located on another server. The Directory Server implements two types of referrals depending on the requirement:

## Referral on Update plugin

The Directory Server provides a Referral on Update plugin to create any referrals for update requests, such as `add`, `delete`, `modify`, or `moddn` operations, on read-only servers. For example, given two replicated directory servers where one server is a master with read-write capabilities, and the other is a read-only server. You can configure a referral for any client update requests on the second directory server to point to the master server. For example, if a client application sends an add request on the second directory server, the directory server responds with a referral that indicates any updates should be made on the master server. All read requests on the read-only server process normally.

## Smart referrals

The Directory Server supports smart referrals that map an entry or a specific branch of a directory information tree (DIT) to an LDAP URL. Any client requests (reads or writes) targeting at or below the branch of the DIT send a referral to the server designated in the LDAP URL.

## Specifying LDAP URLs

Referrals use LDAP URLs to redirect a client application's request to another server.

LDAP URLs have a specific format, described in RFC 4516 and require that all special characters be properly escaped and any spaces indicated as "%20". LDAP URLs have the following syntax.

```
ldap[s]://hostname:port/base-dn?attributes?scope?filter
```

`ldap[s]`

Indicates the type of LDAP connection to the Directory Server. If the Directory Server connects over a standard, non-encrypted connection, then LDAP is used. If it connects over SSL, then LDAPS is used.

### Note:

Any search request initiated by means of an LDAP URL is anonymous by default unless an LDAP client provides authentication.

`hostname`

Specifies the host name or IP address of the Directory Server.

`port`

Specifies the port number of the Directory Server. If no port number is provided, the default LDAP port (389) or LDAPS port (636) is used.

`base-dn`

Specifies the distinguished name (DN) of an entry in the directory information tree (DIT). The Directory Server uses the base DN as the starting point entry for its searches. If no base DN is provided, the search begins at the root of the DIT.

`attributes`

Specifies those attributes for which the Directory Server should search and return. You can indicate more than one attribute by providing a comma-separated list of attributes. If no attributes are provided, the search returns all attributes.

`scope`

Specifies the scope of the search, which could be one of the following:

`base`

Only searches the specified base DN entry.

one

Only search one level below the specified base DN.

sub

Searches the base entry and all entries below the specified base DN.

If no scope is provided, the server performs a base search.

filter

Specifies the search filter to apply to entries within the scope of the search. If no filter is provided, the server uses +.

### Creating referrals

Create a smart referral by adding an entry with the `referral` and `extensibleObject` object classes or adding the object classes to a specific entry.

#### About this task

The `referral` object class designates the entry as a referral object. The `extensibleObject` object class allows you to match the target entry by matching any schema attribute. The following example shows how to set up a smart referral if a portion of a directory information tree (DIT) is located on another server.

To create a referral:

#### Steps

1. Create an LDIF file with an entry that contains the `referral` and `extensibleObject` object classes.

Example:

```
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
objectClass: top
objectClass: referral
objectClass: extensibleObject
ou: Engineering Team1
ref: ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

2. On the first server, add the referral entry using the `ldapmodify` command.

Example:

```
$ bin/ldapmodify --defaultAdd --fileName referral-entry.ldif
```

3. To verify the addition, search for a user.

Example:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com "(uid=user.4)"
```

Result:

```
SearchReference(referralURLs={ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com??sub?})
```

## Modifying a referral

Run a modify command to modify a referral.

### Steps

- To modify the `ref` attribute on the referral entry, run `ldapmodify` with the `manageDSAIT` control.

Example:

```
$ bin/ldapmodify --control manageDSAIT
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
changetype: modify
replace: ref
ref: ldap://server3.example.com/
ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

## Deleting a referral

Run `ldapdelete` to delete a referral.

### Steps

- To delete the referral entry, run `ldapdelete` with the `manageDSAIT` control.

Example:

```
$ bin/ldapdelete \
  --control manageDSAIT "ou=EngineeringTeam1,ou=People,dc=example,dc=com"
```

## Configuring a read-only server

The PingDirectory Server provides a means to configure a hub-like, read-only directory server for legacy systems that require it.

### About this task

The read-only directory server participates in replication but cannot respond to any update requests from an external client. You can configure the Directory Server by setting the writability mode to `internal-only`, which makes the server operate in read-only mode. Read-only mode directory servers can process update operations from internal operations but reject any write requests from external clients. Because the Directory Server cannot accept write requests, you can configure the server to send a referral, which redirects a client's request to a master server. The client must perform the operation again on the server named in the referral.

### Note:

For Implementers of third party extensions, many Server SDK extensions use the `InternalConnection` interface to process operations in the server, rather than issuing LDAP requests over the network. If an extension does so in response to an external update request, then any Directory Server using that extension will effectively respond to external update requests, even though the Directory Server is configured to operate in read-only mode, as described previously. One possible workaround is to split the extension into two extensions, one for reads and one for writes, and then to disable (or not to deploy) the write-only extension when configuring a Directory Server in read-only mode.

### Steps

1. Install two replicating directory servers.

For more information on various ways to set up your servers, see [Enabling Replication](#).

2. On the second server, run the `dsconfig` command to set the writability mode of the server to `internal-only`.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set writability-mode:internal-only
```

3. On the second server, run the `dsconfig` command to create a referral that instructs the server to redirect client write requests under `dc=example,dc=com` to `server1.example.com:1389`.

The referral itself is defined as a plugin of type `referral-on-update`. This command sets up the server to process read operations but redirects all write operations under `dc=example,dc=com` to another server.

Example:

```
$ bin/dsconfig create-plugin --plugin-name "Refer Updates" \
  --type referral-on-update \
  --set enabled:true \
  --set referral-base-url:ldap://server1.example.com:1389/ \
  --set "base-dn:dc=example,dc=com"
```

4. To test the referral, attempt to modify an entry and confirm that the server responds with the result code of 10.

The resulting message is available in the server's access log.

Example:

```
$ bin/ldapmodify -p 2389 -D "cn=Directory Manager" -w password
dn: uid=user.12,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 408 555 1155
```

Result:

```
[06/Aug/2012:15:28:21.468 -0400] MODIFY
RESULT conn=86 op=1 msgID=1 requesterIP="127.0.0.1"
dn="uid=user.12,ou=People,dc=example,dc=com" resultCode=10
referralURLs="ldap://server1.example.com:1389/uid=user.12,
ou=People,dc=example,dc=com" etime=0.223
```

## Configuring HTTP access for the Directory Server

Although most clients communicate with the PingDirectory Server using LDAP, the server also provides support for an HTTP connection handler that uses Java servlets to serve content to clients over HTTP.

Ping Identity offers an extension that uses this HTTP connection handler to add support for the System for Cross-domain Identity Management (SCIM) protocol. Third-party developers can also use the Server SDK to write extensions that leverage this HTTP support.

The following sections describe how to configure HTTP servlet extensions and how to configure an HTTP connection handler.

For more information, see the following topics:

- [Configuring HTTP Servlet Extensions](#) on page 508
- [Configuring HTTP operation loggers](#) on page 509
- [Example HTTP log publishers](#) on page 510
- [Configuring HTTP connection handlers](#) on page 512

## Configuring HTTP Servlet Extensions

You must first configure one or more servlet extensions to use the HTTP connection handler.

Servlet extensions are responsible for obtaining Java servlets, using the Java Servlet 3.0 specification as described in JSR 315, and registering them to be invoked using one or more context paths. If you plan to deploy the System for Cross-domain Identity Management (SCIM) extension, follow the instructions in [Managing the SCIM 2.0 Servlet Extension](#) on page 1486. For custom servlet extensions created using the Server SDK, the process varies based on whether you are using a Java-based or Groovy-scripted extension.

### Configuring web application servlet extensions

About this task

A web application can be deployed either as a WAR file that has been packaged according to the standard layout and containing a `web.xml` deployment descriptor, or from a directory containing the application's source components arranged in the standard layout.

Steps

- When deploying a web application from a directory, specify the location of the `web.xml` deployment descriptor if it is not in the standard location.
- Specify the directory used by the server for temporary files.

Result

At runtime, the web application has access to the server classes.

### Configuring Java-based servlet extensions

About this task

For Java-based extensions, first use the Server SDK to create and build the extension bundle as described in the Server SDK documentation.

Steps

- Use the `manage-extension` tool to install it.

Example:

```
$ bin/manage-extension --install/path/to/extension.zip
```

The Java-based extension can then be configured for use in the server using `dsconfig` or the Administrative Console. Create a new Third Party HTTP Servlet Extension, specifying the fully-qualified name for the `HTTPServletExtension` subclass in the `extension-class` property, and providing any appropriate arguments in the `extension-argument` property.

#### Note:

Web application and Servlet extensions run in a shared embedded web application server environment. Incompatibilities or conflicts might arise from use of different versions of commonly used JARs or including frameworks such as loggers, Spring components, JAX-RS implementations or other resources that might require a dedicated Java virtual machine (JVM) environment. After introducing a custom extension, check the server error log for an indication that the extension loaded successfully. The error log might also contain debug information if the extension failed to load with an initialization exception or did not complete initialization.

## Configuring Groovy-scripted extensions

### Steps

1. For Groovy-scripted extensions, place the necessary Groovy scripts in the appropriate directory based on the package for those scripts after the `lib/groovy-scripted-extensions` directory.
2. Create a new Groovy Scripted HTTP Servlet extension, specifying the fully-qualified Groovy class name for the `script-class` property, and providing any appropriate arguments in the `script-argument` property.

## Configuring HTTP operation loggers

Interactions between servlet extensions and HTTP clients are generally not recorded in the server access log unless a servlet extension performs internal operations to interact with data held in the directory server.

### About this task

To capture information about communication with HTTP clients, you must configure one or more HTTP operations loggers.

By default, the server comes with a single HTTP operation logger implementation, which uses the standard W3C common log format. It records messages in the following format.

```
127.0.0.1 - - [01/Jan/2012:00:00:00 -0600] "GET/hello HTTP/1.1" 200 113
```

The log message contains the following elements:

- The IP address of the client that issued the request
- The RFC 1413 (ident) identity of the client
 

Because the ident protocol is not typically provided by HTTP clients, the HTTP connection handler never requests this information. This identity is always represented as a dash to indicate that information is not available.
- The authenticated identity determined for the request by HTTP authentication or a dash to indicate that the request was not authenticated
- The time that the request was received
- The request issued by the client, including the HTTP method, path and optional query string, and the HTTP protocol version used
- The integer representation of the HTTP status code for the response to the client
- The number of bytes included in the body of the response to the client

### Steps

- To configure an HTTP operation logger to use this common log format, create a new instance of a Common Log File HTTP Operation Log Publisher object.
  - a. Specify the path and name for the active log file.
  - b. Specify the rotation and retention policies to manage the log files.

#### Note:

Properties for Common Log File HTTP Operation Log Publisher objects generally have the same meaning and use as they do for other kinds of loggers.

- To create custom Java-based or Groovy-scripted HTTP operation loggers using the Third Party HTTP Operation Log Publisher and Groovy Scripted HTTP Operation Log Publisher object types, use the Server SDK.

## Example HTTP log publishers

When troubleshooting HTTP connection handler issues, start with the logs to determine any potential problems.

### About this task

The following examples walk you through how to use various **dsconfig** commands and their associated options to configure log files to use for troubleshooting connection handler issues.

The following section shows some **dsconfig** commands and their corresponding log files.

### Steps

- To configure a default detailed HTTP Log Publisher with default log rotation and retention policies, use the `create-log-publisher` option with **dsconfig**.

Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Detailed Access Logger" \
  --type detailed-http-operation \
  --set enabled:true \
  --set log-file:logs/http-detailed-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "retention-policy:Size Limit Retention Policy"
```

Result:

The corresponding log file provides access information below. The log message contains the following elements:

- The time that the request was received
- The request ID issued by the client, including the IP address, port, HTTP method, and URL
- The authorization type, request content type, and status code
- The response content length
- The redirect URI
- The response content type

The HTTP log file shows the following.

```
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300604
  from="10.5.1.10:53269"
  method="GET" url="https://10.5.1.129:443/Gimel/Users/
  uid=user.402914,ou=People,
  dc=gimel" authorizationType="Basic" requestContentType="application/
  json"
  statusCode=200 etime=4.145 responseContentLength=1530
  redirectURI="https://
  x2270-11.example.lab:443/Gimel/Users/uid=user.402914,ou=people,dc=gimel"
  responseContentType="application/json"
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300605
  from="10.5.1.10:53269"
  method="PUT" url="https://10.5.1.129:443/Gimel/Users/
  uid=user.207585,ou=people,
  dc=gimel" authorizationType="Basic" requestContentType="application/
  json"
  statusCode=200 etime=4.872 responseContentLength=1532
  redirectURI="https://
  x2270-11.example.lab:443/Gimel/Users/uid=user.207585,ou=people,dc=gimel"
```

```
responseContentType="application/json"
[23/Feb/2012:11:31:18 -0600] RESULT requestID=4309872 from="10.5.1.10:3
```

- To configure a detailed HTTP Log Publisher with request and response header names and values, including the Content-Type request header, use the set-log-publisher-prop option with dsconfig.

**Note:**

The Content-Type request header is suppressed by default.

**Example:**

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "HTTP Detailed Access Logger" \
  --set log-request-headers:header-names-and-values \
  --remove suppressed-request-header-name:Content-Type \
  --set log-response-headers:header-names-and-values
```

**Result:**

The following is a log example of a query request by a SCIM Server using the property, scim-query-rate. The log message contains the basic log elements shown in the first example plus the following additional information:

- The request header for the host, HTTP method, content type, connection, user agent
- The response header for the access-control credentials

```
[23/Oct/2012:11:39:41-0600] RESULT requestID=4665307
from="10.5.0.20:56044"
method="GET" url="https://10.5.1.129:443/Beth/Users?
attributes=username,title,
emails,urn:scim:schemas:extension:custom:1.0:descriptions,urn:scim:schemas:
extension:enterprise:1.0:manager,groups,urn:scim:schemas:extension:custom:1.0:
blob&filter=username+eq+%22user.18935%22" requestHeader="Host:
x2270-11.example.
lab:443" requestHeader="Accept: application/json" requestHeader="Content-
Type:
application/json" requestHeader="Connection: keep-alive"
requestHeader="User-Agent: Wink Client v1.1.2" authorizationType="Basic"
requestContentType="application/json" statusCode=200 etime=140.384
responseContentLength=11778 responseHeader="Access-Control-Allow-
Credentials:
true" responseContentType="application/json"
```

Another log example shows an example user creation event. The client is curl.

```
[23/Oct/2016:11:50:11-0600] RESULT requestID=4802791
from="10.8.1.229:52357"
method="POST" url="https://10.2.1.113:443/Aleph/Users/"
requestHeader="Host: x2270-
11.example.lab" requestHeader="Expect: 100-continue"
requestHeader="Accept: applica-
tion/xml" requestHeader="Content-Type: application/xml"
requestHeader="User-Agent:
curl/7.21.4 (universal-apple-darwin11.0) libcurl/7.21.4 OpenSSL/0.9.8r
zlib/1.2.5"
authorizationType="Basic" requestContentType="application/xml"
requestContent-
Length=1773 statusCode=201 etime=11.598 responseContentLength=1472
redirec-
```

```
tURI="https://x2270-11.example.lab:443/Aleph/Users/
b2cef63c-5e46-11e1-974b-
60334b1a0d7a" responseContentType="application/xml"
```

The final example shows a user deletion request. The client is the Sync Server.

```
[23/Oct/2016:11:38:06-0600] RESULT requestID=4610261
  from="10.5.1.114:34558"
method="DELETE" url="https://10.2.1.113:443/Aleph/Users/
b8547525-24e0-41ae-b66b-

  requestHeader="Con-
nection: keep-alive" requestHeader="User-Agent: DataSync-6.0.0.0 (Build
20121022173845Z, Revision 11281)" authorizationType="Basic"
  requestContentType="appli-
cation/json" statusCode=200 etime=10.615 responseContentLength=0
```

### Configuring HTTP connection handlers

HTTP connection handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. HTTP connection handlers can be used to host web applications on the server.

Each HTTP connection handler should be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this does not prevent the entire Directory Server from starting. Directory Server's **start-server** tool outputs any errors to the error log. This allows Directory Server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with an HTTP connection handler include the following:

#### listen-address

Specifies the address on which the connection handler listens for requests from clients. If not specified, then requests are accepted on all addresses bound to the system.

#### listen-port

Specifies the port on which the connection handler listens for requests from clients. Required.

#### use-ssl

Indicates whether the connection handler uses SSL/TLS to secure communications with clients, such as whether it uses HTTPS rather than HTTP. If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.

#### http-servlet-extension

Specifies the set of servlet extensions that are enabled for use with the connection handler. You can have multiple HTTP connection handlers listening on different address/port combinations with identical or different sets of servlet extensions. You must configure at least one servlet extension.

#### http-operation-log-publisher

Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers are used.

#### key-manager-provider

Specifies the key manager provider that is used to obtain the certificate presented to clients if SSL is enabled.

### trust-manager-provider

Specifies the trust manager provider that is used to determine whether to accept any client certificates presented to the server.

### num-request-handlers

Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads are automatically selected based on the number of CPUs available to the Java virtual machine (JVM).

### web-application-extension

Specifies the web applications hosted by the server.

## Configuring an HTTP connection handler

### About this task

An HTTP connection handler has two dependent configuration objects:

- One or more HTTP servlet extensions
- An HTTP log publisher

The log publisher is optional, but in most cases, you should configure one or more logs to troubleshoot any issues with your HTTP connection.

#### Note:

You must configure the HTTP servlet extension and log publisher before configuring the HTTP connection handler.

### Steps

1. To configure your HTTP servlet extensions, use the `create-http-servlet-extension` option with **dsconfig**.

Example:

This example uses the `ExampleHTTPServletExtension` example in the Server SDK.

```
$ bin/dsconfig create-http-servlet-extension \
  --extension-name "Hello World Servlet" \
  --type third-party \
  --set "extension-
class:com.unboundid.directory.sdk.examples.ExampleHTTPServletExtension" \
  --set "extension-argument:path=/" \
  --set "extension-argument:name=example-servlet"
```

2. To configure one or more HTTP log publishers, use the `create-log-publisher` option with **dsconfig**.

Example:

This example configures two log publishers: one for common access and one for detailed access. Both log publishers use the default configuration settings for log rotation and retention.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access Logger" \
  --type common-log-file-http-operation \
  --set enabled:true \
  --set log-file:logs/http-common-access \
```

```

--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig create-log-publisher \
--publisher-name "HTTP Detailed Access Logger" \
--type detailed-http-operation \
--set enabled:true \
--set log-file:logs/http-detailed-access \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy"

```

3. To configure the HTTP connection handler, specify the HTTP servlet extension and log publishers using the `create-connection-handler` option with `dsconfig`.

**Note:**

You can update some configuration properties later as needed, but for others, like `listen-port`, you must disable and then re-enable the HTTP Connection Handler for the change to take effect.

**Example:**

```

$ bin/dsconfig create-connection-handler \
--handler-name "Hello World HTTP Connection Handler" \
--type http \
--set enabled:true \
--set listen-port:8443 \
--set use-ssl:true \
--set "http-servlet-extension:Hello World Servlet" \
--set "http-operation-log-publisher:HTTP Common Access Logger" \
--set "http-operation-log-publisher:HTTP Detailed Access Logger" \
--set "key-manager-provider:JKS" \
--set "trust-manager-provider:JKS"

```

4. To monitor the connection handler, use the `ldapsearch` tool.

**Note:**

By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE` by default.

**Example:**

```

$ bin/ldapsearch --baseDN "cn=monitor" \
"(objectClass=ds-http-connection-handler-statistics-monitor-entry)"

```

## Configuring an HTTP connection handler for web applications

### About this task

To host web applications on the server, use HTTP connection handlers.

## Steps

1. To create the web application servlet extension, use the `create-web-application-extension` option with `dsconfig`.

Example:

```
$ bin/dsconfig create-web-application-extension \
  --extension-name "Hello Web Application" \
  --set "base-context-path:/hello-app" \
  --set "document-root-directory:/opt/hello-web-app"
```

2. To monitor the connection handler, use the `ldapsearch` tool.

### Note:

By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE`.

Example:

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

## HTTP correlation IDs

Correlation IDs make it easier to track log messages across a software system request that passes through multiple subsystems.

Scattered and intermingled log messages create challenges for tracing the request flow on distributed systems. A correlation ID can be assigned to a request and added to all associated operations as the request is processed. A correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP or HTTPS Connection Handler.

When an HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID might also be passed to the LDAP subsystem.

The correlation ID appears with associated requests in LDAP logs in the `correlationID` key for the following REST APIs:

- SCIM 1
- Delegated admin
- Consent
- Directory

The correlation ID is used as the default client request ID value in intermediate client request controls used by the following REST APIs:

- SCIM 2
- Consent
- Directory

Values related to the intermediate client request control appear in the LDAP logs in the `via` key and are forwarded to downstream LDAP servers when received by PingDirectoryProxy Server. The correlation ID header is also added to requests forwarded by the PingDataGovernance gateway.

For Server SDK extensions that have access to the current `HttpServletRequest`, the current correlation ID can be retrieved as a string through the `HttpServletRequest.com.pingidentity.pingdata.correlation_id` attribute, as shown.

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

### Configuring HTTP correlation ID support

#### About this task

Correlation ID support is enabled by default for each HTTP Connection Handler.

#### Steps

- To enable or disable correlation ID support for the HTTPS Connection Handler, use the `set-connection-handler-prop` option with `dsconfig`.

Example:

This example shows how to enable correlation ID support.

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set use-correlation-id-header:true
```

Example:

This example shows how to disable correlation ID support.

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set use-correlation-id-header:false
```

- To customize the response header name for the correlation ID, use the `set-connection-handler-prop` option with `dsconfig`.

#### Note:

The server generates a correlation ID for every HTTP request and sends it in the response through the **Correlation-Id** response header.

Example:

This example changes the `correlation-id-response-header` property value to `X-Request-Id`.

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set correlation-id-response-header:X-Request-Id
```

- To designate the names of one or more HTTP request headers that contain an existing correlation ID value, use the `set-connection-handler-prop` option with `dsconfig`.

**Note:**

This enables the server to integrate with a larger system consisting of every servers using correlation IDs.

By default, the server generates a new, unique correlation ID for each HTTP request and ignores any correlation ID that might be set on the request.

**Example:**

```
$ dsconfig set-connection-handler-prop --handler-name "HTTPS Connection
Handler" \
--set correlation-id-request-header:X-Request-Id \
--set correlation-id-request-header:X-Correlation-Id \
--set correlation-id-request-header:Correlation-Id \
--set correlation-id-request-header:X-Amzn-Trace-Id
```

*HTTP correlation ID example*

In this example, a request to the directory REST API is made and the correlation ID enables finding HTTP-specific log messages that also have LDAP-specific log messages. The response to the API call includes a `Correlation-Id` header with the value `ee919049-6710-4594-9c66-28b4ada4b127`.

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
Accept: */*
Accept-Encoding: gzip, deflate
Authorization: Bearer ...
Connection: keep-alive
Host: localhost:1443
User-Agent: HTTPie/0.9.9

HTTP/1.1 200 OK
Content-Length: 266
Content-Type: application/hal+json
Correlation-Id: ee919049-6710-4594-9c66-28b4ada4b127
Date: Fri, 02 Nov 2018 15:16:50 GMT
Request-Id: 369

{
  "_dn": "uid=user.86,ou=People,dc=example,dc=com",
  "_links": {
    "schemas": [
      {
        "href": "https://localhost:1443/directory/v1/schemas/
inetOrgPerson"
      }
    ],
    "self": {
      "href": "https://localhost:1443/directory/v1/
uid=user.86,ou=People,dc=example,dc=com"
    }
  },
  "mail": [
    "user.86@example.com"
  ]
}
```

The correlation ID can be used to search the HTTP trace log for matching log records, as in the following example.

```
$ grep 'correlationID="ee919049-6710-4594-9c66-28b4ada4b127"'

## DNS caching

You can use two global configuration properties to control the caching of host name-to-numeric IP address or DNS lookup results returned from the name resolution services of the underlying operating system.

About this task

Steps

1. To configure these properties, use the `dsconfig` tool.

### Global configuration properties and their descriptions

Global configuration property	Description
<code>network-address-cache-ttl</code>	Sets the Java system property <code>networkaddress.cache.ttl</code> , and controls the length of time in seconds that a host name-to-IP address mapping can be cached. By default, it keeps resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.
<code>network-address-outage-cache-enabled</code>	Caches host name-to-IP address results in the event of a DNS outage. By default, this is set to true, meaning name resolution results are cached. Unexpected service interruptions might occur during planned or unplanned maintenance, network outages, or an infrastructure attack. This cache can allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

2. To reduce delays due to unnecessary DNS lookups, follow these recommendations:
  - a. Maintain a connection pool in the client app rather than opening new connections for each bind.
  - b. Add appropriate records to DNS, including PTR records.
  - c. Add options `timeout:1` or options `single-request` in the `/etc/resolv.conf` file.
  - d. If IPv6 requests are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory Server's `config/java.properties` file, so that running `bin/dsjavaproperties` and restarting the server no longer issues IPv6 PTR requests.

## IP address reverse name lookups

The PingDirectory Server performs numeric IP address-to-host name lookups.

Numeric IP address-to-host name lookups

The following are some of the numeric IP address-to-host name lookups:

- Binding to the Directory: Decoding, examining, or evaluating a DNS bind rule
- Logging: Logging information to certain monitors or writing to the error log
- Java Management Extension (JMX): Creating a server socket
- Key Management: Generating a trust store
- Replication Server: Creating an SSL socket
- Replication Session Management: Obtaining a session or performing a handshake with a replication server
- Simple Authentication and Security Layer (SASL) Authentication: Applying configuration changes
- SMTP Alert Handler: Initializing or sending an alert notification

Configuring address masks

Address masks configured in Access control instructions (ACIs), connection handlers, connection criteria, and certificate handshake processing might trigger implicit reverse name lookups.

For more information about how address masks are configured in the server, see the following information for each server:

- ACI DNS: bind rules in [Managing Access Control](#) on page 718 for Directory Server and Directory Proxy Server
- `ds-auth-allowed-address`: [Restricting access through operational attributes in user entities](#) for Directory Server
- Connection Criteria: [Restricting server access based on client IP address](#) on page 500 for Directory Server and Directory Proxy Server
- Connection Handlers: [Restricting server access using the connection handlers](#) on page 500 for a configuration reference guide for all servers

## Configuring traffic through a load balancer

Configure the PingDirectory Server to get traffic through a load balancer and to record the actual client's IP address.

Before you begin

By default, when a PingDirectory Server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, it logs incoming requests as originating with the intermediate HTTP server instead of the client that sent the request.

Steps

1. To record the actual client's IP address to the trace log, enable `X-Forwarded-*` handling in both the intermediate HTTP server and the PingDirectory Server.
2. Edit the appropriate connection handler object, HTTPS or HTTP, and set `use-forwarded-headers` to `true`.

### Note:

When `use-forwarded-headers` is set to `true`, the server uses the client IP address and port information in the `X-Forwarded-*` headers instead of the address and port of the entity that's

sending the request, the load balancer. This client address information shows up in logs, such as in the `from` field of the HTTP REQUEST and HTTP RESPONSE messages.

3. On the load balancer, configure settings to provide the `X-Forwarded-*` information, such as `X-Forwarded-Host`:

## Working with the Referential Integrity plugin

Referential Integrity is a plugin mechanism that maintains the distinguished name (DN) references between an entry and a group member attribute. If you have a group entry consisting of member attributes specifying the DNs of printers, you can enable the referential integrity plugin to ensure that the group entry is automatically removed if a printer entry is removed from the Directory Server.

### Before you begin

By default, the Referential Integrity plugin is disabled. When enabled, the plugin performs integrity updates on the specified attributes, such as `member` or `uniquemember`, after a delete, modify DN, or a rename, such as subordinate `modifyDN`, operation is logged to the `logs/referint` file. If an entry is deleted, the plugin checks the log file and makes the corresponding change to the associated group entry.

Important points about the Referential Integrity plugin:

- Index all specified attributes that are configured for Referential Integrity.
- On replicated servers, the Referential Integrity plugin configuration is not propagated to other replicas. You must manually enable the plugin on each replica.
- The plugin settings must be identical on all machines.
- If the Referential Integrity plugin is enabled and configured to operate in synchronous mode, subtree delete operations are not allowed. You must configure the plugin to operate in asynchronous mode by specifying a nonzero update interval for subtree delete operations to perform.

### About this task

Enable the Referential Integrity plugin.

### Steps

1. Determine the attributes needed for your system.

By default, the `member` and the `uniquemember` attributes are set for the plugin.

2. To enable the Referential Integrity plugin, run the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
  --set enabled:true
```

## Working with the Unique Attribute plugin

The Unique Attribute plugin enforces uniqueness constraints on the values of one or more attributes across a portion of the Directory Server. The plugin checks for uniqueness prior to an add, modify, or modify distinguished name (DN) request and instructs the server to reject the request if a constraint violation is found.

### About this task

By default, the plugin is disabled because it can affect performance in heavy write load environments. After the plugin is enabled, it does not check for attribute uniqueness on existing entries, only on new `ADD`, `MODIFY`, or `MODDN` operations. To ensure that no such conflicts exist in the data, administrators can use the `identify-unique-attribute-conflicts` command.

**Important:**

Ensure all attributes to enforce for uniqueness are indexed for equality in all backends. Use the LDAP SDK uniqueness request control for enforcing uniqueness on a per-request basis. For more information on the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control, see [Use the server SDK and LDAP SDK](#). See the ASN.1 specification to implement support for it in other APIs.

You can enforce attribute uniqueness in replicated environments in which each replica contains the complete set of data for which to provide uniqueness, regardless of whether clients communicate directly with the server or interact with it through a Directory Proxy Server. In such environments, all servers have identical uniqueness configurations.

**Note:**

It is not possible to prevent conflicts that arise from simultaneous writes on separate replicas. However, such conflicts are detected after the changes have been replicated and then triggers administrative alert notifications.

For proxied environments that do not have the complete set of data on all servers, such as environments that use entry balancing or that store different portions of the DIT on different servers, implement the Global Uniqueness Attribute plugin on the Directory Proxy Server instead of enabling the attribute uniqueness plugin on the PingDirectory Server Admin Guide. For more information, see the [PingDirectory Server Admin Guide](#) and the [PingDirectoryProxy Server Admin Guide](#).

To enable the Unique Attribute plugin:

**Steps**

1. Determine which attributes must be unique in your data.
2. To enable the plugin, run the `dsconfig` tool.

By default, the plugin type property is set to `postsynchronizationadd`, `postsynchronizationmodify`, `postsynchronizationmodifydn`, `preoperationadd`, `preoperationmodify`, and `preoperationmodifydn`.

**Example:** The following example checks for attribute uniqueness prior to ADD operation using the `--set plugin-type:preoperationadd` option.

```
$ bin/dsconfig set-plugin-prop --plugin-name "UID Unique Attribute" \
  --set enabled:true
```

- a. If you want to set one plugin type, use the `--set plugin-type:<operation-type>` option.

**Working with the Purge Expired Data plugin**

Use the Purge Expired Data plugin to delete expired entries or attribute values and cleanup expired PingFederate Persistent Access Grants.

When the plugin is enabled, a background thread in the plugin periodically searches for and purges expired data. For optimal performance, enable the Purge Expired Data plugin on multiple servers in a topology. For example, you can configure one server to delete data while others are searching for expired data.

Create and configure the Purge Expired Data plugin with the `dsconfig` tool. Configuration options include the base distinguished name (DN) and filter, the items to be purged, how to identify expired data, and the frequency of polling and purging. You must index the search for expired data. An alarm is raised if the

server purging data falls behind the configured `max-updates-per-second`. Monitoring information is available in the Admin Console, or `cn=monitor`.

## Configuring the Purge Expired Data plugin for expired entries

### About this task

Use the Purge Expired Data plugin to delete all unverified account entries that have not been accessed in the past eight weeks. This is useful for the following scenarios:

- Accounts that potential customers started to create through an application's registration process but then did not complete.
- The phone number or email address that was provided during registration was not verified and should be allowed to be used by another account.

### Steps

1. If necessary, enable the Last Access Time plugin:

The server can track the last access time automatically in the `ds-last-access-time` attribute by enabling the Last Access Time plugin.

Example:

```
$ bin/dsconfig set-plugin-prop \
  --plugin-name "Last Access Time" \
  --set enabled:true
```

2. To determine expiration order, create an index on the date attribute.

The Purge Expired Data plugin requires the date attribute that is used to determine expiration to be indexed for ordering.

Example:

```
$ bin/dsconfig create-local-db-index \
  --backend-name userRoot \
  --index-name ds-last-access-time \
  --set index-type:ordering
```

3. If there is data present in the directory, rebuild the index.

Example:

```
$ bin/rebuild-index \
  --baseDN dc=example,dc=com \
  --index ds-last-access-time
```

4. Create the plugin that purges account entries `objectclass=account` that are not verified.

Example:

The following example purges account entries `verified=false` after eight weeks of inactivity.

```
$ bin/dsconfig create-plugin \
  --plugin-name "Purge Old Unvalidated Accounts" \
  --type purge-expired-data \
  --set enabled:true \
  --set datetime-attribute:ds-last-access-time \
  --set "expiration-offset:8 w" \
  --set "filter:(&(objectClass=account)(verified=false))"
```

## Configuring the Purge Expired Data plugin for expired attribute values

### About this task

Use the Purge Expired Data plugin to delete values of an attribute that have expired. For example, an application can track information about an employee's session and then expire the session after 24 hours. There can be multiple active sessions tracked across different devices with session information as shown in the following example.

In this example, the LDAP attribute is `sessioninfo` and the JSON field that stores the timestamp is `creationTime`. These are used to configure the Purge Expired Data plugin.

```
sessionInfo: { "sessionId" : "E85FAC04E331FFCA55549B10B7C7A4FA",
  "ipAddress": "10.0.0.00", "userAgent": "Mozilla/5.0 (iPad; U; CPU OS 3_2
  like Mac OS X; en-us)
  AppleWebKit/531.21.10 (KHTML, like Gecko) Version/4.0.4 Mobile/7B367
  Safari/531.21.10",
  "creationTime" : "2018-03-31T13:10:15Z" }
```

Create the plugin to purge the JSON attribute values after 24 hours, rather than the entire session entry.

### Steps

1. Create an index on the `creationTime` field of the `sessioninfo` attribute.

Example:

```
$ bin/dsconfig create-json-attribute-constraints \
  --attribute-type sessioninfo \
  --set enabled:true
```

Example:

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type sessioninfo \
  --json-field creationTime \
  --set index-values:true \
  --set value-type:string
```

2. Create and enable the plugin.

Example:

```
$ bin/dsconfig create-plugin \
  --plugin-name "Purge Old Session Data Plugin" \
  --type purge-expired-data \
  --set enabled:true \
  --set "custom-datetime-format:yyyy-MM-dd'T'HH:mm:ss'Z'" \
  --set datetime-attribute:sessioninfo \
  --set datetime-format:custom \
  --set datetime-json-field:creationTime \
  --set "expiration-offset:1 d" \
  --set purge-behavior:delete-json-attribute-values
```

## Configuring uniqueness across attribute sets

Configure attribute uniqueness across a set of attributes using the `multiple-attribute-behavior` property.

Before you begin

## About this task

To enable uniqueness across attribute sets:

### Steps

- To configure the UID unique attribute plugin to apply across multiple attributes, use the `dsconfig` tool.

The following table details the `multiple-attribute-behavior` property and the values it can take.

#### The `multiple-attribute-behavior` property values, descriptions, and examples

Value	Description	Example
<code>unique-within-each-attribute</code>	If multiple attributes are specified, then uniqueness is enforced for all values of each attribute, but the same value might appear in different attributes in the same entry or in different entries.	<p>For example, assume you have an existing entry that has attributes <code>telephoneNumber=123-456-7890</code> and <code>mobile=123-456-7891</code>.</p> <p>If you set the uniqueness plugin to have <code>--set "multiple-attribute-behavior:unique-within-each-attribute"</code> and add:</p> <ul style="list-style-type: none"> <li>▪ An entry with a <code>telephoneNumber</code> value that matches the <code>telephoneNumber</code> attribute in the existing entry, then the add request fails.</li> <li>▪ An entry with a <code>mobile</code> value that matches the <code>mobile</code> attribute in the existing entry, then the request fails.</li> <li>▪ An entry with the same <code>telephoneNumber</code> and <code>mobile</code> attribute values, such as <code>123-456-7893</code>, but differs from the values in the existing entry, then the add request succeeds.</li> </ul>

Value	Description	Example
<code>unique-across-all-attributes-including-in-same-entry</code>	<p>If multiple attributes are specified, then uniqueness is enforced across all of those attributes. If a value appears in one of those attributes that value might not be present in any other of the listed attributes in the same entry, nor in any of the listed attributes in other entries.</p>	<p>For example, assume you have an existing entry that has attributes, <code>telephoneNumber=123-456-7890</code> and <code>mobile=123-456-7891</code>.</p> <p>If you set the uniqueness plugin to have <code>--set "multiple-attribute-behavior:unique-across-all-attributes-including-in-same-entry"</code> and add:</p> <ul style="list-style-type: none"> <li>▪ An entry with a <code>telephoneNumber</code> value, such as <code>123-456-7890</code>, that matches the <code>telephoneNumber</code> attribute in an existing entry, then the add request fails.</li> <li>▪ An entry with a <code>mobile</code> value that matches the <code>mobile</code> attribute in an existing entry, then the request fails.</li> <li>▪ An entry with a <code>mobile</code> value, such as <code>123-456-7890</code>, that matches the <code>telephoneNumber</code> attribute in an existing entry, then that fails.</li> <li>▪ An entry with the same <code>telephoneNumber</code> and <code>mobile</code> attribute values, such as <code>123-456-7893</code>, but differ from the values in an existing entry, then the add request fails.</li> </ul>

Value	Description	Example
<code>unique-across-all-attributes-except-in-same-entry</code>	<p>If multiple attributes are specified, then uniqueness is enforced across all of those attributes. So, if a value appears in one of those attributes, that value might not be present in any of the listed attributes in other entries. However, the same value might appear in multiple attributes in the same entry.</p>	<p>For example, assume you have an existing entry that has attributes, <code>telephoneNumber=123-456-7890</code> and <code>mobile=123-456-7891</code>.</p> <p>You set the uniqueness plugin to have <code>--set "multiple-attribute-behavior:unique-across-all-attributes-except-in-same-entry"</code> and add:</p> <ul style="list-style-type: none"> <li>▪ An entry with a <code>telephoneNumber</code> value, such as <code>123-456-7890</code>, that matches the <code>telephoneNumber</code> attribute in an existing entry, then the add request fails.</li> <li>▪ An entry with a <code>mobile</code> value that matches the <code>mobile</code> attribute in the existing entry, then the request fails.</li> <li>▪ An entry with a <code>mobile</code> value, such as <code>123-456-7890</code>, that matches the <code>telephoneNumber</code> attribute in an existing entry, then the request fails.</li> <li>▪ An entry with a <code>telephoneNumber</code> value, such as <code>123-456-7891</code>, that matches the <code>mobile</code> attribute in an existing entry, then the request fails.</li> <li>▪ An entry with the same <code>telephoneNumber</code> and <code>mobile</code> attribute values, such as <code>123-456-7893</code>, but that differs from the values in an existing entry, then the add request succeeds.</li> </ul>

**Example:**

The `multiple-attribute-behavior` property is set to `unique-within-each-attribute`, which indicates that uniqueness is enforced for all values of each attribute, such as `telephoneNumber=123-456-7890` and `mobile=123-456-7891`, but the same value, such as either `123-456-7890` or `123-456-7891` might appear in different attributes in the same entry or in different entries.

```
$ dsconfig create-plugin \
  --plug-in "Unique telephoneNumber and mobile" \
```

```
--type "unique-attribute" \
--set "enabled:true" \
--set "type:telephoneNumber" \
--set "type:mobile" \
--set "multiple-attribute-behavior:unique-within-each-attribute" \
--no-prompt
```

## Working with the Last Access Time plugin

Use the Last Access Time plugin to record the timestamp of the last activity targeting an entry. The plugin updates the `ds-last-access-time` attribute of the entry when accessing it using an `ADD`, `BIND`, `COMPARE`, `MODIFY`, `MODIFY DN`, or `SEARCH` operation.

Before you begin

Consider the following before using this plugin:

- An updated `ds-last-access-time` attribute value is replicated like any other change to an entry.
- The `ds-last-access-time` attribute is not returned from a search, unless included in the attributes list explicitly, or given the "+" specification for operational attributes.
- The `ds-last-access-time` value format is `yyyyMMddHHmmss.SSS'Z'`, which provides millisecond-level accuracy, such as `20131207144135.821Z`.
- The `ds-last-access-time` attribute can be indexed with a local database index. The ordering index type is the most relevant, but might require a higher index entry limit (default is 4000) to accommodate searches for entries that are not accessed for a long period of time. The ordering index type with a short time range or high index entry limit results in indexed search results for requests, such as `(ds-last-access-time>=20131207144135.821Z)`.

About this task

Use the plugin with the Directory Server Uncached Attribute Criteria or any application that needs to determine the last access time of an entry. The plugin also enables defining request criteria to limit the scope of tracking the last access time. The `max-search-result-entries-to-update` property also prevents mass updates of `ds-last-access-time` when searches contain many results, but might not reflect end-user access.

Steps

- Enable the plugin on all servers that have the same configuration.

### Important:

For deployments earlier than version 4.5 that use the Last Access Time plugin, disable the plugin before upgrading, and then re-enable it after the update is complete. If servers are running different versions, the `last-access-time` updates might occur with a higher frequency than intended.

## Working with the Pass-Through Authentication plugin

Use the Pass-Through Authentication plugin to delegate bind operations to remote LDAP servers by forwarding simple bind requests to an external LDAP server, including Active Directory.

Before you begin

Consider the following points before using the Pass-Through Authentication plugin:

- Configure the plugin to attempt a local bind, to set or update a local password, and to bypass local password policies to ensure remote passwords are migrated.

- Remote servers that accept a forwarded bind request might require connection security, such as a secure StartTLS or LDAPS TLS connection.
- Updating a password in PingDirectory Server might result in divergent passwords between the local and remote server. If necessary, use PingDataSync Server to synchronize passwords between servers.

The following table identifies and describes the configuration properties associated with the Pass-Through Authentication plugin.

#### The Pass-Through Authentication plugin properties and their descriptions

Property	Description
<code>server-access-mode</code>	Determines whether the servers are accessed in <code>round-robin</code> , <code>failover-on-unavailable</code> , or <code>failover-on-any-failure</code> mode.  The default server access mode is <code>round-robin</code> .
<code>update-local-password</code>	Indicates whether the local password value requires updating to the value used in the bind request in the event that the local bind fails but the forwarded bind succeeds.  To update passwords, a local entry must previously exist.
<code>allow-lax-pass-through-authentication-passwords</code>	Indicates whether updates to the local password value accept passwords that do not meet local password policy requirements.
<code>connection-criteria</code>	Specifies a set of connection criteria that must match the client associated with the local bind request for the bind to be forwarded to the remote server.
<code>request-criteria</code>	Specifies a set of request criteria that must match the local bind request or a local target entry for the bind to be forwarded to the remote server.
<code>dn-map</code>	Specifies one or more distinguished name (DN) mappings that can transform bind DN's before attempting to forward the bind to remote servers.
<code>search-base-dn</code>	Use when searching for a remote user entry by using a filter constructed from the pattern that the <code>search-filter-pattern</code> property defines.  A DN map and search filter pattern cannot both be configured. If neither a DN map nor a search filter pattern is defined, user entries are expected to have the same DN in the local server and the remote servers.

#### Steps

- Enable the plugin on all servers that use the same configuration.

### The Pass-Through Authentication plugin for PingOne

Although PingDataSync Server supports bidirectional synchronization between PingDirectory Server and PingOne, using the Pass-Through Authentication plugin for PingOne can propagate password changes from PingOne into PingDirectory Server.

This plugin features a mandatory `try-local-bind` configuration property that enables one of the following modes of operation:

- When `try-local-bind` is `true`, the plugin attempts to authenticate locally first. It sends a request to PingOne only if the local bind attempt fails.
- When `try-local-bind` is `false`, the plugin attempts to authenticate with PingOne first.

The following table identifies and describes the configuration properties associated with the Pass-Through Authentication plugin for PingOne.

#### Pass-Through Authentication plugin properties and their descriptions for PingOne

Property	Description	Required	Default
<code>api-url</code>	URL that PingDirectory Server uses to communicate with PingOne.	Yes	N/A
<code>auth-url</code>	URL that PingDirectory Server uses to authenticate to PingOne.	Yes	N/A
<code>oauth-client-id</code>	OAuth client ID that PingDirectory Server uses to authenticate to PingOne.	Yes	N/A
<code>oauth-client-secret</code>	OAuth client secret that PingDirectory Server uses to authenticate to PingOne.	Yes	N/A
<code>environment-id</code>	Identifier for the PingOne environment that contains the users for whom pass-through authentication is attempted.	Yes	N/A
<code>included-local-entry-base-dn</code>	If this value is set, authentication attempts are passed to PingOne only for users in a specified DN.  If this value is set, only users who exist within a specified base DN allow their authentication attempts to be passed through to PingOne.	No	All public naming contexts (if not set)
<code>connection-criteria</code>	Reference to a connection criteria object to use to identify the bind requests to pass-through to PingOne based on the server's knowledge of the client expected to be the address, protocol, and security level.  If this property is defined, only client connections that match the criteria are included. If this property is not defined, all clients are included.	No	N/A
<code>request-criteria</code>	Reference to a request criteria object to use to identify the bind requests to pass through to PingOne, based on the contents of the request.  If this property is defined, only bind requests that match the criteria are included. If this property is not defined, all bind requests are included.	No	N/A

Property	Description	Required	Default
<b>try-local-bind</b>	<p>Indicates whether PingDirectory Server tries to process the bind locally before forwarding the bind request to PingOne.</p> <p>If this value is set to <code>true</code> and the bind succeeds locally, PingDirectory Server does not make a request to PingOne. If this value is set to <code>false</code>, PingDirectory Server ignores local credentials and attempts to authenticate only to PingOne.</p>	Yes	True
<b>override-local-password</b>	<p>Indicates whether PingDirectory Server attempts to bind to PingOne if the local account has a password.</p> <p>This property is used if <b>try-local-bind</b> is <code>true</code>. If it has a value of <code>false</code>, the plugin attempts to authenticate to PingOne only if the local user account does not have a password.</p> <p>If the local bind attempt fails while this value is set to <code>true</code>, the server tries to authenticate to PingOne even if the local account has a password.</p>	Yes	True
<b>update-local-password</b>	<p>Indicates whether PingDirectory Server attempts to set the password for the local user account, regardless of whether one is already set, when the local authentication attempt fails but the attempt to authenticate with PingOne succeeds.</p> <p>This property is used only if <b>try-local-bind</b> is <code>true</code>.</p> <p>If the on-premise PingDirectory Server is the authoritative source for passwords, set this property to <code>false</code> and configure PingDataSync Server to synchronize password changes from PingDirectory Server into PingOne. If the passwords differ, either the local password or the password for PingOne allows the user to authenticate.</p> <p>If PingOne is the authoritative source for passwords, set this property to <code>true</code>. To ensure that a pass-through attempt to PingOne does not override local changes, make all password changes in PingOne.</p>	Yes	False

Property	Description	Required	Default
<b>allow-lax-pass-through-authentication-passwords</b>	<p>Indicates whether PingDirectory Server bypasses the normal password-validation process when setting the local password from PingOne. This property is used only when both <b>try-local-bind</b> and <b>update-local-password</b> are <code>true</code>.</p> <p>If this value is <code>true</code> when a local bind attempt fails but the authentication attempt with PingOne succeeds, the user's password is updated locally even if a local attempt to change the password to the same value is rejected because the password is considered too weak.</p> <p>If this value is <code>false</code>, pass-through authentication succeeds if the authentication with PingOne succeeds. However, the password for PingOne does not replace the local password.</p>	Yes	True
<b>ignored-password-policy-state-error-condition</b>	<p>Set of zero or more password policy state error conditions that are ignored for pass-through authentication.</p> <p>For a list of values and their descriptions, see the following table.</p>	No	N/A
<b>user-mapping-local-attribute</b>	<p>Name of an LDAP attribute that is used to map local user entries to the corresponding PingOne account.</p> <p>This property must include the same number of values as the <b>user-mapping-remote-json-field</b> property, and the order of their values is correlated. If multiple values are specified, all attributes must be present in the local entry, and the plugin performs an AND search in PingOne to locate the user account with all the values in the corresponding fields.</p> <p>The <code>entryDN</code> attribute can be used to represent the DN of the local entry.</p>	Yes	N/A
<b>user-mapping-remote-json-field</b>	<p>The name of a PingOne field used to map local user entries to the corresponding PingOne account.</p> <p>This property must include the same number and order of values as the <code>user-mapping-local-attribute</code> property.</p>	Yes	N/A
<b>additional-user-mapping-scim-filter</b>	<p>The System for Cross-domain Identity Management (SCIM) filter included in the search and used to identify the PingOne account that corresponds to the local user entry.</p> <p>If a value is provided for this property, it is used with the SCIM filter that was created to map the local user entry to a PingOne account. If a value is not provided for this property, no additional filter is used.</p>	No	N/A

The following table identifies the values to use with the optional configuration property `ignored-password-policy-state-error-condition` and describes the scenarios in which a user is permitted to bind when using pass-through authentication.

#### Optional configuration property and the scenarios for use when using pass-through authentication

Property	Scenario in which a user can still bind by using pass-through authentication
<code>temporarily-locked-due-to-failures</code>	The account is locked temporarily because of too many failed attempts.
<code>permanently-locked-due-to-failures</code>	The account is locked permanently because of too many failed attempts.
<code>locked-due-to-idle-interval</code>	The account is locked because the user has not authenticated recently.
<code>locked-due-to-maximum-reset-age</code>	The account is locked because an administrator recently reset the password, and the user failed to specify a new password within the allotted time frame.
<code>password-is-expired</code>	The password is expired.

## Troubleshooting server performance issues

The following are the most common reasons that customers encounter performance issues and some suggestions for diagnosing and addressing these issues.

### Slow password storage schemes

Slow password storage schemes are configurable schemes designed to use a lot of CPU and memory to thwart attackers, but they can affect legitimate operations like password validation and authentication.

The following password storage schemes are intentionally expensive:

- PBKDF2
- bcrypt
- scrypt
- Argon2
- The MD5, SHA-2-256 and SHA-2-512 variants of the crypt scheme

These schemes are designed to consume a significant amount of CPU, and memory in some cases, to increase the amount of resources an attacker must expend to crack a password if they happen to get access to the password's encoded representation. This same cost is also incurred for legitimate operations involving the password, including encoding clear-text passwords during account creation and password changes and when validating passwords during authentication. You can configure these schemes to adjust the amount of resources they consume, and you should configure them so that the resource consumption under expected peak load does not exceed the capacity of the topology.

Additionally, if you are initially populating the server using an LDIF import that contains clear-text passwords, using one of these schemes can cause the LDIF import to proceed at a small fraction of the rate that could be achieved with a faster storage scheme, such as one that uses a 256-bit or 512-bit salted SHA-2 digest. In such cases, you might import the data using a faster scheme and then change the configuration to make the desired scheme the new default, and mark the scheme used for import as

deprecated. As a result, accounts with passwords encoded using the import scheme are automatically re-encoded with the new scheme the first time that the user successfully authenticates using that password.

### **Database size versus memory capacity**

Best performance is achieved when the contents of the database can be fully cached in memory.

If possible, the amount of memory allocated to PingDirectory Server should be large enough so that all of the data can fit in the database cache. Memory sizing estimates appear at the end of the output when you run the `import-ldif` tool.

If the amount of data that needs to be stored exceeds the available memory capacity of the individual systems on which the server runs, there are a couple options:

- Break up the data into segments that are small enough to be fully cached on their own, and use PingDirectoryProxy Server's entry balancing functionality to make them appear as a single logical set.
- Tune the server so that the most frequently accessed information can be served from memory while disk access might be required for other data. In disk-bound deployments, you can use backend configuration options such as cache mode, uncached attribute criteria, and uncached entry criteria to help prioritize what data should remain in memory versus what can be retrieved from disk.

### **Large number of access control rules**

As the number of access control rules increases, so does the potential costs of determining whether a client is allowed to request a given operation and of paring down search result entries based on the data that the client is permitted to access.

The server might need to re-evaluate all access control rules after certain update operations, including modify DN operations, to determine whether these are affected by the change.

In many cases, deployments with an extremely large number of access control rules, especially those with large numbers of branches in which the same structure might be repeated across each of these branches, might be able to leverage parameterized access control instructions (ACIs) to dramatically reduce the number of access control rules that need to be defined and evaluated. In other cases, it is possible to refactor the access control configuration to achieve the same effect but with far fewer rules.

### **Large static groups**

PingDirectory Server supports large static groups with hundreds of thousands of members or more, but these can have a significant impact on performance. Consider replacing large static groups with dynamic groups.

It can be expensive in terms of system resources to update the large static group to add or remove members because each update requires rewriting the entire entry. It can also be expensive to decode the entry when retrieving it from the database, even if it is held in the database cache, and to return the list of members to a client in search results.

If possible, consider replacing large static groups with dynamic groups. Dynamic groups automatically determine their membership based on criteria defined in LDAP URLs. A dynamic group consumes little memory and disk space and does not need to be altered as entries are created, updated, and removed. In some cases, it is possible to use virtual static groups in conjunction with dynamic groups to create entries that behave like static groups for read operations. This lets you maintain compatibility with applications that only understand static groups but use dynamic groups behind the scenes to determine membership.

If it is not possible to eliminate large static groups, you can enable the static group entry cache. While this does not reduce the performance impact of updating large static groups, it can make it much more efficient to access those groups for read operations.

### **Large index ID sets**

Indexes store data that make it possible to quickly retrieve matching entries during a search. As the size of an ID set increases, so does the potential resource cost of accessing the ID set.

Each index record maps an index key to a list of the entry IDs for the entries that match that key. If you have an equality index for a given attribute, there is a key for each unique value for that attribute and the

values for each key of the IDs of the entries that contain that value. For substring indexes, there can be multiple keys for the same attribute value (one for each unique six-character substring within the value), and the same substring can apply to many different values of the same attribute.

For an attribute index, you can store ID sets in one of two ways that each affect performance differently:

- In the regular (non-exploded) case, each index key occurs once, and the value of this key is the entire list of IDs for entries that match the key. The ID set for a non-exploded index key can be retrieved quickly because only a single database read is required. However, as the size of the ID set grows, the cost of updating it grows because it is necessary to replace the entire set, which requires larger amounts of disk I/O and can place an increased burden on the database cleaner.
- In the exploded case, the same key can be stored multiple times (one for each entry that matches that key), with each instance of the key associated with a different entry ID. Updating the ID set for an exploded key is always fast because the writes are small, but the cost of reading the ID set increases with the number of IDs.

You can also use composite indexes. These offer many advantages over attribute indexes and when they can be used. Some of these advantages, such as the ability to configure a base DN or combinations of attributes, do not have any effect on performance with regard to large ID sets. They use a hybrid of the exploded and non-exploded approaches to maintaining the ID set, such that a large set can be split into multiple pieces, but each piece can have up to 5000 IDs rather than just one. This means that retrieving a large ID set from a composite index can be thousands of times cheaper than retrieving the same ID set from an exploded attribute index. Updating a large ID set in a composite index should be cheaper in terms of systems resources than updating the same ID set in a non-exploded attribute index because the write is much smaller.

In environments with performance problems related to very large index ID sets, you might consider the following options as a way to help improve performance:

- Consider reducing the index entry limit for that index. The index entry limit specifies the maximum number of IDs that an ID set can have for an index key.
  - If a key matches more entries than this limit, the server stops maintaining the index for that key, and attempts to access it behave as if it were unindexed, while the index continues to be maintained for keys matching smaller numbers of entries. If you don't have searches that depend only on those keys, then this is an excellent way of eliminating the cost of maintaining large ID sets. It isn't logical to set the index entry limit to a value that is a large percentage of the total number of entries in the server. In such cases, there might not be a significant performance difference between indexed and unindexed search performance, but there would be no need to maintain the associated large ID sets.
- If there are cases in which you need a large index entry limit, then consider increasing the limit only for that index, rather than increasing the default limit for all indexes in the backend.
  - The `index-entry-limit` property in the backend applies to all indexes that don't specify their own limit, but each index also offers an `index-entry-limit` property that, if set, overrides the index entry limit configured for the backend. As such, if you need a higher index entry limit for a particular index, set a higher limit just for that one index instead of raising the default limit for all indexes in the backend.
- For attribute indexes with keys matching a large number of entries, consider converting it to a composite index when possible.
  - Composite indexes can completely replace equality and ordering attribute indexes, and they can support "starts with" substring searches, regardless of whether they have "contains" or "ends with" components. Composite indexes can't currently replace approximate match indexes or substring searches that don't have a "starts with" component.
- Consider eliminating any unnecessary substring indexes.
  - As previously noted, substring indexes are more likely to have large ID sets than equality, ordering, or approximate match indexes because substring keys are generally smaller and any given substring key can apply to multiple attribute values. It's also not commonly understood that

equality attribute indexes and equality composite indexes are used for substring searches with a “starts with” component. As such, a substring index is not used for substring searches with a “starts with” unless there isn’t an equality index for that attribute.

- If a substring index is defined for an attribute that isn’t targeted by substring searches, or that is only targeted by substring searches that contain a “starts with” component (regardless of whether it also includes “contains” or “ends with” components), then that substring index is not necessary and can be removed. You can use access logs to determine the types of searches that clients are performing, and the `summarize-access-log` and `search-logs` tools might help with that.
- If a substring index is needed for a given attribute, then consider increasing the substring length for that index.
  - By default, the server creates a separate substring key for each unique six-character substring in an attribute value, and there might be cases in which the same six-character substring appears in several different values. If that occurs and causes substring keys to have large ID sets, then increasing the substring length for that index reduces the number of values that might share the any given key and can reduce the number of IDs associated with that key.
- As a last resort, consider tuning the exploded index threshold for an index (the number of entries that an ID set needs to have for a given key before it will transition from a non-exploded set to an exploded one) based on the expected usage for that index.
  - If search performance is more important than update performance for an attribute with large ID sets, then raising the exploded index threshold helps keep the ID set stored as a monolithic block of IDs. On the other hand, if update performance is more important than search performance, then lowering the exploded index threshold might help.

### Missing indexes

Maintain indexes to determine if an index is missing.

Maintaining unneeded indexes can have a detrimental effect on performance, but it can also be detrimental if a needed index is missing.

The best way to identify expensive searches processed in the server is to examine the access logs for search operations with a high `etime` (elapsed processing time) value. After you identify these search operations, you can filter out any of these operations that do not need to be fast. For example, you might have applications that generate reports by performing inefficient searches, such as searches to retrieve all entries, and it is usually more acceptable for those searches to be slow.

For any remaining searches that are slow or that should be faster, the best way to understand why the search is expensive is to issue a search with the same base DN, scope, and filter, but request only the `debugsearchindex` attribute.

#### Note:

`debugsearchindex` is a special attribute that makes the server return debug information about the index processing that is being performed in the course of evaluating the search, and how long it took to complete each step of the evaluation.

From this output, you can see which indexes were used and which could not be used because there was either no applicable index or the index entry limit had been exceeded for the target key. You can see expensive accesses to exploded indexes and identify indexes you want to add, indexes that can benefit from being converted to composite indexes, or indexes where you might need to increase the index entry limit. Alternatively, you can determine a different way to perform the search so that it does not depend on components that are unindexed or that match a large number of entries.

## Configuring the Directory Server for Oracle compatibility

Configure the Directory Server for Oracle compatibility.

### About this task

For companies that are migrating from an Oracle server to the PingDirectory Server, the PingDirectory Server provides a **dsconfig** batch file, `sun-ds-compatibility.dsconfig`, which describes the various components that can be configured to make the server exhibit behavior closer to an Oracle configuration.

Administrators can use the `sun-ds-compatibility.dsconfig` batch file to apply the Directory Server's configuration with the necessary **dsconfig** commands by uncommenting the example commands listed in the file and then running the **dsconfig** command specifying the batch file.

#### Note:

This batch file is not comprehensive and must be used together with the **migrate-sun-ds-config** tool, located in the `bin` folder, or `bat` folder for Windows systems, during the migration process. Both the tool and the batch file overlap in some areas but provide good initial migration support from the Oracle server to a Ping Identity server.

Another useful tool is the **migrate-ldap-schema** tool in the `bin` folder, or `bat` folder for Windows systems, which migrates schema information from an existing LDAP server onto this instance. All attribute type and object class definitions that are contained in the source LDAP server are added to the targeted instance or written to a schema file.

### Steps

1. From the Directory Server server root directory, open the `sun-ds-compatibility.dsconfig` file in the `docs` folder.

You can use a text editor to view the file.

2. Read the file completely.
3. Apply any changes to the file by removing the comment symbol at any **dsconfig** command example, and then applying the **dsconfig** command specifying the batch file.

Example:

```
$ bin/dsconfig --no-prompt --bindDN "cn=Directory Manager" \
  --bindPassword "password" --batch-file /path/to/dsconfig/file
```

4. Run the **migrate-ldap-schema** tool to move the schema definitions on the source server to the destination Ping Identity server.

Example:

```
$ bin/migrate-ldap-schema
```

5. Run the **migrate-sun-ds-config** tool to see what differences exist in the Ping Identity configuration versus the Oracle configuration.
6. On the PingDirectory Server, run the following command.

Example:

```
$ bin/migrate-sun-ds-config
```

7. Test the server instance for further settings that might not have been set with the batch file, the **migrate-ldap-schema** tool, or the **migrate-sun-ds-config** tool.
8. If you notice continued variances in your configuration, contact your authorized support provider.

## Supporting unindexed search requests

By default, the Directory Server denies all unindexed search requests, except for those issued by the bind distinguished names (DNs) that have the `unindexed-search` privilege.

About this task

This default behavior keeps the server from tying up worker threads on time-consuming, unindexed searches. However, you can turn off the enforcement of the `unindexed-search` privilege to allow any client to perform an unindexed search.

Steps

1. Set the `disabled-privilege` global configuration property to `unindexed-search` as follows.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set disabled-privilege:unindexed-search
```

2. If you choose to allow unindexed searches, cap the maximum number of concurrent unindexed search requests using the `maximum-concurrent-unindexed-searches` global configuration property.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set maximum-concurrent-unindexed-searches:2
```

3. Limit unindexed search privileges for particular clients using the `allow-unindexedsearches` property of the client connection policy.

For more information about configuring client connection policies, see [Client connection policy configuration](#).

## Syncing passwords to PingOne

To sync passwords with PingOne, PingDirectory Server maps the `userPassword` attribute to the `password` attribute through a direct attribute mapping.

About this task

To sync passwords from PingDirectory Server to PingOne: .

Steps

- To create a direct attribute mapping, run the following.

```
dsconfig create-attribute-mapping \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name password \
  --type direct \
  --set from-attribute:userPassword
```

PingDataSync Server can synchronize passwords that have been encrypted by PingDirectory Server or a hashed version of the password, depending on how an administrator chooses to store passwords on PingDirectory Server.

- To sync passwords from a generic relational database management system (RDBMS), create a direct attribute mapping with the **from-attribute** being whichever attribute the RDBMS uses to store the password.

**Note:**

RDBMS passwords cannot be encrypted and should be hashed with a scheme that PingDirectory Server recognizes.

**Important:**

PingDataSync Server cannot synchronize passwords between PingOne systems because PingDataSync Server cannot retrieve passwords from PingOne.

Example:

In the following example, the RDBMS uses the `dbPassword` attribute to store the password.

```
dsconfig create-attribute-mapping \
--map-name Generic_RDBMS_to_PingOne_User_Map \
--mapping-name password \
--type direct \
--set from-attribute:dbPassword
```

## Single sign-on with the PingDirectoryServer administrative console

The OpenID Connect (OIDC) protocol enables single sign-on (SSO) with the PingDirectory Server administrative console using either PingOne or a custom authorization server.

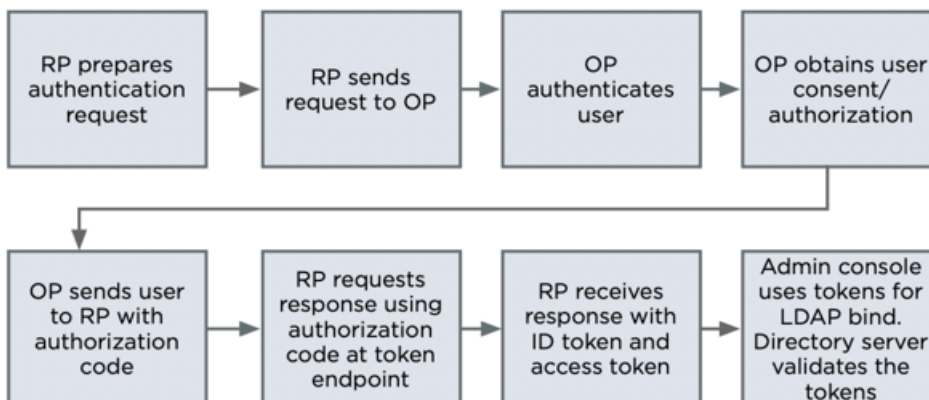

### Overview of OpenID Connect

OIDC is a protocol that allows client applications (called relying parties or RPs) to confirm that a user is who they say they are by contacting an authorization server (called an OpenID Provider or OP).

### The authorization code flow

The PingDirectory Server administrative console uses the authorization code flow implementation of the protocol.

The following is the basic authorization code flow where the PingDirectory Server administrative console acts as the RP in steps 1-7, the managed directory server acts as the RP in step 8, and PingOne or your custom authorization server acts as the OP.

1. The PingDirectory Server administrative console (RP) prepares an authentication request containing the desired request parameters.
2. The administrative console (RP) sends the request to the authorization server.
3. The authorization server (OP) authenticates the user.
4. The authorization server (OP) obtains user consent/authorization.
5. The authorization server (OP) sends the user back to the administrative console with an authorization code.
6. The administrative console (RP) requests a response using the authorization code at the token endpoint.
7. The administrative console (RP) receives a response that contains an ID token and access token in the response body.
8. The administrative console attempts to use the tokens to perform an LDAP bind with the directory server (RP) through the OAUTHBEARER SASL mechanism. In the process of establishing this LDAP bind, the directory server (RP) validates the tokens.

Configuring OIDC with the PingDirectory Server administrative console

The authorization server must be configured with the following settings.

Configuration requirement	Description
An OIDC client with a client ID, client secret, and a Redirection URI.	<p>The client ID and client secret are used by the authorization server to confirm that the authentication and token requests are coming from a valid source.</p> <p>Set the redirection URI value to <code>https://&lt;hostname&gt;:&lt;HTTPS_port&gt;/console/oidc/cb</code>, where <code>https://&lt;hostname&gt;:&lt;HTTPS_port&gt;/console/</code> is where you access the console.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> <b>Note:</b></p> <p>The redirection URI value is used by the authorization server in steps 3 and 5 when sending the end user back to the RP. If the value is incorrect, the authorization server displays an error.</p> </div>
The authorization server must be able to return an ID token that maps to a user on the managed PingDirectory server.	The <code>sub</code> field in the ID token must be mappable.

The PingDirectory Server administrative console must be configured with the following settings.

application.yml configuration name	Embedded console setting name	Settings required
PingData.SSO.OIDC.enabled	SSO Enabled	<p>true. Necessary for the console to start the OIDC login flow.</p> <div style="border: 1px solid black; padding: 5px;">  <b>Note:</b>            If SSO Enabled is set to false, the console asks for a username and password.         </div>
PingData.SSO.OIDC.issuerUri	OIDC Issuer URI	Allows the client to use OIDC discovery to determine the correct addresses to send the authentication request to in step 2, and the token request in step 6.
PingData.SSO.OIDC.clientID	OIDC Client ID	Value obtained from the authorization server. This is sent in the authentication request in step 2.
PingData.SSO.OIDC.clientSecret	OIDC Client Secret	Value obtained from the authorization server. This is sent in the token request in step 6.
ldap.server	LDAP Server	<p>Set to the managed PingDirectory server's hostname and LDAPS port.</p> <p>Used in step 8 when the administrative console attempts to perform an LDAP bind to the managed PingDirectory server using the OAUTHBEARER SASL mechanism.</p>

The managed PingDirectory server must be configured with the ability to accept LDAPS connections and with the following additional configuration properties.

Configuration requirement	Description
A configured ID token validator	<p>For PingOne SSO: the PingOne ID token validator</p> <p>For general OIDC provider SSO: the OpenID Connect ID token validator</p> <div style="border: 1px solid black; padding: 5px;">  <b>Note:</b>            The ID token validator must be configured with an identity mapper that is able to map the sub value in the token to an LDAP user on the server.         </div>

Configuration requirement	Description
A configured OAUTHBEARER SASL mechanism	<p>Set the mechanism's ID token validator configuration property to the previously configured OIDC ID token validator.</p> <p> <b>Note:</b></p> <p>The OAUTHBEARER SASL mechanism is used in step 8 when the PingDirectory server processes the LDAP bind.</p>

Setting up SSO to the PingDirectory administrative console

To set up SSO using PingOne, see [Setting up SSO to PingDirectory from PingOne](#) on page 542.

To set up SSO using a generic OP, see [Setting up SSO to PingDirectory from a generic OpenID Connect provider](#) on page 547.

### Setting up SSO to PingDirectory from PingOne

To set up single sign-on (SSO) access from the administrative console home page to PingDirectory, configure PingOne and test the sign-on experience.

Before you begin

Ensure that you have:

- A PingDirectory server that accepts LDAPS connections
  - This server will host the admin console that is being configured for SSO.
- A PingOne account
  - For more information, see [Getting Started with PingOne](#).

#### Tip:

You can use groups to organize user identities, as explained in [Groups](#). You can also set access to applications, as explained in [Application access control](#).

About this task

During this setup:

- Step 2 sets up a matching user between PingOne and the PingDirectory environments that allows the server's `All Admin Users` identity mapper to map the PingOne ID token to a Directory Server LDAP user.
- Steps 3-8 set up the OpenID Connect (OIDC) client as described in [Single sign-on with the PingDirectoryServer administrative console](#) on page 539.
- Steps 9-11 configure both the administrative console's configuration requirements (except for the `ldap.server` property) and the PingDirectory server's configuration requirements.

#### Note:

These configuration properties are outlined in more detail in [Single sign-on with the PingDirectoryServer administrative console](#) on page 539.

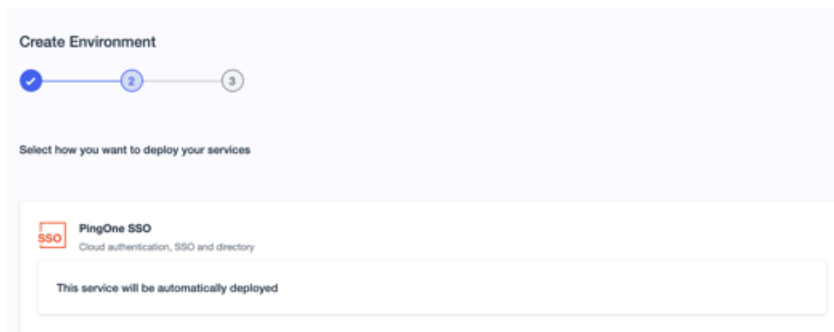

To set up SSO to the PingDirectory administrative console from PingOne:

## Steps

1. From the admin console home page, add PingOne and PingDirectory:  
Choose from:

- To add a new environment for PingOne SSO and PingDirectory:
  - a. On the PingOne console home page, click **Add Environment**.
  - b. Select **Customer solution**, and then click **Next**.
  - c. Click **Next**.
  - d. Enter an **Environment Name** and **Description**, then in the labeled lists, select an **Environment Type**, **Region**, and **License**.
  - e. Click **Finish**.

PingOne SSO, PingOne Risk, PingOne Verify, and PingOne MFA are automatically deployed.

- f. On the PingOne console home page, in the **Your Environments** list, select your new environment, and then click the **+** icon.
- g. Click **Add** next to **PingDirectory**.

**Note:**

Services that have been already added have a green **check mark** icon next to the service name instead of **+ Add**.

- h. Click **Finish**.
- To add PingOne SSO and PingDirectory to an existing environment:
  - a. On the PingOne console home page, in the **Your Environments** list, select the environment, and then click the **+** icon.
  - b. Click **Add** next to **PingOne SSO** and **PingDirectory**.

**Note:**

Services that have been already added have a green **check mark** icon next to the service name instead of **+ Add**.

- c. Click **Finish**.
- a. Click **Add Admin UI Link**, and in the **Enter Admin URL** field, enter `https://<hostname>:<port>/console/login`, replacing the bracketed variables with the PingDirectory server's hostname and HTTP port.

**Tip:**

You can specify the LDAP server to bind to using the query parameters `ldap-hostname` and `ldaps-port` when the administrative console is configured for SSO. By binding to the LDAP server, you can use a single console instance to administer multiple PingDirectory servers. An

LDAPS scheme is always assumed because an encrypted connection is always required for SSO. Using these parameters, you can specify the URL as follows.

```
https://<hostname>:<port>/console?ldap-hostname=<my-ldap-host>&ldaps-port=<my-ldaps-port>
```

- b. Click **Save**.
2. To configure the matching administrator accounts for PingOne and the PingDirectory server, go to the PingOne dashboard for the environment that will be used with the PingDirectory server and repeat the following steps for each PingOne user for whom you want to enable SSO:
  - a. On the admin console home page, select the appropriate environment and click the **PingOne** icon.
  - b. In PingOne, go to **Identities**.
  - c. Select the administrative user you want to configure and click the **Expand** icon.
  - d. Run the following **dsconfig** command and replace the bracketed fields with the values of the administrative user.

```
~/<pd_install>/dsconfig create-root-dn-user --user-name <Username> \
--set first-name:<Given Name> \
--set last-name:<Family Name>
```

3. Register the admin console with PingOne.
  - a. Go to [Add an application - Web application](#) and follow the instructions in the **Add an OIDC application** subsection.
  - b. Enter the application properties, as shown in this table.

Property	Value
Application Name	PingDirectory Administrative Console
Description	Application for the PingDirectory Administrative Console
Redirect URLs	https://<hostname>:<port>/console/oidc/cb  <div style="border: 1px solid #ccc; padding: 5px;">  <b>Note:</b>            Replace the bracketed values in <b>Redirect URLs</b> with your PingDirectory server's hostname and HTTP port. To find the port, run the <b>status</b> command from the <code>bin</code> directory.           <pre>0.0.0.0:11443 : HTTPS      : Enabled  : HTTPS Connection Handler</pre> </div>
Attribute Mapping	'Username' = 'sub'

 **Note:**

No OIDC scopes are required for PingOne to grant access to the PingDirectory console.

4. Select the newly-created **PingDirectory Administrative Console** application in the **Applications** list, and go to the **Configuration** tab.

- To edit the listed configuration properties, click the **Pencil** icon.

Edit the configuration properties using the values in this table.

Property	Value
<b>Response Type</b>	Select the <b>Code</b> check box.
<b>Grant Type</b>	Select the <b>Authorization Code</b> check box.
<b>Token Endpoint Authentication Method</b>	Click <b>Client Secret Basic</b> .

**Note:**

For more information about updating the properties of your new application, see [Edit an application - OIDC](#) in the *PingOne Administration Guide*.

- Click **Save**.
- Click the toggle to enable user access to the application.
- On the **Configuration** tab, record the values for these application properties to use in step 10:
  - Issuer**
  - Client ID**
  - Client Secret**
- Create a copy of the `PingDirectory/config/sample-dsconfig-batch-files/enable-pingone-admin-console-sso.dsconfig` file, leaving the source file as-is.
- Open the copy of the file and replace the bracketed values with the values from step 8.

```
# Create an ID token validator suitable for verifying ID tokens generated
# by the PingOne service. The "All Admin Users" identity mapper will be
# used
# to match users that authenticate with PingOne to either root DN users
# or
# topology admin users defined in the server configuration.
dsconfig create-id-token-validator \
--validator-name "PingOne ID Token Validator" \
--type ping-one \
--set enabled:true \
--set "identity-mapper:All Admin Users" \
--set evaluation-order-index:1 \
--set issuer-url:[PING_ONE_APPLICATION_ISSUER_URL]

[...]

# Configure the Administrative Console with your application's client
# credentials and issuer URI.
dsconfig set-web-application-extension-prop \
--extension-name Console \
--set sso-enabled:true \
--set oidc-client-id:[PING_ONE_APPLICATION_CLIENT_ID] \
--set oidc-client-secret:[PING_ONE_APPLICATION_CLIENT_SECRET] \
--set oidc-issuer-url:[PING_ONE_APPLICATION_ISSUER_URL]
```

- Run the file using the following command.

```
dsconfig --batch-file \
  enable-pingone-admin-console-sso-copy.dsconfig \
  --no-prompt
```

12. Select the link to the PingDirectory server from the PingOne solutions home page.

Result:

A PingOne sign-on page opens.

13. Sign on using the administrative user credentials.

Result:

The PingDirectory Server administrative console home page opens.

### Setting up SSO to PingDirectory from a generic OpenID Connect provider

To set up single sign-on (SSO) access to the PingDirectory administrative console from your OpenID Connect (OIDC) provider, configure the OpenID Connect (OIDC) provider and PingDirectory and test the sign-on experience.

Before you begin

Ensure that you have:

- A PingDirectory server that accepts LDAPS connections
  - This server will host the administrative console that is being configured for SSO.
- An OIDC provider that supports OIDC discovery

About this task

For more information on the configuration properties you are setting up with this task, see [Single sign-on with the PingDirectoryServer administrative console](#) on page 539.

Steps

1. Configure your OIDC provider to access the PingDirectory administrative console.
  - a. Set the redirect URL to `https://<hostname>:<port>/console/oidc/cb` where `<hostname>` and `<port>` are for the PingDirectory server.
  - b. Set the JSON web token (JWT) signing algorithm.
  - c. Record the client ID, client secret, and issuer URL for use in step 5.
2. Create a token validator on the PingDirectory server by running a command similar to the one below.

Example:

```
dsconfig create-id-token-validator \
  --validator-name "OpenID Token Validator" \
  --type openid-connect \
  --set enabled:true \
  --set "identity-mapper:All Admin Users" \
  --set evaluation-order-index:1 \
  --set issuer-url:<OIDC_Provider_Issuer_URL> \
  --set allowed-signing-algorithm:<JWT_signing_algorithm>
```

Provide your own values for `<OIDC_Provider_Issuer_URL>` and `<JWT_signing_algorithm>`, where the algorithm is the one you set in the previous step.

Although not shown below, the command must also set the properties in one of the rows in the following table.

Properties	Descriptions
<code>openid-connect-provider</code> and <code>jwt-key-set-endpoint-path</code>	An OpenID Connect provider, which refers to an HTTP External Server, and a JWKS (JSON Web Key Set) endpoint path

Properties	Descriptions
signing-certificate	A signing certificate

- To create an LDAP user in `cn=Root DNs, cn=config` that the OIDC provider can send an ID token for, use the following `dsconfig` command.

If, in the previous step, you use the `All Admin Users` identity mapper and the ID token validator's `subject-claim-name` is `sub` (the default), then the `sub` value of the ID token that the OIDC provider sends must be the `cn` of an admin user on the PingDirectory server. For example, assume the OIDC provider sends an ID token with the claim `sub=admin-user`. Then, there must be an LDAP user in `cn=Root DNs, cn=config` or in `cn=Topology Admin Users, cn=topology, cn=config` who has `cn=admin-user`.

```
dsconfig create-root-dn-user --user-name admin-user
```

- Create a SASL mechanism handler on the PingDirectory server to use the validator you just created by running a command similar to the following.

Example:

```
dsconfig create-sasl-mechanism-handler \
  --handler-name OAUTHBEARER \
  --type oauth-bearer \
  --set enabled:true \
  --set "id-token-validator:OpenID Token Validator" \
  --set require-both-access-token-and-id-token:false
```

- Run the following command, substituting values for the ID, secret, and issuer URL.

```
dsconfig set-web-application-extension-prop \
  --extension-name Console \
  --set sso-enabled:true \
  --set oidc-client-id:<OIDC_Client_ID> \
  --set oidc-client-secret:<OIDC_Client_Secret> \
  --set oidc-issuer-url:<OIDC_Provider_Issuer_URL>
```

- To finalize your changes, disable and re-enable the HTTPS Connection Handlers with the following commands.

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:false

dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true
```

- Test the sign on.

Result:

The administrative console should open.

## Configuring Soft Deletes

PingDirectory Server 3.2.4 and later supports a soft-delete feature.

This feature preserves a deleted entry's attribute and uniqueness characteristics so it can be undeleted or permanently removed at a later date.

## About soft deletes

Soft deletes preserve a deleted entry's attribute and uniqueness characteristics so it can be undeleted or permanently removed at a later date.

The standard implementation of an LDAP server allows adding, renaming, modifying, searching, comparing, and deleting one or more entries. By specification, the `delete` operation permanently removes an entry and its attributes in a Directory Information Tree (DIT) but records the changes in access, and optionally, audit and change logs. The `delete` operation severs any associations such as references and group memberships. Meta attributes, such as operational attributes, which can be unique to an entry like `entryUUID`, are lost or different if the same entry is re-added to the Directory Server.

There are cases where a company might want to preserve their deleted entries to allow for possible undeletion at a later date. For example, a company might want to retain account and subscriber entries for their users who leave but later rejoin. Artifacts that a user creates such as account histories, web pages, notes, can be tracked and recovered while a user is deleted or when the user returns as an active customer. Soft deletes facilitate this use-case.

A delete request can result in a soft delete either by the client explicitly requesting a soft delete or by the request matching criteria defined in an active soft delete policy. The soft-deleted entries are renamed by prefixing an `entryUUID` operational attribute to the DN and adding an auxiliary object class to the entry, `ds-soft-delete-entry`, which saves the entry in a hidden state. All active references and group memberships are then removed. While in this hidden state, clients cannot access soft-deleted entries under normal operating conditions. Only clients with the `soft-delete-read` privilege can interact with soft-deleted entries.

To allow soft deletes, the Directory Server's attribute uniqueness function has been relaxed to allow for the co-existence of a soft-deleted entry and an active entry with identical naming attributes, such as `uid`. For example, if a user John Smith was soft deleted, but a different John Smith was added to the user accounts system, both entries can reside in the DIT without conflict. One entry would exist in a soft-deleted state and the other in an active state. The Directory Server extends this capability by allowing multiple users with the same DN, who would normally conflict if active, to reside in the soft-deleted state.

Soft-deleted entries can be restored with an `undelete` operation. The same uniqueness constraints that apply when adding a new user to the Directory Server are enforced when a soft-deleted entry is undeleted. In the previous example, John Smith was soft-deleted, but a different John Smith with the same `uid` as the original John Smith was later added to the system. If the original John Smith was undeleted from its soft-deleted state, it would result in a conflict with the active John Smith entry. Administrators must modify the DN of the soft-deleted entry to avoid such conflicts.

Administrators can permanently remove a soft-deleted entry by performing a regular `delete` operation on it. This operation, called a hard delete, permanently removes a soft-deleted entry from the server. You can also permanently remove a regular non-soft-deleted entry using a hard delete. This is useful when the server is configured with a soft-delete policy that would otherwise turn a regular delete request into a soft delete.

The Directory Server provides tool arguments that can use the soft delete request control, the hard delete request control, and other controls necessary to process these operations. Procedures to show how to use these options are presented later in this section.

For replicated topologies, when a participating directory server soft deletes an entry, it notifies the other replicas in the topology to soft delete the same entry on its respective machine. The changelog backend also records these entries by annotating them using an attribute that indicates its soft-deleted state. Modification and hard deletes of soft-deleted entries are not recorded by default in the changelog but can be enabled in the server. For maximum compatibility, make sure all servers in the replication cluster support soft deletes and have identical soft delete configurations.

## General tips on soft deletes

Administrators should be aware of the following tips about soft deletes:

- The LDAP SDK and Server SDK both fully support soft-deletes.

- There is little performance difference between retrieving a regular entry and a soft-deleted entry. However, there might be a performance impact when a search operation has to match criteria, such as `uid=john.smith`, for both active entries and soft-deleted entries. For example, if there is one active `uid=john.smith` entry and two soft-deleted `uid=john.smith` entries, it might take the server more time to retrieve and try to match the criteria before it can return the results.
- The soft delete feature fully supports uncached attributes and uncached entries. For more information, see [Uncached Attributes and Entries](#).
- Soft-deletion is allowed for leaf nodes only. Soft-deletion of any parent entry is not allowed. Likewise, soft-deleted entries that have soft-deleted sub-entries are not allowed.
- There are two available state options for soft-deletes:
  - Administrators can permanently delete a soft-deleted entry or undelete the entry.
  - Administrators cannot soft-delete an already soft-deleted entry, which returns an `UNWILLING_TO_PERFORM` result code.
- Soft-deleted users have no privileges. Soft-deleted users do not have the ability to bind to the Directory Server or have authentication access. They cannot change their passwords and cannot undelete themselves. Soft-deleted entries also cannot be used as an authorization identity using the proxied authorization or immediate client control. The soft-delete process does not destroy privilege assignment. If a soft-deleted entry is undeleted, the restored entry retains the same privileges it originally had before being soft deleted. One possible exception to this are privileges assigned by virtual attributes that no longer match the newly-undeleted entry. Those entries do not retain their original privileges.
- Soft-deleted entries might not be accessible from alternate access methods like SCIM.
- Soft-deleted entries can be modified but not renamed. Administrators can search for all soft-deleted entries and the original source entry attributes can be updated as long as the administrator has modify privileges and access to the `soft-delete-read` privilege. Any attempt to rename a soft-deleted entry using a `modify DN` operation results in an `UNWILLING_TO_PERFORM` result code.
- Replication has access to the LDAP operations with soft delete controls. These operations are transmitted, processed, and replayed as high-level requests, which are re-played on remote replicated servers. The replication conflict-resolution mechanism handles soft-deleted entries like any regular entries. For example, if a soft delete is executed independently on two servers and is then replicated, this results in a replication conflict. For maximum compatibility, all servers in a replication cluster should support soft deletes and have identical soft delete configuration.
- Soft-deletes are supported in transactions. The processing workflow uses the transactions mechanism and maintains the context information necessary to rollback failures to soft delete or undelete.
- There are no special configuration steps to configure soft deletes on the Directory Proxy Server. The soft-deleted entry is routed directly to the underlying Directory Server. There is one exception: in an entry-balancing deployment, the Directory Proxy Server is responsible for routing the soft-deleted entry to the Directory Server containing the originally soft-deleted item. As with standard entry-balanced deployments, it is not possible to use `moddn` to undelete an entry to a different Directory Server.
- The default behavior includes soft-deleted entries as part of the `export-ldif` operation. If soft-deleted entries are to be excluded from export, administrators can use the `--excludeSoftDeleteEntries` option to filter out the entries.
- The soft delete feature can be used with users who have proxied authorization privileges.
- For customers using the PingDataSync Server, soft-deleted entries are not synchronized by the server. Modifications or deletes of a soft-deleted entry are ignored by the Data Sync Server, and do not appear in the changelog by default. An actual soft delete operation appears to the changelog as a regular `delete` operation, and an actual undelete operation appears in the changelog as a regular `add` operation.
- References to a deleted DN are not restored by the referential integrity plugin when you undelete a soft-deleted entry. For example, if you have referential integrity enabled and you soft-delete a DN that is a member of a static group, the referential integrity plugin removes this DN from the group's list of members. When you undelete the soft-deleted entry, the plugin does not add the entry back to the group.

- The soft delete policy configuration supports two new properties, `soft-delete-retention-time` and `soft-delete-retain-number-of-entries`, that perform the purging of soft-deleted entries. For more information, see [Configuring Soft-Delete Automatic Purging](#).
- The root user account, such as `cn=Directory Manager`, has access to all of the controls needed to run the soft delete operations by default. For non-root users, you must grant access to these soft delete controls using access control rules. An example is shown in step 1 of [To Configure Soft Deletes as a Global Configuration](#). The following soft delete controls are available to non-root users:

#### Soft delete request control

Allows the user to perform a soft delete operation. The object identifier (OID) for the control is 1.3.6.1.4.1.30221.2.5.20.

#### Soft delete response control

Allows the server to hold the DN of the soft-deleted entry that results from a soft delete request. The OID for the control is 1.3.6.1.4.1.30221.2.5.21.

#### Hard delete request control

Allows the user to run a hard delete operation on the entry, regardless if it is a regular or soft-deleted entry. The OID for the control is 1.3.6.1.4.1.30221.2.5.22.

#### Undelete request control

Allows the user to undelete a soft-deleted entry using an ADD request. The OID for this control is 1.3.6.1.4.1.30221.2.5.23.

#### Soft-deleted entry access request control

Allows the user to search for any soft-deleted entries. The OID for this control is 1.3.6.1.4.1.30221.2.5.24.

#### Note:

A bind DN with the `stream-values` privilege can perform operations that can reveal soft-deleted entries, even if that bind DN does not have permission to use the soft-deleted entry access request control. For example, if a user can successfully run `dump-dns` or `ldap-diff`, then that user can get a list of soft-deleted entry DNs or soft-deleted entry contents through the output of one of those tools.

## Configuring soft deletes on the Server

### Steps

- Use any of the following methods to configure soft deletes on the Directory Server.

Method	Description
<b>Using a soft-delete policy and global configuration property</b>	Configure soft deletes by creating a soft-delete policy and a global configuration property. The soft-delete policy enables the feature on the server, while the global configuration property sets the controls used for the soft-delete requests. To enter a soft delete request, the <code>ldapmodify</code> or <code>ldapdelete</code> command requires the <code>--useSoftDelete</code> option. A delete request that does not have the <code>--useSoftDelete</code> option is treated as a hard delete, which permanently removes the entry.

Method	Description
	For more information, see <a href="#">Configuring soft deletes as a global configuration</a> on page 552.
<b>Using connection criteria</b>	<p>Configure soft deletes by defining connection criteria within a client connection policy. Any clients that meet the criteria have their deletes processed as soft deletes.</p> <p>For more information, see <a href="#">Configuring soft deletes by connection criteria</a> on page 560.</p>
<b>Using request criteria</b>	<p>Configure soft deletes by defining request criteria within a client connection policy. Any client requests that meet the criteria have their deletes processed as soft deletes.</p> <p>For more information, see <a href="#">Configuring soft deletes by request criteria</a> on page 561.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> <b>Note:</b></p> <p>You can define both connection criteria and request criteria. When both criteria exist within a soft-delete policy, connection criteria is processed first, then request criteria.</p> </div>

### Configuring soft deletes as a global configuration

Configure the soft delete feature by creating a soft delete policy and then setting the configuration property on the server. The presence of the soft-delete policy enables the feature on the server and allows the global configuration property to send the necessary soft delete requests.

#### About this task

For this configuration, use the `--useSoftDelete` option used with the `ldapmodify` or `ldapdelete` commands to send the delete using the soft delete request control. Without the `--useSoftDelete` option, any delete is processed as a hard delete.

To configure soft deletes as a global configuration:

#### Steps

1. Configure a soft delete policy using the `dsconfig` command.

The soft delete configuration requires a soft delete policy, which enables the feature on the server.

Example:

```
$ bin/dsconfig create-soft-delete-policy \
  --policy-name default-soft-delete-policy
```

2. Configure the soft delete as a global configuration property using the `dsconfig` command.

This command sets up the soft delete controls necessary to send them as a request.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
```

```
--set soft-delete-policy:default-soft-delete-policy
```

### Configuring a user to use soft or hard delete controls

To use soft deletes, a user must have access to the appropriate controls. By default, only the Directory Manager has access to these controls.

#### About this task

The user must also have the `soft-delete-read` privilege. Access control instructions (ACIs) allow the user to:

- Modify target entries
- Use the soft delete and undelete controls
- Use the soft-deleted entry access control to modify soft-deleted entries
- Use the hard delete request control to permanently delete an soft-deleted entry

The `uid=admin,dc=example,dc=com` user that is installed with the sample data during setup already has an ACI giving it access to user entries as follows.

```
(targetattr="*")(version 3.0; acl "Grant full access for the admin user";
allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

#### Steps

1. Add the following ACIs to the base suffix or other point in the directory information tree (DIT) to restrict the scope as required.

Example:

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.21")
(version 3.0; acl "Allow admins to use the Soft Delete Request Control and
Soft Delete Response Control";
allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.22") (version 3.0; acl "Allow admins
to use the Hard Delete
Request Control";allow (read) userdn="ldap:///
uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.23") (version 3.0; acl "Allow admins
to use the Undelete
Request Control";allow (read) userdn="ldap:///
uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.24") (version 3.0; acl "Allow admins
to use the Soft-Deleted
Entry Access RequestControl"; allow (read) userdn="ldap:///
uid=admin,dc=example,dc=com";)
```

2. Add the `ds-privilege-name` attribute to the user with the value `soft-delete-read`.

Example:

```
$ ./bin/ldapmodify -s -p 1389 -D uid=admin,dc=example,dc=com -w password
# Successfully connected to localhost:1389.

dn: uid=user.10,ou=people,dc=example,dc=com
changetype: delete

# Deleting entry uid=user.10,ou=people,dc=example,dc=com ...
# Result Code: 0 (success)
# Soft Delete Response Control:
#     OID: 1.3.6.1.4.1.30221.2.5.21
```

```
# Soft-Deleted Entry DN: entryUUID=8dbe8cb4-1aa3-41c5-88ec-
a6280eeff918+uid=user.10,ou=People,dc=example,dc=com
```

## Searching for soft deletes

Soft-deleted entries are excluded from normal LDAP searches because they represent deleted entries. The updated `ldapsearch` tool supports these types of searches.

About this task

There are three different ways to search for soft-deleted entries.

Steps

- To perform a base-level search on a soft-deleted entry by distinguished name (DN), run the `ldapsearch` command and specify the base DN of the specific soft-deleted entry that you are searching for.
- To filter your search by `ds-soft-delete-entry` object class, run a search for all soft-deleted entries with the `ldapsearch` command with a filter on the `ds-soft-delete-entry` object class.
- To return soft-deleted entries, use the `soft-delete-entry-access-control` with the LDAP search.

The `ldapsearch` tool provides a shortcut option, `--includeSoftDeletedEntries`, that sends the control to the server for processing. The control allows for the following search possibilities:

- Return only soft-deleted entries.
- Return non-deleted entries along with soft-deleted entries.
- Return only soft-deleted entries in undeleted form.

### Running a base-level search on a soft-deleted entry

Use the command line to run a base-level search on a soft-deleted entry.

Steps

- Run the `ldapsearch` command using the base distinguished name (DN) of the specified soft-deleted entry.

Example:

```
$ bin/ldapsearch \
  --baseDN entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com \
  --searchScope base "(objectClass=*)"
```

Result:

```
# Soft-deleted entry DN:
# entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-soft-delete-entry
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239
postalCode: 66239
description: This is the description for Aartjan Aalders.
uid: user.1

mail: user.3@maildomain.net
st: TN

```

### Running a filtered search by soft-delete-entry object class

Retrieve all soft-deleted entries using the `ds-soft-delete-entry` object class.

#### Steps

- Run the `ldapsearch` command to retrieve all soft-deleted entries using the `ds-soft-delete-entry` object class.

Example:

```

$ bin/ldapsearch --baseDN dc=example,dc=com \
  "(objectclass=ds-soft-delete-entry)"

```

### Running a search using the soft delete entry access control

The following examples use the `--includeSoftDeleteEntries {with-non-deleted-entries | without-non-deleted-entries | deleted-entries-in-undeleted-form}` option, which uses the soft delete entry access control.

#### About this task

You can use the `--control` option with the soft delete entry access control symbolic name, `softdeleteentryaccess`, or the `--control` option with the actual soft delete entry access control OID, `1.3.6.1.4.1.30221.2.5.24`.

#### Steps

- To return only soft-deleted entries, run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `without-non-deleted-entries`.

Example:

```

$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries without-non-deleted-entries \
  --searchScope sub "(objectclass=*)"

```

- To return non-deleted entries along with soft-deleted entries, run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `with-non-deleted-entries`.

Example:

```

$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries with-non-deleted-entries \
  --searchScope sub "(objectclass=*)"

```

- To return only soft-deleted entries in undeleted form, run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `deleted-entries-in-undeleted-form`.

Some applications require access to all entries in the server, including both active and soft-deleted entries.

Example:

The following command returns all entries that were soft-deleted but presents it in a form that is similar to a regular entry with the soft-delete DN in comments. This regular entry format does not show the actual soft-deleted DN but displays it in an "undeleted" form even though it is not actually "undeleted". The object class, `ds-soft-delete-entry`, is also not displayed.

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries deleted-entries-in-undeleted-form \
  --searchScope sub "(ds-soft-delete-from-dn=*)"

# Soft-deleted entry DN:
# entryUUID=2b5511e2-7616-389b-ab0c-025c805ad32c
+uid=user.14,ou=People,dc=exam-
ple,dc=com
dn: uid=user.14,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson

```

## Undeleting a soft-deleted entry using the same RDN

When you decide to undelete a soft-deleted entry, if the original Relative Distinguished Name (RDN), such as `uid=user.1`, is still available, you can perform the undelete using that same RDN.

### About this task

To undelete a soft-deleted entry, use `ldapmodify` with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore. In an LDIF file or from the command line, specify the `dn:<target entry>` attribute, which is the distinguished name (DN) that the entry is undeleted to, and the `ds-undelete-from-dn` attribute, which is the entry that is undeleted from. An undelete requires the `add changetype` so that the entry can be re-added to the server.

## Steps

- To undelete a soft-deleted entry using the same RDN, run the command `ldapmodify` with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore.

Example:

The first DN is the entry to undelete to and the `ds-undelete-from-dn` is the soft-delete entry to undelete from.

```
$ bin/ldapmodify --allowUndelete
dn: uid=user.1,ou=People,dc=example,dc=com
changetype:add
ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

Result: The `--allowUndelete` option sends the soft undelete request control to the server.

## Undeleting a soft-deleted entry using a new RDN

In some cases, you can allocate the original Relative Distinguished Name (RDN), `uid=user.1`, to a new user. This is permitted when the entry is in a soft-deleted state. To properly undelete this entry, you must specify a new RDN value you can use to restore the entry.

### About this task

In this case, specifying the RDN of `uid=user.5` undeletes the original entry, but with the new distinguished name (DN) in the following example, and the `uid` attribute on the entry is updated with the new value of `user.5`. All other attributes of the users entry, including the `entryUUID`, remain unchanged.

To undelete a soft-deleted-entry using a new RDN:

## Steps

- Run the command `ldapmodify` to undelete a soft-deleted entry that has an original RDN, `uid=user.1`, to a new RDN, `uid=user.5`.

### Note:

If you specify a DN that already exists in the Directory Server as a normal entry, this leads to an `entry already exists` error. Ensure the DN that you are undeleting the entry to does not already exist.

Example:

```
$ bin/ldapmodify --allowUndelete
dn: uid=user.5,ou=People,dc=example,dc=com
changetype:add
ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

- To view the results, run `ldapsearch`.

Example:

```
dn: uid=user.5,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239
postalCode: 66239
```

```

description: This is the description for Aartjan Aalders.
uid: user.5
userPassword: {SSHA}RdBCwQ2kIw57LukRthjrFBS/oFylJARnmTnorA==
employeeNumber: 1
initials: AKA
givenName: Aartjan
pager: +1 197 025 3730
mobile: +1 890 430 9077
cn: Aartjan Aalders
sn: Aalders
telephoneNumber: +1 094 100 7524
street: 59748 Willow Street
homePhone: +1 332 432 4295
l: Green Bay
mail: user.3@maildomain.net
st: TN
entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4

```

Result: The RDN and the `uid` attribute has changed.

## Modifying a soft-deleted entry

Modify a soft-deleted entry the same as a regular entry using the `ldapmodify` tool. The entry remains hidden in its soft-deleted state after the change.

About this task

Soft-deleted entries can be modified like any regular entry. The only restriction is that you cannot change the distinguished name (DN) or run a `moddn` operation. To move a soft-deleted entry from one machine to another, use the `move-subtree` command and specify the DN of the soft-deleted entry. For more information, see [To Move an Entry from One Machine to Another](#).

### Note:

To modify a soft-deleted entry, the user needs the `soft-delete-read` privilege to access the soft-deleted entry.

## Steps

- To modify a soft-deleted entry, run the `ldapmodify` command and specify the soft-deleted DN.

Example:

```

$ bin/ldapmodify
dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 390 103 6918
# Processing MODIFY request for entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
# MODIFY operation successful for DN entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com

```

## Hard deleting a soft-deleted entry

Use this section for instructions on hard deleting a soft-deleted entry from the server when soft-deleted entries are configured as global configuration for requests or configured using a connection or request criteria.

About this task

Consider the following when hard deleting a soft-deleted entry:

Steps

- To permanently remove a soft-deleted entry from the server, run `ldapdelete` on the soft-deleted entry for soft-deleted entries.
- To hard delete a soft-deleted entry, use `ldapdelete` with the `--useHardDelete` option.

The Hard Delete Request Control works with soft deletes. It applies when soft delete policies are in place as a means to override soft deletes requests. If soft deletes are configured, running `ldapdelete` with the Hard Delete Request Control, such as using the `--useHardDelete` option, guarantees that any entry permanently deletes.

### Hard deleting a soft-deleted entry (global configuration)

About this task

Permanently remove a soft-deleted entry from the Directory Server.

Steps

- To permanently remove a soft-deleted entry, run `ldapdelete` on the soft-deleted entry.

Example:

The following example assumes that you configured soft deletes as a global configuration for requests.

```
$ bin/ldapdelete \
  entryUUID=4e9b7847-edcb-3791-
  b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com

Processing DELETE request for entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
DELETE operation successful for DN entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

#### Note:

You cannot soft-delete an already soft-deleted entry. If you use the `--useSoftDelete` subcommand with the `ldapdelete` operation on a soft-deleted entry, an error message generates.

```
DELETE operation failed. Result Code: 53 (Unwilling to Perform) Diagnostic
Message: DELETE operation failed.
```

### Hard deleting a soft-deleted entry (connection or request criteria)

About this task

Permanently remove a soft-deleted entry from the Directory Server.

## Steps

- To permanently remove a soft-deleted entry run `ldapdelete` with the `--useHardDelete` subcommand on the soft-deleted entry.

Example:

The following example assumes that you configured soft deletes using a connection or request criteria.

```
$ bin/ldapdelete --useHardDelete \
  entryUUID=4e9b7847-edcb-3791-
  b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

## Configuring soft deletes by connection criteria

Use this section for instructions on enabling and disabling soft deletes with connection criteria.

The Directory Server supports soft deletes where any delete operation is treated as a soft-delete request as long as the LDAP client meets the connection criteria.

To configure soft deletes:

- Define the connection criteria used in a client connection policy.
- Configure the soft delete connection criteria in the soft-delete policy.

### Enabling soft deletes by connection criteria

Before you begin

Configure a soft-delete policy and global configuration, as shown in [Configuring Soft Deletes as a Global Configuration](#).

## Steps

1. Create a connection criteria using `dsconfig` and name it `Internal Applications`.

Example:

In the following example the soft delete connection criteria is configured for a member of a line of business (LOB) applications group connecting from the 10.8.1.0 network.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Internal Applications" \
  --type simple \
  --set included-client-address:10.8.1.0/8 \
  --set "all-included-user-group-dn:cn=LOB
  Applications,ou=Groups,dc=example,dc=com"
```

2. Set the `auto-soft-delete-connection-criteria` property to the soft-delete connection criteria you created in step 1.

Example:

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set "auto-soft-delete-connection-criteria:Internal Applications"
```

### Disabling soft deletes by connection criteria

About this task

Disable soft deletes by connection criteria.

## Steps

- Reset the `auto-soft-delete-connection-criteria` property on the soft-delete policy.

Example:

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset auto-soft-delete-connection-criteria
```

## Configuring soft deletes by request criteria

Soft deletes can be configured using request criteria within a client connection policy. All delete requests that meet the request criteria are treated as a soft delete.

The presence of a soft delete by connection criteria is exclusive of the soft delete by request criteria.

### Note:

Both a soft delete by connection criteria and a soft delete by request criteria can be present in a soft delete policy.

## Enabling soft deletes by request criteria

Before you begin

[Configure a soft-delete policy and global configuration.](#)

## Steps

1. To configure request criteria for soft deletes, use the `create-request-criteria` option with `dsconfig`.

Example:

In this example, the soft delete request criteria is configured for an external delete request from a member of the internal applications group matching an entry with object class `inetorgperson` with the request excluding the Soft Delete Request Control and the Hard Delete Request Control.

```
$ bin/dsconfig create-request-criteria \
  --criteria-name "Soft Deletes" \
  --type simple \
  --set "description:Requests for soft delete" \
  --set operation-type:delete \
  --set operation-origin:external-request \
  --set "connection-criteria:Internal Applications" \
  --set not-all-included-request-control:1.3.6.1.4.1.30221.2.5.20 \
  --set "all-included-target-entry-filter:(objectClass=inetorgperson)"
```

2. In the soft delete policy you previously created, set the `auto-soft-delete-connection-criteria` property to the simple criteria created in the previous step.

Example:

```
$ bin/dsconfig create-soft-delete-policy \
  --policy-name default-soft-delete-policy \
  --set "auto-soft-delete-request-criteria:Soft Deletes"
```

## Disabling soft deletes by request criteria

### Steps

- To disable soft deletes by request criteria, reset the soft delete policy.

Example:

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset auto-soft-delete-request-criteria
```

## Configuring soft-delete automatic purging

By default, Directory Server retains soft-deleted entries indefinitely.

For companies that want to set up automatic purging of soft-deleted entries, the server provides two configurable properties on the soft delete policy: the maximum retention time for all soft-deleted entries and the retained number of soft-deleted entries.

### Note:

These changes take effect without requiring a server restart.

## Configuring soft-delete automatic purging

### About this task

To enable automatic purging, you can change the retention time, the retained number of entries, or both. By default, both are set to an indefinite retention time and number of entries. The time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w), can be preceded by an integer to specify a quantity for that unit, such as "1 d", "52 w", etc.

### Note:

After you configure the properties, the changes take effect immediately without the need for a server restart.

The server deletes all of the soft-deleted entries according to the policy in effect. If the policy is changed while entries are in the process of being deleted, the new policy takes effect after the in-process batch of entries is deleted and applies to any remaining soft-deleted entries going forward, according to the new policy.

### Steps

1. To retrieve the name of the soft delete policy in effect, use the `get-global-configuration-prop` option with `dsconfig`.

Example:

In this example, the soft delete policy is called `default-soft-delete-policy`.

```
$ bin/dsconfig get-global-configuration-prop \
  --property soft-delete-policy
```

2. To set the retention time or retained number of soft-deleted entries, use the `set-soft-delete-policy-prop` option with **dsconfig**.

Example:

This example shows how to set the retention time for soft-deleted entries.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set "soft-delete-retention-time:52 w"
```

Example:

This example shows how to set the retained number of soft-deleted entries.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set soft-delete-retain-number-of-entries:1000000
```

3. If it has not been assigned yet, assign the soft delete policy to the global configuration.

Example:

This example assigns `default-soft-delete-policy` to the global configuration.

```
$ bin/dsconfig set-global-configuration-prop \
  --set soft-delete-policy:default-soft-delete-policy
```

## Disabling soft-delete automatic purging

About this task

The change takes effect immediately without the need of a server restart. If the server is in the middle of an automatic soft-delete purging, it might continue to purge entries until the next time it evaluates the soft delete policy.

Steps

- To disable soft-delete automatic purging, use the `set-soft-delete-policy` option with **dsconfig**.
- To reset the soft delete policy properties that control automatic purging, use the `set-soft-delete-policy-prop` with **dsconfig**.

Example:

This example resets the `soft-delete-retention-time` and `soft-delete-retain-number-of-entries` properties.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset soft-delete-retention-time \
  --reset soft-delete-retain-number-of-entries
```

## Soft and hard delete processes

See the following tables for the results of actions taken during the soft and hard delete processes.

If no automatic soft delete criteria is configured

The following table summarizes the resulting actions of a `DELETE` operation for soft deletes.

Action	Result
Delete	Performs a hard delete on the entry.
Delete with the Soft Delete Request Control	Performs a soft delete on the entry.
Delete of a soft-deleted entry	Performs a hard delete on the entry.
Delete of a soft-deleted entry with the Soft Delete Request Control	Not allowed. Generates an UNWILLING_TO_PERFORM error.
Delete with a Hard Delete Request Control	Performs a hard delete on the entry.
Delete of a soft-deleted entry with the Hard Delete Request Control.	Performs a hard delete on the entry.

If soft delete connection or request criteria is configured

The following table summarizes the resulting actions of a `DELETE` operation for soft deletes configured by connection criteria or request criteria.

Action	Result
Delete not matching criteria	Performs a hard delete on the entry.
Delete matching criteria	Performs a soft delete on the entry.
Delete of a soft-deleted entry not matching criteria	Performs a hard delete on the entry.
Delete of a soft-deleted entry matching criteria	Performs a hard delete on the entry.
Delete not matching criteria with the Hard Delete Request Control	Performs a hard delete on the entry.
Delete matching criteria with the Hard Delete Request Control	Performs a hard delete on the entry.
Delete with Soft and Hard Delete Request Controls	Not allowed. Generates an UNWILLING_TO_PERFORM error.

## Soft delete controls and tool options

See the following tables for summaries of soft delete controls and tools.

### Soft delete OIDs

The following table shows the OpenIDs (OIDs) for each soft delete control. The soft delete OIDs are defined in the LDAP SDK generated API documentation.

OID Type	OID
Soft Delete Request Control	1.3.6.1.4.1.30221.2.5.20
Soft Delete Response Control	1.3.6.1.4.1.30221.2.5.21
Hard Delete Request Control	1.3.6.1.4.1.30221.2.5.22
Soft Undelete Request Control	1.3.6.1.4.1.30221.2.5.23
Soft Delete Entry Access Control	1.3.6.1.4.1.30221.2.5.24

### Soft delete tool options

The following table shows the new tool options available for the soft delete operations.

Operation	Options
<code>ldapdelete / ldapmodify</code>	<p><code>--useSoftDelete/-s</code>. Process <code>DELETE</code> operations with the Soft Delete Request Control, whereby entries are renamed and hidden instead of being permanently deleted. The Directory Server must be configured to allow soft deletes.</p> <p> <b>Note:</b> Any entries in the LDIF file with the changetype of <code>delete</code> are processed as a soft-delete request.</p>
<code>ldapdelet</code>	<p><code>--useHardDelete</code>. Process <code>DELETE</code> operations with the Hard Delete Request Control, which bypasses any soft delete policies and processes the delete request immediately without retaining the entry as a soft-deleted entry. The Directory Server must be configured to allow soft deletes.</p>

Operation	Options
ldapsearch	<p><code>--includeSoftDeletedEntries</code> {with-non-deleted-entries   without-non-deleted-entries   deleted-entries-in-undeleted-form}. Process search operations with the soft delete entry access control. Soft delete search options are as follows:</p> <p><code>with-non-deleted-entries</code></p> <p>Returns all entries matching the search criteria with the results, including non-deleted and soft-deleted entries.</p> <p><code>without-non-deleted-entries</code></p> <p>Returns only soft-deleted entries matching the search criteria.</p> <p><code>deleted-entries-in-undeleted-form</code></p> <p>Returns only soft-deleted entries matching the search criteria with the results returned in their undeleted entry form.</p> <p>Users must have access to the Soft Delete Entry Access Control to search for soft-deleted entries.</p>
ldapmodify	<p><code>--allowUndelete</code>. Process ADD operations, which include the <code>ds-undelete-from-dn</code> attribute as undelete requests. Undelete requests re-add previously soft-deleted entries back to the server as non-deleted entries by providing the Undelete Request Control with the ADD operation. The Directory Server must be configured to allow soft deletes to process any undelete requests and the client user must have the <code>soft-delete-read</code> privilege.</p>

Soft delete OID symbolic names using with the `--control/-J` option

The following table shows the symbolic names that can be used with the server's LDAP commands using the `--control/-J` option.

Control	Symbolic Name
Soft Delete Request Control	softdelete
Hard Delete Request Control	harddelete
Soft Undelete Request Control	undelete
Soft Delete Entry Access Control	softdeleteentryaccess

## Monitoring soft deletes

The Directory Server provides monitoring entries and logs to track all soft delete operations. The access and debug logs do not have any options specific for soft deletes.

### New monitor entries

Two new monitor entries are present for a backend monitor entry.

Administrators see the following additional monitor entries on `cn=userRoot Backend, cn=monitor`:

`ds-soft-delete-entry-operations-count`

Displays the number of soft deletes performed on the backend since server startup.

`ds-undelete-operations-count`

Displays the number of undeletes performed on the backend since server startup.

`ds-backend-soft-deleted-entry-count`

Displays the current number of soft-deleted entries in the database.

`ds-auto-purged-soft-deleted-entry-count`

Displays the current number of soft-deleted entries purged since the backend or server was restarted.

### Monitoring soft deletes

Monitor soft deletes using the `ldapsearch` command.

#### Steps

- Run `ldapsearch` on the `cn=userRoot Backend, cn=monitor` branch using a search criteria targeting the `ds-backend-monitor-entry` object class.

Example:

```
$ bin/ldapsearch --baseDN "cn=userRoot Backend, cn=monitor" \
  --searchScope sub "(objectclass=ds-backend-monitor-entry)"
```

Result:

```
dn: cn=userRoot Backend, cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-backend-monitor-entry
objectClass: extensibleObject
cn: userRoot Backend
ds-backend-id: userRoot
ds-backend-base-dn: dc=example, dc=com
ds-backend-is-private: FALSE
ds-backend-entry-count: 200001
ds-backend-soft-deleted-entry-count: 1000
ds-soft-delete-operations-count: 40
ds-undelete-operations-count: 20
ds-auto-purged-soft-deleted-entry-count: 0
ds-base-dn-entry-count: 200001 dc=example, dc=com
ds-backend-writability-mode: enabled
```

### Access logs

The access log records the LDAP operations corresponding to soft delete and undelete for `DELETE`, `SEARCH`, `MODIFY`, and `ADD` operations with the related soft-deleted values.

The access log does not require any configuration for soft delete.

#### DELETE (soft-delete) operations

The access log displays the following.

```
[14/May/2012:09:40:16.942 -0500] DELETE RESULT conn=18 op=1 msgID=2
```

```
dn="uid=user.1,ou=People,dc=example,dc=com" resultCode=0 etime=30.367
softDeleteEntryDN="entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,
ou=People,dc=example,dc=com"
```

#### SEARCH operations for soft-deleted entries

The access log displays the following.

```
[14/May/2012:09:40:52.320 -0500] SEARCH RESULT conn=19 op=1 msgID=2
base="dc=example,dc=com" scope=2 filter="(objectclass=ds-soft-delete-
entry)"
attrs="ALL" resultCode=0 etime=1.631 entriesReturned=1
```

#### MODIFY operations of soft-deleted entries

The access log displays the following.

```
[14/May/2012:09:42:43.679 -0500] MODIFY RESULT conn=20 op=1 msgID=1
dn="entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=exam-
ple,dc=com" resultCode=0 etime=2.639 changeToSoftDeletedEntry=true
```

#### ADD (soft-undelete) operations

The access log displays the following.

```
[14/May/2012:09:58:16.728 -0500] ADD RESULT conn=25 op=1 msgID=1
dn="uid=user.0,ou=People,dc=example,dc=com" resultCode=0 etime=22.700
undeleteFromDN="entryUUID=ad55a34a-763f-358f-93f9-
da86f9ecd9e4+uid=user.0,
ou=People,dc=example,dc=com"
```

### Audit logs

The audit log captures any `MODIFY` and `DELETE` operations of soft-deleted entries.

These changes are recorded as fully commented-out audit log entries. The audit log does not require any configuration for soft deletes.

For any soft-deleted entry, the audit log entry displays the `ds-soft-delete-entry-dn` property and its soft-deleted entry distinguished name (DN).

```
# 14/May/2012:10:57:09.054 -0500; conn=30; op=1
# ds-soft-delete-entry-dn: entryUUID=68147342-1f61-3465-8489-
3de58c532130+uid=user.2,ou=People,dc=example,dc=com
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: delete
```

For any `MODIFY` changes made, the log displays the LDIF, the modifier's name, and update time.

```
# 14/May/2012:10:58:33.566 -0500; conn=33; op=1
# dn:
  entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
ple,dc=com
# changetype: modify
# replace: homePhone
# homePhone: +1 003 428 0966
#-
# replace: modifiersName
# modifiersName: uid=admin,dc=example,dc=com
#-
```

```
# replace: modifyTimestamp
# modifyTimestamp: 20131010020345.546Z
```

For any undelete of a soft-deleted entry, the log displays the `ds-undelete-from-dn` attribute plus the entry unique ID, create time, and creator's name.

```
# 14/May/2012:10:59:21.754 -0500; conn=34; op=1
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: add
uid: user.2
ds-undelete-from-dn:
  entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=Peo-
  ple,dc=example,dc=com
ds-entry-unique-id:: vw1jg801S7GWrTiS3UE5DA==
createTimestamp:: 20131010181148.630Z
creatorsName: uid=admin,dc=example,dc=com
```

For hard (permanent) deletes of a soft-deleted entry, the log displays the soft-deleted entry DN that was removed.

```
# 14/May/2012:11:00:14.055 -0500; conn=36; op=1
# dn:
  entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
  ple,dc=com
# changetype: delete
```

### Configuring the file-based audit log for soft deletes

Configure the file-based audit log for soft deletes.

#### Steps

1. Enable the audit log if it is disabled.

Example:

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
  Logger" \
  --set enabled:true
```

2. View the audit log.

The `soft-delete-entry-audit-behavior` property is set to `commented` by default and provides additional information in comments about the soft-deleted entry that was either created or undeleted.

Example:

```
# 11/May/2012:15:33:17.552 -0500; conn=13; op=1
# ds-soft-delete-entry-dn:entryUUID=54716bfd-fbc4-3108-ac37-
  bf6b1b166e37+uid=user.15,ou=People,dc=example,dc=com
dn: uid=user.15,ou=People,dc=example,dc=com
changetype: delete
```

### Changelog

You can configure the changelog to capture soft-delete changes to entries so that external clients, such as PingDataSync Server, can access these changes.

The `ds-soft-delete-entry` attribute represents an entry that has been soft-deleted and is part of the source entry passed into the changelog to indicate the entry has been soft-deleted.

All soft-delete operations appear in the changelog as regular DELETE operations. When a soft delete occurs, the resulting changelog entry includes a `ds-soft-delete-entry-dn` operational attribute with

the value of the soft-deleted entry DN. PingDataSync Server recognizes the `ds-soft-delete-entry-dn` attribute and does nothing with it.

The changelog backend `soft-delete-entry-included-operation` property determines whether MODIFY or DELETE operations of soft-deleted entries appear in the changelog. This property is disabled by default.

### Configuring soft deletes on the changelog backend

#### Steps

1. To configure soft deletes on the changelog backend, run the following.

```
$ bin/dsconfig set-backend-prop \
--backend-name changelog \
--set soft-delete-entry-included-operation:delete \
--set soft-delete-entry-included-operation:modify
```

2. Run a soft-delete operation on an entry.
3. To review the changelog for the soft-deleted entry, run the following.

```
$ bin/ldapsearch --baseDN cn=changelog \
"(objectclass=*)" "+"
```

#### Result:

```
dn: cn=changelog
subschemaSubentry: cn=schema
entryUUID: 9920f7e9-5a04-392a-82a8-32662d7d3863
ds-entry-checksum: 304022441
dn: changeNumber=1,cn=changelog
targetUniqueId: 94f634df-c90e-39aa-bd4a-9183c29746d0
changeTime: 20120511154141Z
ds-soft-delete-entry-dn: entryUUID=94f634df-c90e-39aa-bd4a-
9183c29746d0+uid=user.9,ou=People,dc=example,dc=com
modifyTimestamp: 20131010020345.546Z
createTimestamp:: 20131010181148.630Z
localCSN: 000001373C90085200000000000003
modifiersName: uid=admin,dc=example,dc=com
entry-size-bytes: 298
subschemaSubentry: cn=schema
entryUUID: 459b06c6-89f3-307e-a515-22433eb420b6
createTimestamp: 20120511154141.431Z
modifyTimestamp: 20120511154141.431Z
ds-entry-checksum: 1157320579
```

### Disabling soft deletes as a global configuration

To disable soft deletes on your Directory Server, reset the global configuration property and then remove the soft-delete policy.

#### About this task

From that point, PingDirectory processes all deletes as hard deletes by default. Any use of the soft-deleted options with the LDAP tools results in an error. Any existing soft-deleted entries that are present disabling after the global configuration remain in the server as latent entries.

#### Note:

Be sure to include the LDAP bind parameters for your system when running each of these commands.

## Steps

1. To reset the global configuration property, run the following **dsconfig** command.

Example:

```
$ bin/dsconfig set-global-configuration-prop --reset soft-delete-policy
```

2. To reset the global configuration property, run the following **dsconfig** command.

Example:

```
$ bin/dsconfig delete-soft-delete-policy --policy-name default-soft-delete-policy
```

## Importing and exporting data

---

The PingDirectory Server supports import or export of the database backends in LDIF.

You can use the **bin/import-ldif** and **bin/export-ldif** tools to create or export database backends for online or offline servers. The tools support options that can restrict the input or output to a subset of the entries or a subset of the attributes within entries. The tools also provide features to compress, encrypt, or digitally sign the data.

### Importing data

The PingDirectory Server provides initialization mechanisms to import database files.

The **import-ldif** command line tool imports data from an LDIF file. You can import all or a portion of the entries contained in the LDIF file, including a subset of the entries, a subset of the attributes within entries, or both. The command also supports importing data that has been compressed, encrypted or digitally signed, or both.

You can run the **import-ldif** utility with the server offline or online. If the server is online, administrators can initiate the import from a local or remote client. The LDIF file that contains the import data must exist on the server system. During an online import, the target database repository, or backend, is removed from service and data held in that backend is not available to clients.

The **import-ldif** tool has been modified to help guard against accidental overwriting of existing backend data with the addition of the `--overwriteExistingEntries` option. You must include this option when performing an import into a backend with a branch that already contains entries. If a branch contains just a single base entry, the `--overwriteExistingEntries` option is not required.

### Validating an LDIF file

Prior to importing data, you can validate an import file using Directory Server's **validate-ldif** tool.

#### About this task

The tool binds to the Directory Server locally or remotely and validates the LDIF file to determine whether it violates the server's schema. Elements that do not conform to the schema are rejected and written to standard output. You can specify the output filepath to which the rejected entries and reasons for their rejection are written. The **validate-ldif** tool works with regular non-compressed LDIF files or gzip-compressed LDIF files.

## Steps

- To validate an LDIF file, run the `validate-ldif` tool.

### Note:

Make sure the server is online before running this command.

To process large files faster, you can set the number of threads for validation. The tool also provides options to skip specified schema elements if you are only validating certain items, such as attributes only.

### Example:

```
$ bin/validate-ldif --ldifFile /path/to/data.ldif \
  --rejectFile rejectedEntries
```

- a. Optional: To view the arguments, use the `--help` option.

### Result:

```
1 of 200 entries (0 percent) were found to be invalid.
1 undefined attributes were encountered.
Undefined attribute departmentname was encountered 1 times.
```

## About the database cache estimate

After successful completion of an import, the `import-ldif` command lists detailed information about the database cache usage characteristics of the imported data set.

To guide decisions for changing Java virtual machine (JVM) size and database-cache-percent for the backend, the current server configuration is considered along with the capabilities of the underlying hardware.

The `/logs/tools` directory contains additional files that describe the database cache characteristics in more detail.

## Tracking skipped and rejected entries

During import, skip entries if they do not belong in the specified backend or if they are part of an excluded base distinguished name (DN) or filter.

## Steps

- To write skipped entries to a specified file, use the `--skipFile {path}` option on the command line.

You can add a comment indicating why the entries were skipped.

- To write information about rejected entries and the reasons for rejection to a specified file, use the `--rejectFile {path}` option.

You can reject an entry if:

- It violates the server's schema constraints.
- Its parent entry does not exist.
- Another entry already exists with the same DN.
- It was rejected by a plugin.

## Running an offline import

To import LDIF data encoded with the UTF-8 character set, run the `import-ldif` tool offline.

This data can come from LDIF files, compressed LDIF files (GZIP format), or from data generated with a MakeLDIF template.

**Note:**

You do not need to authenticate as an administrator when performing offline LDIF imports.

**Performing an offline import**

## Steps

1. Confirm the Directory Server is offline.
2. To import data from an LDIF file, use the `import-ldif` command.

Do not specify any connection arguments when running the command.

Example:

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
  --rejectFile /path/to/reject.ldif --skipFile /path/to/skip.ldif
```

**Performing an offline LDIF import using a compressed file**

## Steps

1. Confirm the Directory Server is offline.
2. To import data from a compressed gzip formatted file, use the `import-ldif` command.

**Note:**

You must include the `--isCompressed` option to indicate that the input file is compressed.

Do not specify any connection arguments when running the command.

Example:

```
$ bin/import-ldif --backendID userRoot --isCompressed \
  --ldifFile /path/to/data.gz --rejectFile /path/to/reject.ldif \
  --skipFile /path/to/skip.ldif
```

**Performing an offline LDIF import using a MakeLDIF template**

## Steps

1. Confirm the Directory Server is offline.
2. Use the `import-ldif` command to import data from a MakeLDIF template, which is located in the `<server-root>/config/MakeLDIF` directory.

Do not specify any connection arguments when running the command.

Example:

The following example uses the standard data template and generates 10,000 sample entries, and then imports the file to the server.

```
$ bin/import-ldif --backendID userRoot \
  --templateFile config/MakeLDIF/example.template
```

## Running an online LDIF import

You can run LDIF imports while the server is online from another remote server.

The online import is similar to the offline import, except that you must provide information about how to connect and authenticate to the target server.

To schedule an LDIF file to begin importing at a specific time, use the `--task` and `--start YYYYMMDDhhmmss` options of the `import-ldif` tool.

You can also specify email addresses of users to notify when the import process completes. You can notify them regardless of success or failure or only if the import fails. To set up SMTP notifications, see [Working with the SMTP Account Status Notification Handler](#).

### Performing an online LDIF import

#### Steps

1. Confirm the Directory Server is online.
2. To import data from an LDIF, use the `import-ldif` command.

Example:

```
$ bin/import-ldif --task --hostname server1 --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --backendID userRoot --ldifFile userRoot.ldif
```

### Scheduling an online import

#### Steps

1. Confirm the Directory Server is online.
2. To import data from an LDIF file at a scheduled time, use the `import-ldif` command.

#### Note:

To specify a time in the UTC time zone, include a trailing `Z`. Otherwise, the time zone defaults to the time zone configured on the server.

Example:

```
$ bin/import-ldif --task \
  --hostname server1 \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --bindPassword password \
  --backendID userRoot \
  --ldifFile /path/to/data.ldif \
  --start 20111026010000 \
  --completionNotify import-complete@example.com \
  --errorNotify import-failed@example.com
```

Result:

```
Import task 2011102617321510 scheduled to start Oct 26, 2011 1:00:00 AM
CDT
```

- To confirm that you successfully scheduled your import task, use the **manage-tasks** command to view a summary of all tasks on the system.

Example:

```
$ bin/manage-tasks --summary
```

Result:

```
ID                Type      Status
-----
2011102617321510 Import  Waiting on start time
```

- To monitor the progress of this task, use the **manage-tasks** tool.

**Note:**

Use the task ID of the import task. If you cannot find the task ID, use the `--summary` option to view a list of all tasks scheduled on the Directory Server.

Example:

```
$ bin/manage-tasks --info 2011102617321510
```

Result:

```
Task                Details
-----
ID                  2011102617321510
Type                Import
Status              Waiting on start time
Scheduled Start Time Oct 26, 2011 1:00:00 AM CDT
Actual Start Time
Completion Time
Dependencies Failed  None
Dependency Action   None
Email Upon Completion admin@example.com
Email Upon Error    admin@example.com

Import              Options
-----
LDIF File  /path/to/data.ldif
Backend ID userRoot
```

### Canceling a scheduled import

#### Steps

- To cancel the scheduled task, run the **manage-tasks** tool.

Example:

```
$ bin/manage-tasks --cancel 2011102417321510
```

## Adding entries to an existing Directory Server

To add entries to an existing Directory Server while preserving operational attributes such as `createTimestamp` or `modifiersName`, attach the `Ignore No User Modification` control to the request.

### About this task

The `Ignore No User Modification` control allows modification of certain attributes that have the `No User Modification` constraint.

The `Ignore No User Modification` only applies to `ADD` requests. If you use the control to modify an existing entry, it results in an operational attribute change and fail.

To append entries to an existing Directory Server, perform the following steps:

### Steps

- Run the `ldapmodify` command with the `Ignore No User Modification` control.

Example: The OpenID is `1.3.6.1.4.1.30221.2.5.5`.

```
$ bin/ldapmodify --control 1.3.6.1.4.1.30221.2.5.5 \
--filename change-record.ldif
```

## Filtering data import

The `import-ldif` command lets you include or exclude specific attributes and entries during an import.

The `import-ldif` arguments are summarized in the following table.

### Inclusion and Exclusion Arguments for import-ldif

Argument	Description
<code>--includeBranch</code>	Base distinguished name (DN) of a branch to include in the LDIF import. Can be specified multiple times.
<code>--excludeBranch</code>	Base DN of a branch to exclude from the LDIF import. Can be specified multiple times.
<code>--includeAttribute</code>	Attribute to include in the LDIF import. Can be specified multiple times.
<code>--excludeAttribute</code>	Attribute to exclude from the LDIF import. Can be specified multiple times.
<code>--includeFilter</code>	Search filter to identify entries to include in the LDIF import. Can be specified multiple times.
<code>--excludeFilter</code>	Search filter to identify entries to exclude from the LDIF import. Can be specified multiple times.
<code>--excludeOperational</code>	Exclude operational attributes from the LDIF import.
<code>--excludeReplication</code>	Exclude replication attributes from the LDIF import.

Argument	Description
<code>--excludeSoftDelete</code>	Exclude soft delete entries from the LDIF import.

## Exporting data

The PingDirectory server `export-ldif` command line tool exports data from the server backend to an LDIF file for backups, exporting data to other applications, or reinitializing servers in a replicated topology.

The `export-ldif` tool supports the `--task` argument, which initiates the export process from within the PingDirectory server. When `export-ldif` is run as a task, extra information is available:

- Output from the export process is included in the error log.
- There is a task entry (accessible below the `cn=tasks` base [MISSING glossAcronymn or glossSurfaceform for gDN]) with information about the success or failure of the export along with log messages.

### Note:

An `ldif-export` task can be run from the server system or a remote system. Even if it's run from a remote system, the exported LDIF file is still written to the server system.

The `export-ldif` tool exports a point-in-time snapshot of the backend that is guaranteed to provide a consistent state of the database in LDIF. If necessary, you can re-import with `import-ldif`. The data exported by `export-ldif` can include all or some of the entries (a subset of the entries, or a subset of the attributes within entries, or both) contained in the backend. You accomplish this by specifying branches, filters, and attributes to include or exclude. You can compress, encrypt, or digitally sign the exported LDIF.

### Tip:

You can configure LDIF exports as [recurring tasks](#) with `dsconfig create-recurring-task`. You can schedule them to run by adding them to a recurring task chain.

## Performing an export

Export data to an LDIF file.

### Steps

- To export data to an LDIF file, run the `export-ldif` tool.

Example:

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif
```

## Performing an export from specific branches

### Steps

- To export data to an LDIF file under a specific branch from the `userRoot` backend of the local Directory Server into a compressed file, run the `export-ldif` tool.

Example:

In addition to including a specific branch, the following command excludes operational attributes from the exported data and wraps long lines at column 80.

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif.gz --
compress \
  --includeBranch ou=people,dc=example,dc=com --excludeOperational \
  --wrapColumn 80
```

## Encrypting LDIF exports and signing LDIF files

You can encrypt data during an LDIF export and digitally sign the LDIF file.

The Directory Server provides features to encrypt data during an LDIF export using the `export-ldif --encryptLDIF` option. It also allows the encrypted LDIF file to be imported on the same instance, or another server in the same replication topology, using the `import-ldif` tool. You can use a `--doNotEncrypt` argument to force an LDIF export to be unencrypted even if automatic encryption is enabled. The `--maxMegabytesPerSecond` argument can be used to impose a limit on the rate at which the LDIF file can be written to disk.

You can use the `export-ldif` tool with the `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, and `--encryptionSettingsDefinitionID` arguments to specify which key to use for encrypting the export. The `import-ldif` tool automatically detects encryption and compression and has `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile` options as well.

The Directory Server also provides an additional argument that digitally signs the contents of the LDIF file, which ensures that the content has not been altered since the export. To digitally sign the contents of the exported LDIF file, use the `export-ldif --sign` option. To allow a signed LDIF file to be imported onto the same instance or another server in the same topology, use the `import-ldif --isSigned` option.

### Note:

There is little added benefit to signing and encrypting the same data because encrypted data cannot be altered without destroying the ability to decrypt it.

## Encrypting an LDIF export

### Steps

- To encrypt the data during an export to an output LDIF file, run the `export-ldif` tool with the `--encryptLDIF` option.

Example:

The following command runs an offline export of the `userRoot` backend and encrypts the file when written to an output file called `data.ldif`.

```
$ bin/export-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
  --encryptLDIF
```

## Importing an encrypted LDIF file

Use the `import-ldif` tool to import an encrypted LDIF file.

### About this task

You can import an encrypted LDIF file into the same instance from which it was exported or into another server in the same replication topology with that instance. You cannot import an encrypted LDIF file into a server that is not connected to the instance from which it was exported.

### Steps

- Run the `import-ldif` tool to import the encrypted LDIF file from [Encrypting an LDIF export](#) on page 578.

#### Note:

The command imports the `data.ldif` file and decrypts the contents while overwriting the existing contents to the `userRoot` backend. The tool automatically determines encryption and compression, and it can automatically identify the correct key for exports that were encrypted with a key obtained from an encryption settings definition or an internal topology key.

#### Example:

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \  
--overwriteExistingEntries
```

## Signing an export

### Steps

- To digitally sign the data during an export to an output LDIF file, run the `export-ldif` tool with the `-sign` option.

#### Example:

The following command runs an offline export of the `userRoot` backend and signs the content when written to an output file called `data.ldif`.

```
$ bin/export-ldif --backendID userRoot \  
--ldifFile /path/to/data.ldif --sign
```

## Importing a signed LDIF file

### Steps

- To import the signed LDIF file (`data.ldif`) from [Signing an export](#) on page 579, run the `import-ldif` tool with the `--isSigned` option.

The tool imports the `data.ldif` file and checks the signature of the contents while overwriting the existing contents to the `userRoot` backend.

#### Note:

The command requires the `--isSigned` option, which instructs the tool that the contents of the LDIF file are signed.

#### Example:

```
$ bin/import-ldif --backendID userRoot \
  --ldifFile /path/to/data.ldif \
  --overwriteExistingEntries --isSigned
```

## Filtering data exports

The `export-ldif` command is analogous to the `import-ldif` command to provide a way to include or exclude specific attributes or entries during an export.

### Inclusion and Exclusion Arguments for export-ldif

Argument	Description
<code>--includeBranch</code>	Base distinguished name (DN) of a branch to include in the LDIF export (can be specified multiple times).
<code>--excludeBranch</code>	Base DN of a branch to exclude from the LDIF export (can be specified multiple times).
<code>--includeAttribute</code>	Attribute to include in the LDIF export (can be specified multiple times).
<code>--excludeAttribute</code>	Attribute to exclude from the LDIF export (can be specified multiple times).
<code>--includeFilter</code>	Filter to identify entries to include in the LDIF export (can be specified multiple times).
<code>--excludeFilter</code>	Filter to identify entries to exclude from the LDIF export (can be specified multiple times).
<code>--excludeOperational</code>	Exclude operational attributes from the LDIF export.
<code>--excludeReplication</code>	Exclude replication attributes from the LDIF export.
<code>--excludeSoftDelete</code>	Exclude soft delete entries from the LDIF export.

## Scrambling data files

The Directory Server `transform-ldif` tool provides backward compatibility with the former `scramble-ldif` tool, with additional functionality for configuring input and output files.

The `transform-ldif` tool reads data from one or more source LDIF files and writes the transformed data to a single output file.

Using this tool to scramble data lets you:

- Obscure the values of certain attributes so that it's difficult to determine the original values in the source data.
- Preserve the characteristics of the associated attribute syntax.

This process is repeatable, so if the same value appears multiple times, it yields the same scrambled representation each time. You can apply scrambling to both LDIF entries and LDIF change records.

The process of scrambling data is not the same as encryption. Only use scrambling to provide simple obfuscation of data. The following are general guidelines for scrambling attributes:

- If the attribute is `userPassword` and its value starts with a schema name surrounded by curly braces, such as `{SSHA256}XrgyNd13fid7KYdhd/Ju47KJQ5PYZqlUlyzxQ28f/QXUnNd9fupj9g==`, the schema name is left unchanged and the rest of the value is treated like a generic string.
- If the attribute is `authPassword` and its value contains at least two dollar signs, such as `SHA256$QGbtDCi1i4=$8/X7XRGaFCovC5mn7ATPDY1kVoocDD06Zy31bD4Ao04=`, the portion up to the first dollar sign (which represents the name of the encoding schema) is preserved and the remainder of the value is treated like a generic string.
- If an attribute has a Boolean syntax, the scrambled value will be either `TRUE` or `FALSE`. Scrambling Boolean values is not repeatable because the determination to use a value of `TRUE` or `FALSE` is random. By randomizing the scrambling for Boolean values, the syntax and obfuscation of the original value is preserved.
- If an attribute has a distinguished name syntax (or a related syntax, such as a name and optional UID), scrambling is applied to the values of relative distinguished name (RDN) components for any attributes to be scrambled.

For example, if you configure the tool to scramble both the `member` and `uid` attributes, and an entry has a `member` attribute with a value of `uid=john.doe,ou=People,dc=example,dc=com`, that `member` value is scrambled in a way that only obscures the `john.doe` portion but leaves the attribute names and all values of non-scrambled attributes intact.

- If an attribute has a generalized time syntax, that value is replaced with a randomized timestamp using the same format (the same number of digits and the same time zone indicator). The randomization is over a time range that is double the difference between the time the `transform-ldif` tool launches and the timestamp is scrambled. For values where that time difference is less than one day, one day is added to the difference before it is doubled.
- If an attribute has an integer, numeric string, or telephone number syntax, scrambling is only applied to numeric digits while all other characters are left intact. If there are multiple digits, then the first digit is nonzero.
- If an attribute has an octet string syntax, it's scrambled as follows:
  - Each byte that represents a lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
  - Each byte that represents an uppercase ASCII letter is replaced with a randomly-selected uppercase ASCII letter.
  - Each byte that represents an ASCII digit is replaced with a randomly-selected ASCII digit.
  - Each byte that represents a printable ASCII symbol is replaced with a randomly-selected printable ASCII symbol.
  - Each byte that represents an ASCII control character is replaced with a randomly-selected ASCII letter, digit, or symbol.
  - Each non-ASCII byte will be replaced with a randomly-selected non-ASCII byte.

- If an attribute has a value that represents a valid JSON object, the resulting value is also a JSON object. All field names are left intact, and only the values of those fields can be scrambled. If the `--scrambleJSONField` argument is provided, only the specified fields have values scrambled. Otherwise, the values of all fields are scrambled. Field values are scrambled as follows:
  - Null values aren't scrambled.
  - Boolean values are replaced with randomly-selected Boolean values. As with attributes with a Boolean syntax, these values are non-repeatable.
  - Number values have only their digits replaced with randomly-selected digits and all other characters (minus sign, decimal point, exponentiation indicator) are left unchanged.
  - String values are replaced with a randomly-selected generic string.
  - Array values have scrambling applied as appropriate for each value in the array. If the array field itself should be scrambled, then all values in the array are scrambled. Otherwise, only JSON objects contained inside the array have scrambling applied to appropriate fields.
  - JSON values have scrambling applied as appropriate for their fields.
- If an attribute does not match any of the previous criteria, it is scrambled as follows:
  - Each lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
  - Each uppercase ASCII letter replaced with a randomly-selected uppercase ASCII letter.
  - Each ASCII digit is replaced with a randomly-selected ASCII digit.
  - All other characters are left unchanged.

### Example

The following example reads from an LDIF file named `original.ldif`, scrambles the values of the `telephoneNumber`, `mobile`, and `homeTelephoneNumber` attributes, and writes the results to `scrambled.ldif`.

```
$ bin/transform-ldif --sourceLDIF original.ldif \
  --targetLDIF scrambled.ldif \
  --scrambleAttribute telephoneNumber \
  --scrambleAttribute mobile \
  --scrambleAttribute homeTelephoneNumber \
  --randomSeed 0
```

## Backing Up and Restoring Data

---

PingDirectory Server provides efficient **backup** and **restore** command line tools that support full and incremental backups.

You can schedule backups using either the UNIX-based **cron** scheduler or Directory Server's task-based scheduler.

The Directory Server can run backups while the server is online and processing other requests, so there is no need to shut down the server or place it in read-only mode before starting a backup.

### About backing up and restoring data

Administrators should make a comprehensive backup strategy and schedule that consist of daily, weekly, and monthly backups. The plan should include:

- Incremental backups of the directory server data, configuration, and backends
- Full backups of the directory server data, configuration, and backends
- A backup plan for the underlying file system

This dual purpose approach provides excellent coverage in the event that a server database must be restored for any reason.

**Note:**

You can use `dsconfig create-recurring-task` to configure backups as recurring tasks and schedule those tasks as part of a recurring task chain.

If you back up more than one backend, the `backup` tool creates a subdirectory within a specified backup directory for each backend. If you back up only a single backend, then the backup files are placed in the specified directory. A single directory can only contain files from one backend, so you cannot have backup files from multiple different backends in the same backup directory.

When performing a backup, the server records information about the current state of the server and backend, including:

- The server product name
- The server version
- The backend ID
- The set of base distinguished names (DNs) for the backend
- The Java class used to implement the backend logic

The backup descriptor also includes information about the Berkeley DB Java edition version and information about the attribute and virtual list view (VLV) indexes that have been defined.

When restoring a backup, the server compares the descriptor obtained from the backup with the current state of the server and backend. If any problems are identified, the server generates warnings or errors.

You can choose to ignore warnings using the `ignoreCompatibilityWarnings` option to the `restore` tool. Errors always cause the restore operation to fail.

For example, restoring a newer backup into an older version of the server results in a warning. Restoring an older backup into a new version of the server does not result in a warning, but because the `config` and `schema` backends require special handling, the server generates an error if the server versions do not match exactly the major, minor, point, and patch version numbers.

Both the `backup` and `restore` tools provide encryption options that can be used to specify which key to use for encrypting the backup:

- `--promptForEncryptionPassphrase`
- `--encryptionPassphraseFile`
- `--encryptionSettingsDefinitionID`

For backups encrypted with an encryption settings definition or an internal topology key, the server automatically determines the correct key.

Alternately, you can use the `--doNotEncrypt` argument to force a backup to be unencrypted even if automatic encryption is enabled.

If necessary, you can use the `--maxMegabytesPerSecond` argument to impose a limit on the rate at which the backup can be written to disk.

## Retaining backups

The backup tool can use the `--retainPreviousFullBackupCount` or `--retainPreviousFullBackupAge` arguments to identify which previous backups to preserve.

Any other backups in that directory are removed. A new backup is always preserved. If the new backup is an incremental backup, then any other backups it depends on are also preserved. However, older backups in the same directory are eligible to be removed.

If you include the `--retainPreviousFullBackupCount` argument, that number of the most recent previous full backups are preserved, along with any incremental backups that depend on them. Any other previous full backups, and their dependent incremental backups, are removed. A value of zero can be

specified for the `--retainPreviousFullBackupCount` argument so that only the most recent backup is preserved, along with its dependencies, and all previous backups are removed.

If you include the `--retainPreviousFullBackupAge` argument, its value must be a duration represented as an integer followed by a time unit. Any full backups (and their dependent incremental backups) created longer ago than that duration are eligible to be removed.

If you include both the `--retainPreviousFullBackupCount` and `--retainPreviousFullBackupAge` arguments, then only backups that don't satisfy either condition are deleted.

The `remove-backup` tool also supports the `--retainFullBackupCount` and `--retainFullBackupAge` arguments to delete any backups outside the provided retention criteria.

### Listing the available backups on the system

Use the `restore` tool to list the backups in a `backup` directory.

#### Steps

- To list the existing backups in a specific backup directory, run the following command.

```
$ bin/restore --listBackups --backupDirectory </mybackups>
```

#### Result:

```
[13:26:21] The console logging output is also available in '/ds/PingDirectory/logs/tools/restore.log'
```

```
Backup ID:          20120212191715Z
Backup Date:       12/Feb/2012:13:17:19 -0600
Is Incremental:    false
Is Compressed:     false
Is Encrypted:      false
Has Unsigned Hash: false
Has Signed Hash:  false
Dependent Upon:    none
Backup ID:          20120212192411Z
Backup Date:       12/Feb/2012:13:24:16 -0600
Is Incremental:    true
Is Compressed:     false
Is Encrypted:      false
Has Unsigned Hash: false
Has Signed Hash:  false
Dependent Upon:    20120212191715Z
```

### Backing up all backends

Use `backup` to save the all of the server's backends.

#### About this task

The `--compress` option can reduce the amount of space that the backup consumes, but can also significantly increase the time required to perform the backup.

#### Steps

- To back up all backends and compress the backups, run the following.

```
$ bin/backup --backUpAll --compress --backupDirectory </path/to/backup>
```

### Backing up a single backend

Use the `--backendID` argument to specify a single backend to back up.

#### Steps

- To back up the userRoot directory and compress the backup, use the following command.

```
$ bin/backup --backendID userRoot --compress --backupDirectory </path/to/backup>
```

### Performing an offline restore

Use the `restore` command to restore a backed up backend.

#### About this task

Only a single backend can be restored at a time.

The Directory Server must be shut down before performing an offline restore.

#### Note:

The server root directory should never be restored from a file system backup or snapshot.

#### Steps

1. To stop the Directory Server run the following command.

```
$ bin/stop-server
```

2. To restore a saved backup, run the following command.

```
$ bin/restore --backupDirectory </path/to/backup/userRoot>
```

3. To start the server, run the following command.

```
$ bin/start-server
```

### Assigning an ID to a backup

Use the `--backupID` argument to assign an ID to a backup.

#### Steps

- To back up the userRoot directory, run the following command.

```
$ bin/backup --backupDirectory </path/to/backups/>userRoot \
  --backendID userRoot --backupID weekly
```

The `--backupID` argument identifies the backup being created as "weekly".

**Result:** The backup file appears under `backups/userRoot` directory as `userRoot-backup-weekly`.

### Running an incremental backup on all backends

The Directory Server provides support for incremental backups, which only backs up items that have changed since the last full or incremental backup on the system or since an earlier specified backup.

#### About this task

You must place incremental backups in the same backup directory as the full backup on which they are based.

#### Note:

Not all backends support incremental backups. If a backend does not support incremental backups, the `--incremental` option has no effect, and a full backup occurs.

#### Steps

- To run an incremental backup on all backends based on the most recent backup, run the following command.

```
$ bin/backup --backUpAll --incremental --backupDirectory /path/to/backup
```

### Running an incremental backup on a single backend

#### Steps

- To save the single backend, `userRoot`, in the server root directory, run the `backup` tool.

Example:

```
$ bin/backup --backendID userRoot --incremental --backupDirectory /path/to/backup
```

### Running an incremental backup based on a specific prior backup

You can run an incremental backup based on a specific prior backup that is not the most current version on the system.

#### Steps

- To get the backup ID, run the `restore` tool with the `--listBackups` option.

Example:

```
$ bin/backup --backUpAll --incremental --backupDirectory /path/to/backup
  \
  --incrementalBaseID backup-ID
```

## Restoring an incremental backup

Restoring an incremental backup is the same process as restoring a full backup for both online and offline restore types.

### Steps

- To automatically ensure that the full backup and any intermediate incremental backups are restored before restoring the final incremental backup, use the **restore** tool.

#### Note:

The tool does not restore any files in older backups that no longer exist in the final data set.

## Scheduling an online backup

### About this task

You can schedule a backup to run as a task by specifying the timestamp with the `--task` and `--start` options. The option is expressed in "YYYYMMDDhhmmss" format. If the option has a value of 0, then the task is scheduled for immediate execution. Because you can't run recurring tasks, you must run daily operations using cron or another system that can submit the task.

For online (remote) backups, you can conduct the backup operation while PingDirectory Server is online if you provide information about how to connect and to authenticate to the target Directory Server.

### Steps

- To schedule the backup to occur at a specific time, use the task-based `--start YYYYMMDDhhmmss` option.

#### Note:

To specify a time in the UTC time zone format, add a trailing `Z` to the time. Otherwise, the time is treated as a local time in the time zone configured on the server.

### Example:

```
$ bin/backup --backUpAll --task --start 20111025010000 \
  --backupDirectory /path/to/backup --completionNotify admin@example.com \
  --errorNotify admin@example.com
```

### Result:

```
Backup task 2011102500084110 scheduled to start Oct 28, 2011 1:00:00 AM
CDT
```

## Scheduling an online restore

### About this task

To perform an online restore, use the Tasks subsystem and enter connection and authentication information and an optional start time.

#### Note:

The server must be online.

The Tasks subsystem allows you to schedule certain operations, such as **import-ldif**, **backup**, **restore**, **start-server**, and **stop-server**.

### Steps

- Schedule an online restore.

Example:

```
$ bin/restore --task --start 20111025010000 \
  --backupDirectory /path/to/backup/userRoot \
  --completionNotify admin@example.com --errorNotify admin@example.com
```

You can schedule a restore to run as a task by specifying the timestamp with the **--task** and **--start** options. The option is expressed in **YYYYMMDDhhmmss** format. If the option has a value of 0, then the task is scheduled for immediate execution. You can't run recurring tasks, so you must run daily operations using cron or another system that can submit the task.

#### Note:

To specify a time in the UTC time zone, add a trailing **z** to the time. If you do not specify a time, the configured time zone on the server will be set to a local time.

The backend is unavailable while the restore is in progress.

## Encrypting a backup

About this task

To encrypt a backup:

### Steps

- Go to the server root directory and use the **backup** tool to back up the single backend, **userRoot**, and encrypt it with the **--encrypt** option.

Example:

```
$ bin/backup --encrypt --backendID userRoot --compress --
  backupDirectory /path/to/backup
```

## Signing a hash of the backup

Run the **backup** tool to backup a backend and generate and digitally sign the hash of the backup contents.

### Steps

- To backup the single backend from the server root directory, run the **backup** tool. Choose from:
  - To generate and digitally sign the hash of the backup contents, run the **-signHash** option.

```
$ bin/backup --signHash --backupDirectory backups/userRoot --backendID
  userRoot \
  --backupDirectory /path/to/backup
```

- To only generate a hash of the backup contents, run **backup** with the **--hash** option.

## Restoring a backup

The **backup** tool uses a descriptor file to access property information used for the backup, indicating if the backup was compressed, signed, or encrypted.

### Steps

- To restore a backup, go to the server root directory and run the **restore** tool.

Example:

```
$ bin/restore --backupDirectory /path/to/backup
```

## Moving or restoring a user database

Part of any disaster recovery involves the restoration of the user database from one server to another.

You should have a well-defined backup plan that takes into account whether or not your data is replicated among a set of servers. A plan is the best insurance against significant downtime or data loss in the event of an unrecoverable database issue.

### Note:

The server root directory should never be restored from a file system backup or snapshot. External backup methods, such as virtual machine (VM) snapshots, are not recommended, especially if data was corrupted during a transaction.

Keep in mind the following general points about database recovery:

#### Regular backup from local replicated Directory Server

Take a backup from a local replicated directory server and restore to the failed server. This is more recent than any other backup you have.

#### Restore the most recent backup

Restore the most recent backup from a local server. In some cases, this might be preferred over taking a new backup if that would adversely impact performance of the server being backed up although it takes longer for replication to play back changes.

#### Contact support

If all else fails, contact your authorized support provider and they can work with you, and possibly in cooperation with the Oracle Berkeley DB JE engineers, to try a low-level recovery, including tools that attempt to salvage whatever data they can obtain from the database.

#### Using VM snapshots

Although VM snapshots are not recommended for disaster recovery, remember the following in case you must use them:

- Snapshotting the VM should never result in a corrupted PingDirectory server.
- Shutting down the DB before snapshotting is only recommended for speeding up recovery time.

## Comparing the data in two Directory Servers

The PingDirectory Server provides an **ldap-diff** tool to compare the data on two LDAP servers to determine any differences that they might contain.

The differences are identified by first issuing a subtree search on both servers under the base distinguished name (DN) using the default search filter (`objectclass=*`) to retrieve the DNs of all entries in each server. When the tool finds an entry that is on both servers, it retrieves the entry from each server and compares all of its attributes. The tool writes any differences it finds to an LDIF file in a format

that could be used to modify the content of the source server so that it matches the content of the target server. Any non-synchronized entries can be compared again for a configurable number of times with an optional pause between each attempt to account for replication delays.

You can control the specific entries to be compared with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. You can also exclude specific attributes by prepending a `^` character to the attribute. On Windows operating systems, excluded attributes must be quoted, such as `"^attrToExclude"`. The `@objectClassName` notation is used to compare only attributes that are defined for a given `objectclass`.

The `ldap-diff` tool can be used on servers actively being modified by checking differing entries multiple times without reporting false positives due to replication delays. By default, it re-checks each entry twice, pausing two seconds between checks. You can configure these settings with the `--numPasses` and `--secondsBetweenPass` options. If the utility cannot make a clean comparison on an entry, it lists any exceptions in comments in the output file.

The Directory Server user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the Directory Server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry.

```
ds-cfg-default-root-privilege-name: unindexed-search
ds-cfg-default-root-privilege-name: bypass-acl
ds-rlim-size-limit: 0
ds-rlim-time-limit: 0
ds-rlim-idle-time-limit: 0
ds-rlim-lookthrough-limit: 0
```

The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For Directory Servers that contain hundreds of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. You can customize the memory used by the `ldap-diff` tool by editing the `ldap-diff.java-args` setting in the `config/java.properties` file and running the `dsjavaproperties` command.

If you do not want to use a subtree search filter, you can use an input file of DNs for the source, target, or both. The format of the file can accept various syntaxes for each DN.

```
dn: cn=this is the first dn
dn: cn=this is the second dn and it is wrapped cn=this is the third dn
# The following DN is base-64 encoded dn::
Y249ZG9uJ3QgeW91IGhhdmUgYmV0dGVyIHRoaW5ncyB0byBkbyB0aGFuIHNlZSB3aGF0IHRoaXMgc2F5cw==
# There was a blank line above dn: cn=this is the final entry.
```

#### CAUTION:

Do not manually update the servers when the tool identifies differences between two servers involved in replication. First contact your authorized support provider for explicit confirmation because manual updates to the servers risk introducing additional replication conflicts.

## Comparing two Directory Servers using ldap-diff

### Steps

1. Use `ldap-diff` to compare the entries in two Directory Server instances.

Ignore the `userpassword` attribute due to the one-way password hash used for the password storage scheme.

Example:

```
$ bin/ldap-diff --outputLDIF difference.ldif \
  --sourceHost server1.example.com --sourcePort 1389 \
  --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
  --targetHost server2.example.com --targetPort 2389 \
  --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
  --baseDN dc=example,dc=com --searchFilter "(objectclass=*)" \
  "^userpassword"
```

2. Open the output file in a text editor to view any differences.

The file is set up so that you can re-apply the changes without any modification to the file contents. The file shows any deletes, modifies, and adds from the perspective of the source server as the authoritative source.

Example:

```
# This file contains the differences between two LDAP servers.
#
# The format of this file is the LDIF changes needed to bring server
# ldap://server1.example.com:1389 in sync with server
# ldap://server2.example.com:2389.
#
# These differences were computed by first issuing an LDAP search at
# both
# servers under base DN dc=example,dc=com using search filter
# (objectclass=*)
# and search scope SUB to first retrieve the DNs of all entries. And then
# each
# entry was retrieved from each server and attributes: [^userpassword]
# were
# compared. # # Any entries that were out-of-sync were compared a total
# of 3 times
# waiting a minimum of 2 seconds between each attempt to account for
# replication
# delays.
#
# Comparison started at [24/Feb/2010:10:34:20 -0600]
# The following entries were present only on ldap://
# server2.example.com:2389 and
# need to be deleted. This entry existed only on ldap://
# server1.example.com:1389
# Note: this entry might be incomplete. It only includes attributes:
# [^userpassword]dn: uid=user.200,ou=People,dc=example,dc=com
# objectClass: person
# objectClass: inetOrgPerson
# ... (more attributes not shown) ...
# st: DC
# dn: uid=user.200,ou=people,dc=example,dc=com
# changetype: delete

# The following entries were present on both servers but were out of
# sync.
```

```

dn: uid=user.199,ou=people,dc=example,dc=com
changetype: modify
add: mobile
mobile: +1 300 848 9999
-
delete: mobile
mobile: +1 009 471 1808

# The following entries were missing on ldap://server2.example.com:2389
# and need
# to be added. This entry existed only on ldap://
# server2.example.com:2389
# Note: this entry might be incomplete. It only includes attributes:

# [^userpassword]
dn: uid=user.13,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
... (more attributes not shown) ...
# Comparison completed at [24/Feb/2010:10:34:25 -0600]

```

## Comparing configuration entries using config-diff

### Steps

- Use `config-diff` to compare Directory Server configurations and produce a `dsconfig` batch file needed to bring the source inline with the target.

#### Example:

The following example compares the current configurations of server1 and server2. The changes necessary to bring server1's configuration inline with server2 are written to the console. The same credentials are used to connect to both servers.

```

$ bin/config-diff --sourceHost server1 --sourceBindDN "cn=Directory
  Manager" \
  --sourceBindPassword password --targetHost server2

```

For more information about runtime options, see [Available command-line tools](#) on page 1086 or the `config-diff` tool help.

## Comparing entries using source and target DN files

### Steps

- To compare the entries in two Directory Server instances, use `ldap-diff`.

In the following example, the utility uses a single distinguished name (DN) input file for the source and target servers, so that no search filter is used. Ignore the `userpassword` attribute because of the password storage scheme that uses a one-way hashing algorithm.

#### Example:

```

$ bin/ldap-diff --outputLDIF difference.ldif \
  --sourceHost server1.example.com --sourcePort 1389 \
  --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
  --targetHost server2.example.com --targetPort 2389 \
  --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
  --baseDN "dc=example,dc=com" --sourceDNsFile input-file.ldif \
  --targetDNsFile input-file.ldif "^userpassword"

```

## Comparing Directory Servers for missing entries only using `ldap-diff`

### Steps

- To compare two Directory Servers and return only those entries that are missing on one of the servers, use `ldap-diff` with the `--missingOnly` option.

This can significantly reduce the runtime for this utility.

Example:

```
$ bin/ldap-diff --outputLDIF difference.ldif \
  --sourceHost server1.example.com --sourcePort 1389 \
  --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
  --targetHost server2.example.com --targetPort 2389 \
  --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
  --baseDN dc=example,dc=com --searchFilter "(objectclass=*)" \
  "^userpassword" \
  --missingOnly
```

## Reverting or replaying changes

The PingDirectory Server provides support for an audit logger that records information about the changes to data within the server.

The data is formatted as LDIF, and it can be replayed with tools such as `ldapmodify` or `parallel-update`. The data includes information encoded as comments that provide additional context about the changes. By default, the log records the changes as requested by clients, but it can log the changes in reversible form so that they can be undone.

This audit logger can be useful for the following scenarios:

- If one or more undesirable changes have been made, such as by a malicious or defective client, it can obtain the necessary changes to revert those operations.
- If a catastrophic loss of all servers in the topology occurs that leaves an audit log available with newer data than any backup or LDIF export, such as concurrent database corruption across all instances, it can recover changes that might not otherwise be available.
- Automating the process of identifying changes made in one topology that can be replayed into another topology, such as to replay production changes into an isolated server or topology for testing purposes or to attempt to reproduce a problem.
- Analytics and reporting purposes.

To assist with these and other uses, the LDAP SDK for Java provides an API for consuming, parsing, and reverting audit log messages. This API can be used for the analytics and reporting. Also available is the `extract-data-recovery-log-changes` tool that can extract audit log changes matching a specified set of criteria so that they can be replayed, either as they were originally processed or in a reversible form that makes it possible to revert those changes.

### The Data Recovery Log

The `setup` tool automatically creates an audit logger for data recovery purposes in `logs/data-recovery`. The log is always compressed, and it is encrypted if data encryption is enabled within the server. The logger has the following properties:

- Log files are written into the `logs/data-recovery` directory so that they are isolated from other log files. The active log file is named `data-recovery.gz.encrypted` while rotated files are named `data-recovery.{timestamp}.gz.encrypted`.
- The log files are gzip-compressed. If data encryption is enabled, they are encrypted with a key obtained from the server's preferred encryption settings definition.

- Each log file contains no more than 10 MB of data, and is rotated after 24 hours. Keeping the log files small ensures that the entire contents of a log file easily fits into the `extract-data-recovery-log-changes` tool's memory.
- The server retains rotated data recovery log files for no more than one week. However, as a safeguard against consuming too much disk space in periods of extremely heavy and prolonged write activity, the server also retains no more than 1,000 data recovery log files for a maximum of 500 MB of disk space.
- Changes are logged in reversible form and include the authentication and authorization identity of the requester, as well as the IP address. If present, the log message includes details from any intermediate client request control included in the request, which can provide information about the downstream client.

#### The `extract-data-recovery-log-changes` Tool

The `extract-data-recovery-log-changes` tool creates an LDIF file (compressed and encrypted by default) with a specified subset of changes from the server's data recovery log. That LDIF file can then be applied to the server using either the `ldapmodify` or `parallel-update`. Before applying the changes, the output file can be decrypted and examined to ensure that the changes it contains look correct. This tool can be useful for disaster recovery.

The `extract-data-recovery-log-changes` tool provides arguments for input and output of the extracted changes, including encryption settings, location, and compression.

The direction of whether changes should be extracted in forward mode or reverse mode is also configured. In forward mode (replay), the audit log messages are traversed from oldest to newest, and extracted changes are presented as they were originally requested. In reverse mode (revert), the audit log messages are traversed from newest to oldest, and extracted changes are converted to a form that reverts the original changes. Regardless of the direction chosen, additional arguments enable identifying the changes to extract by time, requester address or DN, connection ID, origin, content type, or alterations.

The following is a sample command to revert all changes by user `uid=malicious,ou=People,dc=example,dc=com` between noon and 2 pm on October 15, 2018.

```
$ bin/extract-data-recovery-log-changes \
  --auditLogFile logs/data-recovery/data-
  recovery.201810161234.567.gz.encrypted \
  --outputFile revert-malicious-user-changes.ldif \
  --direction revert \
  --startTime 201810151200.000 \
  --endTime 201810151359.999 \
  --includeAuthorizationDN "uid=malicious,ou=People,dc=example,dc=com"
```

## Working with Groups

---

LDAP groups are special types of entries that represent collections of users. This section provides an overview of Directory Server groups concepts and procedures on setting up and querying groups in Directory Server.

Groups are often used by external clients to control who has access to a particular application or features. Internally, they might be used by the server to control its behavior. Groups can be used by the access control, criteria, or virtual attribute subsystems.

The specific ways in which clients create and interact with a particular group depends on the type of group being used. There are three primary ways in which clients attempt to use groups:

- To determine whether a specified user is a member of a particular group
- To determine the set of groups in which a specified user is a member
- To determine the set of all users that are members of a particular group

## Overview of groups

Directory Server provides three types of groups: static, dynamic, and virtual static groups.

A description of each group type follows:

### Static groups

A static group is an entry that contains an explicit list of member or uniquemember attributes, depending on its structural object class. Static groups are ideal for small, infrequently changing elements. When the membership list grows, static groups become more difficult to manage because any change in a member base distinguished name (DN) must then be changed in the group. Static groups use one of three structural object classes: `groupOfNames`, `groupOfUniqueNames`, and `groupOfEntries`.

Directory Server also supports nested groups, in which a parent group entry contains child attributes whose DN's reference another group. Nested groups are a flexible means to organize entries that provide inherited group membership and privileges. To maintain good performance throughout, a group cache is enabled by default. The cache supports static group nesting that includes other static, virtual static, and dynamic groups.

### Dynamic groups

A dynamic group has its membership list determined by search criteria using an LDAP URL. Dynamic groups solve the scalability issues for static groups because searches are efficient, constant-time operations. However, searches that range over a large set of data might affect performance.

### Virtual static groups

A virtual static group is a combination of both static and dynamic groups, in which each member in a group is a virtual attribute that is dynamically generated when invoked. Virtual static groups solve the scalability issues for clients that can only support static groups and are best used when the application targets a search operation for a specific member. Avoid using virtual static groups for applications that need to retrieve the entire membership list because the process for constructing the entire membership list can be expensive.

## About the `isMemberOf` and `isDirectMemberOf` virtual attribute

PingDirectory Server can generate either `isMemberOf` or `isDirectMemberOf` virtual attributes in user entries.

The existence of static, nested, dynamic, and virtual static groups can make it complex to work with groups in the server because the ways you interact with them are so different. Static groups can use three different structural object classes, not counting the auxiliary class for virtual static groups, which can further complicate things. PingDirectory Server's virtual attributes simplify the group-related determination process for consistency across all types of groups.

The value of the `isMemberOf` virtual attribute is a list of distinguished names (DNs) of all groups, including static, nested, dynamic, and virtual static groups, in which the associated user is a member. The value of the `isDirectMemberOf` virtual attribute is a subset of the values of `isMemberOf`, which represents the groups for which the entry is an explicit or direct member. Both are enabled by default.

Because `isMemberOf` and `isDirectMemberOf` are operational attributes, only users who have been granted the privilege can see them. The default set of access control rules do not allow any level of access to user data. The only access that is granted is what is included in user-defined access control rules, which is generally given to a `uid=admin` administrator account. You should restrict access to operational and non-operational attributes to the minimal set of users that need to see them. The root bind DN, `cn=Directory Manager`, has the privilege to view operational attributes by default.

### Determine if a user is a member of a specified group

To determine if a user is a member of a specified group using the `isMemberOf` virtual attribute, perform a base-level search against the user's entry with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group. The following table illustrates this base-level search.

Base DN	<code>uid=john.doe,ou=People,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)</code>
Requested Attributes	<code>1.1</code>

If this search returns an entry, then the user is a member of the specified group. If no entry is returned, then the user is not a member of the given group.

### Determine the set of all groups in which a user is a member

To determine the set of all groups in which a user is a member, retrieve the user's entry with a base-level search and include the `isMemberOf` attribute.

Base DN	<code>uid=john.doe,ou=People,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(objectclass=*)</code>
Requested attributes	<code>isMemberOf</code>

### Determine the set of all members for a specified group

To determine the set of all members for a specified group, issue a subtree search with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group and requesting the attributes you wish to have for member entries.

Base DN	<code>ou=People,dc=example,dc=com</code>
Scope	<code>sub</code>
Filter	<code>(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)</code>
Requested Attributes	<code>cn, mail</code>

The `isDirectMemberOf` virtual attribute can be used in the previous examples in place of `isMemberOf` if you only need to find groups that users are an actual member of. You must use `isMemberOf` for nested group membership.

#### Note:

If this filter targets a dynamic group using an unindexed search, then this might be an expensive operation. However, it is not more expensive than retrieving the target group and then issuing a search based on information contained in the member URL.

For static groups, this approach has the added benefit of using a single search to retrieve information from all user entries. Otherwise, it would be required to retrieve the static group and then perform a separate search for each member's entry.

## Using static groups

A static group contains an explicit membership list where each member is represented as a distinguished name (DN)-valued attribute.

There are three types of static groups supported for use in the Directory Server: `groupOfNames`, `groupOfUniqueNames`, and `groupOfEntries`. A description for each follows:

### `groupOfNames`

A static group that is defined with the `groupOfNames` structural object class and uses the `member` attribute to hold the DNs of its members.

RFC 4519 requires that the `member` attribute is in an entry. Directory Server has relaxed this restriction by making the `member` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfNames` object class.

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfNames
cn: Test Group
member: uid=user.1,ou=People,dc=example,dc=com
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

### `groupOfUniqueNames`

A static group that is defined with the `groupOfUniqueNames` structural object class and uses the `uniquemember` attribute to hold the DNs of its members

RFC 4519 requires that the `uniquemember` attribute is in an entry. Directory Server has relaxed this restriction by making the `uniquemember` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfUniqueNames` object class.

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
cn: Test Group
uniquemember: uid=user.1,ou=People,dc=example,dc=com
uniquemember: uid=user.2,ou=People,dc=example,dc=com
uniquemember: uid=user.3,ou=People,dc=example,dc=com
```

### `groupOfEntries`

A static group that is defined with the `groupOfEntries` object class and uses the `member` attribute to hold the DNs of its members

This group specifies that the `member` attribute is optional to ensure that the last member can be removed from the group. Although the draft proposal (draft-findlay-ldap-groupofentries-00.txt) has expired, the Directory Server supports this implementation. The following entry depicts a group defined with the `groupOfEntries` object class.

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfEntries
cn: Test Group
member: uid=user.1,ou=People,dc=example,dc=com
```

```
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

## Creating static groups

Using an LDIF file, you can configure a static group. Static groups contain a membership list of explicit distinguished names (DNs) specified by the `uniquemember` attribute.

### Creating a static group

About this task

To create a static group:

Steps

1. Open a text editor and create a group entry in LDIF.
  - a. Include the `groupOfUniqueNames` object class and `uniquemember` attributes.
  - b. Optional: If you did not have `ou=groups` set up in your server, add it in the same file.
  - c. Save the file.

Example:

In the following example, the file is named `static-group.ldif`.

This example LDIF file creates two groups: `cn=Development` and `cn=QA`.

```
dn: ou=groups,dc=example,dc=com
objectclass: top
objectclass: organizationalunit
ou: groups

dn: cn=Development,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Development
ou: groups
uniquemember: uid=user.14,ou=People,dc=example,dc=com
uniquemember: uid=user.91,ou=People,dc=example,dc=com
uniquemember: uid=user.180,ou=People,dc=example,dc=com

dn: cn=QA,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: QA
ou: groups
uniquemember: uid=user.0,ou=People,dc=example,dc=com
uniquemember: uid=user.1,ou=People,dc=example,dc=com
uniquemember: uid=user.2,ou=People,dc=example,dc=com
```

2. To add the group entries to the server, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --defaultAdd --filename static-group.ldif
```

3. To verify the configuration, use the virtual attribute `isDirectMemberOf` that checks membership for a non-nested group.

The virtual attribute is disabled by default, but you can enable it using `dsconfig`.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name isDirectMemberOf --set
enabled:true
```

4. To determine if a user is a member of a certain group, use `ldapsearch` to search the `isDirectMemberOf` virtual attribute.

Example:

This example inquires if `uid=user.14` is a member of the `cn=Development` group.

This example assumes that the administrator has the privilege to view operational attributes.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14) "
isDirectMemberOf
```

Result:

```
dn: uid=user.14,ou=People,dc=example,dc=com
isDirectMemberOf: cn=Development,ou=groups,dc=example,dc=com
```

5. Use the group as a target in access control instructions (ACI).
  - a. Open a text editor and create an `aci` attribute in an LDIF file.
  - b. Save the file.
  - c. To add the file, use the `ldapmodify` tool.

Example:

In this example, the file is named `dev-group-aci.ldif`.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target ="ldap:///ou=People,dc=example,dc=com")
(targetattr != "cn || sn || uid")
(targetfilter ="(ou=Development)")
(version 3.0; acl "Dev Group Permissions";
allow (write) (groupdn = "ldap:///
cn=Development,ou=groups,dc=example,dc=com");)
```

**Note:**

You can create a similar ACI for the QA group, which is not shown in the previous example, but is shown in the example for step 1.

6. To add the file, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --filename dev-group-aci.ldif
```

## Adding a new member to a static group

### Steps

- To add a new member to the group, add a new value for the `uniquemember` attribute that specifies the DN of the new user.

Example:

This example adds a new `uniquemember: user.4`.

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
add: uniquemember
uniquemember: uid=user.4,ou=People,dc=example,dc=com
```

## Removing a member from a static group

### Steps

- To remove a member from a static group, remove that user's DN from the `uniquemember` attribute.

Example:

This example removes the DN of `user.1`.

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
delete: uniquemember
uniquemember: uid=user.1,ou=People,dc=example,dc=com
```

## Searching static groups

The following section provides a description of how to compose searches to determine if a user is a member of a static group, to determine all the static groups in which a user is a member, and to determine all the members of a static group

### Determining if a user is a static group member

#### Steps

- To determine if a user is a member of a specified group, perform a base-level search to retrieve the group entry with an equality filter looking for the membership attribute of a value equal to the distinguished name (DN) of the specified user.

#### Note:

For best performance, include a specific attribute list, using either `cn`, or a `1.1` request that no attributes be returned, so that the entire member list is not returned.

Example:

This table contains the search criteria to determine if the user `uid=john.doe,ou=People,dc=example,dc=com` is a member of the `groupOfNames` static group `"cn=Test Group,ou=Groups,dc=example,dc=com"`.

Base DN	<code>cn=Test Group,ou=Groups,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(member=uid=john.doe,ou=People,dc=example,dc=com)</code>

Requested attributes	1.1
----------------------	-----

**Example:**

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com"
--searchScope base "(member=uid=john.doe,ou=People,dc=example,dc=com)"
"1.1"
```

**Result:**

If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group.

- If you do not know if the membership attribute for the specified group is `member` or `uniqueMember`, then revise the filter to allow either attribute.

**Example:**

This example adjusts the filter from the previous step's example to expand the membership attribute to allow for `member` and `uniqueMember` attributes.

```
( | (member=uid=john.doe,ou=People,dc=example,dc=com)
(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com) )
```

**Determining the static groups to which a user belongs****Steps**

- To determine the set of all static groups in which a user is specified as a member, perform a subtree search based at the top of the directory information tree (DIT).

**Tip:**

Configure the search filter to match any type of static group in which the specified user is a member.

**Example:**

The following table contains the search criteria to determine the set of all static groups in which the user `uid=john.doc,ou=People,dc=example,dc=com` is a member.

Base DN	dc=example,dc=com
Scope	sub
Filter	(   (&(objectClass=groupOfNames) (member=uid=john.doe,ou=People,dc=example,dc=com) ) (&(objectClass=groupOfUniqueNames) (uniqueMem- ber=uid=john.doe,ou=People,dc=example,dc=com) ) (&(objectClass=groupOfEntries) (member=uid=john.doe,ou=People,dc=example,dc=com) ) )
Requested attributes	1.1

**Example:**

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" --searchScope sub \
" ( | (&(objectClass=groupOfNames)
(member=uid=john.doe,ou=People,dc=example,dc=com) ) \
```

```
( &(objectClass=groupOfUniqueNames) \
(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com) ) \
( &(objectClass=groupOfEntries) \
(member=uid=john.doe,ou=People,dc=example,dc=com) ) " 1.1 "
```

Result:

Entries returned from the search represent each static group in which the specified user is a member.

**Note:**

A base level search of the user's entry for `isMemberOf` or `isDirectMemberOf` virtual attributes gives the same results. You can also use the virtual attributes with virtual static groups.

## Determining the members of a static group

### Steps

- To determine all of the members for a static group, retrieve the group entry, including the membership attribute.

**Tip:**

To retrieve attributes from member entries, search all users whose `isMemberOf` attribute contains the group DN, returning the attributes desired.

To retrieve additional information about the members, such as attributes from member entries, issue a separate search for each member to retrieve the user entry and the desired attributes.

Example:

This table contains the search criteria to retrieve the list of all members for the group `cn=Test Group,ou=Groups,dc=example,dc=com`.

Base DN	<code>cn=Test Group,ou=Groups,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(objectClass=*)</code>
Requested attributes	<code>member uniqueMember</code>

Example:

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com" \
--searchScope base "(objectclass=*)" uniqueMember
```

Result:

The returned entry includes the DNs of all users that are members of that group.

## Using dynamic groups

Dynamic groups contain a set of criteria to identify members rather than maintaining an explicit list of group members.

If a new user entry is created, or if an existing entry is modified so that it matches the membership criteria, then the user is considered a member of the dynamic group. Similarly, if a member's entry is deleted, or if it

is modified so that it no longer matches the group criteria, then the user is no longer considered a member of the dynamic group.

In the Directory Server, dynamic groups include the `groupOfURLs` structural object class and use the `memberurl` attribute to provide an LDAP URL that defines the membership criteria. The base, scope, and filter of the LDAP URL is used in the process of making the determination, and any other elements present in the URL are ignored.

### Example

For example, the following entry defines a dynamic group in which all users below `dc=example,dc=com` with an `employeeType` value of `contractor` are considered members of the group.

```
dn: cn=Sales Group,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: Sales Group
memberURL: ldap:///dc=example,dc=com??sub?(employeeType=contractor)
```

Assuming that fewer than 80,000 entries have the `employeeType` of `contractor`, you must create the following index definition to evaluate the dynamic group.

```
$ bin/dsconfig create-local-db-index --backend-name userRoot \
--index-name employeeType --set index-entry-limit:80000 \
--set index-type:equality
```

### Creating dynamic groups

Configure a dynamic group in the same manner as static groups using an LDIF file.

#### About this task

Dynamic groups contain a membership list of attributes determined by search filter using an LDAP URL. You must use the `groupOfURLs` object class and the `memberURL` attribute.

#### Steps

1. Use `ldapsearch` to verify that `uid=user.15` is not part of any group.
  - a. Assume that `uid=user.15` is not part of any group.

You add the user to the dynamic group in a later step.

Result:

```
dn: uid=user.15,ou=People,dc=example,dc=com
```

- b. Assume for this example that `uid=user.0` has an `ou=Engineering` attribute indicating that he or she is a member of the engineering department.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
"(uid=user.0)" ou isMemberOf
```

Result:

```
dn: uid=user.0,ou=People,dc=example,dc=com
```

```
ou: Engineering
```

**Example:**

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
"(uid=user.15)" ou
```

2. Open a text editor, and then create a dynamic group entry in LDIF. Save the file as `add-dynamic-group.ldif`.

The LDIF defines the dynamic group to include all users who have the `ou=Engineering` attribute.

**Example:**

```
dn: cn=eng-staff,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfURLs
ou: groups
cn: eng-staff
memberURL: ldap:///ou=People,dc=example,dc=com??sub?(ou=Engineering)
```

3. Use `ldapmodify` to add the group entry to the server.

**Example:**

```
$ bin/ldapmodify --defaultAdd --filename add-dynamic-group.ldif
```

4. Use `ldapsearch` to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.0` is a member of the `cn=Engineering` group or any other group.

**Example:**

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" isMemberOf
```

**Result:**

```
dn: uid=user.0,ou=People,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

5. Run the following command to return the DNs of entries that are part of the `cn=eng-staff` dynamic group and sort them in ascending order by the `sn` attribute.

If your data is relatively small (under 1 million entries), you can search for all users in the group that meet the search criteria (`ou=Engineering`). For larger databases, it is not practical to run a database-wide search for all users as there can be a performance hit on the Directory Server.

**Example:**

```
$ bin/ldapsearch --baseDN dc=example,dc=com --sortOrder sn \
"(isMemberOf=cn=eng-staff,ou=groups,dc=example,dc=com)" dn
```

6. Add `uid=user.15` to the `eng-staff` group by adding an `ou=Engineering` attribute to the entry.

This step highlights an advantage of dynamic groups: you can make a change in an entry without explicitly adding the DN to the group as you would with static groups. The entry is automatically added to the `eng-staff` dynamic group.

**Example:**

```
$ bin/ldapmodify
dn: uid=user.15,ou=People,dc=example,dc=com
changetype: modify
add: ou
ou: Engineering
```

## 7. Use `ldapsearch` to check if the user is part of the `cn=eng-staff` dynamic group.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
"(uid=user.15)" isMemberOf
```

Result:

```
dn: uid=user.15,ou=People,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

### Searching dynamic groups

The following sections describe how to compose searches to determine if a user is a member of a dynamic group, to determine all the dynamic groups in which a user is a member, and to determine all the members of a dynamic group.

#### Determining if a user is a dynamic group member

Steps

- To determine whether a user is a member of a specific dynamic group, run a base-level search to verify that the user's entry is both within the scope of the member URL and that it matches the filter contained in that URL.

#### Tip:

You can verify that a user's entry is within the scope of the URL using simple client-side only processing. Evaluating the filter against the entry on the client side is more complicated. While possible, especially in clients able to perform schema-aware evaluation, a simple alternative is to perform a base-level search to retrieve the user's entry with the filter contained in the member URL.

Example:

This table contains the search criteria to determine if the user `uid=john.doe,ou=People,dc=example,dc=com` is a member of the dynamic group with the desired member URL.

Base DN	<code>uid=john.doe,ou=People,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(ou=Engineering)</code>
Requested Attributes	<code>1.1</code>

Example:

```
$ bin/ldapsearch --baseDN "uid=john.doe,ou=People,dc=example,dc=com" \
```

```
--searchScope base "(ou=Engineering)" "1.1"
```

**Note:**

The search requires the user DN to be under the search base defined in the `memberurl` attribute for the user to be a member.

**Result:**

If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group.

**Determining the dynamic groups to which a user belongs****Steps**

- To determine the set of all dynamic groups in which a user is a member, perform a search to find all dynamic group entries defined in the server using a subtree search with a filter of `(objectClass=groupOfURLs)`.

**Tip:**

You should retrieve the `memberURL` attribute so that you can use the logic described in the previous section to determine whether the specified user is a member of each of those groups.

**Example:**

The following table contains the search criteria to determine the set of all dynamic groups defined in the `dc=example,dc=com` tree.

Base DN	<code>dc=example,dc=com</code>
Scope	<code>sub</code>
Filter	<code>(objectClass=groupOfURLs)</code>
Requested Attributes	<code>memberURL</code>

**Example:**

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" \
  --searchScope sub "(objectClass=groupOfURLs)" "memberURL"
```

**Result:**

Each entry returned is a dynamic group definition. You can use the base, scope, and filter of its `memberURL` attribute to determine whether the user is a member of that dynamic group.

## Determining the members of a dynamic group

### Steps

- To determine all members of a dynamic group, issue a search using the base, scope, and filter of the member URL.

#### Note:

The set of requested attributes should reflect the attributes desired from the member user entries or "1.1" if no attributes are needed.

#### Example:

This table contains the search criteria to retrieve the list of all members of the group `dc=example,dc=com` with the `cn` and `mail` attributes.

Base DN	<code>dc=example,dc=com</code>
Scope	<code>sub</code>
Filter	<code>(employeeType=contractor)</code>
Requested Attributes	<code>cn, mail</code>

#### Example:

#### CAUTION:

This search might be extensive if the associated filter is not indexed or if the group contains a large number of members.

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" \
  --searchScope sub "(employeeType=contractor)" "cn, mail"
```

## Using dynamic groups for internal operations

Use dynamic groups for internal operations, such as Access control instruction (ACI) or component evaluation.

The Directory Server performs the `memberurl` parsing and internal LDAP search. However, the internal search operation cannot be performed with access control instructions applied to it.

For example, the following dynamic group represents an organization's employees within the same department.

```
dn: cn=department 202,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: department 202
owner: uid=user.1,ou=people,dc=example,dc=com
owner: uid=user.2,ou=people,dc=example,dc=com
memberURL: ldap:///ou=People,dc=example,dc=com??sub?
  (&(employeeType=employee)(departmentNumber=202))
description: Group of employees in department 202
```

The above group could be referenced from within the ACI at the `dc=example,dc=com` entry, as in the following example.

```
dn:dc=example,dc=com
aci: (targetattr="employeeType")
    (version 3.0; acl "Grant write access to employeeType" ;
      allow (all) groupdn="ldap:///cn=department
202,ou=groups,dc=example,dc=com";)
```

Any user matching the filter can bind to the server with their entry and modify the `employeeType` attribute within any entry under `dc=example,dc=com`.

## Using virtual static groups

Virtual static groups make it possible to get the efficiency and ease of management of a dynamic group while allowing clients to interact with them as a static group.

### About this task

Static groups can be easier to interact with than dynamic groups, but large static groups can be expensive to manage and require a large amount of memory to hold in the internal group cache. Directory Server provides a third type of group: a virtual static group, which references another group and provides access to the members of that group as if it was a static group.

### Steps

- To create a virtual static group, create an entry that has a structural object class of either `groupOfNames` or `groupOfUniqueNames` and an auxiliary class of `ds-virtual-static-group`.

#### Note:

It should include a `ds-target-group-dn` attribute, whose value is the group from which the virtual static group should obtain its members.

You must also enable a virtual attribute that allows the `member` attribute to be generated based on membership for the target group.

#### Example:

This example creates a virtual static group that exposes the members of the `cn=Sales Group,ou=Groups,dc=example,dc=com` dynamic group as if it were a static group.

```
dn: cn=Virtual Static Sales Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfNames
objectClass: ds-virtual-static-group
cn: Virtual Static Sales Group
ds-target-group-dn: cn=Sales Group,ou=Groups,dc=example,dc=com
```

- To enable a configuration object for the virtual static member attribute, use the `set-virtual-attribute-prop` option with `dsconfig`.

#### Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
```

```
--set enabled:true
```

 **Note:**

A configuration object for this virtual attribute is in the server configuration but is disabled by default.

If you want to use virtual static groups with the `groupOfUniqueNames` object class, enable the `Virtual Static uniqueMember` virtual attribute in the same way.

### Creating virtual static groups

If your application only supports static groups but has scalability issues, using a virtual static group is a possible solution.

#### About this task

A virtual static group uses a virtual attribute that is dynamically generated when called after which the operations that determine group membership are passed to another group, such as a dynamic group. You must use the `ds-virtual-static-group` object class and the `ds-target-group-dn` virtual attribute.

Virtual static groups are best used when determining if a single user is a member of a group. Do not use it if an application accesses the full list of group members due to the performance expense at constructing the list.

 **Note:**

If you have a small database and an application that requires that the full membership list be returned, enable the `allow-retrieving-membership` property for the `Virtual Static uniqueMember` virtual attribute using the `dsconfig` tool.

To create a virtual static group:

#### Steps

1. In a text editor, create a group entry in LDIF, and then save the file.

Example:

In this example, the entry contains the `groupOfUniqueNames` object class, but in place of the `uniqueMember` attribute is the `ds-target-group-dn` virtual attribute, which is part of the `ds-virtual-static-group` auxiliary object class.

In this example, the file is named `add-virtual-static-group.ldif`.

```
dn: cn=virtualstatic,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
objectclass: ds-virtual-static-group
ou: groups
cn: virtual static
ds-target-group-dn: cn=eng-staff,ou=groups,dc=example,dc=com
```

2. To add the virtual static group entry to the server, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify -h server1.example.com -p 389 -D
"uid=admin,dc=example,dc=com" \
-w password -a -f add-virtual-static-group.ldif
```

3. To enable the Virtual Static `uniqueMember` attribute, use the `set-virtual-attribute-prop` option with `dsconfig`.

**Note:**

This attribute is disabled by default.

**Example:**

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set enabled:true
```

4. To determine if a user is part of a virtual static group, use `ldapsearch`.

**Example:**

In [Creating dynamic groups](#) on page 603, the example sets up `uid=user.0` to be part of the `cn=eng-staff` dynamic group. This example determines if `uid=user.0` is part of the virtual static group using the `isMemberOf` virtual attribute.

```
$ bin/ldapsearch -h server1.example.com -p 389 -D "cn=Directory Manager"
\
-w secret -b dc=example,dc=com "(uid=user.0) isMemberOf
```

**Example:**

The following example determines if `uid=user.0` is part of the virtual static group without using the `isMemberOf` virtual attribute in the `ldapsearch`.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
-b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
"(&(objectclass=groupOfUniqueNames) \
(uniqueMember=uid=user.0,ou=People,dc=example,dc=com))"
```

**Result:**

Using the `isMemberOf` virtual attribute returns the following.

```
dn: uid=user.0,ou=People,dc=example,dc=com
isMemberOf: cn=virtualstatic,ou=groups,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

**Note:**

You should see the returned `cn=virtualstatic` entry if successful.

5. Optional: To try searching for a user that is not part of the `cn=eng-staff` dynamic group, use `ldapsearch`.

**Example:**

This example searches for `uid=user.20`.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password
\
-b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
"(&(objectclass=groupOfUniqueNames) \
```

```
(uniquemember=uid=user.20,ou=People,dc=example,dc=com) "
```

Result:

No entries are returned.

### Searching virtual static groups

Virtual static groups behave like static groups, so the process for determining whether a user is a member of a virtual static group is identical to that of a member in a static group.

The process for determining all virtual static groups in which a user is a member is similar to the process for standard static groups in which a user is a member. The query provided in the static groups discussion returns virtual static groups in addition to standard static groups because the structural object class of a virtual static group is the same as the structural object class for a static group.

You can retrieve a list of all members of a virtual static group in the same way as a standard static group: retrieve the `member` or `uniqueMember` attribute of the desired group. However, because virtual static groups are backed by dynamic groups and the process for retrieving member information for dynamic groups can be expensive, virtual static groups do not allow retrieving the full set of members by default.

To make the configuration change to allow full membership retrieval, update the virtual attribute used to expose membership.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
--set allow-retrieving-membership:true
```

#### Note:

This can be an expensive operation, so you should leave the option to allow retrieving virtual static group membership as disabled unless it is required.

## Creating nested groups

PingDirectory Server supports nested groups where the distinguished name (DN) of an entry that defines a group is included as a member in the parent entry.

About this task

The following example shows a nested static group, such as `cn=Engineering Group`, that has `uniquemember` attributes consisting of other groups, such as `cn=Developers Group` and the `cn=QA Group` respectively.

```
dn: cn=Engineering Group,ou=Groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=Groups,dc=example,dc=com
uniquemember: cn=QA,ou=Groups,dc=example,dc=com
```

By default, nested group support is enabled on the Directory Server.

The Directory Server uses a group cache to support nested groups without the performance hit. The cache supports static group nesting that includes other static, virtual static, and dynamic groups. The Directory Server provides a new monitoring entry for the group cache, `cn=Group Cache,cn=Monitor`.

In practice, nested groups are not commonly used for the following reasons:

- LDAP specifications do not directly address the concept of nested groups, and some servers do not provide any level of support for them.

- Supporting nested groups in LDAP clients is not trivial, and many directory server-enabled applications that can interact with groups do not provide any support for nesting.

**Tip:**

Disable this support if:

- Nesting support is not needed in your environment.
- Nesting support is only required for clients but is not needed for server-side evaluation, such as for groups used in access control rules, criteria, virtual attributes, or other ways that the server might need to make a membership determination.

To create nested static groups:

### Steps

1. Open a text editor, and create a group entry in LDIF.
  - a. Include the `groupOfUniqueNames` object class and `uniquemember` attributes.
  - b. If you did not have `ou=groups` set up in your server, then add it in the same file.
  - c. Save the file as `nested-group.ldif`.

Assume that the static groups, `cn=Developers Group` and `cn=QA Group`, have been configured.

#### Example:

The following example shows how to set up a nested static group, which is a static group that contains `uniquemember` attributes whose values contain other groups (static, virtual static, or dynamic).

```
dn: ou=groups,dc=example,dc=com
objectclass: top
objectclass: organizationalunit
ou: groups

dn: cn=Engineering Group,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=groups,dc=example,dc=com
uniquemember: cn=QA,ou=groups,dc=example,dc=com
```

2. To add the group entry, use `ldapmodify`.

#### Example:

```
$ bin/ldapmodify --defaultAdd --filename nested-static-group.ldif
```

3. Using the `isMemberOf` virtual attribute that checks the group membership for an entry, verify the configuration.

By default, the virtual attribute is enabled. Use `ldapsearch` to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.14` is a member of the `cn=Development` group.

#### Example:

In this example, assume that the administrator has the privilege to view operational attributes.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)" isMemberOf

dn: uid=user.14,ou=People,dc=example,dc=com
isMemberOf: cn=Development,ou=groups,dc=example,dc=com
```

- In a text editor, create an Access control instruction (ACI) in LDIF. Save the file as `eng-group-aci.ldif`.

**Tip:**

Use the group as a target in ACI.

**Example:**

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target = "ldap:///ou=People,dc=example,dc=com")
      (targetattr != "cn || sn || uid")
      (targetfilter = "(ou=Engineering Group)")
      (version 3.0; acl "Engineering Group Permissions";
        allow (write) (groupdn = "ldap:///cn=Engineering
        Group,ou=groups,dc=example,dc=com");)
```

- Add the file using the `ldapmodify` tool.

**Example:**

```
$ bin/ldapmodify --filename eng-group-aci.ldif
```

**Note:**

When nesting dynamic groups, you cannot include other groups as members of a dynamic group. You can only support nesting by including the members of another group with a filter in the member URL. For example, if you have two groups, `cn=dynamic1` and `cn=dynamic2`, you can nest one group in another by specifying it in the member URL.

```
cn=dynamic1,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
memberURL: ldap:///dc=example,dc=com??sub?
(isMemberOf=cn=dynamic2,ou=groups,dc=example,dc=com)
```

The members included from the other group using this method are not considered nested members and are returned even when using `isDirectMemberOf` when retrieving the members.

## Maintaining referential integrity with static groups

The Directory Server automatically updates references to an entry whenever that entry is removed or renamed in the referential integrity process.

### About this task

If a user entry is deleted, the referential integrity plugin removes that user from any static groups in which the user was a member. This is not necessary for dynamic groups because no explicit membership is maintained. Similarly, if a modify distinguish name (DN) operation is performed to move or rename a user entry, then referential integrity updates static groups in which that user is a member with the new user DN.

In the default configuration, the referential integrity processing performs synchronously. Because the necessary cleanup work must complete before the response to the original operation returns, the throughput and response time of delete and modify DN operations might be adversely impacted. To alleviate this performance impact, change the configuration to use a non-zero update interval. As a result,

the referential integrity process uses a separate background thread and does not significantly delay the response to delete or modify DN operations.

Performing referential integrity processing in a background thread can introduce a race condition that might adversely impact clients that delete a user and then immediately attempt to re-add it and establish new group memberships. For example, if referential integrity processing has not yet been completed for the delete, then newly-established group memberships might be removed along with those that existed for the previous user. Similarly, if the newly-created user is to be a member of one or more of the same groups as the previous user, then the client attempts to re-establish those memberships can fail if the referential integrity processing has not removed the previous membership. Use the default synchronous behavior unless the performance impact associated with synchronous referential integrity processing is unacceptable or clients might be affected by delayed referential integrity processing.

Other configuration attributes for this plugin include:

### Referential integrity plugin configuration attributes and their descriptions

Configuration attribute	Description
<code>attribute-type</code>	This attribute specifies the names or OIDs of the attribute types for which referential integrity will be maintained. By default, referential integrity is maintained for the <code>member</code> and <code>uniqueMember</code> attributes. Any attribute types specified must have a syntax of either distinguished name (OID "1.3.6.1.4.1.1466.115.121.1.12") or name and optional UID (OID "1.3.6.1.4.1.1466.115.121.1.34"). The specified attribute types must also be indexed for equality in all backends for which referential integrity is to be maintained.
<code>base-dn</code>	This attribute specifies the subtrees for which referential integrity will be maintained. If one or more values are provided, then referential integrity processing will only be performed for entries which exist within those portions of the DIT. By default, if no values are provided then entries within all public naming contexts will be included.
<code>log-file</code>	This attribute specifies the path to a log file that may be used to hold information about the DNs of deleted or renamed entries. If the plugin is configured with a nonzero update interval, this log file helps ensure that appropriate referential integrity processing occurs even if the server is restarted.

Configuration attribute	Description
update-interval	This attribute specifies the maximum length of time that a background thread may sleep between checks of the referential integrity log file to determine whether any referential integrity processing is required. By default, this attribute has a value of "0 seconds", which indicates that all referential integrity processing is to be performed synchronously before a response is returned to the client. A duration greater than 0 seconds indicates that referential integrity processing will be performed in the background and will not delay the response to the client.

By default, referential integrity support is disabled. To enable the support:

#### Steps

- Use the `dsconfig` tool as shown.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
--set enabled:true
```

#### Note:

The internal operations of the referential integrity plugin are not replicated. In a replicated topology, you must enable the referential integrity plugin on all servers in the topology to ensure that changes made by the referential integrity plugin are passed along to a replication server.

For more information about administering the referential integrity plugin, see [Configuring the Server](#) in PingDirectory Server Administration Guide.

## Monitoring the group membership cache

At startup, the Directory Server logs information about the group membership cache's memory consumption.

The hard-coded cache contains information about the group memberships for internal processing, such as Access control instructions (ACIs). By default, the group membership cache is enabled.

The information about this cache logs to the standard output log `server.out` and the standard error log. When using groups, use the log information to tune the server for best performance. At startup, the server logs a message to the `server.out` log.

The following is a sample standard output log.

```
[16/Aug/2011:17:14:39.462 -0500] category=JEB severity=NOTICE
msgID=1887895587
msg="The database cache now holds 3419MB of data and is 32 percent full"
```

The following is a sample error log.

```
[16/Aug/2011:18:40:39.555 -0500] category=EXTENSIONS severity=NOTICE
msgID=1880555575
msg="'Group cache (174789 static group(s) with 7480151 total memberships and
1000002
```

```
unique members, 0 virtual static group(s), 1 dynamic group(s))' currently
consumes
149433592 bytes and can grow to a maximum of 149433592 bytes"
```

## Using the entry cache to improve the performance of large static groups

The PingDirectory Server provides an entry cache implementation, which allows for fine-grained control over entries that are held in the cache.

You can define filters to specify the entries included in or excluded from the cache, and you can restrict the cache so that it holds only entries with at least a specified number of values for a given set of attributes.

For most circumstances, use the Directory Server without an entry cache. In most cases, the Directory Server efficiently retrieves and decodes entries from the database. The database cache is more space-efficient than the entry cache, and heavy churn in the entry cache can adversely impact garbage collection behavior.

### Entry caches with large static groups

If the Directory Server contains large static groups, such as those containing thousands or millions of members, and clients need to frequently retrieve or otherwise interact with these groups, enable an entry cache that holds only large static groups.

In servers containing large static groups, define an entry cache to hold only those large static groups. To define this entry cache, include a filter that matches only group entries, as shown in the following example.

```
(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)
(objectclass=groupOfEntries))
```

The filter contains a minimum value count so that only groups with a large number of members, such as those with at least 100 `member` or `uniqueMember` values are included. By default, the Directory Server entry cache implementation with these settings is disabled. To use this implementation, you must enable these settings.

### Enabling the entry cache

#### Steps

- To enable the entry cache, use the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-entry-cache-prop --cache-name "Static Group Entry
Cache" \
--set enabled:true
```

### Creating your own entry cache for large groups

#### Steps

- To create your own entry cache for large groups, use the `dsconfig create-entry-cache` subcommand.

Example:

```
# bin/dsconfig create-entry-cache --type fifo \
--set enabled:true \
--set cache-level:10 \
--set max-entries:175000 \
--set "include-filter:(objectClass=groupOfUniqueNames)" \
--set min-cache-entry-value-count:10000 \
```

```
--set min-cache-entry-attribute:uniquemember
```

## Monitoring the entry cache

### Steps

- To monitor the memory consumed by your entry cache, use the `entry-cache-info` property in the periodic stats logger.
  - To retrieve the monitor entry over LDAP, issue a search on `baseDN="cn=monitor"` using `filter="(objectClass=ds-fifo-entry-cache-monitor-entry)"`.

#### Note:

By default, the entry cache memory is set to 75% with a maximum of 90%.

### Example:

```
dn: cn=Static Group Entry Cache Monitor,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-fifo-entry-cache-monitor-entry
objectClass: extensibleObject
cn: Static Group Entry Cache Monitor
cacheName: Static Group Entry Cache
entryCacheHits: 6416407
entryCacheTries: 43069073
entryCacheHitRatio: 14
maxEntryCacheSize: 12723879900
currentEntryCacheCount: 1
maxEntryCacheCount: 175000
entriesAddedOrUpdated: 1
evictionsDueToMaxMemory: 0
evictionsDueToMaxEntries: 0
entriesNotAddedAlreadyPresent: 0
entriesNotAddedDueToMaxMemory: 0
entriesNotAddedDueToFilter: 36652665
entriesNotAddedDueToEntrySmallness: 0
lowMemoryOccurrences: 0
percentFullMaxEntries: 0
jvmMemoryMaxPercentThreshold: 75
jvmMemoryCurrentPercentFull: 24
jvmMemoryBelowMaxMemoryPercent: 51
isFull: false
capacityDetails: NOT FULL: The JVM is using 24% of its available memory.
  Entries can be
  added to the cache until the overall JVM memory usage reaches the
  configured limit of
  75%. Cache has 174999 remaining entries before reaching the configured
  limit of 175000.
```

## Tuning the index entry limit for large groups

The Directory Server uses indexes to improve database search performance and to provide consistent search rates regardless of the number of database objects stored in the directory information tree (DIT).

### About this task

You can specify an index entry limit property that defines the maximum number of entries allowed to match a given index key before the server no longer maintains it.

## Steps

- When the index keys have reached the default limit of 4000, rebuild the indexes using the `rebuild-index` tool.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index objectclass
```

- For Directory Server environment directories containing more than 4000 groups with the same structural object class, such as more than 4000 entries, 4000 `groupOfUniqueNames` entries, 4000 `groupOfEntries` entries, or 4000 `groupOfURLs` entries, increase the index entry limit for the `objectClass` attribute so that it has a value larger than the maximum number of group entries of each type by setting the `index-entry-limit` property in the command line.

### Note:

For most Directory Server environments, the default index entry limit value of 4000 entries is sufficient. However, group-related processing might be necessary to increase the index entry limit.

Example:

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name objectClass --set index-entry-limit:175000
```

- As an alternative, create a separate backend to hold these group entries so that an unindexed search in that backend yields primarily group entries.

### Note:

If you make no changes, then the internal search performed at startup to identify all groups and any user searches looking for groups of a given type can be expensive.

- For directories in which any single user is be a member of more than 4000 static groups of the same type, increase the index entry limit for the `member` or `uniqueMember` attribute to a value larger than the maximum number of groups in which any user is a member.

### Note:

If you do not increase the limit, searches to retrieve the set of all static groups in which the user is a member can be unindexed and therefore expensive.

## Summary of commands to search for group membership

The following summary of commands show the fastest way to retrieve direct or indirect member distinguished names (DNs) for groups.

- To retrieve direct member, non-nested DN's of group `cn=group.1,ou=groups,dc=example,dc=com`, run the following.

```
$ bin/ldapsearch --baseDN "cn=group.1,ou=Groups,dc=example,dc=com"
  "(objectClass=*)" uniqueMember member
```

- To retrieve direct member entries or non-nested under `dc=example, dc=com` of group `cn=group.1, ou=groups, dc=example, dc=com`, run the following.

```
$ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com"
"(isDirectMemberOf=cn=group.1,ou=Groups,dc=example,dc=com) "
```

This is useful when attributes from member entries are used in the filter or being returned.

- To retrieve group DN's in which user `uid=user.2, ou=people, dc=example, dc=com` is a direct member or non-nested, static groups, run the following.

```
$ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com"
"(objectClass=*) " isDirectMemberOf
```

- To retrieve all member entries under `ou=people, dc=example, dc=com` of group `cn=group.1, ou=groups, dc=example, dc=com`, run the following.

```
$ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com"
"(isMemberOf=cn=group.1,ou=Groups,dc=example,dc=com) "
```

- To retrieve the group DN's in which user `uid=user.2, ou=people, dc=example, dc=com` is a member, run the following.

```
$ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com"
"(objectClass=*) " isMemberOf
```

## Migrating Oracle groups

The following sections outline the procedures for migrating static groups to both Ping Identity static groups and virtual static groups as well as how to migrate dynamic groups.

You can migrate Oracle static and dynamic groups to PingDirectory Server groups. For more information about the differences in access control evaluation between Oracle and PingDirectory Server, see [Migrating ACIs from Oracle to PingDirectory Server](#) on page 746.

### Migrating static groups

About this task

PingDirectory Server supports static LDAP groups with structural object classes of `groupOfNames`, `groupOfUniqueNames`, or `groupOfEntries`. In general, you can import static groups without modification.

You can enable a First-In, First-Out (FIFO) entry cache to cache group-to-user mappings, which improves performance when accessing large entries at the expense of greater memory consumption. PingDirectory Server provides an out-of-the-box FIFO entry cache object for this purpose. You must enable this object using `dsconfig` as described in [Using the Entry Cache to Improve the Performance of Large Static Groups](#).

To migrate static groups:

Steps

1. To enumerate any schema differences between the DSEE deployment and the Ping Identity deployment, use the `migrate-ldap-schema` tool.
2. To enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment, use the `migrate-sun-ds-config` tool.
3. Import or configure any necessary schema or configuration changes recorded by the tools in steps 1 and 2.
4. Import the existing users and groups using the `import-ldif` tool.

5. From the PingDirectory Server root directory, open the `docs/sun-ds-compatibility.dsconfig` file using a text editor.
6. Go to the **FIFO Entry Cache** section.
  - a. Read the accompanying comments.
  - b. To enable the corresponding `dsconfig` command, delete the comment character ("`#`").

Example:

```
$ bin/dsconfig set-entry-cache-prop \
  --cache-name "Static Group Entry Cache" --set enabled:true
```

7. To ensure that references to an entry are updated automatically when the entry is deleted or renamed, enable the Referential Integrity plugin.

Example:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" --
set enabled:true
```

### Next steps

If the Directory Server is part of a replication topology, enable the Referential Integrity plugin for each replica.

## Migrating static groups to virtual static groups

### About this task

In many cases, using virtual static groups in place of static groups can produce marked performance gains without having to update client applications. Migrating to virtual static groups varies depending on the original directory information tree (DIT), but the general approach involves identifying common membership traits for all members of each group and then expressing those traits in the form of an LDAP URL.

For this task, consider the following:

- The common membership trait for all members of the `All Users` group is the parent distinguish name (DN) `ou=People,dc=example,dc=com`.
- In other cases, a common attribute might need to be used. For example, groups based on the location of its members could use the `l location` or `st state` attribute.
- The common case of an `All Users` group, which contains all entries under the parent DN `ou=People,dc=example,dc=com`.
- When implemented as a virtual static group, this group can have a large membership set without incurring the overhead of a static group.

To migrate Oracle Directory Server Enterprise Edition static groups to virtual static groups:

### Steps

1. Create a dynamic group.

Example:

```
dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: Dynamic All Users
memberURL: ldap:///ou=People,dc=example,dc=com??sub?(objectClass=person)
```

2. Create a virtual static group that references the dynamic group.

Example:

```
dn: cn=All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
objectClass: ds-virtual-static-group
cn: All Users
ds-target-group-dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
```

3. To populate the All Users group with uniqueMember virtual attributes, enable the Virtual Static uniqueMember virtual attribute.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set enabled:true
```

4. To confirm that the virtual static group is correctly configured, check a user's membership in the group.

Example:

```
$ bin/ldapsearch --baseDN "cn=All Users,ou=Groups,dc=example,dc=com" \
--searchScope base
"(uniqueMember=uid=user.0,ou=People,dc=example,dc=com)" 1.1
```

Result:

```
dn: cn=All Users,ou=Groups,dc=example,dc=com
```

5. If a client application requires it, enable the ability to list all members of a virtual static group.

By default, this feature is disabled.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set allow-retrieving-membership: true
```

**Tip:**

You can implement the virtual static group using the `groupOfNames` object class instead of `groupOfUniqueNames`. To do this, update the Virtual Static member configuration object instead of the Virtual Static uniqueMember configuration object.

## Migrating dynamic groups

About this task

The PingDirectory Server supports dynamic groups with the `groupofURLs` object class. In general, you can import dynamic groups without modification.

To migrate dynamic groups:

Steps

1. To enumerate any schema differences between the Directory Server Enterprise Edition (DSEE) deployment and the Ping Identity deployment, run the `migrate-ldap-schema` tool.

2. To enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment, run the `migrate-sun-ds-config` tool.
3. Import or configure any necessary schema and configuration changes recorded by the tools used in steps 1 and 2.
4. Import the existing users and groups using the `import-ldif` tool.

## Working with Indexes

---

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the directory information tree (DIT).

Indexes are associated with attributes and stored in database index files, which are managed separately for each base distinguished name (DN) in the Directory Server.

### Overview of indexes

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the directory information tree (DIT).

Indexes are associated with attributes and stored in database index files, which are managed separately for each base distinguished name (DN) in the Directory Server. The Directory Server automatically creates index files when you initialize a base DN or run the `dsconfig` tool to create a local DB backend. During modify operations, the Directory Server updates the database index files.

#### Note:

If you enable encryption on the server, indexes will be encrypted.

The PingDirectory Server comes with the following types of indexes:

#### Default system indexes

Ensures that the server operates efficiently. Indexes consist of database files that contain index keys mapping to the list of entry IDs.

#### Default Local DB indexes

Created for each database suffix. Modify the index to meet your system's requirements using the `dsconfig` tool.

#### Local DB VLV indexes

Allows a client to request the server to send search results using the virtual list view (VLV) control.

#### Filtered Indexes

Provides the ability to index an attribute, but only for entries that match a specified filter based on an equality index. You can only use the filtered index for searches containing your specified filter. The filtered index can be maintained independently of the equality index for the attribute even if a normal equality index is not maintained for the attribute.

## General tips on indexes

### Important critical indexes

The Directory Server has several built-in indexes on the local DB backend that are critical to internal server processing and should never be removed.

```
aci, ds-entry-unique-id, objectClass
```

## Built-in indexes for efficient queries

The Directory Server has built-in indexes on the local DB backend. Internal processing of the server relies on the `aci`, `ds-soft-delete-from-dn`, `ds-soft-delete-timestamp`, `entryUUID`, `member`, `objectClass`, and `uniqueMember` indexes, which must not be removed. You can remove the `mail` and `uid` indexes, but these attributes are referenced from the Password Modify Extended Operation and their removal causes problems with components, such as the Exact Match Identity Mapper. If you remove the `mail` or `uid` indexes, additional configuration changes might be necessary to ensure that the server starts properly. You can safely remove the `cn`, `givenName`, `mail`, `sn`, and `telephoneNumber` indexes if clients do not query on these attributes. This reduces the size of the database both on disk and in memory.

## Online rebuilds

When an online index rebuild is in progress, the data in that backend is available and writable although the index being rebuilt is not used. Searches that attempt to use that attribute might be unindexed.

## Index rebuild administrative alert

The Directory Server generates an administrative alert when the rebuild process begins and ends. It has a degraded-alert-type of `index-rebuild-in-progress` so that a Directory Proxy Server, such as the Directory Server can avoid using that server while the rebuild is in progress.

## System indexes cannot be rebuilt

The contents of the backend must be exported and re-imported in order to rebuild system indexes. For more information, see the list of [System indexes](#) on page 625.

## Indexing certain attributes

Ensure that the following recommendations are used when setting up the indexes:

- Do not use equality and substring indexes for attributes that contain binary data.
- Avoid approximate indexes for attributes containing numbers, such as telephone numbers.

## Unindexed searches

Unindexed attributes result in longer search times as the database itself has to be searched instead of the database index file. Only users with the `unindexed-search` privilege are allowed to carry out unindexed searches. In general, you should prevent applications from performing unindexed searches so that searches that are not indexed would be rejected rather than tying up a worker thread. Ways to achieve this include the following:

- Make sure that only the absolute minimum set of users have the `unindexed-search` privilege. This privilege can be used without any other restrictions.
- To allow unindexed searches with some control, the Permit Unindexed Search request control can be used with the `unindexed-search-with-control` privilege. With this privilege, a user is only permitted to request an unindexed search if the search request includes the Permit Unindexed Search request control. The `unindexed-search` privilege allows a client to request an unindexed search without this control.
- You can use the Reject Unindexed Search request control to explicitly indicate that a client does not want the server to process an unindexed search request, regardless of privileges. For information about these controls, see the LDAP SDK. These capabilities are also available with the `ldapsearch` tool.
- Make sure that `allow-unindexed-searches` property is set to `false` in all client connection policies, in which unindexed searches should never be necessary. If the client connection policy should allow unindexed searches, set the `allow-unindexed-searches-with-control` property to `true`. If `allow-unindexed-searches` is `false` but, `allow-unindexed-searches-with-control` is

true, the policy only permits an unindexed search if the request includes the Permit Unindexed Search request control. For more information, see the LDAP SDK and the `ldapsearch` tool.

- Set a nonzero value for the `maximum-concurrent-unindexed-searches` global configuration property to ensure that if unindexed searches are allowed, only a limited number of them are active at any given time. Administrators can configure the maximum number of concurrent unindexed searches by setting a property under Global Configuration.

To change the maximum number of concurrent unindexed searches, use the `dsconfig` tool to set a value for the number. A default value of "0" represents no limit on the number of concurrent unindexed searches.

```
$ bin/dsconfig set-global-configuration-prop \
  --set maximum-concurrent-unindexed-searches:2
```

### Index entry limit

The Directory Server specifies an index entry limit property. This property defines the maximum number of entries that are allowed to match a given index key before it is no longer maintained by the server. If the index keys have reached this limit (default value is 4000), then you must rebuild the indexes using the `rebuild-index` tool. If an index entry limit value is set for the local DB backend, it overrides the value set for the overall JRE backend index entry limit configuration, such as 4000.

To change the default index entry limit, use the `dsconfig` tool, as in the following example.

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name cn --set index-entry-limit:5000
```

### Rebuild index vs. full import

Expect a limited amount of database growth due to the existence of old data when running `rebuild-index` versus doing a full import of your database.

## Index types

PingDirectory Server supports several types of indexes to quickly find entries that match search criteria in LDAP operations.

### Entry IDs

Directory Server uses an attribute's matching rules to normalize its values and uses those values as index keys to a list of matching entry IDs.

Entry IDs are integer values that are used to uniquely identify an entry in the backend by means of a set of database index files.

Entry IDs can look like the following:

- `id2entry`
- `dn2id`
- `dn2uri`
- `id2children`
- `id2subtree`

### Index types

Matching rules are elements defined in the schema that tell the server how to interact with the particular attribute. For example, the `uid` attribute has an equality matching rule and thus has an equality index maintained by the Directory Server. The following table describes the index types.

## Directory Server Index Types

Index Type	Description
Approximate	Used to efficiently locate entries that are approximately equal to a given assertion. Approximate indexes can only be applied to attributes that have a corresponding approximate matching rule.
Equality	Used to efficiently locate entries are exactly equal to a given assertion. Equality indexes can only be applied to attributes that have a corresponding equality matching rule.
Filtered	Uses a defined search filter for a specific attribute. This is an offshoot of the equality index, but you can maintain it independently of the equality index for a specific attribute.
Ordering	Used to efficiently identify which entries have a relative order of values for an attribute. Ordering indexes can only be applied to attributes that have a corresponding ordering matching rule.
Presence	Used to efficiently locate entries that have at least one value for a specified attribute. There is only one presence index key per attribute.
Substring	Used to efficiently locate entries that contain specific substrings to a given assertion. Substring indexes can only be applied to attributes that have a corresponding substring matching rule.

## System indexes

PingDirectory Server contains a set of system database index files that ensure that the server operates efficiently. These indexes cannot be modified or deleted.

### System Indexes

Index	Description
dn2id	Allows quick retrieval of distinguished names (DNs). The <code>dn2id</code> database has one record for each entry. The key is the normalized entry DN and the value is the entry ID.
id2entry	Allows quick retrieval of entries. The <code>id2entry</code> database contains the LDAP entries. The database key is the entry ID and the value is the entry contents.
referral	Allows quick retrieval of referrals. The referral database called <code>dn2uri</code> contains URIs from referral entries. The key is the DN of the referral entry and the value is that of a labeled URI in the <code>ref</code> attribute for that entry.
id2children	Allows quick retrieval of an entry and its children. The <code>id2children</code> database provides a mapping between an entry's unique identifier and the entry unique identifiers of the corresponding entry's children.
id2subtree	Allows quick retrieval of an entry's subtree. The <code>id2subtree</code> database provides a mapping between an entry's unique identifier and the unique identifiers in its subtree.

## Viewing the system indexes

### Steps

- To view the system and user indexes, use the `dbtest` command.

Example:

```
$ bin/dbtest list-index-status --baseDN dc=example,dc=com --backendID
userRoot
```

The index status indicates whether or not an index is trusted. An untrusted index requires rebuilding.

## Managing local DB indexes

To modify the local database (DB) indexes to meet your system's requirements, use the `dsconfig` tool. If you are using the `dsconfig` tool in interactive command-line mode, access the **Local DB Index** menu from the **Basic object** menu.

### Viewing the list of local DB indexes

#### Steps

- To view the default list of indexes, run `dsconfig` with the `list-local-db-indexes` option.

Example:

```
$ bin/dsconfig list-local-db-indexes --backend-name userRoot
```

Result:

Local DB Index	: Type	: index-type
aci	: generic	: presence
cn	: generic	: equality, substring
ds-entry-unique-id	: generic	: equality
givenName	: generic	: equality, substring
mail	: generic	: equality
member	: generic	: equality
objectClass	: generic	: equality
sn	: generic	: equality, substring
telephoneNumber	: generic	: equality
uid	: generic	: equality
uniqueMember	: generic	: equality

### Viewing a property for all local DB indexes

#### Steps

- To view a property assigned set for all local DB indexes, run `dsconfig` with the `--property` option.

Repeat the option for each property that you want to list.

Example:

In this example, the `prime-index` property specifies if the backend is configured to prime the index at startup.

```
$ bin/dsconfig list-local-db-indexes --property index-entry-limit \
--property prime-index --backend-name userRoot
```

## Viewing the configuration parameters for local DB index

### Steps

- To view the configuration setting of a local DB index, run **dsconfig** with the `get-local-db-index-prop` option and the `--index-name` and `--backend-name` properties.

#### Tip:

To view the advanced properties, add the `--advanced` option to your command.

#### Example:

```
$ bin/dsconfig get-local-db-index-prop --index-name aci \
  --backend-name userRoot
```

## Modifying the configuration of a local DB index

### About this task

To modify an index, run the **dsconfig** tool. Any modification or addition of an index requires rebuilding the indexes. In general, an index only needs to be built once after it has been added to the configuration.

#### Note:

If you add an index and then import the data using the **import-ldif** tool, the index is automatically rebuilt. If you add an index and then add the data using a different method, you must rebuild the index using the **rebuild-index** tool.

### Steps

- To modify an index, run **dsconfig** with the `set-local-db-index-prop` option and the `--index-name` and `--backend-name` properties.

#### Example:

This example updates the `prime-index` property, which loads the index at startup. To access this command, use the `--advanced` option.

```
$ bin/dsconfig set-local-db-index-prop --index-name uid \
  --backend-name userRoot --set prime-index:true
```

- To view the index and verify the change, run **dsconfig** with the `get-local-db-index-prop` option.

#### Example:

```
$ bin/dsconfig get-local-db-index-prop --index-name uid \
  --backend-name userRoot
```

3. Stop the Directory Server.

**Note:**

Although you can rebuild an index with the server online, it is not recommended. For more information, see [General tips on indexes](#) on page 622.

Example:

```
$ bin/stop-server
```

4. To rebuild the index, run the **rebuild-index** tool.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index uid
```

5. Restart the Directory Server.

Example:

```
$ bin/start-server
```

## Creating a new local DB index

### Steps

1. To create a new local DB index, run **dsconfig** with the `--create-local-db-index` option and the `--index-name`, `--backend-name`, and `--set index-type:<value>` options.

Example:

```
$ bin/dsconfig create-local-db-index \
  --index-name roomNumber --backend-name userRoot \
  --set index-type:equality
```

2. To view the index, run **dsconfig** with the `get-local-db-index-prop` option.

Example:

```
$ bin/dsconfig get-local-db-index-prop \
  --index-name roomNumber --backend-name userRoot
```

3. Stop the Directory Server.

**Note:**

Although you can rebuild an index with the server online, it is not recommended. For more information, see [General tips on indexes](#) on page 622.

Example:

```
$ bin/stop-server
```

4. To rebuild the index, run the **rebuild-index** tool.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index roomNumber
```

## 5. Restart the Directory Server.

Example:

```
$ bin/start-server
```

### Deleting a local DB index

About this task

Check that no plugin applications are using the index before deleting it.

#### Note:

When the index is deleted, the corresponding index database is also deleted. The disk space is reclaimed after the cleaner threads begin.

Steps

- To remove an index from the database, run **dsconfig** with the `delete-local-db-index` option.

Example:

```
$ bin/dsconfig delete-local-db-index \
  --index-name roomNumber --backend-name userRoot
```

### Composite indexes

A PingDirectory Server composite index can generate from multiple pieces of information, such as a combination of multiple filter components or a combination of filter components and a base distinguished name (DN), or from a single piece of information.

#### Note:

Because composite indexes are much more efficient than exploded indexes when dealing with large numbers of identical keys, use composite indexes for data sets where large numbers of entries (several thousand or more) share the same value for an indexed attribute.

To improve the performance of searches in directories with a large number of entries, especially with a large number of non-leaf entries, use equality composite indexes to combine a mandatory equality filter pattern with an optional base DN pattern.

Equality composite indexes offer two advantages over existing equality attribute indexes in the these types of deployments, a base DN pattern and index pages.

Base DN pattern

If a directory environment has many branches, but searches are often done within specific individual branches, use the base DN pattern to make search processing more efficient. The server only needs to search entries within a target branch.

For example, if the directory contains an `"ou=Customers,dc=example,dc=com"` branch with separate branches below that for sets of customers, such as `"ou=ACME,ou=Customers,dc=example,dc=com"` and `"ou=SHOPCO,ou=Customers,dc=example,dc=com"`, you can define a composite index with a filter pattern of `"(sn=?)"` and a base DN pattern of `"ou=?,ou=Customers,dc=example,dc=com"`. Then use a search with a filter of `"(sn=Smith)"` and a base DN of `"ou=ACME,ou=Customers,dc=example,dc=com"` to narrow the search to the Smiths in the ACME branch.

## Index Pages

If many entries have the same value for a specific attribute, you can use composite indexes to break large ID sets up across multiple pages, unlike a traditional attribute index.

Using the previous example, if a search of the directory returns 50,000 Smiths, the results can be served in blocks of 5,000 IDs. An attribute index returns either:

- One Smith record whose value is a block that contains all 50,000 of the matching entry IDs when the index isn't exploded.

### Note:

The exploded form is efficient for writing, for example, adding or removing a Smith involves just that one entry ID, but it is expensive for searching because it takes 50,000 reads to get all entry IDs for all of the Smiths.

- 50,000 Smith records that each have a value of the matching entry ID when the index is exploded.

### Note:

The non-exploded form is efficient for searching because all of the entry IDs return in a single read, but it is expensive for writing. If a Smith must be added or removed, the entire block of 50,000 entry IDs must be rewritten.

Composite indexes break up the block of entry IDs across multiple pages, a page size of up to 5000. If the directory contains 50,000 Smiths, instead of having to choose between one block of 50,000 IDs or 50,000 blocks of one ID, the composite index returns 10 blocks of 5,000 IDs. This improves the efficiency of a read or write across many entries.

There is little performance overhead to the paging mechanism. Use an equality composite index for an attribute that has a lot of entries that have the same value, such as `givenName` or `sn`. Do not use an equality composite index for an attribute with very few entries with the same value, such as `id` or `mail`. For attributes in which all of the values match a small number of entries, use an equality attribute index.

## Rebuilding indexes

When rebuilding specific non-attribute indexes, it is important to include any appropriate prefixes or postfixes with the index name to avoid errors.

- To rebuild a composite index, use the **rebuild-index** tool. The index name must be preceded by `composite`.

```
bin/rebuild-index --index composite.thisIndexName
```

### Note:

For the exact name to use in rebuilding the index, run the **dbtest** tool with the `list-database-containers` option and `--backendID` property.

```
bin/dbtest list-database-containers --backendID {backendID}
```

Define the following properties when configuring a composite index.

Composite Index Properties	Description
<code>index-filter-pattern</code> (required)	Specifies a single-valued filter property used to identify a portion of the index criteria. You can only specify this at the time that the index definition is created.
<code>index-base-dn-pattern</code> (optional)	Specifies a single-valued DN property that indicates that the index is scoped to a specific subtree or subtree pattern. You can only specify this at the time the index definition is created.

## JSON indexes

JSON indexing is similar to general attribute indexing. Where a general attribute can be indexed several ways and requires a separate database for each index type, with JSON indexing, there is a single database for each JSON field to use for different JSON filter types.

This database primarily behaves like the database for an equality attribute index. Each database entry key is the normalized form for a value for the target JSON field. The corresponding database entry value is a list of the entry IDs for all entries in which the associated attribute type has a JSON object with that value for the target field. The database is configured with a comparator based on the data type for the target field that enables iterating through values in a logical order to facilitate inequality and subinitial searches.

When the JSON field constraint indicates to index a JSON field, JSON indexes are automatically created. View indexes with the following command.

```
$ bin/dbtest list-index-status \
  --backendID userRoot \
  --baseDN dc=example,dc=com
```

The JSON object filter types that can be enhanced through the use of JSON indexes include:

### `equals`

Identifies entries that have a specific value for the target field. This filter type only requires retrieving a single index key. Depending on the nature of the search filter, the ID list might contain references to entries that do not actually match the filter, such as if the field is a string and if the filter is configured to use case-sensitive matching.

### `equalsAny`

Identifies entries that have a specified set of values for the target field. This filter type only requires retrieving the index keys that correspond to the target values in the filter and merging their ID lists.

### `greaterThan/lessThan`

Identifies entries that have at least one value for the target field that is greater or less than (or possibly equal to) a specified value. This index is similar in use to the `containsField` index, but it only needs to iterate through a subset of the keys. A filter can contain both `greaterThan` and `lessThan` filters to represent a bounded range.

### `substring`

Identifies entries that have a string value for the target field that matches a given `substring`. The index can only be used for substring filters that include a `subInitial` component. In this case, the server iterates through all of the index keys that match the `startsWith` component and manually compares values against the remainder of the substring assertion.

JSON indexing is available in local database backends backed by Berkeley DB Java Edition. This includes:

- Add, delete, modify, and modify distinguish name (DN) operations that make changes to JSON objects stored in the server.
- LDIF imports that include JSON objects, including updates to the cache size estimates for the JSON indexes.
- The **rebuild-index** tool and corresponding backend code make it possible to generate and rebuild indexes for JSON data. It must be possible to build all JSON indexes for all or a specified subset of fields associated with a given attribute type. The **verify-index** tool also works with JSON indexes to make it possible to check their validity.
  - When rebuilding a JSON index with the **rebuild-index** tool, the attribute name must be followed by `.json`. Optionally, you can also add `.<fieldName>`, where `<fieldName>` is replaced by the name of the JSON field.

```
bin/rebuild-index --index <attributeName>.json.<fieldName>
```

**Note:**

For the exact name to use in rebuilding the index, run the **dbtest** tool with the `list-database-containers` option and `--backendID` property.

```
bin/dbtest list-database-containers --backendID {backendID}
```

- Matching entry count control and `debugsearchindex` return attribute provide information about relevant JSON index usage.
- Support for monitoring index content and usage.

**Note:**

Exploded indexes and the entry balancing global index do not support JSON objects.

## Working with local DB VLV indexes

Local database (DB) virtual list view (VLV) indexes allow a client to request a subset of results from a sorted list that match a specific search base, scope, and filter.

The client can navigate through the list by passing a context back to the server with the virtual list view control. The local DB VLV index can be used only when the client request contains the VLV control and the client has been authorized with an access control instruction (ACI) with a `targetcontrol` of `2.16.840.1.113730.3.4.9`.

**Note:**

A client request, which includes a virtual list view control, can be successfully processed without a matching local DB VLV index if the search is completely indexed. This is not an efficient means of using VLV since the server has to retrieve each entry twice.

## Viewing the list of local DB VLV indexes

### Steps

- To view the default list of indexes, use **dsconfig** with the `list-local-db-indexes` option.

Example:

In this example, no VLV indexes are defined.

```
$ bin/dsconfig list-local-db-ylv-indexes --backend-name userRoot
```

## Creating a new local DB VLV index

### Steps

- Use **dsconfig** with the `create-local-db-ylv-index` option and the `--index-name`, `--backend-name`, and `--set index-type:(propertyValue)` options.

#### Note:

If you do not set any property values, the default values are assigned.

Example:

```
$ bin/dsconfig create-local-db-ylv-index \
  --index-name givenName --backend-name userRoot --set base-
dn:dc=example,dc=com \
  --set scope:whole-subtree --set filter:"(objectclass=*)" \
  --set sort-order:givenName
```

- Rebuild the index using the **rebuild-index** tool.

#### Note:

You must add the `ylv.` prefix to the index name to rebuild the VLV index.

Example:

The following command can be run with the server on or offline with the addition of the `--task` and `connection` options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index vlv.givenName
```

## Modifying a VLV index's configuration

### Steps

- Use **dsconfig** with the `set-local-db-ylv-index-prop` option and the `--index-name` and `--backend-name` properties.

Example:

In this example, update the `base-dn` property.

```
$ bin/dsconfig set-local-db-ylv-index-prop --index-name givenName \
  --backend-name userRoot --set base-dn:ou=People,dc=example,dc=com
```

2. Rebuild the index using the **rebuild-index** tool.

**Note:**

You must add the prefix `vlv.` to the index name.

**Example:**

The following command can be run with the server on or offline with the addition of the `--task` and connection options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index vlv.givenName
```

### Rebuilding a VLV index

When rebuilding specific non-attribute indexes, it is important to include any appropriate prefixes or postfixes with the index name to avoid errors.

#### Steps

- When rebuilding a VLV index with the **rebuild-index** tool, the index name must be preceded by `vlv.`

```
bin/rebuild-index --index vlv.thisIndexName
```

**Note:**

For the exact name to use in rebuilding the index, run the **dbtest** tool with the `list-database-containers` option and `--backendID` property.

```
bin/dbtest list-database-containers --backendID {backendID}
```

### Deleting a VLV index

#### About this task

Delete a VLV index using the **dsconfig** tool. Before deleting it, check that the index is not being used in any plugin applications.

#### Steps

1. To remove a VLV index from the database, use **dsconfig** with the `delete-local-db-vlv-index` option.

**Example:**

```
$ bin/dsconfig delete-local-db-vlv-index --index-name givenName \
  --backend-name userRoot
```

2. To verify the deletion, try to view the VLV index.

**Example:**

```
$ bin/dsconfig get-local-db-vlv-index-prop --index-name givenName \
  --backend-name userRoot
```

## Working with filtered indexes

The PingDirectory Server filtered index is useful when client search requests consisting of a compound & filter with individual components matching a large number of entries, potentially greater than the index entry limit, have an intersection of a relatively small number of entries.

### About this task

Filtered indexing is primarily useful for cases in which clients frequently issue searches with & filters that meet the following criteria:

- The & filter itself matches a small number of entries, but each of the individual components can match a large number of entries.
- The filter has a dynamic component that does change, and that dynamic component always uses the same attribute.
- The filter has a static component that does not change.
- The filter must be narrowed to a base distinguished name (DN) for data structures with many branches or if indexed attribute values appear in a large number of entries.

For an example, consider the following use case process. A database contains several thousand company profiles and each company profile is represented by many entries. The `(objectClass=company)` filter matches a small set of entries per company and can exceed the index entry limit because there are many companies. Also, the `(companyDomain=example.com)` filter matches many of the entries for the company with domain `example.com` and can also result in an unindexed search. The more narrow filter `(&(objectClass=company)(companyDomain=example.com))` also results in an unindexed search but only matches a small number of entries. The filtered index makes it possible to index this compound filter by defining an equality index on the `companyDomain` attribute with a static filter of `(objectClass=company)` in the `equality-index-filter` property of the index.

When configuring a filtered index, define the following properties.

### Filtered Index Properties and their descriptions

Filtered Index Properties	Description
<code>equality-index-filter</code>	Specifies a search filter that can be used in conjunction with an equality component for the associated attribute type. If an equality index filter is defined, then an additional equality index is maintained for the associated attribute, but only for entries that match the provided filter. The index is used only for searches containing an equality component with the associated attribute type used with this filter.
<code>maintain-equality-index-without-filter</code>	Specifies whether to maintain a separate equality index for the associated attribute without any filter, in addition to maintaining an index for each equality index filter that is defined. If this is false, then the attribute does not indexed for equality by itself but only in conjunction with the defined equality index filters.

### Steps

- Define the `equality-index-filter` filter index property.
- Define the `maintain-equality-index-without-filter` filter index property.

#### Note:

Maintain the filtered index independently from the equality filter for that attribute. Use the filtered index only for searches containing the equality component with the associated attribute type used with this

filter. When configuring a filtered index, be aware of the **equality-index-filter** and **maintain-equality-index-without-filter** properties of the index.

#### Result:

The searches are configured and built with the **rebuild-index** tool or **import-ldif** tool.

This example shows the result of searches built with filters based on the use case process described above with the following index.

```
(&(objectClass=company)(companyDomain=example.com))
(&(objectClass=company)(|(companyDomain=example.com)
(companyDomain=example.org)))
(&(companyDomain=example.com)(objectClass=company))
(&(companyDomain=example.com)(&(objectClass=company)))
(&(companyDomain=example.com)(objectClass=company)(something=else))
(&(companyDomain=example.com)(&(objectClass=company)(something=else)))
(|(&(objectClass=company)(companyDomain=example.com))
(&(objectClass=company)(companyDomain=example.org)))
```

## Creating a filtered index

### Steps

1. To create a filtered index, use the **dsconfig** tool.

The following command creates an equality index on the `companyDomain` attribute and maintains an index for the equality filter defined `"(objectclass=company)"`.

#### Example:

```
$ bin/dsconfig create-local-db-index --backend-name "userRoot" \
  --index-name companyDomain --set maintain-equality-index-without-
  filter:true \
  --set index-type:equality --set equality-index-
  filter:"(objectclass=company)"
```

2. After you have created the index, rebuild the indexes.
  - a. Stop the Directory Server using **bin/stop-server**.
  - b. Run the **rebuild-index** tool.

#### Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index companyDomain
```

3. Start the Directory Server using **bin/start-server**.

## Tuning indexes

The PingDirectory Server provides several tools to help you optimize your indexes and improve the overall read and write performance for your system.

To process high write load operations, the server supports an optional expanded index database using an exploded format. To view the current state of the server's indexes and make adjustments to the index databases, the Directory Server automatically generates an Index Summary Statistics table after each LDIF import or index rebuild. To determine the key data size for the indexes, the **dbtest** tool includes an index histogram. This section describes each of these tools.

### About the exploded index format

The `index-entry-limit` backend configuration property specifies the maximum number of entries kept in an index record before the server stops maintaining that record, begins scanning the whole database, and runs an expensive unindexed search.

#### Note:

Because composite indexes are much more efficient than exploded indexes when dealing with large numbers of identical keys, use composite indexes for data sets where large numbers of entries (several thousand or more) share the same value for an indexed attribute.

If any index keys have already reached this limit, you must rebuild these indexes before they can use a new limit. If you configure `index-entry-limit` to be greater than 50000, any keys with more than 50000 entries are stored in a separate database in an expanded, or exploded, format.

All keys with less than 50000 entries continue to be stored in one database in a consolidated format so that changes to the key require rewriting all the entry IDs matching the key. All keys with more than 50000 entries and less than the `index-entry-limit` are stored in a separate database in an exploded format so that changes to the key require writing to the updated entry ID only.

If you increase the `index-entry-limit` to 100000, any key with an entry count less than 50000 continues to be stored in consolidated format. If a key has an entry count greater than 50000, it is stored in a separate database where each key is stored with its entry ID individually. The consolidated format is efficient for read operations because the server can retrieve a row of entry IDs at once, while the exploded format is efficient for high volumes of write operations because it avoids large on-disk growth.

### About monitoring index entry limits

Index keys that have reached their limit require indexes to be rebuilt before they can use a new limit. To avoid a potentially costly rebuild, there are several ways to monitor index limits.

In certain cases, it's acceptable for index keys to exceed the index entry limit. For example, the `objectClass` attribute type should be indexed for equality because the server needs to use it to find all group entries when bringing a backend online, and applications frequently need to find entries of a specific type. However, the top `objectClass` key doesn't need to be indexed because it appears in every entry in the server.

Select an index entry limit value that is high enough to ensure that all of the right keys are indexed, but keys that occur too frequently are not. The `--listKeysNearestIndexEntryLimit` argument of the `verify-index` tool lists a specified number of keys that are closest to the limit without having exceeded it. Make the index entry limit larger than the number of entries matching the largest key to remain indexed, with enough overhead to account for future growth. Use this command regularly to determine if you need to adjust the index entry limit needs to be adjusted.

The `--listKeysExceedingIndexEntryLimit` argument of the `verify-index` tool lists all keys for which the value has exceeded the index entry limit and the number of entries in which they appear. If there are keys for which the limit has been exceeded that need to be maintained, adjust the index entry limit to be higher than the number of entries that contain that key, with additional room for future growth. Then, run the `rebuild-index` tool or export to LDIF and re-import.

The server provides other methods for determining if index keys have exceeded or are close to exceeding the index entry limit, including:

- When performing an LDIF import, the tool includes an Index Summary Statistics section that provides usage information for each index, including:
  - The number of keys for which the index entry limit has been exceeded.
  - The number of keys for which the number of matching entries falls within a number of predefined buckets, such as 1–4 entries, 5–9 entries, 10–99 entries, and 100–999 entries.

and

- During a search operation, if the server accesses one or more index keys whose values have exceeded the index entry limit, the access log message for that operation includes an `indexesWithKeysAccessedExceedingEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field can appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to, or tried to write to, at least one index key whose value exceeded the index entry limit.
- During a search operation, if the server accesses one or more index keys whose values have not yet exceeded the index entry limit but are greater than 80 percent of it, the access log message for that operation includes an `indexesWithKeysAccessedNearEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field can appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to at least one index key whose value was within 80% of the index entry limit.
- If a search operation request includes either the `debugsearchindex` attribute or the matching entry count request control with debugging enabled, the debug information includes any indexes accessed that have exceeded the index entry limit or that are within 80% of the configured index entry limit.
- The monitor entry for each configured index includes attributes that provide information about the number of index keys that have been encountered since the backend was brought online, or since the index entry limit was changed in a number of different categories. These monitor attributes include:

`ds-index-exceeded-entry-limit-count-since-db-open`

The number of index keys for which the number of matching entries has crossed the index entry limit due to a write operation.

`ds-index-unique-keys-near-entry-limit-accessed-by-search-since-db-open`

The number of unique index keys that have been accessed by a search operation for which the number of matching entries is within 80% of the index entry limit.

`ds-index-unique-keys-exceeding-entry-limit-accessed-by-search-since-db-open`

The number of unique index keys that have been accessed by a search operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.

`ds-index-unique-keys-near-entry-limit-accessed-by-write-since-db-open`

The number of unique index keys that have been accessed by a write operation for which the number of matching entries is within 80% of the index entry limit.

`ds-index-unique-keys-exceeding-entry-limit-accessed-by-write-since-db-open`

The number of unique index keys that have been accessed by a write operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.

### About the `dbtest` Index Status table

The `dbtest` tool has a `list-all --analyze` option that generates the current status of all of the databases on your system, including all index databases.

The table shows the following information:

- Type
- Entry count (the number of records in the database)
- Index status
  - `TRUSTED` indicates the indexes are up-to-date.
  - `UNTRUSTED` indicates the index needs rebuilding.
- Each key's total data size
- Each key's average data size

- Each key's maximum data size

#### Note:

Any indexes that are in exploded format are also listed in this table.

Index Name	Index Type	JE Database Name	Index Status
id2children	Index	dc_example_dc_com_id2children	TRUSTED
id2subtree	Index	dc_example_dc_com_id2subtree	TRUSTED
uid.equality	Index	dc_example_dc_com_uid.equality	TRUSTED
aci.presence	Index	dc_example_dc_com_aci.presence	TRUSTED
ds-soft-delete-timestamp.ordering	Index	dc_example_dc_com_ds-soft-delete-timestamp.ordering	TRUSTED
ds-soft-delete-from-dn.equality	Index	dc_example_dc_com_ds-soft-delete-from-dn.equality	TRUSTED
givenName.equality	Index	dc_example_dc_com_givenName.equality	TRUSTED
givenName.substring	Index	dc_example_dc_com_givenName.substring	TRUSTED
objectClass.equality	Index	dc_example_dc_com_objectClass.equality	TRUSTED
member.equality	Index	dc_example_dc_com_member.equality	TRUSTED
uniqueMember.equality	Index	dc_example_dc_com_uniqueMember.equality	TRUSTED
cn.equality	Index	dc_example_dc_com_cn.equality	TRUSTED
cn.substring	Index	dc_example_dc_com_cn.substring	TRUSTED
sn.equality	Index	dc_example_dc_com_sn.equality	TRUSTED
sn.substring	Index	dc_example_dc_com_sn.substring	TRUSTED
telephoneNumber.equality	Index	dc_example_dc_com_telephoneNumber.equality	TRUSTED
mail.equality	Index	dc_example_dc_com_mail.equality	TRUSTED
ds-entry-unique-id.equality	Index	dc_example_dc_com_ds-entry-unique-id.equality	TRUSTED

### dbtest output including index databases

#### Configuring the index properties

By default, the `index-entry-limit` value is 4000, meaning the server stops maintaining index values for keys that match more than 4000 entries. You can change the value with the `dsconfig` tool.

#### About this task

Before running the following commands, be aware that you must do an index rebuild on the system, which requires a system shutdown unless the command is run as a task.

To configure the index properties:

#### Steps

1. Run `dsconfig` with the `set-backend-prop` subcommand.
2. Set the `index-entry-limit` to 5000. Confirm that you want to apply the changes.

By default, this value is set to 4000.

#### Note:

Remember to include the bind parameters for your system.

#### Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set index-entry-limit:5000 \
  One or more configuration property changes require administrative action
  or confirmation/notification. Those properties include:
  * index-entry-limit: If any index keys have already reached this limit,
  indexes must be rebuilt before they will be allowed to use the new limit.
  Setting a large limit (greater than 10,000) could have a big impact on
```

```
write performance and database growth on disk.
Continue? Choose 'no' to return to the previous step (yes / no) [yes]:
yes
```

### 3. Stop the server.

Example:

```
$ bin/stop-server
```

### 4. Rebuild the index.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com \
  --index cn --index givenName --index objectClass \
  --index sn --maxThreads 10
```

### 5. View the Index Summary Statistics table, which automatically displays to system out after running the `rebuild-index` command.

You can also access the table at `logs/tools/rebuild-index-summary.txt`.

Example:

```
--- Index Summary Statistics ---
Index : Limit : >Limit : Max : 1-9 : 10-99 : 100-999 : 1000-9999 : 10000-99999 : 100000-999999
-----
dc_example_dc_com_cn.equality : 5000 : 9 : 1 : 100001 : : : : : :
dc_example_dc_com_cn.substring : 5000 : 9 : 15401 : 131746 : 22372 : 545 : 39 : 3 : :
dc_example_dc_com_givenName.equality : 5000 : : 16 : 3788 : 4817 : : : : : :
dc_example_dc_com_givenName.substring : 5000 : 8 : 23809 : 7039 : 12062 : 483 : 42 : 3 : :
dc_example_dc_com_objectClass.equality : 5000 : 4 : 100003 : 3 : : : : : : 4
dc_example_dc_com_sn.equality : 5000 : : 8 : 13419 : : : : : : :
dc_example_dc_com_sn.substring : 5000 : 9 : 15401 : 33967 : 7055 : 459 : 39 : 3 : :

The first three columns of numbers provide (1) "Limit" - the index entry limit (or blank if there is no limit),
(2) ">Limit" - the number of keys whose entry count exceeds the entry limit, and (3) "Max" - the
maximum entry count for any key in the index. The remaining columns provide the number of keys
whose entry count falls in the range indicated in the column heading
```

### 6. Repeat steps 1-4 to make more adjustments to your indexes.

### 7. Restart the server.

Example:

```
$ bin/start-server
```

## About the Index Summary Statistics table

The Directory Server automatically generates an Index Summary Statistics table, which you can use to determine the optimal configuration for your system's indexes.

The table only generates when you run the `rebuild-index` tool in offline mode. The table generates after any LDIF import or an index rebuild. It is written to system out and to `logs/tools/rebuild-index-summary.txt`.

The table displays the following information:

- The current index entry limit set by the `index-entry-limit` property on the local database configuration
- The number of keys whose entry count exceeds this limit, if any
- The maximum entry count for any key in the index
- A histogram of the number of keys whose entry falls within a range of values

The following image is an example of the Index Summary Statistics table for the `sn.equality` and the `sn.substring` indexes.

In this figure, there are seven substrings whose entry counts exceed the `index-entry-limit` of 4000. Six of the substrings are in the 10000-99999 range with the maximum entry count being 13419. By deduction, one more substring must be present in the 1000-9999 range that exceeds the `index-entry-limit` of 4000. These substrings could be expensive for search operations.

```

--- Index Summary Statistics ---
Index      : Limit : >Limit : Max   : 1-9   : 10-99  : 100-999 : 1000-9999 : 10000-99999
-----
dc_example_dc_com_sn.equality : 4000 : 7       : 2     : 100000 : 13419  : 150814  : 7109   : 407    : 36     : 6
dc_example_dc_com_sn.substring : 4000 : 7       : 13419 : 150814 : 7109   : 407     : 36     : 6

```

### Example of an Index Summary Statistics Table

## Managing Entries

---

The Directory Server is a fully LDAPv3-compliant server that comes with a comprehensive set of LDAP command-line tools to search, add, modify, and delete entries.

### Searching entries

The Directory Server provides an `ldapsearch` tool to search for entries or attributes within your server.

The `ldapsearch` tool requires the LDAP connection parameters to bind to the server, including the `baseDN` option to specify the starting point of the search within the server, and the search scope. The `searchScope` option determines the depth of the search.

`base`

Searches only for the specified entry.

`one`

Searches only the children of the entry and not the entry itself.

`sub`

Searches the entry and its descendants.

The `ldapsearch` tool provides basic functionality specified by the RFC 2254 and provides additional features that use the Directory Server's control mechanisms.

#### Note:

For more information, run the `ldapsearch --help` function.

### Searching the root DSE

The root DSA-specific entry (DSE) is a special entry that resides at the root of the directory information tree (DIT). The entry holds operational information about the server and its supported controls.

About this task

Specifically, the root DSE entry provides information about the supported LDAP3 controls, Simple Authentication and Security Layer (SASL) mechanisms, password authentication schemes, supported LDAP protocols, additional features, naming contexts, extended operations, and server information.

The Directory Server provides an option to retrieve the Root DSE's operational attributes and add them to the user attribute map of the generated entry. This feature allows client applications that have difficulty handling operational attributes to access the root DSE using the `show-all-attributes` configuration property. After you set this property, the associated attribute types are recreated and re-registered as user attributes in the schema (in memory, not on disk). After you set the property, you can use `ldapsearch` without "+" to view the root DSE.

## Steps

1. To set the `show-all-attributes` property to `TRUE`, run the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-root-dse-backend-prop --set show-all-attributes:true
```

2. Run the `ldapsearch` tool to view the root DSE entry on the Directory Server.

### Note:

To display the operational attributes in the entry, use `+`.

Example:

```
$ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" "+"
```

## Searching all entries in the Directory Server

### Steps

- To search all entries in the Directory Server, run the `ldapsearch` tool.

### Note:

The filter `"(objectclass=*)"` matches all entries. If you do not specify the `--searchScope` subcommand, it defaults to a search scope of `sub`.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --searchScope sub "(objectclass=*)"
```

## Searching for an access control instruction

### Steps

- To search the `dc=example,dc=com` base distinguished name (DN) entry, run the `ldapsearch` tool.

### Note:

The filter `"(aci=*)"` matches all `aci` attributes under the base DN, and the `aci` attribute is specified so that only it is returned. The `cn=Directory Manager` bind DN has the privileges to view an access control instruction (ACI).

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(aci=*)" aci
```

Result:

The system displays the following ACI information.

```
dn: dc=example,dc=com
aci: (targetattr!="userPassword")
  (version 3.0; acl "Allow anonymous read access for anyone";
  allow (read,search,compare) userdn="ldap:///anyone";)
```

```
aci: (targetattr="*")
  (version 3.0; acl "Allow users to update their own entries";
   allow (write) userdn="ldap:///self");
aci: (targetattr="*")
  (version 3.0; acl "Grant full access for the admin user";
   allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

## Searching for the schema

### Steps

- To search the `cn=schema` entry, run the `ldapsearch` tool.

#### Note:

The base distinguished name (DN) is specified as `cn=schema`, and the filter `"(objectclass=*)"` matches all entries. The command uses a special attribute `+` to return all operational attributes.

#### Example:

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base "(objectclass=*)" "+"
```

## Searching for a single entry using base scope and base DN

### Steps

- To search for a single entry, run the `ldapsearch` tool and specify the base scope and DN.

#### Example:

```
$ bin/ldapsearch --baseDN uid=user.14,ou=People,dc=example,dc=com \
  --searchScope base "(objectclass=*)" "
```

## Searching for a single entry using the search filter

### Steps

- To search for a single entry, specify the `sub` scope and a search filter that describes a single entry.

#### Example:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub "(uid=user.14) "
```

## Searching for all immediate children for restricted return values

### Steps

- To search for all immediate children of restricted return values, run the `ldapsearch` tool.

#### Note:

The special attribute "+" returns all operational attributes.

#### Example:

In this sample, the immediate children are `ou=People,dc=example,dc=com`, and the restricted returned values are `sn` and `givenName`.

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope one '(objectclass=*)' sn givenName "+"
```

## Searching for all children of an entry in sorted order

### Steps

- To search for all children of an entry in the appropriate subtree, run the `ldapsearch` command. Choose from:
  - To sort the resulting entries by the server in ascending order, use `sn`.
  - To sort the orders in descending order, use `givenName`.

#### Example:

For this example, the `ldapsearch` command searches for children in the `ou=People,dc=example,dc=com` subtree.

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub --sortOrder sn,-givenName '(objectclass=*)'
```

## Limiting the number of returned search entries and search time

### Steps

- To search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree, specify a compound filter.

#### Example:

In the following example, no more than 200 entries will be returned and the server will spend no more than 5 seconds processing the request. Returned attributes are restricted to a few operational attributes.

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub --sizeLimit 200 --timeLimit 5 \
  "(&(sn<=Doe)(employeeNumber<=1000))" ds-entry-unique-id entryUUID
```

## Getting information about how indexes are used in a search operation

### Before you begin

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT).

## Steps

- To search for how indexes are used in a search operation, you can either:  
Choose from:
  - Issue a search request with the desired base distinguished name (DN), scope, and filter, and request that the server return the special `debugsearchindex` attribute using the `ldapsearch` command.

```
$ bin/ldapsearch --hostname ds.example.com \
--port 389 --bindDN uid=admin,dc=example,dc=com \
--bindPassword password \
--baseDN dc=example,dc=com \
--searchScope sub "(&(givenName=John)(sn=Doe))" debugsearchindex
dn: cn=debugsearch
debugsearchindex: 0.040 ms - Beginning index processing for search
    request with base DN 'dc=example,dc=com', scope wholeSubtree,
    and filter (&(givenName=John)(sn=Doe)).
debugsearchindex: 0.067 ms - Unable to optimize the AND filter
    beyond what the client already provided.
debugsearchindex: 0.834 ms - Candidate set obtained for single-key
    filter (givenName=John) from index
    dc_example_dc_com_givenName.equality.
    Candidate set: CandidateSet(isDefined=true, isExploded=false,
    isResolved=true, size=2, originalFilter=(givenName=John),
    remainingFilter=null, matchingEntryCountType=UNEXAMINED_COUNT)
debugsearchindex: 0.030 ms - Final candidate set for filter
    (givenName=John)
    obtained from an unexploded index key in
    dc_example_dc_com_givenName.equality.
    Since the scope of the search includes the entire entry
    container, there is
    no need to attempt to further pare down the results based on the
    search scope.
    Candidate set: CandidateSet(isDefined=true, isExploded=false,
    isResolved=true,
    size=2, originalFilter=(givenName=John), remainingFilter=null,
    matchingEntryCountType=UNEXAMINED_COUNT)
debugsearchindex: 0.020 ms - Short-circuiting index processing for
    AND filter
    (&(givenName=John)(sn=Doe)) after evaluating single-key component
    (givenName=John) because the current ID set size of 2 is within
    the
    short-circuit threshold of 5.
debugsearchindex: 0.030 ms - Obtained a candidate set of size 2 for
    AND filter
    (&(givenName=John)(sn=Doe)) with remaining filter (sn=Doe). Even
    though
    there is still more of the filter to evaluate, the current
    candidate set is
    within the short-circuit threshold of 5, so no additional index
    processing will
    be performed to try to pare down the results based on the
    remaining filter or the
    search scope. Candidate set: CandidateSet(isDefined=true,
    isExploded=false,
    isResolved=true, size=2, originalFilter=(&(givenName=John)
    (sn=Doe)),
    remainingFilter=(sn=Doe), matchingEntryCountType=UPPER_BOUND)
debugsearchindex: 0.016 ms - Completed all index processing.
Candidate set:
    CandidateSet(isDefined=true, isExploded=false, isResolved=true,
    size=2,
```

```
originalFilter=(amp(givenName=John)(sn=Doe)),
remainingFilter=(sn=Doe),
matchingEntryCountType=UPPER_BOUND)
```

 **Note:**

Users must have access to the **debugsearchindex** operational attribute and the **cn=debugsearch** portion of the DIT with the following command.

```
$ bin/dsconfig set-access-control-handler-prop \
--add "global-aci:(targetattr=\"debugsearchindex\") (target=\"ldap:///
cn=debugsearch\")
(version 3.0; acl \"Allow members of the Index Debugging Users
group
to request the debugsearchindex operational attribute \"; allow
(read,search,compare) groupdn=\"ldap:///cn=Index Debugging
Users,ou=Groups,dc=example,dc=com\");"
```

- Issue a search request with the desired base DN, scope, and filter, and include the matching entry count request control with the debug option set to **true** using **ldapsearch**.

```
$ bin/ldapsearch --hostname ds.example.com --port 389 \
--bindDN uid=admin,dc=example,dc=com --bindPassword password \
--baseDN dc=example,dc=com \
--searchScope sub --matchingEntryCountControl examineCount=0:debug
"(&(givenName=John)(sn=Doe))"
Upper Bound on Matching Entry Count: 2
Matching Entry Count Debug Messages:
* naw-desktop:1389 - 0.104 ms - Beginning index processing for search
request with
base DN 'dc=example,dc=com', scope wholeSubtree, and filter
(&(givenName=John)(sn=Doe)).
* naw-desktop:1389 - 0.105 ms - Unable to optimize the AND filter
beyond what the client already provided.
* naw-desktop:1389 - 0.614 ms - Candidate set obtained for single-key
filter (givenName=John) from index
dc_example_dc_com_givenName.equality. Candidate set:
CandidateSet(isDefined=true, isExploded=false, isResolved=true,
size=2, originalFilter=(givenName=John), remainingFilter=null,
matchingEntryCountType=UNEXAMINED_COUNT)
* naw-desktop:1389 - 0.090 ms - Final candidate set for filter
(givenName=John) obtained from an unexploded index key in
dc_example_dc_com_givenName.equality. Since the scope of the
search
includes the entire entry container, there is no need
to attempt to further pare down the results based on the search
scope.
Candidate set: CandidateSet(isDefined=true, isExploded=false,
isResolved=true,
size=2, originalFilter=(givenName=John), remainingFilter=null,
matchingEntryCountType=UNEXAMINED_COUNT)
* naw-desktop:1389 - 0.045 ms - Short-circuiting index processing for
AND filter
(&(givenName=John)(sn=Doe)) after evaluating single-key component
(givenName=John) because the current ID set size of 2 is within
the short-circuit threshold of 5.
* naw-desktop:1389 - 0.111 ms - Obtained a candidate set of size 2
for AND filter
(&(givenName=John)(sn=Doe)) with remaining filter (sn=Doe). Even
though there is
```

```

still more of the filter to evaluate, the current candidate set is
within
the short-circuit threshold of 5, so no additional index
processing will be performed
to try to pare down the results based on the remaining filter or
the search scope.
Candidate set: CandidateSet(isDefined=true, isExploded=false,
isResolved=true, size=2,
originalFilter=(&(givenName=John) (sn=Doe)),

* naw-desktop:1389 - The search is partially indexed
(candidatesAreInScope=true,
unindexedFilterPortion=(sn=Doe))
* naw-desktop:1389 - Constructing an UPPER_BOUND response with a
count of 2

```

## Working with the matching entry count control

You can use the `ldapsearch` command with the `--matchingEntryCountControl` option to determine the count of entries that match a search filter.

Users must be granted access to this control by its OID `1.3.6.1.4.1.30221.2.5.36` with the following command.

```

$ bin/dsconfig set-access-control-handler-prop \
--add "global-aci:(targetcontrol=\"1.3.6.1.4.1.30221.2.5.36\")
(version 3.0; acl \"Allow members of the Index Debugging Users group to
use the matching entry count request control \"; allow (read)
groupdn=\"ldap:///cn=Index Debugging Users,ou=Groups,dc=example,dc=com
\");)"

```

You can use an `examineCount` control for searches that are at least partially indexed to determine whether to return an examined count, an unexamined count, or an upper bound count. The following factors determine what is returned:

- A search is fully indexed if indexes can be used to identify the entry IDs for all entries that match the filter without ambiguity. You can also use indexes to make sure that all of those candidates are within the scope of the search.
- A search is partially indexed if you can use indexes to identify the entry IDs for all entries that match the search criteria.

### Note:

The candidate list might also include entries that either don't match the filter or are outside the scope of the search.

- A search is unindexed if it's not possible to retrieve a candidate list based on either the filter or the search scope.
- An unexamined count is a count of the exact number of entries that match the search criteria, only through the use of index processing.
- An examined count is the same as an unexamined count except that all of the candidate entries are examined to determine whether they would have been returned to the client. An examined count might

be less than an unexamined count if the set of matching entries includes those that would be removed by access control evaluation or special entries, such as LDAP sub-entries, replication conflict entries, or soft-deleted entries.

- An upper bound count is the maximum number of entries that match the criteria, but indicates that the server could not determine exactly how many matching entries there were without examining each candidate, which it doesn't do.
- If a search is fully indexed, the result is an examined count or an unexamined count. If **alwaysExamine** is true and **examineCount** is greater than or equal to the number of candidates, the result is an examined count. If **alwaysExamine** is false, or if the number of candidates exceeds **examineCount**, the result is an unexamined count.
- If a search is partially indexed, the result is either an examined count or an upper bound count. The **alwaysExamine** flag isn't relevant in this case. If **examineCount** is greater than or equal to the number of candidates, the result is an examined count. If not, the result is an upper bound count.
- If a search is unindexed, the result is either an examined count or an unknown count. If **allowUnindexed** is true, the unindexed search is processed, which can be very expensive. Instead of getting the matching entries back, the examined count is returned. If **allowUnindexed** is false, an unknown count is returned. If **allowUnindexed** is true, the requester needs to have the **unindexed-search** privilege to get the exact count.

### Example

The following example is a `ldapsearch` with the `--matchingEntryCountControl` option.

```
$. /ldapsearch \
  --bindDN "cn=directory manager" \
  --bindPassword password \
  --baseDN dc=example,dc=com \
  --matchingEntryCountControl
examineCount=100:alwaysExamine:allowUnindexed:debug \
  "(objectclass=*)" "
```

## Adding entries

Depending on the number of entries that you want to add to your Directory Server, you can use the `ldapmodify` tool for small additions.

The `ldapmodify` tool provides two methods for adding a single entry:

- Using an LDIF file
- Using the command line

The attributes must conform to your schema and contain the required object classes.

Adding requests with the **ignore-no-user-modification** control enables a client to include attributes that are not normally allowed from external sources, such as the **userPassword** attribute, which is a user-modifiable attribute. An add request with the **ignore-no-user-modification** control allows a one-time exception to the password policy, even if the requesting client does not have the **bypass-pw-policy** privilege. This exception enables specifying pre-encoded passwords.

### Note:

When adding an entry, the server can ensure that the entry's relative distinguished name (RDN) is unique and does not contain any sensitive information by replacing the provided entry's RDN with the server-generated `entryUUID` value. An LDAP client written with the LDAP SDK for Java can use the **NameWithEntryUUIDRequestControl** to explicitly indicate which add requests should be named in this way or the `ldapmodify` tool with the `--nameWithEntryUUID` argument.

The `auto-name-with-entry-uuid-connection-criteria` and `auto-name-with-entry-uuid-request-criteria` global configuration properties can be used to identify which add requests should be automatically named this way.

You can also use the uniqueness request control with `ldapmodify` for enforcing uniqueness on a per-request basis. Provide at least one of the `uniquenessAttribute` or `uniquenessFilter` arguments with the request. For more information about this control, see the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control.

### Adding an entry using an LDIF file

Use the `ldapmodify` tool to add an entry from an LDIF file.

#### Steps

1. Open a text editor and create an entry that conforms with your schema.

#### Note:

The Directory Server encrypts the password and stores its encrypted value in the server. Make sure that the LDIF file has limited read permissions for only authorized administrators.

#### Example:

The following example adds the entry in the file and saves the file as `add-user.ldif`. For the `userPassword` attribute, enter the cleartext password.

```
dn: uid=user.2000,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Toby Hall$73600 Mash Street$Cincinnati, OH 50563
  postalCode: 50563
description: This is the description for Toby Hall.
uid: user.2000
userPassword: wordsmith employeeNumber: 2000
initials: TBH
givenName: Toby
pager: +1 596 232 3321
mobile: +1 039 311 9878
cn: Toby Hall
sn: Hall
telephoneNumber: +1 097 678 9688
street: 73600 Mash Street
homePhone: +1 214 233 8484
l: Cincinnati
mail: user.2000@maildomain.net
st: OH
```

2. To add the entry specified in the LDIF file, run the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --defaultAdd --filename add-user.ldif
```

Result:

A confirmation message of the new addition appears. If the command is successful, you'll see generated success messages with the "#" symbol.

```
# Processing ADD request for uid=user.2000,ou=People,dc=example,dc=com
# ADD operation successful for DN
uid=user.2000,ou=People,dc=example,dc=com
```

## Adding an entry using the changetype LDIF directive

About this task

RFC 2849 specifies LDIF directives that you can use within your LDIF files. The most commonly used directive is `changetype`, which follows the `dn:` directive and defines the operation on the entry. The main advantage of using this method in an LDIF file is that you can combine `add` and `modify` in one file.

Steps

1. Open a text editor and create an entry that conforms with your schema.

Example:

This example uses `changetype: add` to add the following entry in the file and saves the file as `add-user2.ldif`.

```
dn: uid=user.2001,ou=People,dc=example,dc=com
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Seely Dorm$100 Apple Street$Cincinnati, OH 50563
postalCode: 50563
description: This is the description for Seely Dorm.
uid: user.2001
userPassword: pleasantry
employeeNumber: 2001
initials: SPD
givenName: Seely pager: +1 596 665 3344
mobile: +1 039 686 4949
cn: Seely Dorm
sn: Dorm
telephoneNumber: +1 097 257 7542
street: 100 Apple Street
homePhone: +1 214 521 4883
l: Cincinnati
mail: user.2001@maildomain.net
st: OH
```

- To add the entry specified in the LDIF file, run the `ldapmodify` tool.

Example:

In this example, you do not need to use the `--defaultAdd` or its shortform `-a` option with the command.

```
$ bin/ldapmodify --filename add-user2.ldif
```

Result: A confirmation message displays confirming the addition.

## Adding multiple entries in a single file

About this task

Add multiple entries in your LDIF file by separating each distinguished name (DN) and its entry with a blank line from the next entry.

Steps

- Open a text editor and create some entries that conform to your schema.

Example:

For example, add the following entries in the file and save the file as `add-user3.ldif`. Separate each entry with a blank line.

```
dn: uid=user.2003,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass:
organizationalPerson
objectClass: inetOrgPerson
...(similar attributes to previous examples)...

dn: uid=user.2004,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
...(similar attributes to previous examples)...
```

- To add the entries specified in the LDIF file, run the `ldapmodify` tool.

Example:

This example uses the short form arguments for the `ldapmodify` tool.

```
$ bin/ldapmodify -h server.example.com -p 389 \
-D "cn=admin,dc=example,dc=com" -w password -a -f add-user3.ldif
```

The `-h` option specifies the host name, the `-p` option specifies the LDAP listener port, `-D` specifies the bind DN, `-w` specifies the bind DN password, `-a` specifies that entries that omit a changetype are treated as add operations, and `-f` specifies the path to the input file. If the operation is successful, you will see commented messages (those beginning with "#") for each addition.

Result:

```
# Processing ADD request for uid=user.2003,ou=People,dc=example,dc=com
# ADD operation successful for DN
uid=user.2003,ou=People,dc=example,dc=com
# Processing ADD request for uid=user.2004,ou=People,dc=example,dc=com
```

```
# ADD operation successful for DN
uid=user.2004,ou=People,dc=example,dc=com
```

## Deleting entries using `ldapdelete`

You can delete an entry using the `ldapdelete` tool.

### Note:

Ensure that there are no child entries below the entry because that can create an orphaned entry.

Back up your system prior to removing any entries.

### Deleting an entry using `ldapdelete`

#### Steps

To delete an entry, run the `ldapdelete` command.

Example:

The following example deletes the `uid=user.14` entry.

```
$ bin/ldapdelete uid=user.14,ou=People,dc=example,dc=com
```

### Deleting multiple entries using an LDIF file

#### About this task

To generate a file of distinguished names (DNs) to delete from the Directory Server:

#### Steps

1. To search for all entries in a branch and return the DN of the subentries, run the following command.

Example:

For this example, the search is for all entries in the `ou=Accounting` branch.

```
$ bin/dump-dns -D "cn=admin,dc=example,dc=com" -w password --baseDN \
    "ou=Accounting,ou=People,dc=example,dc=com" --
outputFile /usr/local/entry_dns.txt
```

2. Run the `ldapdelete` command with the file to delete the entries.

Example:

The following command uses the `--continueError` option, which continues deleting through the whole list even if an error is encountered for a DN entry.

```
$ bin/ldapdelete --filename /usr/local/entry_dns.txt --continueError
```

## Deleting entries using `ldapmodify`

#### About this task

You can use the LDIF `changetype` directive to delete an entry from the Directory Server using the `ldapmodify` tool.

### Note:

You can only delete leaf entries.

### Steps

Delete an entry using the `ldapmodify` tool.

- a. From the command line run the `ldapmodify` tool with the `changetype:delete` option.
- b. Enter the distinguished name (DN) and press `Enter` to go to the next line.
- c. Enter the `changetype` directive.
- d. Press `Ctrl+D` twice to enter the end-of-file (EOF) sequence (UNIX) or `Ctrl+Z` (Windows).

Example:

```
$ bin/ldapmodify --hostname server1.example.com -port 389 --bindDN
"uid=admin,dc=example,dc=com" --bindPassword password
dn:uid=user.14,ou=People,dc=example,dc=com
changetype: delete
```

## Modifying entries using `ldapmodify`

You can use the `ldapmodify` tool to modify entries from the command line or by using an LDIF file that has the `changetype:modify` directive and value.

If you have more than one change, you can separate them using the `-` (dash) symbol.

### Modifying an attribute from the command line

#### Steps

1. To locate a specific entry, run the `ldapsearch` tool.

Example:

```
$ bin/ldapsearch -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password -b dc=example,dc=com "(uid=user.2004)"
```

2. To change attributes from the command line, run the `ldapmodify` command.
  - a. Specify the modification using the `changetype:modify` directive and then specify which attributes are to be changed using the `replace` directive.

Example:

In this example, we change the telephone number of a specific user entry.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

3. Process the request:

Choose from:

- For Unix EOF escape sequence, enter `ctrl+d` twice.
- For Windows, enter `ctrl+z`.

## Modifying multiple attributes in an entry from the command line

### Steps

1. To locate a specific entry, run the `ldapsearch` tool.

Example:

```
$ bin/ldapsearch -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password -b dc=example,dc=com "(uid=user.2004) "
```

2. To change attributes from the command line, use the `ldapmodify` command.
  - a. Specify the modification using the `changetype:modify` subcommand.
  - b. Specify the attributes to change using the `add` and `replace` subcommand.

Example:

In this example, we add the `postOfficeBox` attribute and change the mobile and telephone numbers of a specific user entry. The `postOfficeBox` attribute must be present in your schema to allow the addition. The three changes are separated by a dash ("-").

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postOfficeBox
postOfficeBox: 111
-
replace: mobile
mobile: +1 039 831 3737
-
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

3. Process the request.

Choose from:

- For Unix, enter `ctrl+d` twice.  
This is the Unix EOF escape sequence.
- For Windows, enter `ctrl+z`.

## Adding an attribute from the command line

### Steps

1. Run the `ldapmodify` tool from the command line interface.
2. Specify the modification using the `changetype:modify` subcommand.
3. Specify which attributes to add using the `add` option.

Example:

In this example, we add another value for the `cn` attribute, which is multi-valued.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: cn
cn: Sally Tea Tree
```

- To process the request, enter `ctrl+d` twice.

This is the UNIX EOF escape sequence.

**Note:**

An error might occur if the attribute is single-valued, if the value already exists, if the value does not meet the proper syntax, or if the value does not meet the entry's `objectclass` requirements.

Remove any trailing spaces after the attribute value.

## Adding an attribute using the language subtype

### About this task

The Directory Server provides support for attributes using language subtypes. The operation must specifically match the subtype for successful operation. Any non-ASCII characters must be in UTF-8 format.

### Steps

- Run the `ldapmodify` tool from the command line interface.
- Specify the modification using `changetype:modify`.
- Specify which attributes to add using the `add` option.

Example:

In this example, we add another value for the `lang` attribute.

```
$ bin/ldapmodify -h server.example.com -p 389 -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postalAddress; lang-ko
postalAddress; lang-ko:Byung-soon Kim$2020-14 Seoul
```

- To process the request, enter `ctrl+d` twice.

This is the UNIX EOF escape sequence.

## Adding an attribute using the binary subtype

### About this task

The Directory Server provides support for attributes using binary subtypes, which are typically used for certificates or JPEG images that you can store in an entry. The operation must specifically match the subtype for successful operation. You must use the version directive with a value of "1" for binary subtypes. Typical binary attribute types are `userCertificate` and `jpegPhoto`.

### Steps

- To add an attribute with a binary subtype, run the `ldapmodify` tool from the command line interface.
- Specify the modification using `changetype:modify`.
- Specify which attributes to add using the `add` option.

Example:

The attribute in this example points to the filepath of the certificate.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
```

```
version: 1
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: userCertificate;binary
userCertificate;binary:<file:///path/to/cert
```

## Deleting an attribute

### Steps

To delete an attribute, run the `ldapmodify` tool with the LDIF `delete` subcommand.

Example:

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
delete: employeeNumber
```

## Deleting one value from an attribute with multiple values

### About this task

Use the LDIF `delete` subcommand to delete a specific attribute value from an attribute.

### Steps

1. Run the `ldapmodify` tool from the command line.
2. Specify the modification using `changetype:modify`.
3. Specify the attribute pair that you want to delete using `delete`.

Example:

The following sample assumes you have multiple values of `cn` in an entry, such as `cn: Sally Tree, cn: Sally Tea Tree`. This sample keeps `cn:Sally Tree` and deletes the `cn: Sally Tea Tree`.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
delete: cn
cn: Sally Tea Tree
```

## Renaming an entry

Rename an entry by changing the relative distinguished name (RDN) of an entry.

### About this task

#### Note:

You cannot rename an RDN if it has children entries because this violates the LDAP protocol.

## Steps

Run the **ldapmodify** tool to rename an entry.

- a. Run the `changetype`, `newrdn`, and `deleteoldrdn` directives.

Example:

The following command changes `uid=user.14` to `uid=user.2014` and uses the `changetype`, `newrdn`, and `deleteoldrdn` directives.

```
$ bin/ldapmodify
dn: uid=user.14,ou=People,dc=example,dc=com
changetype:moddn
newrdn: uid=user.2014
deleteoldrdn: 1
```

## Moving an entry within a Directory Server

Run the **ldapmodify** tool to move an entry from one base distinguished name (DN) to another base DN.

Before you begin

- Assign access control instructions (ACIs) on the parent entries.
  - The source parent entry must have an ACI that allows export operations: `allow(export)`.
  - The target parent entry must have an ACI that allows import operations: `allow(import)`.

About this task

For more information on access control instructions, see [Working with Access Control](#).

## Steps

1. To move an entry from one branch to another, run the **ldapmodify** tool.

Example:

In this example, an entry moves from the `ou=contractors` branch to the `ou=People` branch.

```
$ bin/ldapmodify
dn: uid=user.14,ou=contractors,dc=example,dc=com
changetype:moddn
newrdn: uid=user.2014
deleteoldrdn: 0
newsuperior: ou=People,dc=example,dc=com
```

2. Specify the modification using `changetype:moddn`.

## Moving an entry from one machine to another

About this task

The Directory Server provides the **move-subtree** tool to move a subtree or one entry on one machine to another.

The **move-subtree** tool moves a subtree or multiple entries from one machine to another. The tool does not copy the entries. After the entries are moved, they are no longer present on the source server.

**Note:**

The subtree or entry must exist on the source server and cannot be present on the target server. The source server must also support the `real attributes only` request control. The target server must support the `Ignore NO-USER-MODIFICATION` request control.

## Steps

- To move an entry, such as `uid=test.user,ou=People,dc=example,dc=com`, from the source host to the target host, run the **move-subtree** tool.

Example:

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
--sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword
password \
--targetHost target.example.com --targetPort 389 \
--targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword
password \
--entryDN uid=test.user,ou=People,dc=example,dc=com
```

## Moving multiple entries from one machine to another

### About this task

The **move-subtree** tool provides the ability to move multiple entries listed in a distinguished name (DN) file from one machine to another. Lines that begin with the octothorpe character (`#`) and empty lines will be ignored. You can prefix entry DNs with `dn:` , but long DNs can't be wrapped across multiple lines.

## Steps

- In a text editor, create a new text file, enter a list of DNs, one DN per line, and then save the file.

You can also use the **ldapsearch** command with the special character `"1.1"` to create a file containing a list of DNs that you want to move.

Example:

The following example searches for all entries that match `"(department=Engineering)"` and returns only the DNs that match the criteria. The results are re-directed to an output file, `test-dns.ldif`.

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
--searchScope sub "(department=Engineering)" "1.1" > test-dns.ldif
```

- To specify the file of DNs to move from one machine to another, run the **move-subtree** tool with the `--entryDNFile` option.

Example:

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
--sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword
password \
--targetHost target.example.com --targetPort 389 \
--targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword
password \
```

```
--entryDNFile /path/to/file/test-dns.ldif
```

**Note:**

If an error occurs with one of the DNs in the file, the output message shows the error. The `move-subtree` tool keeps processing the remaining DNs in the file.

```
An error occurred while communicating with the target server: The entry
uid=user.2,ou=People,dc=example,dc=com cannot be added because an entry
with that name
already exists
Entry uid=user.3,ou=People,dc=example,dc=com was successfully moved from
source.example.com:389 to target.example.com:389
Entry uid=user.4,ou=People,dc=example,dc=com was successfully moved from
source.example.com:389 to target.example.com:389
```

## Working with the parallel-update tool

The PingDirectory Server provides a **parallel-update** tool, which reads change information (`add`, `delete`, `modify`, and `modify DN`) from an LDIF file and applies the changes in parallel.

This tool is a multi-threaded version of the `ldapmodify` tool that is designed to process a large number of changes as quickly as possible.

The **parallel-update** tool provides logic to prevent conflicts resulting from concurrent operations targeting the same entry or concurrent operations involving hierarchically-dependent entries, such as modifying an entry after it has been added or adding a child after its parent.

The tool also has a retry capability that can help ensure that operations are ultimately successful even when interdependent operations are not present in the correct order in the LDIF file, such as if the change to add a parent entry is provided later in the LDIF file than a change to add a child entry.

After the tool applies the changes and reaches the end of the LDIF file, it automatically displays the update statistics described in the following table.

Processing Statistic	Description
Attempts	Number of update attempts
Successes	Number of successful update attempts
Rejects	Number of rejected updates
ToRetry	Number of updates that will be retried
AvgOps/S	Average operations per second
RctOps/S	Recent operations per second Total number of operations from the last interval of change updates
AvgDurMS	Average duration in milliseconds
RctDurMS	Recent duration in milliseconds Total duration from the last interval of change updates

## Running the parallel-update tool

### Steps

1. Create an LDIF file with your changes.

Example:

The third change in this example generates a rejected entry because its `userPassword` attribute contains an encoded value, which is not allowed.

```
dn:uid=user.2,ou=People,dc=example,dc=com
changetype: delete

dn:uid=user.99,ou=People,dc=example,dc=com
changetype: moddn
newrdn: uid=user.100
deleteoldrdn: 1

dn:uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==

dn:uid=user.100,ou=People,dc=example,dc=com
changetype: modify
replace: st
st: TX
-
replace: employeeNumber
employeeNumber: 100
```

2. To apply the changes in the LDIF file to a target server, run `parallel-update` with the `--ldifFile` and `--rejectFile` options.

#### Note:

The `--ldifFile` and `--rejectFile` options are required.

Example:

In this example, there are ten concurrent threads. The optimal number of threads depends on your underlying system.

```
$ bin/parallel-update --hostname 127.0.0.1 \
  --ldifFile changes.ldif --rejectFile reject.ldif --numThreads 10
```

Result:

```
Reached the end of the LDIF file
Attempts Successes Rejects ToRetry AvgOps/S RctOps/S AvgDurMS RctDurMS
-----
          4           3           1           0           3           3          26          26
All processing complete Attempted 4 operations in 1 seconds
```

3. View the rejects files for any failed updates.

Result:

The following sample elaborates on the rejected file.

```
# ResultCode=53, Diagnostic Message=Pre-encoded passwords are not allowed
for
# the password attribute userPassword
dn: uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==
```

## Working with the watch-entry Tool

The PingDirectory Server provides a **watch-entry** tool that demonstrates replication or synchronization latency by watching an LDAP entry for changes.

About this task

You can directly modify attributes with the `watch-entry` tool.

### Note:

If the LDAP entry changes, the background of modified attributes will briefly be red.

### Steps

- Run the **watch-entry** tool.

Example:

This example connects to `server.example.com` as `uid=admin,dc=example,dc=com` and watches entry `uid=kate,ou=people,dc=example,dc=com` for changes.

```
$ bin/watch-entry --hostname server.example.com --port 389 \
--bindDN uid=admin,dc=example,dc=com --bindPassword password \
--entryDN uid=user,ou=people,dc=example,dc=com
```

## Working with LDAP transactions

The PingDirectory Server provides support for batched transactions, which are processed together at commit time.

Applications developed to perform batched transactions should include as few operations in the transaction as possible. The changes aren't actually processed until the commit request is received. Therefore, the client can't know whether the changes are successful until commit time. If any of the operations fail, then the entire set of operations fails.

Batched transactions are write operations that are processed as a single atomic unit when the commit request is received. The write operations include the following:

- add
- delete

- modify
- modify DN
- password modify

If an abort request is received or an error occurs during the commit request, the changes are rolled back. The batched transaction mechanism supports the standard LDAP transaction implementation based on RFC 5805. It's not currently possible to process a transaction that requires changes to be processed across multiple servers or multiple Directory Server backends.

Directory servers can limit the set of controls that are available for use in requests that are part of a transaction. RFC 5805 section 4 indicates that you can use the following controls in conjunction with the transaction specification request control:

- Assertion request control
- manageDsaIT request control
- Pre-read request control
- Post-read request control

The proxied authorization v1 and v2 controls can't be included in requests that are part of a transaction, but they can be included in the start transaction request to indicate that all operations within the transaction should be processed with the specified authorization identity.

The PingDirectory Server supports the following additional controls in conjunction with operations included in a transaction:

- Account usable request control
- Hard delete request control
- Intermediate client request control
- Password policy request control
- Replication repair request control
- Soft delete request control
- Soft-deleted entry access request control
- Subtree delete request control, and undelete request control

## Requesting a batched transaction using `ldapmodify`

About this task

You can run the `ldapmodify` tool's `--useTransaction` option to process multiple operations as part of a single batched transaction.

Steps

1. Create a batch text file with the changes that you want to apply as a single atomic unit.

Example:

```
dn:uid=user.3,ou=People,dc=example,dc=com
changetype: delete
dn:uid=user.1,ou=People,dc=example,dc=com
changetype: modify
replace: pager
pager: +1 383 288 1090
```

- To run the batched transaction, run the `ldapmodify` tool with the `--useTransaction` and `--filename` options.

Example:

```
$ bin/ldapmodify --useTransaction --filename test.ldif
```

Result:

```
#Successfully created a transaction with transaction ID 400
#Processing DELETE request for uid=user.3,ou=People,dc=example,dc=com
#DELETE operation successful for DN
uid=user.3,ou=People,dc=example,dc=com
#This operation will be processed as part of transaction 400
#Processing MODIFY request for uid=user.1,ou=People,dc=example,dc=com
#MODIFY operation successful for DN
uid=user.1,ou=People,dc=example,dc=com
#This operation will be processed as part of transaction 400
#Successfully committed transaction 400
```

## Working with Virtual Attributes

PingDirectory Server supports virtual attributes.

Virtual attributes are abstract, dynamically generated attributes that are invoked through an LDAP operation, such as `ldapsearch`, but are not stored in the Directory Server backend.

Most virtual attributes are operational attributes, providing processing-related information that the server requires. The directory server virtual attribute subsystem allows you to create user-defined virtual attributes to suit your requirements.

### Viewing the list of default virtual attributes

Use the `dsconfig` tool to view the list of Directory Server virtual attributes.

Some virtual attributes are enabled by default and are useful for most applications.

The default set of virtual attributes is described in the table below. You can enable or disable these attributes using the `dsconfig` tool.

#### Virtual Attributes

Virtual Attributes	Description
<code>ds-entry-checksum</code>	Generates a simple <b>checksum</b> of an entry's contents, which can be used with an LDAP assertion control to ensure that the entry has not been modified since it was last retrieved.
<code>ds-instance-name</code>	Generates the name of the Directory Server instance from which the associated entry was read. This virtual attribute can be useful in load-balancing environments to determine the instance from which an entry was retrieved.
<code>ds-pwp-state-json</code>	Generates an operational attribute whose values is a JSON object with information about a user's current password policy state.
<code>entryDN</code>	Generates an <code>entryDN</code> operational attribute in an entry that holds a normalized copy of the entry's current distinguished name (DN). Clients can use this attribute in search filters.

Virtual Attributes	Description
hasSubordinates	Creates an operational attribute that has a value of <code>TRUE</code> if the entry has subordinate entries.
isDirectMemberOf	<p>Generates an <code>isDirectMemberOf</code> operational attribute that contains the DNs of the groups in which the user is a member.</p> <p><code>isDirectMemberOf</code> includes only static groups in which the user is explicitly named as a member.</p> <p>Compare to <code>isMemberOf</code>.</p>
isMemberOf	<p>Generates an <code>isMemberOf</code> operational attribute that contains the DNs of the groups in which the user is a member.</p> <p><code>isMemberOf</code> includes all of the following:</p> <ul style="list-style-type: none"> <li>▪ Static groups in which the user is explicitly named as a member</li> <li>▪ Dynamic groups in which the user is a member because of the criteria for that group</li> <li>▪ Static groups in which the user is a member because they are a member of a nested group that is listed as a member of the static group</li> </ul> <p>Compare to <code>isDirectMemberOf</code>.</p>
numSubordinates	<p>Generates an operational attribute that returns the number of child entries. While there is no cost if this operational attribute is enabled, there could be a performance cost if it is requested.</p> <div data-bbox="537 1031 1472 1209" style="border: 1px solid black; padding: 5px;"> <p> <b>Note:</b></p> <p>This operational attribute only returns the number of immediate children of the node.</p> </div>
subschemaSubentry	<p>A special entry that provides information in the form of operational attributes about the schema elements defined in the server. It identifies the location of the schema for that part of the tree.</p> <ul style="list-style-type: none"> <li>▪ <code>ldapSyntaxes</code> - set of attribute syntaxes</li> <li>▪ <code>matchingRules</code> - set of matching rules</li> <li>▪ <code>matchingRuleUse</code> - set of matching rule uses</li> <li>▪ <code>attributeTypes</code> - set of attribute types</li> <li>▪ <code>objectClasses</code> - set of object classes</li> <li>▪ <code>nameForms</code> - set of name forms</li> <li>▪ <code>dITContentRules</code> - set of DIT content rules</li> <li>▪ <code>dITStructureRules</code> - set of DIT structure rules</li> </ul>
User Defined Virtual Attribute	Generates virtual attributes with user-defined values in entries that match the criteria defined in the plugin's configuration. User-defined virtual attributes are intended to specify a hard-coded value for entries matching a given set of criteria.

Virtual Attributes	Description
Virtual Static Member	<p>Generates a member attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group.</p> <p>Do not modify the filter in the <code>Virtual Static Member</code> attribute as it is an advanced property and modifying it can lead to undesirable side effects.</p>
Virtual Static Uniquemember	<p>Generates a <code>uniqueMember</code> attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group.</p> <p>Do not modify the filter in the <code>Virtual Static Uniquemember</code> attribute because it is an advanced property, and modifying it can lead to undesirable side effects.</p>

## Viewing the list of default virtual attributes using dsconfig non-interactive mode

### Steps

- To list the virtual attributes, use `dsconfig`.

```
$ bin/dsconfig list-virtual-attributes
```

## Viewing virtual attribute properties

View the basic properties of each virtual attribute using the `dsconfig` tool.

### About this task

For a complete list of properties, see [General Consent Service configuration](#) on page 1529. The following table shows some basic properties.

To view virtual attribute properties:

Property	Description
<code>description</code>	A description of the virtual attribute.
<code>enabled</code>	Specifies whether the virtual attribute is enabled for use.
<code>base-DN</code>	<p>Specifies the base DNs for the branches containing entries that are eligible to use this virtual attribute.</p> <p>If no values are given, the server generates virtual attributes anywhere in the server.</p>

Property	Description
<b>group-DN</b>	<p>Specifies the DNs of the groups whose members can use this virtual attribute.</p> <p>If no values are given, the group membership is not taken into account when generating the virtual attribute.</p> <p>If one or more group DNs are specified, then only members of those groups are allowed to have the virtual attribute.</p>
<b>filter</b>	<p>Specifies the filters that the server applies to entries to determine if they require virtual attributes</p> <p>If no values are given, then any entry is eligible to have a virtual attribute value generated.</p>

### Steps

- To view the properties of a virtual attribute, use **dsconfig**.

Example:

```
$ bin/dsconfig get-virtual-attribute-prop --name isMemberOf
```

## Enabling a virtual attribute

You can enable a virtual attribute using the **dsconfig** tool.

If you are using **dsconfig** in interactive command-line mode, you can access the virtual attribute menu from the `Standard object` menu.

### Enabling a virtual attribute using dsconfig interactive mode

#### Steps

- To enable a virtual attribute, use **dsconfig**.
  - Specify the connection port, bind DN, password, and host information.
  - Enter the LDAP connection parameter for your Directory Server:
    - For LDAP, enter 1.
    - For SSL, enter 2.
    - For StartTLS, enter 3.

Example:

```
bin/dsconfig
```

- On the Directory Server main menu, enter `o` to change the object menu, and then enter the number corresponding to `Standard`.
  - On the Directory Server main menu, enter the number corresponding to virtual attributes.
  - On the `Virtual Attribute management` menu, enter the number to view and edit an existing virtual attribute.
  - From the list of existing virtual attributes on the system, select the virtual attribute.
- For this example, enter the number corresponding to the `numSubordinates` virtual attribute.

6. On the `numSubordinates` Virtual Attribute Properties menu, enter the number to enable the virtual attribute.
7. On the `Enabled Property` menu for the `numSubordinates` virtual attribute, enter the number to change the value to `TRUE`.
8. On the `numSubordinates` Virtual Attribute Properties menu, enter `f` to apply the changes.
9. Verify that the virtual attribute is enabled.

Example:

**Note:**

This example assumes you have configured the group entries.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(ou=People)" numSubordinates
```

Result: The system returns the following.

```
dn: ou=People,dc=example,dc=com
numSubordinates: 1000
```

### Enabling a virtual attribute using `dsconfig` non-interactive mode

#### Steps

- To enable a virtual attribute, such as `numSubordinates`, use `dsconfig`.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop \
  --name numSubordinates --set enabled:true
```

### Creating user-defined virtual attributes

User-defined virtual attributes allow you to specify an explicit value to use for the virtual attribute.

There are no restrictions on the length of the value for a user-defined virtual attribute. You must only ensure that the new virtual attribute conforms to your schema, or you will see an error message when you configure it.

You can define your virtual attributes using the `dsconfig` tool from the `Standard object` menu. Only the `value` property is specific to the user-defined virtual attribute. All the other properties are common across all kinds of virtual attributes, which include the following.

Property	Description
<code>enabled</code>	Indicates whether the virtual attribute should be used.
<code>attribute-type</code>	The attribute type for the virtual attribute that is generated.
<code>base-dn</code> <code>group-dn</code> <code>filter</code>	Can be used to select which entries are eligible to contain the virtual attribute.

Property	Description
<code>client-connection-policy</code>	Can be used to select which entries are eligible to contain the virtual attribute.
<code>conflict-behavior</code>	Used to indicate how the server should behave if there are one or more real values for the same attribute type in the same entry.  The server can either return only the real values, only the virtual values, or merge both real and virtual values.
<code>require-explicit-request-by-name</code>	Used to indicate whether the server should only generate values for the virtual attribute if it was included in the list of requested attributes.
<code>multiple-virtual-attribute-evaluation-order-index</code> <code>multiple-virtual-attribute-merge-behavior</code>	Used to control the behavior of the server if multiple virtual attributes can be used to contribute values to the same attribute.

### Creating a user-defined virtual attribute in interactive mode

#### About this task

The following example shows how to create a user-defined virtual attribute that assigns an Employee Password Policy to any entry that matches the filter "`(employeeType=employee)`".

#### Steps

1. To configure the user-defined virtual attribute:
  - a. Run `dsconfig`.
  - b. Specify the connection port, bind DN, password, and host information.
  - c. Type the LDAP connection parameter for your Directory Server:
    - For LDAP, enter 1.
    - For SSL, enter 2.
    - For StartTLS, enter 3.
2. To change the object menu, in the Directory Server main menu, type `o`, and then type the number to select `Standard`.
3. In the Directory Server main menu, type the number corresponding to virtual attributes.
4. To create a new virtual attribute, in the `Virtual Attribute management` menu, type the number.
5. Use an existing virtual attribute as a template for your new attribute, or create a new attribute from scratch.  
  
In this example, type `n` to create a new Virtual Attribute from scratch.
6. In the `Virtual Attribute Type` menu, enter a number corresponding to the type of virtual attribute that you want to create.  
  
In this example, type the number corresponding to User Defined Virtual Attribute.
7. Enter a name for the new virtual attribute.  
  
In this example, enter `Employee Password Policy Assignment`.
8. In the `Enabled Property` menu, enter the number to set the property to `TRUE` (enable).

9. In the `Attribute-Type Property` menu, type the **attribute-type** property for the new virtual attribute.

You can enter the OID number or attribute name. The **attribute-type** property must conform to your schema. For this example, type `ds-pwp-password-policy-dn`.

10. Enter the value for the virtual attribute, and then press `Enter` or `Return` to continue.

In this example, enter `cn=Employee Password Policy,cn=Password Policies,cn=config`, and then type `Enter` or `Return` to continue.

11. In the `User Defined Virtual Attributes` menu, enter a description for the virtual attribute.

Though optional, this step is useful if you plan to create multiple virtual attributes. Enter the option to change the value, and then type a description of the virtual attribute. In this example, type `Virtual attribute that assigns the Employee Password Policy to all entries that match (employeeType=employee)`.

12. In the `User Defined Virtual Attribute` menu, type the number corresponding to the filter.

13. In the `Filter Property` menu, enter the option to add one or more filter properties, type the filter, and then press `Enter` to continue.

In this example, type `(employeeType=employee)`. Press the number to use the filter value entered.

14. In the `User Defined Virtual Attribute` menu, type `f` to finish creating the virtual attribute.

15. Verify that the attribute was created successfully.

- a. Add the `employeeType=employee` attribute to an entry, such as `uid=user.0`, using **`ldapmodify`**.

- b. Add the `employeeType=contractor` attribute to another entry, such as `uid=user.1`.

16. To search for the user with the `employeeType=employee` attribute, such as `uid=user.0`, use **`ldapsearch`**.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
ds-pwp-password-policy-dn
```

**Result:** The `ds-pwp-password-policy-dn` attribute has the assigned password policy as its value.

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Employee Password Policy,cn=Password
Policies,cn=config
```

17. Run **`ldapsearch`** again using the filter `(uid=user.1)`.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.1)" \
ds-pwp-password-policy-dn
```

**Result:** The `ds-pwp-password-policy-dn` attribute is not present in the entry because the entry has the attribute `employeeType=contractor`.

```
dn: uid=user.1,ou=People,dc=example,dc=com
```

## Creating a user-defined virtual attribute using `dsconfig` in non-interactive mode

### About this task

You can create a virtual attribute in non-interactive command-line mode using **`dsconfig`**.

## Steps

- To set up the Employee Password Policy Assignment virtual attribute introduced in the previous section, run the following command.

Example:

```
$ bin/dsconfig create-virtual-attribute \
  --name "Employee Password Policy Assignment" \
  --type user-defined \
  --set enabled:true \
  --set attribute-type:ds-pwp-password-policy-dn \
  --set "filter:(employeeType=employee)" \
  --set "value:cn=Employee Password Policy,cn>Password Policies,cn=config"
```

## Creating mirror virtual attributes

PingDirectory Server provides a feature to mirror the value of another attribute in the same entry or mirror the value of the same or a different attribute in an entry referenced by the original entry.

For example, consider a directory information tree (DIT) where users have a `manager` attribute with a value of the DN of the employee as follows.

```
dn: uid=apeters,ou=people,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
uid: apeters
... (more attributes) ...
```

You can set up a mirror virtual attribute so that the returned value for the `managerName` virtual attribute can be the `cn` value of the entry referenced by the `manager` attribute.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)" \
dn: uid=apeters,ou=people,dc=example,dc=com

objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
managerName: John Doe
uid: apeters
... (more attributes not shown) ...
```

## Creating a mirror virtual attribute using dsconfig in non-interactive mode

Create a mirror virtual attribute using `dsconfig` in non-interactive command-line mode.

### About this task

The following example sets up the `managerName` virtual attribute introduced in the previous section:

## Steps

1. Update the schema to define the `managerName` attribute.

You can optionally add the attribute to an object class.

- a. In a text editor, create a file with the following schema definition for the attribute.

```
dn: cn=schema
```

```
objectClass: top
objectClass: ldapSubentry
objectClass: subschema attributeTypes: ( 1.3.6.1.4.1.32473.3.1.9.4
  NAME 'managerName'
  EQUALITY caseIgnoreMatch SUBSTR caseIgnoreSubstringsMatch SYNTAX
  1.3.6.1.4.1.1466.115.121.1.44{256}
  X-ORIGIN 'Directory Server Example' )
```

b. Save the file as `98-myschema.ldif` in the `<server-root>/config/schema` folder.

## 2. Restart the Directory Server.

```
$ bin/stop-server --restart
```

## 3. To create the virtual attribute, use `dsconfig`.

```
$ bin/dsconfig create-virtual-attribute \
  --name "managerName" \
  --type mirror \
  --set "description:managerName from manager cn" \
  --set enabled:true \
  --set attribute-type:managerName \
  --set source-attribute:cn \
  --set source-entry-dn-attribute:manager
```

## 4. To verify the mirror virtual attribute, search for an entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)"
```

Result: Your search results in the following.

```
dn: uid=apeters,ou=People,dc=example,dc=com
... (attributes) ...
manager: uid=jdoe,ou=People,dc=example,dc=com
managerName: John Doe
```

## Editing a virtual attribute

You can edit virtual attributes with the `dsconfig` tool.

Make sure that the virtual attribute conforms to your plugin schema. Otherwise, an error message appears when you attempt to edit the virtual attribute.

If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu from the Standard object menu.

### Editing a virtual attribute using `dsconfig` in non-interactive mode

#### Steps

- To change a property value, use `dsconfig`.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name dept-number \
  --set "value:111"
```

## Deleting a virtual attribute

Delete virtual attributes using the `dsconfig` tool.

About this task

If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu from the `Standard object` menu.

Steps

- To delete the `dept-number` virtual attribute, use `dsconfig`.

```
$ bin/dsconfig delete-virtual-attribute --name dept-number
```

## Working with Composed Attributes

---

This section provides information on composed attributes, which dynamically generate attribute values to complement virtual attributes.

PingDirectory Server's support for virtual attributes is a useful facility that dynamically generates values in entries for a wide range of use cases. These values are used to generate key operational attributes such as:

- `entryDN`
- `subschemaSubentry`
- `isMemberOf`
- `numSubordinates`
- `hasSubordinates`
- `ds-entry-checksum`

The values of other attributes in the same or different entries can be mirrored, and values can be constructed from other attributes in the same entry. Items such as password policies and privileges can be dynamically generated, and you can create custom virtual attribute providers with the Server SDK using a wide variety of logic.

Virtual attributes should not be used for all use cases. Composed attributes, which complement virtual attributes, are more suited for scenarios that virtual attributes do not support.

## Virtual attribute limitations

This section describes the limitations of virtual attributes, such as performance, indexing, and consistency limitations.

### Performance limitations

The performance impact of virtual attribute generation is limited by computing these values only if they are returned to the client. However, performance can still be impacted because of other factors. Virtual attributes might be included or excluded based on a range of criteria and the evaluation of this criteria (for example, based on group membership) can impact performance.

### Indexing limitations

You cannot index the values of a virtual attribute because the values can change from one invocation to the next.

Some virtual attributes implement support for an index-like functionality by offering logic that can quickly identify entries with specified virtual attribute values. These include the following:

- When mirroring values from another attribute in the same entry, and when that source attribute type is indexed, the mirror virtual attribute provider can use an internal search to identify matching entries.
- The `entryDN` virtual attribute provider retrieves the entry with the specified distinguished name (DN).
- The `isMemberOf` virtual attribute provider uses the server's group manager to identify the members of a targeted group.

#### Note:

This is not an option for all types of virtual attributes.

Index-like functionality is not available for the following virtual attribute types:

- User-defined virtual attributes that have a static value
- Constructed virtual attributes whose values are composed from multiple other attributes in the same entry
- Mirror virtual attributes whose values come from other entries
- Any custom virtual attribute types implemented using the Server SDK

If you want to have a mix of standard and virtual values for the same attribute type, whether in the same entry or in different entries, there is not a good solution. If you define an index for that attribute type, it only includes entries with standard values and entries with virtual values are overlooked. If there is no index but the virtual attribute provider supports some search functionality, only entries with virtual values are matched and entries with only standard values are excluded.

### Unexpected behavior for write operations

A significant issue with virtual attributes is that they can result in unexpected behaviors when targeted by write operations.

These unexpected behaviors include the following:

- Attempting to delete a virtual value fails with a `no such attribute` result.
- If the virtual attribute provider is configured with a `conflict-behavior of real-overrides-virtual`, then attempting to add a value to an entry that only has virtual values causes the virtual values to disappear.
- If the virtual attribute provider is configured with a `conflict-behavior of real-overrides-virtual`, then attempting to remove all real values of an entry causes the virtual values to appear.
- If the virtual attribute provider is configured with a `conflict-behavior of virtual-overrides-real`, then attempting to add new values or replace the set of existing values yields a success result, but the operation has no visible effect on the entry.
- If the virtual attribute provider is configured with a `conflict-behavior of merge-real-and-virtual`, then attempting to replace the set of values for an entry yields a success result, but only the real values are replaced and the virtual values remain.

There is currently no method to prevent attempts to write to attributes with virtual values. The `NO-USER-MODIFICATION` constraint in attribute type definitions is honored, but this constraint only applies to operational attribute types. This is not an acceptable limitation in many cases. Access control restrictions could work for many clients, but do not have any effect for requesters with the `bypass-acl` privilege.

## Overview of composed attributes

Composed attributes are generated when an entry is written.

This includes entries that are created by add operations and LDIF imports. These entries can be created, updated, or removed when processing `modify` and `modifyDN` operations. The server might optionally permit or reject attempts to alter the generated values.

Composed values are based on a combination of static text and the contents of the entry in which the value is being generated. You cannot construct values using content from other entries in the server because the necessary content might not be available at the time the value is being generated. An

example of this is if the referenced entry does not yet exist. It would also be difficult to ensure that the value is kept up to date whenever the referenced entry changes or is removed. Values are generated using the same logic that is available for constructed virtual attributes and constructed attribute mapping functionality in the Synchronization Server.

The composed attribute functionality is implemented using a plugin. The plugin is invoked during the pre-operation phases for `add`, `modify`, and `modifyDN` operations and also operates during LDIF import.

The server provides an administrative task that can be used to iterate through all entries in a backend and generate values. This is useful when a new composed attribute plugin instance is created after the backend has already been populated and you do not want to export the data to LDIF and re-import.

The server does not provide any first-class extensibility mechanisms for composed attributes. Unlike virtual attributes, which can be created through the Server SDK, composed attribute support is limited to what the server can provide. You can implement your own plugins to generate your own data.

## Composed attribute plugin configuration properties

The composed attribute plugin provides the following configuration properties.

Configuration properties

### **plugin-type**

The plugin type values for which the server is registered.

This is a mandatory multi-valued property with a default that includes all of the `ldifimport`, `preoperationadd`, `preoperationmodify`, and `preoperationmodifydn` values. In general, you should not override this default set, but this might be useful in some rare corner cases. The available options include:

#### **ldifimport**

Indicates that values should be generated for the target attribute in any appropriate entries created during LDIF import processing.

#### **preoperationadd**

Indicates that values should be generated for the target attribute in any appropriate entries created by add operations.

#### **preoperationmodify**

Indicates that values should be generated or altered for the target attribute in any appropriate entries updated by modify operations.

#### **preoperationmodifydn**

Indicates that values should be generated or altered for the target attribute in any appropriate entries updated by modify distinguished name (DN) operations.

### **attribute-type**

The name or OID of the attribute type for which values are generated.

This attribute type must be defined in the schema. This is a mandatory, single-valued property with no default. To have multiple composed attribute types, configure a separate instance of the plugin for each attribute type. To compose multiple values for the same attribute type from different sets of source attributes, use a single instance of the plugin with multiple value patterns.

### **value-pattern**

The value pattern that specifies the logic that should be used when constructing values.

This pattern must be compatible with the format expected by the `com.unboundid.directory.server.sync.mapping.ConstructedValue` class. This is a mandatory, multi-valued property in which the order of the values is preserved. If this is configured with multiple values, then the behavior the plugin should exhibit is controlled by the `multiple-value-pattern-behavior` property.

 **Note:**

A value pattern is only used for an entry if that entry contains all of the attributes referenced in the value pattern.

Virtual attributes are not considered when generating values.

### `multiple-value-pattern-behavior`

The behavior that the server should exhibit if multiple value-pattern values are configured.

This is a single-valued property with a default value of `use-first-non-rejected-value-pattern-with-non-empty-values-but-might-reject`.

 **Note:**

The primary reason that a rejection might occur is as a result of multivalued source attributes, but it could also occur if an unexpected error occurs while trying to generate values.

The available options include:

#### `use-first-non-rejected-value-pattern-with-non-empty-values-but-might-reject`

Indicates that the server should only use values generated from the first value pattern that is not rejected and yields a non-empty result.

If all value patterns yield empty results, for example, if the entry is missing at least one source attribute for each of the value patterns, then no composed value is generated. If no value pattern yields a non-empty result but at least one is rejected, then the operation fails, or the entry is rejected if performing an LDIF import.

#### `use-first-non-rejected-value-pattern-with-non-empty-values-and-never-reject`

Indicates that the server should only use values generated from the first value pattern that is not rejected and yields a non-empty result.

If none of the value patterns yield non-empty results, regardless of whether any of them is rejected, then no composed value is generated.

#### `use-first-rejection-or-first-value-pattern-with-non-empty-values`

Indicates that the server should only use values generated from the first value pattern that yields non-empty results, but if a rejection is encountered before a non-empty result is obtained, then the operation or LDIF entry is rejected.

If none of the value patterns is not rejected and yields a non-empty result, then no composed value is generated.

#### `use-all-non-rejected-value-patterns-with-non-empty-values-but-might-reject`

Indicates that the server should use all values generated by all of the value patterns that were not rejected for the entry.

As long as at least one value pattern generated a non-empty result, then the entire set of values generated by all value patterns is used. If none of the value patterns yielded non-empty results but none were rejected, then no composed value is generated. If none of the value patterns yielded non-empty results and at least one was rejected, then the operation fails or the LDIF entry is rejected.

**`use-all-non-rejected-value-patterns-with-non-empty-values-and-never-reject`**

Indicates that the server should use all values generated by all of the value patterns that were not rejected for the entry.

As long as at least one value pattern generated a non-empty result, then the entire set of values generated by all value patterns is used. If none of the value patterns yielded non-empty results, regardless of whether any of them was rejected, then no composed value is generated.

**`use-first-rejection-or-all-value-patterns-with-non-empty-values`**

Indicates that the server should use all of the values generated by all of the value patterns as long as none of them is rejected.

If any value pattern is rejected, then the operation fails or the LDIF entry is rejected. If none of the value patterns is rejected but none of them generates any values, then no composed values are generated.

**`multi-valued-attribute-behavior`**

The behavior that the server should exhibit if any of the attributes used in the value pattern have multiple values.

**Note:**

No more than one source attribute should have multiple values. If multiple source attributes have multiple values, and if this property is configured to try to use all of them, then the attempt to generate composed values for the entry might fail.

This is a single-value property with a default value of `use-all-values-if-possible-but-reject-if-not`. Available options include:

**`use-first-value`**

Indicates that the server should only use the first value for each source attribute referenced in the value pattern.

With this value, entries should never be rejected for having multivalued attributes.

**`reject-entries-with-any-multivalued-source-attribute`**

Indicates that the server should reject any entry that has more than one value for any of the source attributes.

**`use-all-values-if-possible-but-reject-if-not`**

Indicates that the server should use all values for the source attributes as long as at most one of them has multiple values.

If multiple source attributes have multiple values, the entry is rejected.

**`use-all-values-if-possible-but-only-first-value-if-not`**

Indicates that the server should use all values for the source attributes as long as at most one of them has multiple values.

If multiple source attributes have multiple values, then only the first value from each source attribute is used so that the entry is not rejected.

#### **target-attribute-exists-during-initial-population-behavior**

The behavior that the server should exhibit for add operations and LDIF imports for entries that already contain one or more values for the target attribute.

This is a single-valued property with a default of **preserve-existing-values**. The available options include:

##### **preserve-existing-values**

Indicates that the server should preserve existing values in entries that are added or imported and should only construct values for entries that do not already contain the target attribute.

##### **overwrite-existing-values**

Indicates that the server should only use generated values for the target attribute and that any values provided during an add or LDIF import is discarded.

##### **merge-existing-and-composed-values**

Indicates that the server should preserve any existing values for the target attribute and should construct any additional values.

#### **Note:**

This option can only be used if the target attribute type allows multiple values.

#### **reject-existing-values-in-add-but-preserve-in-ldif-import**

Indicates that the server should reject any add operation that attempts to provide any values for the target attribute but should preserve any existing values when performing an LDIF import.

#### **Note:**

The server does not reject entries that already contain the target attribute when performing an LDIF import since this would interfere with the ability to export data to LDIF from a server that contains composed values and then re-import the LDIF file.

#### **reject-existing-values-in-add-but-overwrite-in-ldif-import**

Indicates that the server should reject any add operation that attempts to provide any values for the target attribute but should replace any existing values in an LDIF import with the values which would be composed for that entry.

#### **reject-existing-values-in-add-but-merge-in-ldif-import**

Indicates that the server should reject any add operation that attempts to provide any values for the target attribute but should preserve any existing values when performing an LDIF import and add any additional values that should be composed for the entry.

#### **update-source-attribute-behavior**

The behavior that the server should exhibit for entries that are updated by `modify` or `modifyDN` operations that alter values for one of the attributes used in the value pattern.

This is a single-valued property with a default of **replace-composed-values**. The available options include:

**replace-composed-values**

Indicates that the server should only update values for the target attribute that match those that would have been generated by the plugin.

Values that would not have been generated by the plugin are preserved.

**replace-all-values**

Indicates that the server should always replace the target attribute with new composed values even if the existing values were not generated by the plugin.

**preserve-existing-values**

Indicates that the server should always preserve the existing values for the target attribute even if they were generated by the plugin.

**source-attribute-removal-behavior**

The behavior that the server should exhibit when an entry is updated in a manner that removes one or more source attributes needed to compose values for the target attribute.

This is a single-valued property with a default of **preserve-non-composed-values**. The available options include:

**preserve-non-composed-values**

Indicates that the server attempts to remove any values for the target attribute that would have been generated for that entry by the associated value patterns but preserves any other values that might exist for the target attribute.

If the target attribute is required by any of the object classes in the entry and if that entry only contains composed values for the target attribute, then the composed values are preserved to avoid violating the schema.

**preserve-all-values**

Indicates that the server preserves any values that exist for the target attribute regardless of whether they would have been composed by any of the value patterns.

**remove-all-values-but-preserve-all-if-required**

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of **preserve-all-values** if the target attribute type is required by any of the entry's object classes.

**remove-all-values-but-preserve-non-composed-values-if-required**

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of **preserve-non-composed-values** if the target attribute type is required by any of the entry's object classes.

**update-target-attribute-behavior**

The behavior that the server should exhibit when a client attempts to alter the target attribute with a `modify` or `modifyDN` operation.

This is a single-valued property with a default of **always-allow**. The available options include:

**always-allow**

Indicates that the server always permits clients to alter the value of the target attribute regardless of whether these values were generated.

**allow-only-for-non-composed-values**

Indicates that the server only permits clients to alter values for the target attribute that were not generated by the plugin.

Attempts to alter composed values are rejected.

**never-allow**

Indicates that the server should reject any attempt to alter the target attribute regardless of the values it might have.

**include-base-dn**

A base DN that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

**exclude-base-dn**

A base DN that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

**include-filter**

A search filter that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

**exclude-filter**

A search filter that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

**updated-entry-newly-matches-criteria-behavior**

The behavior that the server should exhibit if an entry that previously did not satisfy either the base DN or filter criteria, but is updated so that it does match any configured base DN or filter criteria.

This is a single-valued property with a default value of **preserve-existing-values-and-compose-new-values**. The available options include:

**preserve-existing-values-without-composing-new-values**

Indicates that if the entry already had one or more values for the target attribute, those values are preserved and no additional composed values are added.

If the entry did not contain the target attribute, then no composed values are generated for the entry.

**preserve-existing-values-or-compose-new-values**

Indicates that if the entry already had one or more values for the target attribute, those values are preserved and no additional composed values are added.

If the entry did not contain the target attribute, then composed values are generated for the entry.

**preserve-existing-values-and-compose-new-values**

Indicates that if the entry already had one or more values for the target attribute, those values are preserved and any additional values that would be composed for that entry is also added.

If the entry did not contain the target attribute, then composed values are generated for the entry.

#### **compose-new-values-without-preserving-existing-values**

Indicates that if the entry already had one more composed values for the target attribute, then those values are removed and replaced with the composed values that would be generated for it

If the entry did not contain the target attribute, then composed values are generated for it. If no composed values would be generated for the entry, for example, if it was missing at least one source attribute for each value pattern, then the entry does not include the target attribute, regardless of whether it contained existing values for the attribute.

#### **updated-entry-no-longer-matches-criteria-behavior**

The behavior that the server should exhibit if an entry previously satisfied the configured base DN and filter criteria but has been updated so that it no longer matches that criteria.

This is a single-valued property with a default of **preserve-all-values**. The available options include:

##### **preserve-all-values**

Indicates that the server preserves any values that exist for the target attribute regardless of whether they would have been composed by any of the value patterns.

##### **preserve-non-composed-values**

Indicates that the server attempts to remove any values for the target attribute that would have been generated for that entry by the associated value patterns but preserves any other values that might exist for the target attribute.

However, if the target attribute is required by any of the object classes in the entry, and if that entry only contains composed values for the target attribute, then the composed values are preserved to avoid violating the schema.

##### **remove-all-values-but-preserve-all-if-required**

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of **preserve-all-values** if the target attribute type is required by any of the entry's object classes.

##### **remove-all-values-but-preserve-non-composed-values-if-required**

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of **preserve-non-composed-values** if the target attribute type is required by any of the entry's object classes.

#### Include and exclude criteria configuration

Attribute values are composed by default for every entry in any public backend that contains all of the source attributes used in the appropriate value patterns. To restrict composed values to a specific set of entries, use the **include-base-dn**, **exclude-base-dn**, **include-filter**, and **exclude-filter** properties.

If the `include-base-dn` property is provided, then values are composed for entries at or below one of those base DNs. If the `exclude-base-dn` property is provided, then values are not composed for any entries at or below one of those base DNs. If both properties are provided and a given entry follows both an include and an exclude base DN, then the exclude base DN takes precedence and values are not generated for that entry. If neither property is specified, then the naming contexts of all public backends are used as the default set of include base DNs.

If the `include-filter` property is provided, then values are composed for entries that match at least one of those filters. If the `exclude-filter` property is provided, then values are not composed for any entries that match at least one of those filters. If both properties are provided and a given entry matches both include and exclude filters, then the exclude filter takes precedence and values are not generated for that entry. If neither property is specified, then the server behaves as if an include filter of "&" had been specified.

**Note:**

No virtual attributes are considered when evaluating this filter although composed values might be taken into consideration. For more information about the order in which composed attribute definitions are evaluated, see [Composed attribute dependency considerations](#) on page 682.

## Populate composed attribute values task

When a composed attribute plugin is created in the server, it takes effect immediately and starts creating values for any appropriate `add`, `modify`, and `modifyDN` operations.

Existing entries are not automatically populated with generated values. To populate existing entries with generated values, export the data to LDIF and then re-import it. This requires temporarily taking each instance out of service, since importing into a single instance has no effect on the data in other instances. The LDIF import option is only feasible when you are starting from scratch, not when you have existing data. To address this need, a “populate composed attribute values” task is provided. The populate composed attribute values task iterates through all entries in one or more backends and generates values as appropriate for any entries.

This task provides several number of configuration attributes, including the following:

### `ds-task-populate-composed-attribute-plugin-config`

An optional, multi-valued attribute that can be used to specify the names or distinguished names (DNs) of the composed attribute plugin configuration entries for which values should be generated.

**Note:**

If this attribute is omitted, then values are generated for all defined and enabled composed attribute plugin instances.

### `ds-task-populate-composed-attribute-backend-id`

An optional, multi-valued attribute that can be used to specify the backend IDs of the backends in which values should be generated.

**Note:**

If this attribute is omitted, then an appropriate set of backends is determined based on the include and exclude base DNs for the selected plugins.

### `ds-task-populate-composed-attribute-max-rate-per-second`

An optional, single-valued integer attribute that can be used to specify the maximum number of entries to be updated per second.

 **Note:**

If this attribute is omitted, then no rate limit is imposed.

The task uses the same logic that the plugin uses for entries imported from LDIF when deciding what values to include in the entry, but it uses internal modify operations to make any updates to the entry. These changes are replicated to other servers in the topology, so the task only needs to be invoked on a single instance. However, you should only run it after the composed attribute plugins have been configured on all instances in the topology because this ensures that no entries, including those added or updated while the task is running, are overlooked.

To invoke the task and monitor its progress, use the `populate-composed-attribute-values` command-line tool. This processing is not expected to be needed on a regular basis, so it is not offered as a recurring task.

## Composed attribute dependency considerations

Composed attributes must not have dependencies on virtual attributes.

The server does not use virtual attribute values when generating values from a value pattern, nor does it use virtual attribute values when determining if an entry matches an include or exclude filter.

In general, there is no need to have one composed attribute depend on another. If one composed attribute is constructed from other attributes in the entry, then a composed attribute that needs to use another composed attribute as its source can include the value pattern for the initial composed attribute as part of its own value pattern. However, this might not be sufficient if clients can override the composed values.

If there is a reason that one composed attribute needs to depend on another, then ensure that the following requirements are satisfied:

- Any composed attribute plugins that have dependencies should be configured so that they are invoked in the appropriate order.

 **Tip:**

To configure the order in which composed attribute plugins are invoked, use `plugin-order-ldif-import`.

- Run the populate composed attribute values task separately for each of the attributes to be generated.
- The first run should be to generate values for any composed attributes that are not dependent on any other composed attributes.
- The second run should generate values for any composed attributes that were created during the first run. If multiple levels of nesting are required, you must perform additional runs of the task.
- Enable the `plugin-order-pre-operation-add`, `plugin-order-pre-operation-modify`, and `plugin-order-pre-operation-modify-dn` properties in the plugin root configuration.

## Schema validation considerations

The server only generates composed attributes for entries in which that attribute is allowed to be present.

For user attributes, the target attribute type must be permitted by at least one of the object classes associated with the entry. If an entry does not have any object class that permits the target attribute, then an attempt to generate composed values for the entry fails with an `objectClassViolation` (65) result. This restriction does not exist for operational attributes.

The server allows composed attributes to satisfy mandatory attribute requirements. If the target attribute is declared as a `MUST` type for any of the entry's object classes, then a client should be able to add an entry that does not include values for that attribute type as long as the server composes a value for that attribute.

The server enforces attribute syntax restrictions for composed attributes. If a composed attribute violates the syntax for the associated attribute type, then the operation resulting in that composed attribute value is rejected with an `INVALID_ATTRIBUTE_SYNTAX` result. This can be overridden on a per-attribute-type basis using the `permit-syntax-violations-for-attribute` property in the global configuration.

**Note:**

If this option is used to permit values that violate the associated syntax, then matching operations involving malformed values might not behave in a predictable manner.

The server should also enforce the `SINGLE-VALUE` constraint for the target attribute type. If an attribute type is defined with this constraint, you cannot configure the composed attribute plugin to generate multiple values for that attribute, and any operation that results in multiple values for the target attribute is rejected.

Composed attributes cannot set values for operational attributes that are defined with the `NO-USER-MODIFICATION` constraint.

## Replication considerations

The composed attribute configuration should be identical for all servers in the replication topology. When a composed attribute plugin is configured for one instance, the same definition should be added to all other instances in the topology.

Composed attribute values should only be generated for the server that processes the request from the client. When that operation is replicated to other servers, the composed attribute changes should be included as part of that operation.

Replicated changes involving composed attributes should not be restricted in a way that prevents external clients from writing to those values. This includes composed values for operational attribute types with the `NO-USER-MODIFICATION` constraint as well as for cases in which the plugin forbids clients from modifying values.

**Note:**

The plugin rejects any `modifyDN` operation that alters source attributes in a way that results in composed attribute changes.

## Synchronization Server considerations

Changes involving composed attributes should be synchronized from a PingDirectory Server instance to another endpoint type without issues. Changes that create or update composed attributes should be written to the LDAP changelog, just like changes to regular attributes.

Synchronization to PingDirectory Server configured with one or more composed attribute plugin instances might be more problematic. It might not be possible to synchronize a composed attribute type if the plugin that generates values for that attribute is configured to prohibit external clients from altering values of that attribute.

If PingDirectory Server is used as a sync destination in an environment in which some attribute values might need to be composed, then you should compose those values in the Synchronization Server using a constructed attribute mapping rather than attempt to generate them in the Directory Server with the composed attribute plugin.

## Directory Proxy Server considerations

Using PingDirectoryProxy Server should not require any special consideration in an environment involving composed attributes. This should be true for both simple and entry-balanced proxy configurations.

## Troubleshooting considerations

For operations that are rejected for reasons related to composed attribute processing, the diagnostic message is returned to the client and included in the access log.

Examples of rejected operations that result in a diagnostic message include:

- If an `add`, `modify`, or `modifyDN` operation is rejected because the composed value violated the syntax for the target attribute type.
- If an attempt was made to alter a composed attribute value in a way that is not permitted by the plugin.

The composed attribute plugin also contains detailed debug logging support. If you encounter unexpected behavior when using the composed attribute plugin, you should enable debugging for the plugin to provide information to help diagnose the problem.

## Security considerations

The primary security consideration for composed attributes is that they can expose the values of other attributes.

For example, if the `cn` attribute is composed from the values of the `givenName` and `sn` attributes, then a user with permission to read the `cn` attribute could determine the values of the `givenName` and `sn` attributes even if they do not have permission to read these attributes directly.

This is not typically a significant concern, and you can address it by ensuring that the user's access-control configuration restricts access to source attributes used in a composed attribute value pattern and imposes similar restrictions to the composed attribute.

## Limitations of composed attributes relative to virtual attributes

Composed attribute support provides an alternative to a specific set of use cases that might also be addressed by virtual attribute support. The composed attribute solution might improve performance, searchability, and write behavior, but it also has limitations relative to the virtual attribute subsystem.

Limitations of composed attributes relative to virtual attributes include:

- When creating a composed attribute plugin in the server, you must use manual action to populate composed values in existing entries. When enabling a virtual attribute, the attribute is immediately available to clients.
- When removing a virtual attribute from the server, values that would have been generated for the attribute are no longer present. When removing or disabling a composed attribute plugin, previously generated composed values remain.
- Virtual attributes can be configured so that the values are only generated under certain conditions, such as only for certain clients, and to enable different values being generated for different clients. Composed attributes are the same for all clients although access controls can be used to restrict which clients have access to them.
- Virtual attributes do not require any additional storage or memory usage. Composed attributes exist in the database, so they require additional disk space and memory for caching.
- The composed attribute plugin can only generate values from a combination of static text and values from other attributes in the same entry. Virtual attributes can use a much wider range of logic when generating values, including custom logic implemented using the Server SDK.

## Encrypting Sensitive Data

---

This section covers how to configure the Directory Server to protect sensitive information in the server.

Some of the ways to protect sensitive data covered in this section are enabling on-disk encryption for data in backends, the changelog, and the replication databases. You can protect sensitive attributes by limiting the ways that clients can interact with them.

For more information, see the following topics:

- [About encrypting and protecting sensitive data](#) on page 685
- [About backing up and restoring the encryption-settings definitions](#) on page 693
- [Configuring sensitive attributes](#) on page 699
- [Configuring global sensitive attributes](#) on page 703
- [Excluding a global sensitive attribute on a client connection policy](#) on page 703

### About encrypting and protecting sensitive data

The Directory Server provides an encryption-settings database that holds encryption and decryption definitions to protect sensitive data. You can enable on-disk encryption for data:

- in backends
- in the changelog
- in the replication databases

You can protect sensitive attributes by limiting the ways that clients can interact with them.

#### About the Encryption-Settings Database

The encryption-settings database is a repository that holds information for encrypting and decrypting data.

The database contains any number of encryption-settings definitions that specifies information about the cipher transformation and encapsulates the key used for encryption and decryption.

Before enabling data encryption, you must create an encryption-settings definition. An encryption-settings definition specifies the cipher transformation to use to encrypt the data and encapsulates the encryption key.

Use the `encryption-settings` command-line tool to manage the encryption settings database, including:

- Creating, deleting, exporting, and importing encryption-settings definitions
- Listing the available definitions
- Indicating which definition to use for subsequent encryption operations

#### Implementing encryption-settings definitions

Although the encryption-settings database can have multiple encryption-settings definitions, designate only one of them as the preferred definition. The preferred encryption-settings definition is the one used for any subsequent encryption operations. Any existing data that has not yet been encrypted remains unencrypted until it is rewritten, such as a result of a `modify` or `modifyDN` operation or if the data is exported to LDIF and re-imported. Similarly, if you introduce a new preferred encryption-settings definition, then any existing encrypted data continues to use the previous definition until it is rewritten. If you do change the preferred encryption-settings definition for the server, retain the previous definitions until you are confident that no remaining data uses those older keys.

## Supported Encryption Ciphers and Transformations

This topic covers implementing encryption ciphers, cipher algorithms, and Cipher Stream Providers in Directory Server.

### Cipher Algorithms

The Directory Server supports encryption cipher suites that are compliant with the Java virtual machine (JVM) in which the server is running. When configuring encryption, you must specify the cipher using a key length in bits and either a cipher algorithm name, such as AES, or a full cipher transformation that explicitly specifies the mode and padding to use for the encryption, such as AES/CBC/ PKCS5Padding. If only a cipher algorithm is given, then the default mode and padding for that algorithm is automatically selected.

The following cipher algorithms and key lengths have been tested using the Oracle JVM.

### Cipher Algorithms and key length

Cipher Algorithm	Key Length (bits)
AES	128
Blowfish	128
DES	64
DESede	192
RC4	128

#### Note:

By default, some JVM implementations come with limited encryption strength, which might restrict the usable key lengths. For example, the Oracle JVM does not allow AES with 192-bit or 256-bit keys unless you download and install the unlimited encryption strength policy files.

For specific reference information about the algorithms and transformations available in all compliant JVM implementations, see the [Java Cryptography Architecture Reference Guide](#) and [Java Cryptography Architecture Standard Algorithm Name Documentation](#) documentation.

### Cipher Stream Providers

Directory Server supports the following Cipher Stream Providers, which are used to obtain cipher input and output streams to read and write encrypted data.

### Cipher Stream Providers and their descriptions

Cipher Stream Providers	Description
Default	Default cipher stream provider using a hard-coded default key.
File-Based	Reads a specified file in order to obtain a password used to generate cipher streams for reading and writing encrypted data.
Third-Party	Provides cipher stream provider implementations created in third-party code using the Server SDK.

Cipher Stream Providers	Description
Wait-for-Passphrase	Causes the server to wait for an administrator to enter a passphrase to use to derive the key for cipher streams. To supply the passphrase to the server, run <code>encryption-settings supply-passphrase</code> .

### Using the `encryption-settings` Tool

The `encryption-settings` tool provides a mechanism for interacting with the server's encryption-settings database.

About this task

Use the `encryption-settings` tool to:

- List the available definitions.
- Create new definitions.
- Delete existing definitions.
- Indicate which definition is the preferred definition.
- Export definitions to a file for backup purposes and to allow them to be imported for use in other Directory Server instances.

To list the available encryption definitions:

### Steps

- To display the set of available encryption settings definitions, use the `encryption-settings` tool with the `list` subcommand.

#### Note:

This subcommand does not take any arguments.

#### Example:

```
$ bin/encryption-settings list
```

#### Result:

For each definition, the result includes the unique identifier for the definition as well as the cipher transformation and key length that is used for encryption and whether it is the preferred definition. See the following example.

```
Encryption Settings Definition ID:
 4D86C7922F71BB57B8B5695D2993059A26B8FC01
Preferred for New Encryption: false
Cipher Transformation: DESede
Key Length (bits): 192

Encryption Settings Definition ID:
 F635E109A8549651025D01D9A6A90F7C9017C66D
Preferred for New Encryption: true
Cipher Transformation: AES
Key Length (bits): 128
```

## Creating encryption-settings definitions

The `create` subcommand provides a mechanism for creating a new encryption-settings definition.

About this task

To create an encryption-settings definition:

### Steps

- To specify the definition, use the `encryption-settings` tool with the `create` subcommand. This subcommand takes the following arguments.

### The `create` subcommand accepted arguments

Argument	Description
<code>--cipher-algorithm &lt;algorithm&gt;</code> (required)	Specifies the base cipher algorithm to use. Make sure the <code>&lt;algorithm&gt;</code> input is the name of the algorithm, such as AES, DES, DESede, Blowfish, RC4.
<code>--cipher-transformation &lt;transformation&gt;</code> (optional)	Specifies the full cipher transformation to use including the cipher mode and padding algorithms, such as AES/CBC/ PKCS5Padding.  If you do not provide this argument, the JVM-default transformation is used for the specified cipher algorithm.
<code>--key-length-bits &lt;length&gt;</code> (required)	Specifies the length of the encryption key in bits, such as 128.
<code>--set-preferred</code>	Indicates that the new encryption-settings definition is made the preferred definition and used for subsequent encryption operations in the server.  By default, the first definition you create in the encryption-settings database is the preferred definition.

### Example:

```
$ bin/encryption-settings create --cipher-algorithm AES \
  --key-length-bits 128 --set-preferred
```

### Result:

```
Successfully created a new encryption settings definition with ID
F635E109A8549651025D01D9A6A90F7C9017C66D
```

## Changing the preferred encryption-settings definition

The **encryption-settings** tool with the `set-preferred` subcommand provides a mechanism for changing the preferred encryption-settings definition.

About this task

To change a definition to a preferred definition:

### Steps

- To change a definition, use the **encryption-settings** tool with the `set-preferred` subcommand to change a definition to a preferred definition.

This subcommand takes the following argument.

### The `set-preferred` subcommand accepted argument

Argument	Description
<code>--id &lt;id&gt;(required)</code>	Specifies the ID to export for the encryption-settings definition.

Example:

```
$ bin/encryption-settings set-preferred --id
4D86C7922F71BB57B8B5695D2993059A26B8FC01
```

Result:

```
Encryption settings definition 4D86C7922F71BB57B8B5695D2993059A26B8FC01
was
successfully set as the preferred definition for subsequent encryption
operations
```

## Deleting an encryption-settings definition

The **encryption-settings** tool with the `delete` subcommand provides a mechanism for deleting an encryption-settings definition.

About this task

If data in the server is encrypted using the settings contained in that definition, never delete an encryption-settings definition. Any data encrypted with a definition that has been removed from the database is inaccessible to the server and causes errors for any attempt to access it. This includes the `replicationChanges` and Changelog Databases in which the **re-encode-entries** tool does not re-encode with the new encryption-settings definition. Before removing previous encryption-settings definitions, wait for the amount of time defined in the **replication-purge-delay** of the Replication Server and **changelog-maximum-age** of the Changelog Backend, if enabled. To safely delete a compromised encryption-settings definition, see [Dealing with a Compromised Encryption Key](#).

To stop using a definition for encryption and use a different definition, make sure that the desired definition exists in the encryption-settings database and set it as the preferred definition. As long as the encryption key is not compromised, there is no harm in having old encryption-settings definitions available to the server. Retain the old encryption-settings definitions in case they are referenced by something.

**Note:**

The preferred encryption-settings definition cannot be deleted unless it is the only one left. To delete the currently-preferred definition when one or more other definitions are available, make one of the other definitions preferred as described in the previous section.

To delete an encryption-settings definition:

### Steps

- To delete an encryption-settings definition, use the **encryption-settings** command with the **delete** subcommand.

#### Remember:

Make sure to include the `--id` argument to specify the definition.

#### The `delete` subcommand accepted argument

Argument	Description
<code>--id &lt;id&gt;(required)</code>	Specifies the ID to export for the encryption-settings definition.

#### Example:

```
$ bin/encryption-settings delete --id
F635E109A8549651025D01D9A6A90F7C9017C66D
```

#### Result:

```
Successfully deleted encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D
```

## Configuring the encryption-settings database

Configure the encryption-settings database to protect server data.

### About this task

The encryption-settings database contains encryption keys to protect server data, which automatically encrypts the contents of the encryption-settings database. By default, the server derives a key to use for this purpose. Because of this, customize the logic used to access the encryption-settings database with a cipher stream provider. To create custom cipher stream provider implementations, the Server SDK provides an API. The server contains an API you can use to obtain the key from a PIN file that you create. See the following example procedure.

### Steps

1. To configure the server so that the encryption-settings database is encrypted with a PIN contained in the file `config/encryption-settings.pin`, use the **dsconfig** tool.

#### Example:

```
$ bin/dsconfig create-cipher-stream-provider \
--provider-name "Encryption Settings PIN File" \
--type file-based \
--set enabled:true \
--set password-file:config/encryption-settings.pin
```

2. To set the global configuration property and the on-disk encryption for the cipher stream provider, use the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set "encryption-settings-cipher-stream-provider:Encryption Settings
  PIN File"
```

3. To create a new encryption-settings definition, use the `encryption-settings` tool.

 **Note:**

This command fails if you do not have the unlimited encryption strength policy installed as described in the previous section. Without this policy installed, you are restricted to a 128-bit key for AES encryption.

Example:

```
$ bin/encryption-settings create \
  --cipher-algorithm AES \
  --key-length-bits 256 \
  --set-preferred
```

Result: This command automatically generates a new 256-bit encryption key for use with AES encryption and marks it as the preferred definition for future encryption operations in the server.

4. To obtain a list of the definitions in the encryption-settings database, use the `encryption-settings` tool with the `list` subcommand.

Example:

```
$ bin/encryption-settings list
```

5. Export an encryption-settings definition from the database using the `encryption-settings` tool with the `export` subcommand.

 **Note:**

Change the encryption-settings ID as necessary to suit your deployment.

Example:

```
$ bin/encryption-settings export \
  --id DA39A3EE5E6B4B0D3255BF95601890AFD80709 \
  --output-file /tmp/exported-key \
  --pin-file /tmp/exported-key.pin
```

6. To import an encryption-settings definition into the database on another server, use the `encryption-settings` tool with the `import` subcommand.

If you do not specify a PIN file, the tool interactively prompts you to provide it.

Example:

```
$ bin/encryption-settings import \
  --input-file /tmp/exported-key \
  --pin-file /tmp/exported-key.pin \
  --set-preferred
```

## Encrypting passphrase files

Use an encrypted passphrase or a `tools.properties` file to enable the server and command-line tools to use credentials available but not store them in the clear.

About this task

Encrypt these files with the following considerations:

- If the file is encrypted with a key obtained from the server's encryption settings database, the server and associated command-line tools retrieve the appropriate key from the encryption settings database, so the clear-text contents of the file are accessed without any interaction. However, if the cipher stream provider configured to protect the contents of the encryption settings database requires interaction, such as the wait for passphrase cipher stream provider, then command-line tools might require interaction to unlock the encryption settings database.
- If the file is encrypted with a passphrase that the user specifies rather than one obtained from the encryption settings database, the user is interactively prompted for that passphrase when running the tool.

### Note:

Do not use this option for key store and trust store PIN files that need to be accessed by the server.

You can encrypt these files using the `encrypt-file` tool and the following tools:

### Certificate keystore and truststore PIN files

When setting up an instance with encryption and either SSL or StartTLS enabled, the installer automatically encrypts the PIN files for the `config/keystore`, `config/truststore`, and `config/ads-truststore` certificate databases.

### Command-line arguments

Specify passphrase files using command-line arguments. Most LDAP tools offer `--bindPasswordFile`, `--keystorePasswordFile`, and `--truststorePasswordFile` arguments.

### The `config/tools.properties` file

Use the `config/tools.properties` file to obtain a default set of arguments for most command-line tools. Alternately, you can use the `--propertiesFilePath` argument to specify an alternate properties file.

## Steps

1. Encrypt a file with the server's preferred encryption settings definition.

Example:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted
```

- To use a key from an encryption settings definition that isn't the default and specify the ID of the desired encryption settings definition, use the `--encryption-settings-id` argument.

**Note:**

You can obtain the `--encryption-settings-id` with `encryption-settings list`.

Example:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted \
  --encryption-settings-id 4B6899D6716FC3AFFD71F7B447EB135063A0E724
```

- To encrypt the file with a passphrase rather than a key from an encryption settings definition, choose one of the following options:

Choose from:

- Use the `--prompt-for-passphrase` argument to interactively prompt for the passphrase.
- Use the `--passphrase-file` argument to specify the path to a file containing the clear-text passphrase.

Example:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted \
  --prompt-for-passphrase
```

## About backing up and restoring the encryption-settings definitions

The Directory Server provides two different mechanisms for backing up and restoring encryption-settings definitions.

The two ways you can backup and restore encryption-settings definitions:

- Export and import one or more encryption-settings definitions using the `encryption-settings` tool.
- Backup and restore the entire encryption-settings database using the `backup` and `restore` tools.

If a PIN file is used to define a passphrase to the encryption-settings database, you must backup the passphrase and secure it independently of the userRoot and encryption-settings database backups. If the encryption-settings database is restored into a different server root, the passphrase in the PIN file is required.

**Attention:**

Make sure the encryption-settings definitions are backed up regularly so you don't lose the encryption-settings definitions used to encrypt data in the server. If an encryption-settings definition is lost, any data encrypted with that definition is completely inaccessible.

### Exporting encryption-settings definitions

The `encryption-settings` tool with the `export` subcommand provides a mechanism for exporting encryption-settings definitions.

About this task

Use the `export` subcommand with the `encryption-settings` command for the following scenarios:

- To back up an individual definition
- To export an individual definition from one server and import it into another

## Steps

- To export the definition to a file, use the **encryption-settings** tool with the **export** subcommand. The subcommand takes the following arguments.

<code>--id &lt;id&gt;</code>	Specifies the ID to export for the encryption-settings definition.  You can specify this argument multiple times. If it's omitted, all definitions are exported.
<code>--output-file &lt;path&gt;(required)</code>	Specifies the path to the output file to write the encryption-settings definition.
<code>--pin-file &lt;path&gt;</code>	Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition.  If this argument isn't provided, then the PIN is interactively requested from the server.

### Example:

```
$ bin/encryption-settings export --id
F635E109A8549651025D01D9A6A90F7C9017C66D \
  --output-file /tmp/exported-key
Enter the PIN to use to encrypt the definition:
Re-enter the encryption PIN:
```

### Result:

```
Successfully exported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D to file /tmp/exported-key
```

## Importing encryption-settings definitions

### About this task

To import an encryption-settings definition that has been previously exported, use the **encryption-settings** tool with the **import** subcommand. The subcommand takes the following arguments:

`--input-file {path}`

Specifies the path to the file containing the exported encryption-settings definition. This argument is required.

`--pin-file {path}`

Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition. If this argument isn't provided, then the PIN is interactively requested from the server.

`--set-preferred`

Specifies that the newly-imported encryption-settings definition should be made for the preferred definition for subsequent encryption-settings.

## Steps

- Use the **encryption-settings** tool with the **import** subcommand to import the definition to a file.

Example:

```
$ bin/encryption-settings import --input-file /tmp/exported-key --set-preferred
Enter the PIN used to encrypt the definition:
```

Result:

```
Successfully imported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D from file /tmp/exported-key
```

## Enabling data encryption in the server

Enable data encryption during server setup or after server setup.

### About this task

When enabling data encryption in the server, configure for backups and LDIF exports with the following global properties.

Global property	Configuration description
<b>automatically-compress-encrypted-ldif-exports</b>	<p>Indicates whether to automatically compress LDIF exports that are also encrypted.</p> <ul style="list-style-type: none"> <li>If set to <code>true</code>, any LDIF export that is encrypted, either explicitly with <code>--encryptLDIF</code> or implicitly with the <code>encrypt-ldif-exports-by-default</code> configuration property, is gzip-compressed.</li> <li>If set to <code>false</code>, manually compress encrypted LDIF exports using the <code>--compress</code> command-line argument.</li> </ul>

Global property	Configuration description
<code>backup-encryption-settings-definition-id</code>	<p>The unique identifier for the encryption settings definition to use to generate the encryption key for encrypted backups by default.</p> <ul style="list-style-type: none"> <li>▪ If this property is given a value, then a definition with that ID must exist in the server's encryption settings database.</li> <li>▪ If this property is not given a value, but the server is configured with at least one encryption settings definition, then the preferred definition is used.</li> <li>▪ If no encryption settings definitions are available, the server will use an internal key shared among servers in the topology. Regardless of this property's value, it can be overridden with the <code>backup</code> command-line tool. Providing one of the <code>--promptForEncryptionPassphrase</code> or <code>--encryptionPassphraseFile</code> arguments will generate the encryption key from the provided passphrase. Or, the <code>--encryptionSettingsDefinitionID</code> argument can be used to generate the key from the specified encryption settings definition.</li> </ul>
<code>encrypt-backups-by-default</code>	<p>Indicates whether the server should encrypt backups by default.</p> <ul style="list-style-type: none"> <li>▪ If set to true, a defined <code>backup-encryption-settings-definition-id</code> value is used to generate the encryption key for the backup.</li> <li>▪ If this property is true, and if a <code>backup-encryption-settings-definition-id</code> value is not specified, the server tries to use the preferred encryption settings definition to generate the encryption key.</li> <li>▪ If the server is not configured with any encryption settings definitions, an internal key that is shared among instances in the topology is used.</li> </ul> <p> <b>Note:</b></p> <p>Regardless of this property's value, even if this property is set to <code>false</code>, you can overwrite it with the <code>backup</code> command-line tool's <code>--encrypt</code> argument.</p> <p>Even if this property has a value of <code>true</code>, the <code>--doNotEncrypt</code> argument always causes the backup to be unencrypted.</p>

Global property	Configuration description
<p><code>encrypt-ldif-exports-by-default</code></p>	<p>Indicates whether the server should encrypt LDIF exports by default.</p> <ul style="list-style-type: none"> <li>▪ If set to <code>true</code>, and an <code>ldif-export-encryption-settings-definition-id</code> value is specified, then that encryption settings definition is used to generate the encryption key for the export.</li> <li>▪ If this property is <code>true</code>, and an <code>ldif-export-encryption-settings-definition-id</code> value is not specified, the server first tries to use the preferred encryption settings definition to generate the encryption key.</li> <li>▪ If the server is not configured with any encryption settings definitions, an internal key that is shared among instances in the topology is used.</li> </ul> <p> <b>Note:</b></p> <p>Regardless of this property's value, you can overwrite the default behavior with the <code>export-ldif</code> command-line tool.</p> <p>The tool's <code>--encryptLDIF</code> argument always encrypts the export, and the <code>--doNotEncryptLDIF</code> argument always creates an unencrypted export.</p>

Perform the following steps to enable data encryption:

#### Steps

1. To enable encryption, choose from one of the following setups:  
Choose from:
  - During server setup, define an encryption key and passphrase.
  - On legacy systems or post setup, configure data encryption by having at least one encryption-settings definition available for use.
2. Set the value of the `encrypt-data` global configuration property to `true` using the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-global-configuration-prop --set encrypt-data:true
```

Result:

Setting the global configuration property automatically enables data encryption for all types of backends that support it, including the changelog backend and indexes, as well as for the replication server database. All subsequent write operations cause the corresponding records that are written into any of these locations to be encrypted. Any existing data remains unencrypted until it is rewritten by a write operation.

## Next steps

To have existing data encrypted, export that data to LDIF and re-import it. This works for both the data backends, the changelog, and indexes.

### Note:

This does not work for the replication database, so existing change records remain unencrypted until they are purged. To purge a compromised encryption settings definition, safely purge the replication database by following the steps in [Dealing with a Compromised Encryption Key](#).

## Using data encryption in a replicated environment

Use data encryption for on-disk storage for data within the server.

Whenever clients access stored data in the server, it's presented in unencrypted form although the communication with those clients can itself be encrypted using SSL or StartTLS. Replication, the communication of updates between replication servers, is always encrypted using SSL. Each server can apply data encryption in an independent manner and have different sets of encryption-settings definitions. It's possible to have a replication topology containing some servers that have data encryption enabled and others with it disabled.

When initializing the backend of one server from another server with data encryption enabled, the server being initialized must have access to all encryption-settings definitions that might have been used for data contained in that backend.

To do this, perform an export of the encryption-settings database on the source server using `bin/encryption-settings export` and import it on the target server using `bin/encryption-settings import`.

## Dealing with a compromised encryption key

When an encryption-settings definition is compromised, all data encrypted with that definition is vulnerable, and you must stop using the definition immediately.

### About this task

If an encryption-settings definition becomes compromised, such as an unauthorized individual obtaining access to the encryption key, then any data encrypted with that definition is vulnerable because it can be decrypted using that key. It's important that the encryption-settings database is protected to ensure that its contents remain secure. For example, using file permissions or file system access control lists (ACLs).

In the event that an encryption-settings definition is compromised, stop using the definition immediately. You must re-encrypt any data encrypted with the compromised key with a new definition or purged from the server. Do this on one server at a time to avoid an environment-wide downtime and complete it as quickly as possible on all servers that used this definition at any point in the past to minimize the risk of data exposure.

To respond to a compromised encryption settings definition:

### Steps

1. Create a new encryption-settings definition and make it the preferred definition for new writes.
2. Ensure that client traffic is routed away from the server instance to be updated.

If the Directory Server is accessed through a Directory Proxy Server, then you can set the `health-check-state` configuration property for any LDAP external server definitions that reference that server to have a value of `unavailable`.

3. To ensure that external clients are not allowed to write operations in the directory server instance, set the `writability-mode` global configuration property to have a value of `internal-only`.

4. Look at the monitor entries with the `ds-replication-server-handler-monitor-entry` object class to ensure that the value of the `update-sent` attribute is no longer increasing.

This signals that all outstanding local changes are replicated out to other servers.

5. Stop the directory server instance.
6. Delete the replication server database by removing all files in the `changeLogDb` directory below the server root.

 **Important:**

As long as all local changes have been replicated out to other servers, this does not result in any data loss in the replication environment.

7. Export the contents of all local DB and changelog backends to LDIF.
8. Re-import the data from LDIF.

This causes the data to be encrypted using the new preferred encryption settings definition.

9. Export the compromised key from the encryption settings database.

 **Note:**

For precautionary measures, do this to back up the key in case you need it in the future, such as if some remaining data was later found to have been encrypted with the key contained in that definition.

10. To no longer allow the directory server instance to use the key, delete the key from the encryption settings database.
11. Start the directory server instance.
12. Allow replication to bring the server back up-to-date with any changes processed while it was offline.
13. To re-allow externally-initiated write operations, change the value of the global `writability-mode` configuration property to `enable`.
14. To allow client traffic to be routed again to that server instance, reconfigure the environment.

An example is changing the value of the `health-check-state` property in the corresponding LDAP external instance definitions in the Directory Proxy Server instances back to `dynamically-determined`.

## Configuring sensitive attributes

Use and configure sensitive attribute definitions to customize the level of client data access and encryption protection needed.

For a Directory Server instance, data encryption only applies to the on-disk storage. Although it doesn't automatically protect information accessed or replicated between servers, the server offers mechanisms to provide that protection, such as SSL, StartTLS, and SASL.

All client communication using either SSL or StartTLS encryption and all replication traffic using SSL encryption helps ensure that the data is protected from unauthorized individuals who might eavesdrop on network communication. You can enable this communication security independently of data encryption.

 **Note:**

If data encryption is enabled, you should use secure communication to protect network access to that data.

Protecting client data access isn't as simple as enabling secure communication. In some cases, you might want to allow insecure access to some data. In other cases, you might need to have additional levels of

protection in place to ensure that some attributes are more carefully protected. To achieve varying levels of protection, use sensitive attribute definitions.

The following table explains the sensitive attribute definitions and their configuration properties.

Sensitive attribute	Configuration details
attribute-type	<p>Specifies the set of attribute types whose values might be considered sensitive.</p> <p>You must provide at least one attribute type and define all specified attribute types in the server schema.</p>
include-default-sensitive-operational-attributes	<p>Indicates whether the set of sensitive attributes that might contain sensitive information should automatically be updated to include any operational attributes maintained by the Directory Server itself.</p> <p>This includes the <code>ds-sync-hist</code> operation attribute, which is used for data required for replication conflict resolution and can contain values from other attributes in the entry.</p>
allow-in-filter	<p>Indicates whether sensitive attributes can be used in filters.</p> <p>This applies not only to the filter used in search requests, but also to filters that can be used in other places, such as the assertion and join request controls.</p> <p>The value of this property must be one of the following:</p> <ul style="list-style-type: none"> <li>▪ <code>Allow</code>: allows sensitive attributes to be used in filters over both secure and insecure connections.</li> <li>▪ <code>Reject</code>: rejects any request that includes a filter targeting one or more sensitive attributes over both secure and insecure connections.</li> <li>▪ <code>Secure-only</code>: allows sensitive attributes to be used in filters over secure connections but rejects any such requests over insecure connections.</li> </ul>

Sensitive attribute	Configuration details
allow-in-add	<p>Indicates whether sensitive attributes can be included in entries created by <code>ldapadd</code> operations.</p> <p>The value of this property must be one of the following:</p> <ul style="list-style-type: none"> <li>▪ <code>Allow</code>: allows sensitive attributes included in add requests over both secure and insecure connections.</li> <li>▪ <code>Reject</code>: rejects any add request containing sensitive attributes over both secure and insecure connections.</li> <li>▪ <code>Secure-only</code>: allows sensitive attributes included in add requests received over secure connections but rejects any such requests over insecure connections.</li> </ul>
allow-in-compare	<p>Indicates whether sensitive attributes can be targeted by the assertion used in a compare operation.</p> <p>The value of this property must be one of the following:</p> <ul style="list-style-type: none"> <li>▪ <code>Allow</code>: allows sensitive attributes to be targeted by requests over both secure and insecure connections.</li> <li>▪ <code>Reject</code>: rejects compare requests targeting a sensitive attribute over both secure and insecure connections.</li> <li>▪ <code>Secure-only</code>: allows compare requests targeting sensitive attributes over secure connections but rejects compare requests over insecure connections.</li> </ul>
allow-in-modify	<p>Indicates whether sensitive attributes can be updated using modify operations.</p> <p>The value of this property must be one of following:</p> <ul style="list-style-type: none"> <li>▪ <code>Allow</code>: allows sensitive attribute to be modified by requests over both secure and insecure connections.</li> <li>▪ <code>Reject</code>: rejects any modify request updating a sensitive attribute over both secure and insecure connections.</li> <li>▪ <code>Secure-only</code>: allows only modify requests updating sensitive attributes over secure connections but rejects modify requests over insecure connections.</li> </ul>

**Note:**

By default, `allow-in-returned-entries`, `allow-in-filter`, `allow-in-add`, `allow-in-compare`, and `allow-in-modify` properties have values of `secure-only` only. This prevents the possibility of exposing sensitive data in the clear to anyone able to observe network communication.

### Sensitive attributes and client connection policies

If a client connection policy references a sensitive attribute definition, any restrictions imposed by that definition are enforced for clients associated with this client connection policy. If multiple sensitive attribute definitions are associated with a client connection policy, the server uses the most restrictive combination of all of those sets.

### Sensitive attributes and other security mechanisms

The sensitive attribute definitions work in conjunction with other security mechanisms defined in the server and can only be used to enforce additional restrictions on clients.

Never use sensitive attribute definitions to grant a client additional access to information that it didn't have already through other means. For example, if the `employeeSSN` attribute is declared a sensitive attribute and the `allow-in-returned-entries` property has a value of `Secure-only`, then the `employeeSSN` attribute is only returned to those clients that have both permissions granted by the access control rules defined in the server and are communicating with the server over a secure connection.

The `employeeSSN` attribute is stripped out of entries returned to clients normally authorized to see it if they are using insecure connections. It is also stripped out of entries for clients normally not authorized to see it even if they have established secure connections.

### Creating a sensitive attribute

Creating sensitive attributes involves creating and associating definitions to set configuration properties and policies according to your business needs.

#### About this task

To create a sensitive attribute:

#### Steps

1. Create one or more sensitive attribute definitions using `dsconfig create-sensitive-attribute`.

##### Example:

For example, to create a sensitive attribute definition that only allows access to the `employeeSSN` attribute by clients using secure connections, make the following configuration changes.

```
$ bin/dsconfig create-sensitive-attribute \
  --attribute-name "Employee Social Security Numbers" \
  --set attribute-type:employeeSSN \
  --set include-default-sensitive-operational-attributes:true \
  --set allow-in-returned-entries:secure-only \
  --set allow-in-filter:secure-only \
  --set allow-in-add:secure-only \
  --set allow-in-compare:secure-only \
  --set allow-in-modify:secure-only
```

2. Associate the sensitive attribute definitions with the client connection policies that you want to enforce using `dsconfig set-client-connection-policy-prop`.

##### Example:

```
$ bin/dsconfig set-client-connection-policy-prop --policy-name default \
```

```
--set "sensitive-attribute:Employee Social Security Numbers"
```

## Configuring global sensitive attributes

The Directory Server supports the ability to define sensitive attributes as a global configuration option so that they're automatically used across all client connection policies.

About this task

Administrators can assign one or more sensitive attribute definitions to a client connection policy.

### Note:

When working in an environment with multiple client connection policies, it can be easy to add a sensitive attribute definition to one policy but overlook it in another.

Steps

- To add a global sensitive attribute across all client connection policies, run the `dsconfig` tool.

Example:

The following command adds the `employeeSSN` as a global sensitive attribute, which is applied across all client connection policies.

```
$ bin/dsconfig set-global-configuration-prop --add "sensitive-attribute:employeeSSN"
```

## Excluding a global sensitive attribute on a client connection policy

Administrators can exclude a global sensitive attribute on a client connection policy when it's not needed for client connection requests.

About this task

Administrators can set a global sensitive attribute across all client connection policies. However, there can be cases when a specific directory server must exclude the sensitive attribute because it's not needed for client connection requests.

For example, in most environments, it's good to declare the `userPassword` attribute to be a sensitive attribute that prevents external clients reading it. This solution is more secure than protecting the `password` attribute using the server's default global access control instruction (ACI), which only exists for backwards compatibility purposes. If the Data Sync Server is installed, then it does need to access passwords for synchronization purposes. In this case, the administrator can set `userPassword` to be a sensitive attribute in all client connection policies, but exclude it in a policy specifically created for use by the Data Sync Server. The Directory Server provides an `exclude-global-sensitive-attribute` property for this purpose.

## Steps

1. To remove the global ACI that limits access to the `userPassword` or `authPassword` attribute, run the `dsconfig` tool.

### Note:

The global ACI is present for backwards compatibility.

### Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --remove 'global-aci:(targetattr="userPassword || authPassword")
  (version 3.0; acl "Prevent clients from retrieving passwords from the
  server";
  deny (read,search,compare) userdn="ldap:///anyone");'
```

2. To add the `userPassword` attribute as a global sensitive attribute, run the `dsconfig` tool and add the built-in "sensitive-attribute:Sensitive Password Attributes" definition to the global configuration.

This applies to all client connection policies.

### Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --add "sensitive-attribute:Sensitive Password Attributes"
```

3. If the server is designated to synchronize passwords with a Sync Server, configure a client connection policy for the Sync User to exclude the global sensitive attribute.

### Example:

The following example shows how to create a new policy if the Data Sync Server binds with the default distinguished name (DN) of `cn=Sync User,cn=Root DNs,cn=config`.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Requests by Sync Users" \
  --type simple \
  --set user-auth-type:internal \
  --set user-auth-type:sasl \
  --set user-auth-type:simple \
  --set "included-user-base-dn:cn=Sync User,cn=Root DNs,cn=config"

$ bin/dsconfig create-client-connection-policy \
  --policy-name "Data Sync Server Connection Policy" \
  --set enabled:true \
  --set evaluation-order-index:9998 \
  --set "connection-criteria:Requests by Sync Users" \
  --set "exclude-global-sensitive-attribute:Sensitive Password
  Attributes"
```

## Working with the LDAP Changelog

The Directory Server provides a client-accessible LDAP changelog, based on the Changelog Internet Draft Specification, for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format. The LDAP changelog is typically used by external software to maintain application compatibility between client services.

## Overview of the LDAP changelog

The Directory Server provides a client-accessible LDAP changelog, based on the Changelog Internet Draft Specification, for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format.

The LDAP changelog is used by external software to maintain application compatibility between client services. For example, you can install the Data Sync Server that monitors the LDAP changelog for any updates that occur on a source directory server and synchronizes these changes to a target directory information tree (DIT) or database server.

The Directory Server provides an additional feature in that the LDAP changelog supports virtual attributes.

### Note:

The LDAP changelog should not be confused with the Replication changelog. The main distinction is as follows:

- The LDAP changelog (the external changelog that clients can access) physically resides at `<server-root>/db/changelog`.
- The Replication changelog backend (the changelog that replication servers use) physically resides at `<server-root>/changelogDB`.

### Key changelog features

As of 3.2, the Directory Server supports two new changelog backend properties that allow access control filtering and sensitive attribute evaluation for targeted entries.

External client applications can change the contents of attributes seen in the targeted entry based on the access control rules applied to the associated base DN.

Attribute	Description
<code>apply-access-controls-to-changelog-entry-contents</code>	Indicates whether the contents of changelog entry attributes, such as <code>changes</code> , <code>deletedEntryAttrs</code> , <code>ds-changelog-entry-key-attr-values</code> , <code>ds-changelog-before-values</code> , and <code>ds-changelog-after-values</code> , are subject to access control and sensitive attribute evaluation to limit data that LDAP clients can see. The client must have the access control permissions to read changelog entries to retrieve them in any form. If this feature is enabled and the client does not have permission to read an entry at all, or if that client does not have permission to see any attributes that were targeted by the change, then the associated changelog entries targeted by those operations are suppressed. If a client does not have permission to see certain attributes within the target entry, then references to those attributes in the changelog entry are also suppressed. This property only applies to standard LDAP searches of the <code>cn=changelog</code> branch.

Attribute	Description
<p>report-excluded-changelog-attributes</p>	<p>Indicates whether to include additional information about any attributes that might have been removed due to access control filtering. This property only applies to content removed as a result of processing performed by the <code>apply-access-controls-to-changelog-entry-contents</code> property. Possible values are:</p> <p><code>none</code></p> <p>Indicates that changelog entries should not include any information about attributes that have been removed.</p> <p><code>attribute-counts</code></p> <p>Indicates that changelog entries should include a count of user and operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, the number of the excluded user attributes are reported in the <code>ds-changelog-num-excluded-user-attributes</code> attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the number of the excluded operational attributes are reported in the <code>ds-changelog-num-excluded-operational-attributes</code> attribute of the changelog entry. Both the <code>ds-changelog-num-excluded-user-attributes</code> and <code>ds-changelog-num-excluded-operational-attributes</code> are operational and must be explicitly requested by clients or all operational attributes requested using <code>+</code> to be returned.</p> <p><code>attribute-names</code></p> <p>Indicates that changelog entries should include the names of user and operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, then the names of the excluded user attributes are reported in the <code>ds-changelog-excluded-user-attributes</code> attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the names of the excluded operational attributes are reported in the <code>ds-change-log-excluded-operational-attribute</code> attribute of the changelog entry. Both the <code>ds-changelog-excluded-user-attribute</code> and <code>ds-changelog-excluded-operational-attribute</code> attributes are operational and must be explicitly requested by clients or all operational attributes requested using <code>+</code> to be returned.</p>

## Enabling access control filtering in the LDAP changelog

Use the `dsconfig` tool to enable the properties to the changelog backend to set up access control to the LDAP changelog.

About this task

Only admin users with the `bypass-acl` privilege can read the changelog.

### Steps

1. To allow LDAP clients to undergo access control filtering using standard LDAP searches of the `cn=changelog` backend, enable the `apply-access-control-to-changelog-entry-contents` property.

Access control filtering is applied regardless of the value of the `apply-access-controls-to-changelog-entry-contents` setting when the changelog backend is servicing requests from an PingDataSync Server that has the `filter-changes-by-user` Sync Pipe property set.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
  --set "apply-access-controls-to-changelog-entry-contents:true"
```

2. To include a count of users that have been removed through access control filtering, set the `report-excluded-changelog-attributes` property.

The count appears in the `ds-changelog-num-excluded-user-attributes` attribute for users and in the `ds-changelog-num-excluded-operational-attributes` attribute for operational attributes.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
  --set "report-excluded-changelog-attributes:attribute-counts"
```

## Useful changelog features

The Directory Server provides two changelog configuration properties: `changelog-max-before-after-values` and `changelog-include-key-attribute`.

### `changelog-max-before-after-values`

Setting this property to a non-zero value causes all of the old values and all of the new values, up to the specified maximum, for each changed attribute to be stored in the changelog entry. The values are stored in the `ds-change-log-before-values` and `ds-changelog-after-values` attributes on the changelog entry. These attributes are not present by default.

#### Note:

The `changelog-max-before-after-values` property can be expensive for attributes with hundreds or thousands of values, such as a group entry.

If any attribute has more than the maximum number of values, their names and number of before and after values are stored in the `ds-changelog-attr-exceeded-max-values-count` attribute on the changelog entry. This is a multi-valued attribute with the following format.:

```
attr=attributeName,beforeCount=100,afterCount=101
```

`attributeName` is the name of the attribute, and the `beforeCount` and `afterCount` are the total number of values for that attribute before and after the change, respectively. This attribute indicates that

you must reset the `changelog-max-before-after-values` property to a higher value. When this attribute is set, an alert is generated.

**Note:**

If the number of values for an attribute exceeds the maximum value set by the `changelog-max-before-after-values` property, then those values are not stored.

### changelog-include-key-attribute

This property is used for correlation attributes that need to be synchronized across servers, such as `uid`. It causes the current (after-change) value of the specified attributes to be recorded in the `ds-changelog-entry-key-attr-values` attribute on the changelog entry. This applies for all change types. On a `DELETE` operation, the values are from the entry before they were deleted.

The key values are recorded on every change and override the settings configured in `changelog-include-attribute`, `changelog-exclude-attribute`, `changelog-deleted-entry-include-attribute`, or `changelog-deleted-entry-exclude-attribute`.

### Example of the changelog features

After the `changelog-max-before-after-values` property is set, the before and after values of any change attribute are recorded in the LDAP changelog.

For example, consider a simple entry with two multi-valued mail attributes.

```
dn: uid=test,dc=example,dc=com
objectclass: inetorgperson
cn: test user
sn: user
description: oldDescription
mail: test@yahoo.com
mail: test@gmail.com
```

Then, apply the following changes to the entry.

```
dn: uid=test,dc=example,dc=com
changetype: modify
add: mail
mail: test@hotmail.com
-
delete: mail
mail: test@yahoo.com
-
replace: description
description: newDescription
```

The resulting changelog would record the following attribute values.

```
dn: changeNumber=1,cn=changelog
objectClass: top
objectClass: changeLogEntry
targetDN: uid=test,dc=example,dc=com
changeType: modify
changes::

changenumber: 1

```

Run the `bin/base64 decode -d` command line tool to view the decoded value for the `changes`, `ds-changelog-before-values`, and `ds-changelog-after-values` attributes.

After base64 decoding, the `changes` attribute displays the following.

```

add: mail
mail: test@hotmail.com
-
delete: mail
mail: test@yahoo.com
-
replace: description
description: newDescription
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z
-

```

After base64 decoding, the `ds-changelog-before-values` attribute displays the following.

```

description: oldDescription
mail: test@yahoo.com
mail: test@gmail.com
modifyTimestamp: 20131010020345.546Z
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config

```

After base64 decoding, the `ds-changelog-after-values` attribute displays the following.

```

description: newDescription
mail: test@gmail.com
mail: test@hotmail.com
modifyTimestamp: 20131010020345.546Z
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config

```

## Viewing the LDAP changelog properties

To view the LDAP changelog properties, run the `dsconfig get-backend-prop` command and specify the changelog backend.

### Viewing the LDAP changelog properties using dsconfig non-interactive mode

#### Steps

- To view the changelog properties on the Directory Server, use `dsconfig`.

#### Tip:

To view "advanced" properties that are normally hidden, add the `--advanced` option when running the command. For a specific description of each property, see the PingDirectory Server [Configuration Reference](#).

#### Example:

```
$ bin/dsconfig get-backend-prop --backend-name changelog
```

#### Result:

```
Property                               : Value(s)
-----
backend-id                             : changelog
description                             : -
enabled                                 : false
writability-mode                        : disabled
base-dn                                 : cn=changelog
set-degraded-alert-when-disabled        : false
return-unavailable-when-disabled        : false
db-directory                             : db
db-directory-permissions                 : 700

## Enabling the LDAP changelog

Enable the LDAP changelog to maintain application compatibility between client services.

The LDAP changelog is disabled by default on the Directory Server. If you are using the `dsconfig` tool in interactive mode, the changelog appears in the backend configuration as a Standard object menu item.

#### Note:

Enable the feature using the `dsconfig` tool only if required because it can affect LDAP update performance.

## Enabling the LDAP changelog using dsconfig non-interactive mode

### Steps

- Use `dsconfig` to enable the changelog property on the Directory Server.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name changelog --set enabled:true
```

## Enabling the LDAP changelog using interactive mode

### Steps

- Use `dsconfig` to enable the changelog on each server in the network.
- Authenticate to the server by entering the host name, LDAP connection, port, bindDN, and bind password.
- In the `Directory Server` main menu, enter `o` to change from the Basic object level to the Standard object level.
- Enter the option to select the `Standard object level`.
- In the `Directory Server` main menu, enter the number corresponding to `backend`.
- In the `Backend Management` menu, enter the option to view and edit an existing backend.  
Result: The system displays a list of the accessible backends. For example, you see options for the `changelog` and `userRoot` backends.
- Enter the option to work with the changelog backend.
- In the `Changelog Backend properties` menu, enter the number corresponding to the `Enabled` property.
- In the `Enabled Property` menu, enter the number to change the `Enabled` property to `TRUE`.
- In the `Backend Properties` menu, enter `f` to apply the change.  
If you set up the server in a server group, enter `g` to update all of the servers in the group. Otherwise, repeat steps 1-10 on the other servers.
- Verify that changes made to the data are recorded in the changelog.

## Changing the LDAP changelog database location

If you have disk space issues, you can change the on-disk location of the LDAP changelog database.

The changelog backend supports a `db-directory` property that specifies the absolute or relative path (relative to the local server root) to the file system directory that is used to hold the Oracle Berkeley DB Java Edition database files containing the data for this backend.

If you change the changelog database location, you must stop and restart the Directory Server for the change to take effect. If the changelog backend is already enabled, then the database files must be manually moved or copied to the new location while the server is stopped.

## Changing the LDAP changelog location using dsconfig non-interactive mode

### Steps

1. Use **dsconfig** to change the database location for the LDAP changelog, which by default is at `<server-root>/db`.

Example:

The following command sets the LDAP changelog backend to `<server-root>/db2`.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \  
--set "db-directory:db2" --set "enabled:true"
```

#### Note:

Remember to include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

The database files are stored under `<server-root>/db2/changelog`. The files for this backend are stored in a sub-directory named after the `backend-id` property.

2. Stop and restart the server.

Because the LDAP changelog backend was previous disabled, you do not need to manually relocate any existing database files.

Example:

```
$ bin/stop-server  
$ bin/start-server
```

## Resetting the LDAP changelog location using dsconfig non-interactive mode

### Steps

1. If you have changed the LDAP changelog location, to reset it to its original location, use **dsconfig**.

Example:

The following command resets the LDAP changelog backend to `<server-root>/db` location.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \  
--reset "db-directory"
```

#### Note:

Remember to include the LDAP connection parameters such as host name, port, bindDN, and bindPassword.

2. If the LDAP changelog backend at the previous location is enabled:
  - a. Stop the server.
  - b. Copy the database files to the new LDAP changelog location.
  - c. Restart the server.

**Note:**

The server attempts to use whatever it finds in the configured location when it starts. If there is nothing there, it creates an empty database.

## Viewing the LDAP changelog parameters in the Root DSE

The Root DSE is a special entry that holds operational information about the server.

### About this task

The entry provides information about the LDAP controls, extended operations, and Simple Authentication and Security Layer (SASL) mechanisms available in the server as well as the state of the data within the changelog. For changelog parameters, the attributes of interest include:

`firstChangeNumber`

Change number for the first (oldest) change record contained in the LDAP changelog.

`lastChangeNumber`

Change number for the last (most recent) change record contained in the LDAP changelog.

`lastPurgedChangeNumber`

Change number for the last change that was purged from the LDAP changelog. It can be 0 if no changes have yet been purged.

`firstReplicaChange`

Information about the first (oldest) change record for a change received from the specified replica. This is a multi-valued attribute and should include a value for each server in the replication topology.

`lastReplicaChange`

Information about the last (most recent) change record for a change received from the specified replica.

The `firstReplicaChange` and `lastReplicaChange` attributes use the following syntax.

```
serverID:CSN:changeNumber
```

### Where:

`serverID`

Specifies the unique identifier for the server updating the change log.

`CSN`

Specifies the Change Sequence Number, which is the time when the update was made to the given replica.

`changeNumber`

Specifies the order of the change that is logged to the LDAP changelog.

The `firstReplicaChange` and `lastReplicaChange` attributes can be used to correlate information in the local LDAP changelog with data in the LDAP changelog of other servers in the replication topology.

The order of the individual changes in the LDAP changelog can vary between servers based on the order in which they were received from a replica.

### Steps

- Use `ldapsearch` to view the Root DSE.

Example:

```
$ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" ""
```

## Viewing the LDAP changelog using `ldapsearch`

View changelog entries using `ldapsearch`.

All records in the changelog are immediate children of the `cn=changelog` entry and are named with the `changeNumber` attribute. Changes are represented in the form documented in the `draft-good-ldap-changelog` specification with the `targetDN` attribute providing the distinguished name (DN) of the updated entry, the `changeType` attribute providing the type of operation (`add`, `delete`, `modify`, or `modDN`), and the `changes` attribute providing a base64-encoded representation of the attributes included in the entry (for `add` operations) or the changes made (for `modify` operations) in LDIF form. View the changes by decoding the encoded value using the `base64 decode` utility. The LDAP SDK for Java also provides support for parsing changelog entries.

### Viewing the LDAP changelog using `ldapsearch`

#### Steps

1. Grant access to the `cn=changelog` backend to the `uid=admin` account using access control rules.

By default, only the root user has access to this backend.

Example:

```
$ bin/ldapmodify
dn: cn=changelog
changetype: modify
add: aci
aci: (targetattr="*|+")
    (version 3.0; acl "Access to the changelog backend for the admin
    account";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

2. Use `ldapsearch` to view the changelog.

Example:

```
$ bin/ldapsearch --baseDN cn=changelog --dontWrap "(objectclass=*)" "
```

Result:

```
dn: cn=changelog
objectClass: top
objectClass: untypedObject
cn: changelog

dn: changeNumber=1,cn=changelog
objectClass: changeLogEntry
objectClass: top
targetDN: uid=user.0,ou=People,dc=example,dc=com
changeType: modify
changes::
    cmVwbGFjZTogbW9iaWxlCm1vYmlsZTogKzEgMDIwIDE1NCA5Mzk4Ci0KcmVwbGFjZToga
```

```

changenumber: 1
dn: changeNumber=2,cn=changelog
objectClass: changeLogEntry
objectClass: top
targetDN: dc=example,dc=com
changeType: modify
changes::
  cmVwbGFjZTogZHMtc3luYy1zdGF0ZQpkcy1zeW5jLXN0YXRlOiAwMDAwMDExQ0ZGMzM0Q
  zYwNDA5MzAwMDAwMDAyCgo=
changenumber: 2
```

## Viewing the LDAP change sequence numbers

### About this task

The changelog displays the server state information, which is important for failover between servers during synchronization operations. The server state information is exchanged between the servers in the network (LDAP servers and replication servers) as part of the protocol start message. It also helps the client application determine which server is most up-to-date.

### Steps

- Make sure the `uid=admin` account has the necessary access rights to the `cn=changelog` backend.

#### Example:

```
$ bin/ldapsearch --baseDN cn=changelog --dontWrap "(objectclass=*)" "+"
```

#### Result:

```
dn: cn=changelog

dn: changeNumber=1,cn=changelog
entry-size-bytes: 182
targetUniqueId: 68147342-1f61-3465-8489-3de58c532130
changeTime: 20111023002624Z
lastReplicaCSN: 0000011D27184D9E303000000001
replicationCSN: 0000011D27184D9E303000000001
replicaIdentifier: 12336

dn: changeNumber=2,cn=changelog
entry-size-bytes: 263
targetUniqueId: 4e9b7847-edcb-3791-b11b-7505f4a55af4
changeTime: 20111023002624Z
lastReplicaCSN: 0000011D27184F2E303000000002
replicationCSN: 0000011D27184F2E303000000002
replicaIdentifier: 12336
```

## Viewing LDAP changelog monitoring information

### About this task

The changelog contains a monitor entry accessed over LDAP, JConsole, the Administrative Console, or SNMP. Make sure the `uid=admin` account has the necessary access rights to the `cn=changelog` backend.

## Steps

- Use `ldapsearch` to view the changelog monitor entry.

Example:

```
$ bin/ldapsearch --baseDN cn=changelog,cn=monitor "(objectclass=*)" "
```

Result:

```
dn: cn=changelog,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: extensibleObject
cn: changelog
changelog: cn=changelog
firstchangenumber: 1
lastchangenumber: 8
lastpurgedchangenumber: 0
firstReplicaChange: 16225:0000011D0205237F3F6100000001:5
firstReplicaChange: 16531:0000011CFF334C60409300000002:1
lastReplicaChange: 16225:0000011D02054E8B3F6100000002:7
lastReplicaChange: 16531:0000011CFF334C60409300000002:1
oldest-change-time: 20081015063104Z
... (more data) ...
```

## Indexing the LDAP changelog

The Directory Server supports attribute indexing in the Changelog Backend to allow Get Changelog Batch requests to filter results that include only changes involving specific attributes.

Normally, the directory server that receives a request must iterate over the whole range of changelog entries and then match entries based on search criteria for inclusion in the batch. The majority of this processing also involves determining whether or not the changelog entry includes changes to a particular attribute or set of attributes. Using changelog indexing, client applications can dramatically speed up throughput when targeting the specific attributes.

You can configure attribute indexing using the `index-include-attribute` and `index-exclude-attribute` properties on the Changelog Backend. The properties can accept the specific attribute name or special LDAP values `*` to specify all user attributes or `+` to specify all operational attributes.

To determine if the directory server supports this feature, view the Root DSE for the following entry.

```
supportedFeatures: 1.3.6.1.4.1.30221.2.12.3
```

## Indexing a changelog attribute

### Steps

- Use `dsconfig` to set attribute indexing on an attribute in the changelog backend.

Example:

Index different attributes by adding specific properties. In the following example, the command enables the Changelog Backend and sets the backend to include all user attributes (`*`) for `ADD` or `MODIFY` operations using the `changelog-include-attribute` property. The `changelog-deleted-entry-include-attribute` property is set to all attributes (`*`) to specify a set of attribute types that should be included in a changelog entry for `DELETE` operations. Attributes specified in this list are recorded in the `deletedEntryAttrs` attribute on the changelog entry when an entry is deleted.

The attributes `displayName` and `employeeNumber` are indexed using the `index-include-attribute` property.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set "enabled:true" \
  --set "changelog-include-attribute:*" \
  --set "changelog-deleted-entry-include-attribute:*" \
  --set "index-include-attribute:displayName" \
  --set "index-include-attribute:employeeNumber"
```

2. To add another attribute to index, use the `dsconfig --add` option, which adds the attribute to an existing configuration setting.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --add "index-include-attribute:cn"
```

## Excluding attributes from indexing

### Steps

- Use `dsconfig` to set attribute indexing on all user attributes in the changelog backend.

Example:

The following command includes all user attributes except the description and location attributes.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set "index-include-attribute:*" \
  --set "index-exclude-attribute:description" \
  --set "index-exclude-attribute:location"
```

## Tracking virtual attribute changes in the LDAP changelog

While the LDAP Changelog primarily tracks changes to real attributes, it can also provide information about virtual attributes included in created, updated, or deleted entries.

### About this task

The `include-virtual-attributes` property controls the virtual attribute information to include in changelog entries, and this property might include any or all of the following values:

#### `add-attributes`

Indicates that changelog entries for `add` operations should include a `ds-changelog-virtual-attributes` attribute that lists the virtual attribute values generated for the entry at the time it was created.

#### `deleted-entry-attributes`

Indicates that changelog entries for `delete` operations should include a `ds-changelog-virtual-attributes` attribute that lists the virtual attribute values generated for the entry at the time it was deleted.

#### `before-and-after-values`

Indicates that changelog entries for `modify` and `modify DN` operations should include `ds-changelog-before-virtual-values` and `ds-changelog-after-virtual-values` attributes that contain the values of virtual attributes that have been updated.

#### `key-attribute-values`

Indicates that changelog entries should include a `ds-changelog-entry-key-virtual-values` attribute that holds the values for any virtual attributes included in the set of key attributes, as defined by the `changelog-include-key-attribute` property.

The `add-attributes` and `before-and-after-values` values are selected by default.

To enable virtual attribute change tracking in the LDAP Changelog:

#### Steps

- Use `dsconfig`.

Example:

#### Note:

The following command enables the LDAP changelog and sets `include-virtual-attributes` to `add-attributes`, which indicates that virtual attributes be included in the set of attributes listed for an add operation. The `delete-entry-attributes` value indicates that virtual attributes should be included in the set of deleted entry attributes listed for a delete operation. The `before-and-after-values` value indicates that virtual attributes should be included in the set of before and after values for attributes targeted by the changes. The `key-attribute-values` value indicates that virtual attributes should be included in the set of entry key attribute values.

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
  --set "enabled:true" \
  --set "include-virtual-attributes:add-attributes" \
  --set "include-virtual-attributes:deleted-entry-attributes" \
  --set "include-virtual-attributes: before-and-after-values" \
  --set "include-virtual-attributes: key-attribute-values"
```

## Managing Access Control

---

The PingDirectory Server provides a fine-grained access control model to ensure that users are able to access the information they need but are prevented from accessing information that they shouldn't see.

The access control model includes a privilege subsystem that provides even greater flexibility and protection.

This section presents the access control model and provides examples that illustrate the use of key access control functionality.

### Overview of access control

The access control model uses access control instructions (ACIs) to determine what a user or a group of users can do with a set of entries, down to the attribute level.

The ACIs are stored in the `aci` operational attribute. The operational attribute can appear on any entry and affects the entry or any subentries within that branch of the directory information tree (DIT).

Access control instructions specify four items:

#### Resources

Resources are the targeted items or objects that specifies the set of entries and operations to which the access control instruction applies. For example, you can specify access to certain attributes, such as the `cn` or `userPassword` password.

#### Name

Name is the descriptive label for each ACI. Typically, you have multiple ACIs for a given branch of your DIT. The access control name helps describe its purpose. For example, you can configure an ACI labeled "ACI to grant full access to administrators."

#### Clients

Clients are the users or entities to which you grant or deny access. You can specify individual users or groups of users using an LDAP URL. For example, you can specify a group of administrators using the LDAP URL: `groupdn="ldap:///cn=admin,ou=groups,dc=example,dc=com."`

#### Rights

Rights are permissions granted to users or client applications. You can grant or deny access to certain branches or operations. For example, you can grant `read` or `write` permission to a `telephoneNumber` attribute.

### Key access control features

The PingDirectory Server provides important access control features that provide added security for the Directory Server's entries.

#### Improved validation and security

The Directory Server provides an access control model with strong validation to help ensure that invalid access control instructions (ACIs) are not allowed into the server.

The Directory Server ensures that all access control rules (ACRs) added over LDAP are valid and can be fully parsed. The Directory Server rejects any operation that attempts to store one or more invalid ACIs. It also validates ACIs contained in data imported from an LDIF file. The Directory Server rejects any entry containing a malformed `aci` value.

As an additional level of security, the Directory Server examines and validates all ACIs stored in the data whenever a backend is brought online. If the server finds any malformed ACIs in the backend, it generates an administrative alert to notify administrators of the problem and places itself in lockdown mode. While in lockdown mode, the server only allows requests from users who have the `lockdown-mode` privilege. This action allows administrators to correct the malformed ACI while ensuring that no sensitive data is inadvertently exposed because of an ACI not being enforced. When the problem has been corrected, the administrator can use the `leave-lockdown-mode` tool or restart the server to allow it to resume normal operation.

#### Global ACIs

Global ACIs are a set of ACIs that apply to entries anywhere in the server or scoped to only apply to a specific set of entries.

Global ACIs work in conjunction with ACRs stored in user data and provide a convenient way to define ACIs that span disparate portions of the directory information tree (DIT).

In the PingDirectory Server, global ACIs are defined within the server configuration, in the `global-aci` property of the configuration object for the access control handler. To view and manage global ACIs, use configuration tools like `dsconfig` and the administrative console.

The global ACIs available by default in the PingDirectory Server include:

- Allow anyone, including unauthenticated users, to access key attributes of the root DSA-specific entry (DSE), including:
  - `namingContexts`
  - `subschemaSubentry`
  - `supportedAuthPasswordSchemes`
  - `supportedControl`
  - `supportedExtension`
  - `supportedFeatures`
  - `supportedLDAPVersion`
  - `supportedSASLMechanisms`
  - `vendorName`
  - `vendorVersion`
- Allow anyone, including unauthenticated users, to access key attributes of the subschema subentry, including:
  - `attributeTypes`
  - `dITContentRules`
  - `dITStructureRules`
  - `ldapSyntaxes`
  - `matchingRules`
  - `matchingRuleUse`
  - `nameForms`
  - `objectClasses`
- Allow anyone, including unauthenticated users, to include the following controls in requests made to the server:
  - Authorization identity request
  - Manage DSA IT
  - Password policy
  - Real attributes only
  - Virtual attributes only
- Allow anyone, including unauthenticated users, to request the following extended operations:
  - Get symmetric key
  - Password modify request
  - Password policy state
  - StartTLS
  - Who Am I?

### **Access controls for public or private backends**

Depending on their intended purpose, the PingDirectory Server classifies backends as either public or private.

A backend is private if one of the following applies:

- Its content is generated by the Directory Server itself, such as the root DSE, monitor, and backup backends.
- It is used in the operation of the server, such as the configuration, schema, task, and trust store backends.
- Its content is maintained by the server, such as the LDAP changelog backend.

A public backend is intended to hold user-defined content, such as user accounts, groups, application data, and device data.

The PingDirectory Server access control model also supports the distinction between public backends and private backends. Many private backends do not allow writes of any kind from clients, and some of

the private backends that do allow writes only allow changes to a specific set of attributes. As a result, you should define any ACI intended to permit or restrict access to information in private backends as global ACIs, rather than attempting to add those instructions to the data for that private backend.

### General format of the access control rules

Access control instructions (ACIs) are represented as strings that are applied to one or more entries within the directory information tree (DIT).

Typically, an ACI is placed on a subtree, such as `dc=example,dc=com`, and applies to that base entry and all entries below it in the tree. The Directory Server iterates through the DIT to compile the access control rules into an internally-used list of denied and allowed targets and their permissible operations. When a client application, such as `ldapsearch`, enters a request, the Directory Server checks that the user who binds with the server has the necessary access rights to the requested search targets. ACIs are cumulatively applied so that a user who has an ACI at an entry can also have other access rights available if ACIs are defined higher in the DIT and are applicable to the user. In most environments, ACIs are defined at the root of a main branch or a subtree, and not on individual entries unless absolutely required.

### ACI

An access control rule has the following basic syntax.

```
aci : (targets) (version 3.0; acl "name";
      permissions
      bind rules
      ;)
```

### Access Control Components

Access Control Component	Description
targets	Specifies the set of entries and attributes to which an access control rule applies. Use the following syntax: (target keyword =    != expression)
name	Specifies the name of the ACI
permissions	Specifies the type of operations to which an access control rule might apply. Use the following syntax: allow  deny (permission)
bind rules	Specifies the criteria that indicate whether an access control rule should apply to a given requester. Use the following syntax: bind rule keyword =    != expression;
	 <b>Note:</b> The bind rule syntax requires that it be terminated with a ; .

### Summary of access control keywords

This section provides an overview of the supported keywords in the PingDirectory Server access control implementation.

#### Targets

A target expression specifies the set of entries and attributes to which an access control rule applies.

A target expression has three components:

#### Keyword

The keyword specifies the type of target element.

#### Expression

The expression specifies the items that are targeted by the access control rule.

#### Operator

The operator is either equal, =, or not-equal, !=.

#### Note:

You cannot use the != operator with the `targetattrfilters` and `targetscope` keywords.

For specific examples of each target keyword, see [Working with Targets](#).

```
(keyword [=|!=]expression)
```

You can use the following keywords in the target portion of ACIs:

### Summary of Access Control Target Keywords

Target Keyword	Description	Wildcards
<code>extop</code>	Specifies the OIDs for any extended operations to which the access control rule should apply.	No
<code>target</code>	Specifies the set of entries, identified using LDAP URLs, to which the access control rule applies.	Yes
<code>targetattrfilters</code>	Identifies specific attribute values based on filters that can be added to or removed from entries to which the access control rule applies.	Yes
<code>targetattr</code>	Specifies the set of attributes to which the access control rule should apply.	Yes
<code>targetcontrol</code>	Specifies the OIDs for any request controls to which the access control rule should apply.	No
<code>targetfilter</code>	Specifies one or more search filters that can be used to indicate the set of entries to which the access control should apply.	Yes
<code>targetscope</code>	Specifies the scope of entries, relative to the defined target entries or the entry containing the ACI if there is no target, to which the access control rule should apply.	No

## Permissions

Permissions indicate the types of operations to which an access control rule could apply.

You can specify if the user or group of users are allowed or not allowed to carry out a specific operation. For example, you can grant read access to targeted entries using the `allow (read)` permission. You can also deny access to the target entries and attributes using the `deny (read)` permission. You can list multiple permissions as required in the ACI.

```
allow (permission1
    ...,
    permission2
    ,...permissionN)
```

```
deny (permission1
    ...,
    permission2
    ,...permissionN)
```

You can use the following keywords in the permissions portion of ACIs.

Keyword	Description
<code>add</code>	Indicates that the access control applies to <code>add</code> operations.
<code>compare</code>	Indicates that the access control applies to <code>compare</code> operations and to search operations with a base-level scope that targets a single entry.
<code>delete</code>	Indicates that the access control applies to <code>delete</code> operations.
<code>export</code>	Indicates that the access control applies only to <code>modify DN</code> operations in which an entry is moved below a different parent by specifying a new superior distinguished name (DN) in the <code>modify DN</code> request. The requestor must have the <code>export</code> permission for operations against the entry's original DN. The requestor must have the <code>import</code> permission for operations against the entry's new superior DN.  For <code>modify DN</code> operations that alter the relative distinguished name (RDN) of an entry but keeps it below the same parent, such as renaming the entry, only the <code>write</code> permission is required. This is true regardless of whether the entry being renamed is a leaf entry or has subordinate entries.
<code>import</code>	See the description for the <code>export</code> permission.
<code>proxy</code>	Indicates that the access control rule applies to operations that attempt to use an alternate authorization identity, such as operations that include a proxied authorization request control, an intermediate client request control with an alternate authorization identity, or a client that has authenticated with a Simple Authentication and Security Layer (SASL) mechanism that allows an alternate authorization identity to be specified.
<code>read</code>	Indicates that the access control rule applies to search result entries returned by the server.
<code>search</code>	Indicates that the access control rule applies to <code>search</code> operations with a non-base scope.
<code>selfwrite</code>	Indicates that the access control rule applies to operations in which a user attempts to add or remove their own DN to the values for an attribute, such as users adding or removing themselves from groups.

Keyword	Description
write	Indicates that the access control rule applies to <code>modify</code> and <code>modify DN</code> operations.
all	An aggregate permission that includes all other permissions except <code>import</code> , <code>export</code> , and <code>proxy</code> . This is equivalent to providing a permission of <code>add</code> , <code>compare</code> , <code>delete</code> , <code>read</code> , <code>search</code> , <code>selfwrite</code> , and <code>write</code> .

### Bind rules

The bind rules indicate whether an access control rule should apply to a given requester.

The syntax for the target keyword has three components:

#### Keyword

The keyword specifies the type of target element.

#### Expression

The expression specifies the items that are targeted by the access control rule.

#### Operator

The operator is either equal, `=`, or not-equal, `!=`.

You must use the semicolon delimiter symbol, `;`, after the end of the final bind rule.

```
keyword [=|!= ] expression;
```

For added access control precision, you can combine multiple bind rules using the Boolean operations `AND`, `OR`, and `NOT`. The standard Boolean rules for evaluation apply:

- Innermost to outer parentheses first
- Left to right expressions
- `NOT` before `AND` or `OR`

For example, an access control instruction (ACI) with the following bind rule targets all users who are not `uid=admin,dc=example,dc=com` and use simple authentication.

```
(userdn!="ldap:///uid=admin,dc=example,dc=com" and authmethod="simple");
```

The following bind rule targets users that are `uid=admin,dc=example,dc=com` and authenticate using Simple Authentication and Security Layer (SASL) `EXTERNAL` or access the server from a loopback interface.

```
(userdn="ldap:///uid=admin,dc=example,dc=com and (authmethod="SSL" or ip="127.0.0.1"));
```

You can use the following keywords in the bind rule portion of ACIs.

Bind Rule Keyword	Description
authmethod	<p>Indicates that the requester's authentication method is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.</p> <p>Use the syntax <code>authmethod = <i>method</i></code> where <i>method</i> is one of the following representations:</p> <ul style="list-style-type: none"> <li>▪ <code>none</code></li> <li>▪ <code>simple</code> Indicates that the client is authenticated to the server using a bind DN and password.</li> <li>▪ <code>ssl</code> Indicates that the client is authenticated with an SSL/TLS certificate (for example, via SASL EXTERNAL), and not just over a secure connection to the server.</li> <li>▪ <code>sasl {<i>sasl_mechanism</i>}</code>. Indicates that the client is authenticated to the server using a specified SASL mechanism.</li> </ul> <p>The following example allows users who authenticate with an SSL/TLS certificate (for example, using SASL EXTERNAL) to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (userdn="ldap:///self" and authmethod="ssl");)</pre>
dayofweek	<p>Indicates that the day of the week is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.</p> <p>You can separate multiple day of week values by commas. Use the following syntax.</p> <pre>dayofweek = <i>day1</i>, <i>day2</i>, ...</pre> <p><i>day</i> is one of the following:</p> <ul style="list-style-type: none"> <li>▪ <code>sun</code></li> <li>▪ <code>mon</code></li> <li>▪ <code>tues</code></li> <li>▪ <code>wed</code></li> <li>▪ <code>thu</code></li> <li>▪ <code>fri</code></li> <li>▪ <code>sat</code></li> </ul> <p>The following example allows users who authenticate on weekdays with an SSL/TLS certificate, such as SASL EXTERNAL, to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (dayofweek!="sun,sat" and userdn="ldap:/// self" and authmethod="ssl");)</pre>

Bind Rule Keyword	Description
dns	<p>Indicates that the requester's DNS-resolvable host name is taken into account when determining whether the access control rule should apply to an operation. You can use wildcards in this expression.</p> <p>You can separate multiple DNS patterns by commas. Use the following syntax.</p> <pre>dns = dns-host-name</pre> <p>The following example allows users on host name <code>server.example.com</code> to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (dns="server.example.com" and userdn="ldap:///self");)</pre>
groupdn	<p>Indicates that the requester's group membership is taken into account when determining whether the access control rule should apply to any operation. You cannot use wildcards in this expression.</p> <pre>groupdn [ =    != ] "ldap:///groupdn [    ldap:///groupdn ] ..."</pre> <p>The following example allows users in the managers group to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (groupdn="ldap:///cn=managers,ou=groups,dc=example,dc=com");)</pre>
ip	<p>Indicates that the requester's IP address is taken into account when determining whether the access control rule should apply to an operation. You can use wildcards in this expression.</p> <p>You can separate multiple IP address patterns by commas. Use the following syntax.</p> <pre>ip [ =    != ] &lt;ipAddressList&gt;</pre> <p><i>ipAddressList</i> is one of the following:</p> <ul style="list-style-type: none"> <li>▪ A specific IPv4 address: 127.0.0.1</li> <li>▪ An IPv4 address with wildcards to specify a subnetwork: 127.0.0.*</li> <li>▪ An IPv4 address or subnetwork with subnetwork mask: 123.4.5.0+255.255.255.0</li> <li>▪ An IPv4 address range using CIDR notation: 123.4.5.0/24</li> <li>▪ An IPv6 address as defined by RFC 2373.</li> </ul> <p>The following example allows users on 10.130.10.2 and localhost to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (ip="10.130.10.2,127.0.0.1" and userdn="ldap:///self");)</pre>

Bind Rule Keyword	Description
oauthscope	<p>Indicates that the scopes associated with any OAuth 2.0 access token presented by a SCIMv2 client is taken into account when determining whether the access control rule applies to an operation.</p> <p>Use the following syntax.</p> <pre>oauthscope [ =    != ] "&lt;scopeIdentifier&gt;"</pre> <p><i>scopeIdentifier</i> is one of the following:</p> <ul style="list-style-type: none"> <li>▪ The name of a single scope to match. The name will be treated as case-sensitive.</li> <li>▪ A substring assertion that contains one or more asterisks as wildcards.</li> <li>▪ A single asterisk by itself, which will match any scope.</li> </ul> <p>The following example grants all rights to any client that presented an OAuth 2.0 token that is associated with the <code>scim_admin</code> scope.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Full rights for users with the scim_admin OAuth 2.0 scope"; allow (all) oauthscope="scim_admin";)</pre>
timeofday	<p>Indicates that the time of day is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.</p> <p>Use the following syntax.</p> <pre>timeofday [ =    !=    &gt;=    &gt;    &lt;=    &lt; ] &lt;time&gt;</pre> <p><i>time</i> is one of the following:</p> <ul style="list-style-type: none"> <li>▪ 4-digit 24-hour time format (0000 to 2359, where the first two digits represent the hour of the day and the last two represent the minute of the hour)</li> <li>▪ You cannot use wildcards in this expression</li> </ul> <p>The following example allows users to update their own entries if the request is received before 12 noon.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users who authenticate before noon to update their own entries"; allow (write) (timeofday&lt;1200 and userdn="ldap:///self" and authmethod="simple");)</pre>

Bind Rule Keyword	Description
oauthscope	<p>Indicates that the scopes associated with any OAuth 2.0 access token presented by a SCIMv2 client is taken into account when determining whether the access control rule should apply to an operation. The keyword's syntax is as follows:</p> <pre data-bbox="448 363 1464 422">oauthscope [ =    != ] "&lt;scopeIdentifier&gt;"</pre> <p><i>scopeIdentifier</i> is one of the following:</p> <ul data-bbox="467 485 1464 590" style="list-style-type: none"> <li>▪ The name of a single scope to match. The name will be treated as case-sensitive.</li> <li>▪ A substring assertion that contains one or more asterisks as wildcards.</li> <li>▪ A single asterisk by itself, which will match any scope.</li> </ul> <p>The following example grants all rights to any client that presented an OAuth 2.0 token that is associated with the <code>scim_admin</code> scope:</p> <pre data-bbox="448 688 1464 821">aci: (targetattr="*") (version 3.0; acl "Full rights for users with the scim_admin OAuth 2.0 scope"; allow (all) oauthscope="scim_admin";)</pre>

Bind Rule Keyword	Description
userattr	<p>Indicates that the requester's relation to the value of the specified attribute is taken into account when determining whether the access control rule should apply to an operation.</p> <p>Use the following syntax.</p> <pre data-bbox="446 411 1456 470">userattr = &lt;attrName&gt;# [ &lt;bindType&gt;    &lt;attrValue&gt; ]</pre> <p>Where:</p> <ul data-bbox="467 533 1456 663" style="list-style-type: none"> <li>▪ <i>attrName</i> = name of the attribute for matching</li> <li>▪ <i>bindType</i> = USERDN, GROUPODN, LDAPURL</li> <li>▪ <i>attrValue</i> = an attribute value. The <i>attrVALUE</i> of the attribute must match on both the bind entry and the target of the ACI.</li> </ul> <p>A <i>bindType</i> value of <code>USERDN</code> indicates that the target attribute should have a value which matches the DN of the authenticated user. A <i>bindType</i> value of <code>GROUPODN</code> indicates that the target attribute should have a value which matches the DN of a group in which the authenticated user is a member. A <i>bindType</i> value of <code>LDAPURL</code> indicates that the target attribute should have a value that is an LDAP URL whose criteria matches the entry for the authenticated user.</p> <p>Any value other than <code>USERDN</code>, <code>GROUPODN</code>, or <code>LDAPURL</code> is expected to be present in the target attribute of the authenticated user's entry.</p> <p>The following example allows a manager to change employee's entries. If the bind DN is specified in the manager attribute of the targeted entry, the bind rule is evaluated to <code>TRUE</code>.</p> <pre data-bbox="446 1094 1456 1213">aci: (targetattr="*") (version 3.0; acl "Allow a manager to change employee entries"; allow (write) userattr="manager#USERDN";)</pre> <p>The following example allows any member of a group to change employee's entries. If the bind DN is a member of the group specified in the <code>allowEditors</code> attribute of the targeted entry, the bind rule is evaluated to <code>TRUE</code>.</p> <pre data-bbox="446 1367 1456 1486">aci: (targetattr="*") (version 3.0; acl "Allow allowEditors to change employee entries"; allow (write) userattr="allowEditors#GROUPODN";)</pre> <p>The following example allows a user's manager to edit that user's entry and any entries below the user's entry up to two levels deep. You can specify up to five levels (0, 1, 2, 3, 4) below the targeted entry, with zero 0 indicating the targeted entry.</p> <pre data-bbox="446 1640 1456 1759">aci: (targetattr="*") (version 3.0; acl "Allow managers to change employees entries two levels below"; allow (write) userattr="parent[0,1,2].manager#USERDN";)</pre> <p>The following example allows any member of the engineering department to update any other member of the engineering department at or below the specified ACI.</p> <pre data-bbox="446 1881 1456 2018">aci: (targetattr="*") (version 3.0; acl "Allow any member of Eng Dept to update any other member of the engineering department at or below the ACI"; allow (write) userattr="department#ENGINEERING";)</pre> <p>The following example allows an entry to be updated by any user whose entry matches the criteria defined in the LDAP URL contained in the</p>

Bind Rule Keyword	Description
userdn	<p>Indicates that the user's DN is taken into account when determining whether the access control rule should apply to an operation.</p> <p>Use the following syntax.</p> <pre>. userdn [ =    != ] "ldap:///&lt;value&gt; [    "ldap:///&lt;value&gt; ..."]</pre> <p>Where <i>value</i> is one of the following representations:</p> <ul style="list-style-type: none"> <li>▪ The DN of the target user</li> <li>▪ A value of <i>anyone</i> to match any client, including unauthenticated clients.</li> <li>▪ A value of <i>all</i> to match any authenticated client.</li> <li>▪ A value of <i>parent</i> to match the client authenticated as the user defined in the immediate parent of the target entry.</li> <li>▪ A value of <i>self</i> to match the client authenticated as the user defined in the target entry.</li> </ul> <p>If the value provided is a DN, then that DN can include wildcard characters to define patterns. A single asterisk will match any content within the associated DN component, and two consecutive asterisks can be used to match zero or more DN components.</p> <p>The following example allows users to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) userdn="ldap:///self");</pre>

## Access token validators

Access token validators verify the tokens that HTTP client applications submit when they request access to protected resources and associate each token with an identity stored in the directory server.

To authenticate to PingDirectory Server's HTTP services, clients use OAuth 2 bearer token authentication to present an access token in the HTTP Authorization request header.

To process the incoming access tokens, PingDirectory Server uses access token validators, which determine whether to accept an access token and translate it into a set of properties, called claims, which PingDirectory Server's HTTP services use to make access control decisions.

Most access tokens identify a user as its subject using the `sub` claim. Access token validators can retrieve the token subject's attributes from the directory using an identity mapper, which correlates the access token subject to an LDAP entry.

Access token validators are used by the following services:

- Directory REST API
- SCIM 2
- Delegated Admin
- Consent API

You can configure PingDirectory Server to accept access tokens provided by LDAP clients using the OAUTHBEARER Simple Authentication and Security Layer (SASL) authentication method.

### About access token validator processing

You can configure any number of access token validators for PingDirectory Server.

Each access token validator has an evaluation order index, which is an integer that determines the processing priority when multiple access token validators are configured. Lower values are processed before higher values.

#### Note:

Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by PingDirectory Server.

### Processing steps

1. If an incoming HTTP request contains an access token, the token is sent to the access token validator with the lowest evaluation order index.
2. The access token validator validates the access token. Validation logic varies by access token validator type, but the validator generally verifies the following information:
  - A trusted source issued the token.
  - The token is not expired.
3. If the access token contains a subject, the access token validator uses its identity mapper to find a matching LDAP entry.
4. If the access token validator is unable to validate the access token, it passes the token to the access token validator with the next lowest evaluation order index, and the previous two steps are repeated.
5. HTTP request processing continues, and the policy request is sent to the HTTP service, such as the Directory REST API, for further evaluation.
6. Using either the access token claims parsed by the access token validator or the LDAP entry found by the identity mapper, the HTTP service determines whether the request should be accepted and which access control rules should be applied. This access control behavior varies by each HTTP service.

### Access token validator types

PingDirectory Server works with a variety of access token validators.

#### Configuring a sample PingFederate access token validator

To verify the access tokens that a PingFederate authorization server issues, the PingFederate access token validator uses HTTP to submit the tokens to PingFederate Server's token introspection endpoint.

### Before you begin

Before using a PingFederate access token validator, create a client that represents the access token validator in the PingFederate configuration. This client must use the Access Token Validation grant type.

### About this task

This step allows the authorization server to determine whether a token is valid.

#### Note:

Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by PingDirectory Server.

Because this step requires an outgoing HTTP request to the authorization server, the PingFederate access token validator might perform slower than other access token validator types. The validation result is guaranteed to be current, which is an important consideration if the authorization server permits the revocation of access tokens.

## Steps

1. In PingFederate, create a client with the following properties:
  - Client ID: Ping Identity
  - Client authentication: Client Secret
  - Allowed grant types: Access Token Validation
2. Take note of the client secret and use the PingDirectory Server's `dsconfig` command to create an access token validator, as shown.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com
# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031
# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "PingFederate Access Token Validator" \
  --type ping-federate \
  --set enabled:true \
  --set "authorization-server:PingFederate External Server" \
  --set client-id:PingDataGovernance \
  --set "client-secret:<client secret>" \
  --set evaluation-order-index:2000 \
  --set "identity-mapper:User ID Identity Mapper"
```

3. Replace `<client secret>` with the client secret value generated by the PingFederate client.

### JWT access token validator

The JWT access token validator verifies access tokens that are encoded in JSON Web Token (JWT) format, which can be signed in JSON web signature (JWS) format or signed and encrypted in JSON web encryption (JWE) format.

The JWT access token validator inspects the JWT token without presenting it to an authorization server for validation. Because the JWT access token validator does not make a token introspection request for every access token that it processes, it performs faster than the PingFederate access token validator. The access token is self-validated, so the JWT access token validator cannot determine whether the token has been revoked.

### Supported JWS/JWE features

For signed tokens, the JWT access token validator supports the following JWT web algorithm (JWA) types:

- RS256
- RS384
- RS512
- ES256
- ES384
- ES512

For encrypted tokens, the JWT access token validator supports the following key-encryption algorithms:

- RSA-OAEP

- ECDH-ES
- ECDH-ES+A128KW
- ECDH-ES+A192KW
- ECDH-ES+A256KW

For encrypted tokens, the JWT access token validator supports the following content-encryption algorithms:

- A128CBC-HS256
- A192CBC-HS384
- A256CBC-HS512

The JWT access token validator configuration defines three allow lists for the JWS/JWE signing and encryption algorithms that it accepts. Customize these allow lists to reflect only the signing and encryption algorithms used by your access token issuer and no others. This minimizes the access token validator's security threat surface.

Configure these allow lists using the following configuration properties:

`allowed-signing-algorithm`

Specifies the signing algorithms that the access token validator accepts.

`allowed-key-encryption-algorithm`

Specifies the key-encryption algorithms that the access token validator accepts.

`allowed-content-encryption-algorithm`

Specifies the content-encryption algorithms that the access token validator accepts.

#### *Handling signed tokens*

The token issuer must cryptographically sign all access tokens that the JSON web token (JWT) access token validator handles. The JWT access token validator validates a token's signature using a public signing key provided by the issuer.

#### Steps

- Configure the JWT access token validator with the issuer's public signing key:  
Choose from:
  - Store the public key as a trusted certificate in PingDirectory Server's local configuration using the `trusted-certificate` property.
  - Provide the issuer's JSON Web Key Set (JWKS) endpoint using the `jwtks-endpoint-path` property.

#### **Note:**

The JWT access token validator then retrieves the issuer's public keys when it initializes. This method ensures that the JWT access token validator uses updated copies of the issuer's public keys.

**Example:** Use a locally configured trusted certificate

The following example configures a JWT access token validator to use a locally stored public signing certificate to validate access token signatures. The signing certificate is assumed to have been obtained out-of-band and must be a PEM-encoded X.509v3 certificate.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
```

```

--type exact-match \
--set enabled:true \
--set match-attribute:uid \
--set match-base-dn:ou=people,dc=example,dc=com

# Add the public signing certificate to the server configuration
dsconfig create-trusted-certificate \
  --certificate-name "JWT Signing Certificate" \
  --set "certificate</path/to/signing-certificate.pem"

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "JWT Access Token Validator" \
  --type jwt \
  --set enabled:true \
  --set evaluation-order-index:1000 \
  --set allowed-signing-algorithm:RS256 \
  --set "trusted-certificate:JWT Signing Certificate"
  --set "identity-mapper:User ID Identity Mapper"

```

#### Example: Use the issuer's JWKS endpoint

The following example configures a JWT access token validator to retrieve public keys from a PingFederate authorization server's JWKS endpoint.

```

# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "JWT Access Token Validator" \
  --type jwt \
  --set enabled:true \
  --set evaluation-order-index:1000 \
  --set allowed-signing-algorithm:RS256 \
  --set "authorization-server:PingFederate External Server" \
  --set jwks-endpoint-path:/ext/oauth/jwks
  --set "identity-mapper:User ID Identity Mapper"

```

#### *Handling encrypted tokens*

Configure the JSON web token (JWT) access token validator to accept encrypted access tokens. You must configure the access token validator with a private and public key pair and provide the public key to the token issuer.

#### Steps

1. Create an encryption key pair.
2. Create the JWT access token validator.

- Export the public encryption key from Server and provide it to your token issuer.

Choose from:

- To copy the public key to a file, run **dsconfig**.
- Copy the value of the key pair's `certificate-chain` property in the administrative console.

**Note:**

Without this public encryption key, the issuer cannot encrypt tokens that can be decrypted by the JWT access token validator.

### Example

The following example configures a JWT access token validator to handle access tokens signed and encrypted using elliptic curve algorithms.

For RSA signing and encryption algorithms, the configuration is similar, but you choose different values for the `allowed-signing-algorithm` and `allowed-encryption-algorithm` properties.

- Create an encryption key pair.

```
# Create an encryption key pair
dsconfig create-key-pair \
  --pair-name "JWT Elliptic Curve Encryption Key Pair" \
  --set key-algorithm:EC_256
```

- Create the JWT access token validator.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "JWT Access Token Validator" \
  --type jwt \
  --set enabled:true \
  --set evaluation-order-index:1000 \
  --set allowed-signing-algorithm:ES256 \
  --set "authorization-server:PingFederate External Server" \
  --set jwks-endpoint-path:/ext/oauth/jwks \
  --set "encryption-key-pair:JWT Elliptic Curve Encryption Key Pair" \
  --set allowed-key-encryption-algorithm:ECDH_ES
  --set "identity-mapper:User ID Identity Mapper"
```

- Export the public encryption key from PingDataGovernance Server and provide it to your token issuer.

The following command copies the key to a file.

```
dsconfig get-key-pair-prop \
  --pair-name "JWT Elliptic Curve Encryption Key Pair" \
  --property certificate-chain \
```

```
--no-prompt \  
--script-friendly > jwt-public-encryption-key.pem
```

### Mock access token validator

A mock access token validator is a special access token validator type for development or testing purposes.

A mock access token validator accepts arbitrary tokens without validating whether a trusted source issued them. This allows you to make bearer token-authenticated requests without first setting up an authorization server.

Mock access tokens are formatted as plain-text JSON objects using standard JSON web token (JWT) claims.

Always provide the boolean `active` claim when creating a mock token. If this value is `true`, the token is accepted. If this value is `false`, the token is rejected.

If the `sub` claim is provided, a token owner lookup populates the `TokenOwner` policy request attribute as with the other access token validator types.

The following example cURL command shows a mock access token in an HTTP request.

```
curl -k -X GET https://localhost:8443/scim/v2/Me -H 'Authorization:  
Bearer {"active": true, "sub":"user.3", "scope":"email profile",  
"client":"client1"}'
```

#### Important:

Never use mock access token validators in a production environment because they do not verify whether a trusted source issued an access token.

### Example

#### Sample configuration

The configuration for a mock access token validator resembles the configuration for a JWT access token validator. However, the JSON web signature (JWS) signatures require no configuration because mock tokens are not authenticated.

```
# Create an identity mapper that expects the token subject to be a uid  
dsconfig create-identity-mapper \  
  --type exact-match \  
  --set enabled:true \  
  --set match-attribute:uid \  
  --set match-base-dn:ou=people,dc=example,dc=com  
  
# Create the Access Token Validator  
dsconfig create-access-token-validator \  
  --validator-name "Mock Access Token Validator" \  
  --type mock --set enabled:true \  
  --set evaluation-order-index:9999  
  --set "identity-mapper:User ID Identity Mapper"
```

### Third-party access token validator

To create custom access token validators, use the Server SDK.

## Working with targets

The following section presents a detailed look and examples of the target access control instruction (ACI) keywords:

- `target`
- `targetattr`
- `targetfilter`
- `targattrfilters`
- `targetscope`
- `targetcontrol`
- `extop`

### target

The `target` keyword indicates that the ACI should apply to one or more entries at or below the specified distinguished name (DN).

The target DN must be equal or subordinate to the DN of the entry in which the ACI is placed. For example, if you place the ACI at the root of `ou=People,dc=example,dc=com`, you can target the DN, `uid=user.1,ou=People,dc=example,dc=com`, within your ACI rule. The DN must meet the string representation specification of distinguished names, outlined in RFC 4514, and requires that special characters be properly escaped.

The `target` clause has the following format, where *DN* is the distinguished name of the entry or branch:

```
(target = ldap:///<DN>)
```

For example, to target a specific entry, use a clause like the following.

```
(target = ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

#### Note:

In most cases, you should avoid specifying a target DN. Instead, define the ACI in that entry and omit the `target` element altogether.

For example, although you can have `(target="ldap:///uid=john.doe,ou=People,dc=example,dc=com)` in any of the `dc=example,dc=com` or `ou=People` entries, you should define it in the `uid=john.doe` entry and not explicitly include the `target` element.

The expression allows for the not equal operator (`!=`) to indicate that all entries within the scope of the given branch that do not match the expression be targeted for the ACI. The following expression targets all entries within the subtree that do not match `uid=john.doe`.

```
(target != ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

The `target` keyword also supports the use of asterisk (`*`) characters as wildcards to match elements within the distinguished name.

- The following target expression matches all entries that contain and begin with `john.d`.

```
(target = ldap:///uid=john.d*,ou=People,dc=example,dc=com)
```

Entries such as `john.doe,ou=People,dc=example,dc=com` and `john.davies,ou=People,dc=example,dc=com` would match the target expression.

- The following target expression matches all entries whose DN begins with `john.d` and matches the `ou` attribute.

```
(target = ldap:///uid=john.d*,ou=*,dc=example,dc=com)
```

Entries such as `john.doe,ou=People,dc=example,dc=com` and `john.davies,ou=asia-branch,dc=example,dc=com` would match the target expression.

Another example of a complete ACI targets the entries in the `ou=People,dc=example,dc=com` branch and the entries below it and grants the users the privilege to modify all of their user attributes within their own entries.

```
aci: (target="ldap:///ou=People,dc=example,dc=com")
(targetattr="*")
(version 3.0; acl "Allow all the ou=People branch to modify their own
entries";
allow (write) userdn="ldap:///self";)
```

### targetattr

The `targetattr` keyword targets the attributes for which the access control instruction should apply.

There are four general forms that it can take in the PingDirectory Server:

```
(targetattr="*")
```

Indicates that the access control rule applies to all user attributes. Operational attributes are not automatically included in this set.

```
(targetattr="+")
```

Indicates that the access control rule applies to all operational attributes. User attributes are not automatically included in this set.

```
(targetattr="<attr1>||<attr2>||<attr3>||...||<attrN>")
```

Indicates that the access control rule applies only to the named set of attributes.

```
(targetattr!="attr1||attr2||attr3||...||attrN")
```

Indicates that the access control rule applies to all user attributes except the named set of attributes. It does not apply to any operational attributes.

The targeted attributes can be classified as user attributes and operational attributes. User attributes define the actual data for that entry while operational attributes provide additional metadata about the entry that can be used for informational purposes, such as when the entry was created, last modified and by whom. Metadata can also include attributes specifying which password policy applies to the user, or overridden default constraints like size limit, time limit, or look-through limit for that user.

The PingDirectory Server distinguishes between these two types of attributes in its access control implementation. The Directory Server does not automatically grant any access at all to operational attributes. For example, the following clause applies only to user attributes and not to operational attributes.

```
(targetattr="*")
```

You can also target multiple attributes in the entry. The following clause targets the common name (`cn`), surname (`sn`) and state (`st`) attribute.

```
(targetattr="cn||sn||st")
```

You can use the `+` symbol to indicate that the rule should apply to all operational attributes.

```
(targetattr="+")
```

To include all user and all operational attributes, use both symbols.

```
(targetattr="*||+")
```

If you need to target a specific operational attribute rather than all operational attributes, include it in the values of the `targetattr` clause.

```
(targetattr="ds-rlim-size-limit")
```

If you want to target all user attributes and a specific operational attribute, use them in the `targetattr` clause.

```
(targetattr="*||ds-rlim-size-limit")
```

The following sample ACIs are placed on the `dc=example,dc=com` tree. The first ACI allows any user anonymous read access to all entries except the `userPassword` attribute. The second ACI allows users to update their own contact information. The third ACI allows the `uid=admin` user full access privileges to all user attributes in the `dc=example,dc=com` subtree.

```
aci: (targetattr!="userPassword") (version 3.0; acl "Allow anonymous
  read access for anyone"; allow (read,search,compare) userdn="ldap:///
  anyone");
aci: (targetattr="telephonenumber||street||homePhone||l||st")
  (version 3.0; acl "Allow users to update their own contact info";
  allow (write) userdn="ldap:///self");
aci: (targetattr="*") (version 3.0; acl "Grant full access for the admin
  user";
  allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

When assigning access to user and operational attributes, it is easy to inadvertently create an access control instruction that grants far more capabilities to a user than originally intended. The following example shows the implications of the Directory Server not distinguishing between these attributes.

```
aci: (targetattr!="uid||employeeNumber")
  (version 3.0; acl "Allow users to update their own entries";
  allow (write) userdn="ldap:///self");
```

This instruction is intended to allow a user to update any attribute in his or her own entry with the exception of `uid` and `employeeNumber`. This ACI is a common rule and seems harmless, but has serious consequences for a Directory Server that does not distinguish between user attributes and operational attributes. It allows users to update operational attributes in their own entries, and could be used for a number of malicious purposes, including:

- A user could alter password policy state attributes to become exempt from password policy restrictions.
- A user could alter resource limit attributes and bypass size limit, time limit, and look-through-limit constraints.
- A user could add access control rules to his or her own entry, which could allow them to make their entry completely invisible to all other users, including administrators granted full rights by access

control rules, but excluding users with the `bypass-acl` privilege allows them to edit any other attributes in their own entry, including those excluded by rules like `uid` and `employeeNumber` in the previous example, or add, modify, or delete any entries below his or her own entry.

Because the PingDirectory Server does not automatically include operational attributes in the target attribute list, these types of ACIs do not present a security risk for it. Users cannot add ACIs to any entries unless they have the `modify-acl` privilege.

Another danger in using the `(targetattr!="x")` pattern is that two ACIs within the same scope could have two different `targetattr` policies that cancel each other out. For example, if one ACI has `(targetattr!="cn|sn")` and a second ACI has `(targetattr!="userPassword")`, then the net effect is `(targetattr="*")`, because the first ACI inherently allows `userPassword` and the second allows `cn` and `sn`.

### targetfilter

The `targetfilter` keyword targets all attributes that match results returned from a filter.

The `targetfilter` clause has the following syntax.

```
(targetfilter = <ldap_filter>)
```

For example, the following clause targets all entries that contain the `ou=engineering` attribute.

```
(targetfilter = "(ou=engineering)")
```

You can only specify a single filter, but that filter can contain multiple elements combined with the `OR` operator. The following clause targets all entries that contain `ou=engineering`, `ou=accounting`, and `ou=marketing`.

```
(targetfilter = "(|(ou=engineering)(ou=accounting)(ou=marketing)")
```

The following example allows the user, `uid=eng-mgr`, to modify the `departmentNumber`, `cn`, and `sn` attributes for all entries that match the filter `ou=engineering`.

```
aci:(targetfilter="(ou=engineering)")
(targetattr="departmentNumber|cn|sn")
(version 3.0; acl "example"; allow (write)
 userdn="ldap:///uid=eng-mgr,dc=example,dc=com";)
```

### targattrfilters

The `targattrfilters` keyword targets specific attribute values that match a filtered search criteria.

This keyword allows you to set up an ACI that grants or denies permissions on an attribute value if that value meets the filter criteria. The `targattrfilters` keyword applies to individual values of an attribute, not to the whole attribute. The keyword also allows the use of wildcards in the filters.

The keyword clause has the following format.

```
(target = "add=attr1:Filter1 && attr2:Filter2... && attrN:FilterN,
del=attr1:Filter1 && attr2:Filter2 ... && attrN:FilterN" )
```

Where:

`add`

Represents the operation of adding an attribute value to the entry.

`del`

Represents the operation of removing an attribute value from the entry.

`<attr1>, <attr2> ... <attrN>`

Represents the targeted attributes.

`<filter1>, <filter2> ... <filterN>`

Represents filters that identify matching attribute values.

The following conditions determine when the attribute must satisfy the filter:

- When adding or deleting an entry containing an attribute targeted a `targattrfilters` element, each value of that attribute must satisfy the corresponding filter.
- When modifying an entry, if the operation adds one or more values for an attribute targeted by a `targattrfilters` element, each value must satisfy the corresponding filter. If the operation deletes one or more values for a targeted attribute, each value must satisfy the corresponding filter.
- When replacing the set of values for an attribute targeted by a `targattrfilters` element, each value removed must satisfy the delete filters and each value added must satisfy the add filters.

The following example allows any user who is part of the `cn=directory server admins` group to add the `soft-delete-read` privilege.

```
aci: (targattrfilter="add=ds-privilege-name:(ds-privilege-name=soft-delete-read) ")
  (version 3.0; acl "Allow members of the directory server admins group to grant the
  soft-delete-read privilege"; allow (write)
  groupdn="ldap:///cn=directory server admins,ou=group,dc=example,dc=com";)
```

### targetscope

Use the `targetscope` keyword to restrict the scope of an access control rule (ACR).

ACIs use a subtree scope by default, meaning they are applied to the target entry and all entries below it, either as defined by the target clause of the ACI or the entry in which the ACI is defined if it does not include a target. However, you can add the `targetscope` element into an ACR to restrict the set of entries to which it applies.

The following `targetscope` keyword values are allowed:

`base`

Indicates that the ACR applies only to the target entry and not to any of its subordinates.

`onelevel`

Indicates that the ACR applies only to entries that are immediate children of the target entry and not to the target entry itself nor to any subordinates of the immediate children of the target entry.

`subtree`

Indicates that the ACR applies to the target entry and all of its subordinates. This is the default behavior if no `targetscope` is specified.

`subordinate`

Indicates that the ACR applies to all entries below the target entry but not the target entry itself.

The following ACI targets all users to view the operational attributes present in the root DSA-specific entry (DSE):

- `supportedControl`
- `supportedExtension`
- `supportedFeatures`
- `supportedSASLMechanisms`
- `vendorName`

- `vendorVersion`

In the following example, `targetscope` is set to `base` to limit users to view only those attributes in the root DSE.

```
aci: (target="ldap:///") (targetscope="base")
    (targetattr="supportedControl||supportedExtension||
    supportedFeatures||supportedSASLMechanisms||vendorName||vendorVersion")
    (version 3.0; acl "Allow users to view Root DSE Operational Attributes";
    allow (read,search,compare) userdn="ldap:///anyone")
```

### targetcontrol

Use the `targetcontrol` keyword to indicate whether a given request control can be used by users targeted in the ACI.

You can provide multiple OIDs by separating them with two pipe characters, optionally surrounded by spaces. When specifying control OIDs, wildcards are not allowed.

The following ACI example shows the controls required to allow an administrator to use and manage the soft delete feature. The soft delete request control allows the user to soft-delete an entry, so that it could be undeleted at a later time. The hard delete request control allows the user to permanently remove an entry or soft-deleted entry. The undelete request control allows the user to undelete a currently soft-deleted entry. The soft-deleted entry access request control allows the user to search for any soft-deleted entries in the server.

```
aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.22||
    1.3.6.1.4.1.30221.2.5.23||1.3.6.1.4.1.30221.2.5.24")
    (version 3.0; acl "Allow admins to use the Soft Delete Request Control,
    Hard Delete Request Control, Undelete Request Control, and
    Soft-deleted entry access request control";
    allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

### extOp

Use the `extop` keyword to indicate whether a given extended request operation can be used.

You can provide multiple OIDs by separating them with two pipe characters, optionally surrounded by spaces. When specifying extended request OIDs, wildcards are not allowed.

The following ACI example allows the `uid=user-mgr` to use the password modify request, `OID=1.3.6.1.4.1.4203.1.11.1`, and the `StartTLS`, `OID=1.3.6.1.4.1.1466.20037`, which are extended request OIDs.

```
aci: (extop="1.3.6.1.4.1.4203.1.11.1 || 1.3.6.1.4.1.1466.20037")
    (version 3.0; acl "Allows the mgr to use the Password Modify Request and
    StartTLS;
    allow(read) userdn="ldap:///uid=user-mgr,ou=people,dc=example,dc=com";)
```

## Examples of common access control rules

This section demonstrates access controls that are commonly used in your environment.

To modify access control definitions in the server, a user must have the `modify-acl` privilege.

### Administrator access

The following access control instructions (ACIs) grant members of the `cn=admins,ou=groups,dc=example,dc=com` group the following permissions:

- Add, modify, and delete entries
- Reset passwords

- Read operational attributes, such as `isMemberOf` and password policy state

```
aci: (targetattr="+") (version 3.0; acl "Administrators can read, search or
  compare operational attributes";
  allow (read,search,compare) groupdn="ldap:///
  cn=admins,ou=groups,dc=example,dc=com");
aci: (targetattr="*") (version 3.0; acl "Administrators can add, modify and
  delete entries";
  allow (all) groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com");
```

### Anonymous and authenticated access

The following ACIs allow anonymous read, search, and compare on select attributes of `inetOrgPerson` entries while authenticated users can access several more. An authenticated user inherits the privileges of the anonymous ACI and can also change `userPassword`.

```
aci: (targetattr="objectclass || uid || cn || mail || sn || givenName")
  (targetfilter="(objectClass=inetorgperson)")
  (version 3.0; acl "Anyone can access names and email addresses of entries
  representing people";
  allow (read,search,compare) userdn="ldap:///anyone");
aci: (targetattr="departmentNumber || manager || isMemberOf")
  (targetfilter="(objectClass=inetorgperson)")
  (version 3.0; acl "Authenticated users can access these fields for entries
  representing people";
  allow (read,search,compare) userdn="ldap:///all");
aci: (targetattr="userPassword") (version 3.0; acl "Authenticated users can
  change password";
  allow (write) userdn="ldap:///all");
```

To prevent anonymous access to the Directory Server, set the global configuration property `reject-unauthenticated-requests` to `true`.

### Delegated access to a manager

The following ACI allows an employee's manager to edit the value of the employee's `telephoneNumber` attribute. This ACI uses the `userattr` keyword with a bind type of `USERDN`, which indicates that the target entry's manager attribute must have a value equal to the distinguished name (DN) of the authenticated user.

```
aci: (targetattr="telephoneNumber")
  (version 3.0; acl "A manager can update telephone numbers of her direct
  reports";
  allow (read,search,compare,write) userattr="manager#USERDN");
```

### Proxy authorization

The following ACI allows the application `cn=OnBehalf,ou=applications,dc=example,dc=com` to use the proxied authorization V2 control to request that operations be performed using an alternate authorization identity.

```
aci: (version 3.0;acl "Application OnBehalf can proxy as another entry";
  allow (proxy) userdn="ldap:///
  cn=OnBehalf,ou=applications,dc=example,dc=com");
```

#### Note:

The application user must have the `proxied-auth` privilege.

## Validating ACIs before migrating data

Identify any access control instruction (ACI) syntax problems before migrating data.

Many directory servers allow for a less restrictive application of their access control instructions so that they accept invalid ACIs. For example, if an Oracle directory server encounters an access control rule that it can't parse, it ignores the rule without providing a warning, and the server might not offer the intended access protection. The PingDirectory Server rejects any ACIs that it can't interpret, which ensures that data access is limited as intended. However, this can cause problems when migrating data with existing access control rules to a PingDirectory Server.

To validate an ACI, the PingDirectory Server provides a `validate-aci` tool in the `bin` directory on UNIX or Linux systems or in the `bat` directory on Windows systems.

The `validate-aci` tool identifies any ACI syntax problems before you migrate data. The tool can examine access control rules contained in either an LDIF file or an LDAP directory and write its result in LDIF with comments providing information about any problems that were identified.

Each entry in the output contains a single ACI. If an entry in the input contains multiple ACIs, then it can be present multiple times in the output, each time with a different ACI value. The entries contained in the output contains only ACI values. All other attributes are ignored.

### Validating ACIs from a file

Use the `validate-aci` tool to process data contained in an LDIF file.

About this task

#### Note:

The `validate-aci` tool ignores all attributes except `aci` and ignores all entries that do not contain the `aci` attribute. You can use any existing LDIF file that contains access control rules.

### Steps

1. Run the `validate-aci` tool and specify the input file and output file.

Choose from:

- UNIX or Linux: `bin/validate-aci`
- Windows: `bat\validate-aci`

If the output file already exists, the existing file contents are re-written. If no output file is specified, the results are written to standard output.

Example:

```
$ bin/validate-aci --ldifFile test-aci.ldif --outputFile validated-aci.ldif
```

Result:

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

## 2. Open the output file and review the results.

### Example:

For example, the `validated-acis.ldif` file generated in the previous step reads as follows.

```
# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr!="userPassword")
    (version 3.0; acl "Allow anonymous read access for anyone";
      allow (read,search,compare) userdn="ldap:///anyone");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
    (version 3.0; acl "Allow users to update their own entries";
      allow (write) userdn="ldap:///self");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
    (version 3.0; acl "Grant full access for the admin user";
      allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

### Example:

If the input file has any malformed access control instructions (ACIs), then the generated output file will show what was incorrectly entered. For example, if `userPassword` in the `test-acis.ldif` file does not have quotation marks around it, the output file reports an error. The following command uses the `--onlyReportErrors` option to write any error messages to the output file only if a malformed ACI syntax is encountered.

```
$ bin/validate-acis --ldifFile test-acis.ldif --outputFile validated-
acis.ldif \
  --onlyReportErrors
```

### Result:

```
# Processing complete
# Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 1
# Other processing errors encountered: 0
```

The output file shows the following message.

```
# The following access control rule is malformed or contains an
  unsupported
# syntax: The provided string '(targetattr!=userPassword)(version 3.0;
  acl
# "Allow anonymous read access for anyone"; allow (read,search,compare)
# userdn="ldap:///anyone");' could not be parsed as a valid Access
  Control
# Instruction (ACI) because it failed general ACI syntax evaluation
dn: dc=example,dc=com
aci: (targetattr!=userPassword)
    (version 3.0; acl "Allow anonymous read access for anyone";
      allow (read,search,compare) userdn="ldap:///anyone");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
```

```
(version 3.0; acl "Allow users to update their own entries";
  allow (write) userdn="ldap:///self");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

### Validating ACIs in another Directory Server

Use the `validate-acis` tool to examine access control instructions (ACIs) in data that exists in another Directory Server that you are planning to migrate to the PingDirectory Server.

About this task

The tool helps to determine whether the Ping Identity Server accepts those ACIs.

Steps

- Run the `validate-acis` tool.  
Choose from:
  - UNIX or Linux: `bin/validate-acis`
  - Windows: `bat\validate-acis`

Provide arguments that specify:

- The address and port of the target Directory Server
- Credentials to use to bind
- The base DN of the subtree containing the ACIs to validate

Example:

```
$ bin/validate-acis
```

Result:

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

## Migrating ACIs from Oracle to PingDirectory Server

This section describes the most important differences in access control evaluation between Oracle and the PingDirectory Server.

### Support for macro ACIs

Oracle supports macro access control instructions (ACIs), making it possible to define a single ACI that you can use to apply the same access restrictions to multiple branches in the same basic structure.

Macro ACIs are infrequently used and can cause severe performance degradation, so the PingDirectory Server does not support them. However, you can achieve the same result by creating the same ACIs in each branch.

### Support for the roleDN bind rule

Oracle roles are a proprietary, non-standard grouping mechanism that provide little value over standard grouping mechanisms.

The PingDirectory Server does not support DSEE roles and does not support the use of the `roleDN` ACI bind rule. However, you can achieve the same behavior by converting the DSEE roles to standard groups and using the `groupDN` ACI bind rule.

### Targeting operational attributes

The Oracle access control model doesn't differentiate between user attributes and operational attributes.

In the Oracle access control model, using `targetattr="*"` automatically targets both user and operational attributes. Using an exclusion list like `targetattr!="userPassword"` automatically targets all operational attributes in addition to all user attributes except `userPassword`. This presents several significant security holes in which users are unintentionally given access to operational attributes. In some cases, it can allow users to exempt themselves from password policy restrictions.

The PingDirectory Server treats operational attributes differently from user attributes and never automatically includes operational attributes. For example, `targetattr="*"` targets all user attributes but no operational attributes, and `targetattr!="userPassword"` targets all user attributes except `userPassword`, but no operational attributes.

You can target specific operational attributes by including the names in the list, such as `targetattr="creatorsName|modifiersName"`. You can target all operational attributes by using the `+` character. For example, `targetattr="+"` targets all operational attributes but no user attributes and `targetattr="*|+"` targets all user and operational attributes.

#### Example

The following example searches for all immediate children of `ou=People,dc=example,dc=com`. The attributes returned are restricted to `sn`, `givenName`, and all operational attributes.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --baseDN ou=People,dc=example,dc=com --searchScope one
  '(objectclass=*)' \
  sn givenName "+"
```

#### Example

You can use compound filters to search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree. The following example limits the returned entry amount to 200 and the server will spend no more than 5 seconds processing the request.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --baseDN ou=People,dc=example,dc=com --searchScope sub --sizeLimit 200
  \
  --timeLimit 5 "(&(sn<=Doe) (employeeNumber<=1000))" ds-entry-unique-id \
  entryUUID
```

### Specification of global ACIs

Both DSEE and PingDirectory Server support global ACIs, which you can use to define ACIs that apply throughout the server.

In servers with multiple naming contexts, this feature allows you to define a rule once as a global ACI rather than maintaining an identical rule in each naming context.

In DSEE, global ACIs are created by modifying the root DSA-specific entry (DSE) to add values of the `aci` attribute. In the PingDirectory Server, you manage global ACIs with `dsconfig` referenced in the `global-aci` property of the access control handler.

## Defining ACIs for non-user content

In DSEE, you can write to the following backends to define ACIs:

- Configuration
- Monitor
- Changelog
- Tasks

In the PingDirectory Server, you should define access control for private backends as global ACIs, such as the following backends:

- Configuration
- Monitor
- Schema
- Changelog
- Tasks
- Encryption settings
- Backups
- Alerts

## Limiting access to controls and extended operations

DSEE provides limited support for restricting access to controls and extended operations.

To the extent that you can control access to controls and extended operations with access control instructions (ACIs), DSEE defines entries with a distinguished name (DN), such as `oid={oid},cn=features,cn=config`, where `{oid}` is the OID of the associated control or extended operation. For example, the following DSEE entry defines ACIs for the persistent search control.

```
oid=2.16.840.1.113730.3.4.3,cn=features,cn=config
```

In the PingDirectory Server, you can use the `targetcontrol` keyword to define ACIs that grant or deny access to controls. You can use the `extop` keyword to define ACIs that grant or deny access to extended operation requests.

## Tolerance for malformed ACI values

If the server is running with less than the intended set of access control instructions (ACIs), it might prevent access to data that should be allowed or grant access to data that should be restricted. In DSEE, if the server encounters a malformed access control rule (ACR), it ignores the rule. This can cause the server to run with less than the intended set of ACIs. To guard against this, the PingDirectory Server is more strict about the ACRs that it accepts.

When performing an LDIF import, the PingDirectory Server rejects any entry containing a malformed or unsupported ACR. The PingDirectory Server also rejects any `add` or `modify` request that attempts to create an invalid ACI.

In the unlikely event that a malformed ACI is accepted into the data, the server immediately places itself in lockdown mode. In lockdown mode, the server terminates connections and rejects requests from users without the `lockdown-mode` privilege. Lockdown mode allows an administrator to correct the problem without risking exposure to user data.

### Note:

To review any rejected ACIs, run the `import-ldif` tool with the `--rejectFile` option.

### About the privilege subsystem

In DSEE, only the root user is exempt from access control evaluation.

While administrators can create access control instructions (ACIs) that give normal users full access to any content, they can also create ACIs that would make a portion of the data inaccessible to those users. Additionally, some tasks can only be accomplished by the root user and the capabilities assigned to the root user can't be restricted.

The PingDirectory Server uses a privilege subsystem to control the capabilities available to various users. Non-root users can be granted limited access to certain administrative capabilities, and restrictions can be enforced on root users. Additionally, certain risky actions require that the requester have certain privileges in addition to the sufficient access control rights to process the operation.

These risky actions include:

- Interacting with the server configuration
- Changing another user's password
- Impersonating another user
- Shutting down and restarting the server

### Identifying unsupported ACIs

To determine whether access control instructions (ACIs) are suitable for use, the PingDirectory Server provides a `validate-acis` tool that you can use to examine content in an LDIF file or data in another directory server, such as a DSEE instance.

When migrating data from a DSEE deployment into a PingDirectory Server instance, use the `validate-acis` tool to determine whether ACIs contained in the data are acceptable. If any problems exist, update the data to redefine the ACIs so they are suitable for use in the PingDirectory Server.

For more information, see [Validating ACIs Before Migrating Data](#).

## Working with privileges

In addition to the access control implementation, the PingDirectory Server includes a privilege subsystem that you can use to control what users are allowed to do.

The privilege subsystem works in conjunction with the access control subsystem to only allow privileged operations that are permitted by the access control configuration. The user must also have all of the necessary privileges.

You can use privileges to grant normal users the ability to perform certain tasks that, in most other directories, would only be allowed for the root user. The capabilities given to root users in the PingDirectory Server are all granted through privileges, so you can create a normal user account with the ability to perform the same actions as root users.

Administrators can also remove privileges from root users so that they are unable to perform certain types of operations. To restrict root users to only the tasks that they must perform, define multiple root users in the server with different sets of privileges.

### Available privileges

The following privileges are defined in the PingDirectory Server.

#### Summary of Privileges

Privilege	Description
<code>audit-data-security</code>	This privilege is required to initiate a data security audit on the server, which is invoked by the <code>audit-data-security</code> tool.

Privilege	Description
<code>backend-backup</code>	This privilege is required to initiate an online backup through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
<code>backend-restore</code>	This privilege is required to initiate an online restore through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
<code>bypass-acl</code>	<p>This privilege allows a user to bypass access control evaluation. For a user with this privilege, any access control determination made by the server immediately returns that the operation is allowed.</p> <p> <b>Note:</b></p> <p>This does not bypass privilege evaluation, so the user must have the appropriate set of additional privileges to be able to perform any privileged operation. For example, a user with the <code>bypass-acl</code> privilege but without the <code>config-read</code> privilege is not allowed to access the server configuration.</p>
<code>bypass-pw-policy</code>	This privilege allows a user entry to bypass password policy evaluation. This privilege is intended for cases where external synchronization might require passwords that violate the password validation rules. The privilege is also evaluated for bind operations, meaning password restrictions are also bypassed when binding as a user who has this privilege.
<code>bypass-read-acl</code>	This privilege allows the associated user to bypass access control checks performed by the server for bind, search, and compare operations. Access control evaluation may still be enforced for other types of operations.
<code>config-read</code>	This privilege is required for a user to access the server configuration. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to see.
<code>config-write</code>	This privilege is required for a user to alter the server configuration. The user must also have the <code>config-read</code> privilege. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to alter.
<code>disconnect-client</code>	This privilege is required for a user to request that an existing client connection be terminated. The connection is terminated through the disconnect client task. The server's access control configuration must also allow the user to add the corresponding entry to the tasks backend.
<code>jmx-notify</code>	This privilege is required for a user to subscribe to Java Management Extensions (JMX) notifications generated by the Directory Server. The user is also required to have the <code>jmx-read</code> privilege.
<code>jmx-read</code>	This privilege is required for a user to access any information provided by the Directory Server through the JMX.

Privilege	Description
jmx-write	<p>This privilege is required for a user to update any information exposed by the Directory Server through the JMX. The user is also required to have the <code>jmx-read</code> privilege.</p> <p> <b>Note:</b> Currently, all of the information exposed by the server over JMX is read-only.</p>
ldif-export	<p>This privilege is required to initiate an online LDIF export through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, you can set up a global access control instruction (ACI) that allows access to members of an Administrators group.</p>
ldif-import	<p>This privilege is required to initiate an online LDIF import through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, configure the global ACI as described in the previous description of the <code>ldif-export</code> privilege.</p>
lockdown-mode	<p>This privilege allows the associated user to request that the server enter or leave lockdown mode, or to perform operations while the server is in lockdown mode.</p>
modify-acl	<p>This privilege is required for a user to add, modify, or remove access control rules defined in the server. The server's access control configuration must also allow the user to make the corresponding change to the <code>aci</code> operational attribute.</p>
password-reset	<p>This privilege is required for one user to be allowed to change another user's password. This privilege is not required for a user to be allowed to change his or her own password. The user must also have the access control instruction privilege to write the <code>userPassword</code> attribute to the target entry.</p>
privilege-change	<p>This privilege is required for a user to change the set of privileges assigned to a user, including the set of privileges, which are automatically granted to root users. The server's access control configuration must also allow the user to make the corresponding change to the <code>ds-privilege-name</code> operational attribute.</p>
proxied-auth	<p>This privilege is required for a user to request that an operation be performed with an alternate authorization identity. This privilege applies to operations that include the proxied authorization v1 or v2 control operations that include the intermediate client request control with a value set for the client identity field, or for Simple Authentication and Security Layer (SASL) bind requests that can include an authorization identity different from the authentication identity.</p>
server-restart	<p>This privilege is required to initiate a server restart through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.</p>

Privilege	Description
<code>server-shutdown</code>	This privilege is required to initiate a server shutdown through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
<code>soft-delete-read</code>	This privilege is required for a user to access a soft-deleted-entry.
<code>stream-values</code>	This privilege is required for a user to perform a stream values extended operation, which obtains all entry distinguished names (DNs) and all values for one or more attributes for a specified portion of the directory information tree (DIT).
<code>unindexed-search</code>	This privilege is required for a user to be able to perform a search operation in which a reasonable set of candidate entries cannot be determined using the defined index and instead, a significant portion of the database needs to be traversed to identify matching entries. The server's access control configuration must also allow the user to request the search.
<code>update-schema</code>	This privilege is required for a user to modify the server schema. The server's access control configuration must allow the user to update the operational attributes that contain the schema elements.

### Privileges automatically granted to root users

The special abilities that root users have are granted through privileges.

You can assign privileges to root users in two ways:

- By default, root users can be granted a specified set of privileges.

#### Note:

You can create root users which are not automatically granted these privileges by including the `ds-cfg-inherit-default-root-privileges` attribute with a value of `FALSE` in the entries for those root users.

- You can grant additional privileges to individual root users and remove some automatically-granted privileges from individual root users.

The `default-root-privilege-name` property of the root distinguished name (DN) configuration object controls the set of privileges that are automatically granted to root users. By default, these privileges include:

- `audit-data-security`
- `backend-backup`
- `backend-restore`
- `bypass-acl`
- `config-read`
- `config-write`
- `disconnect-client`
- `ldif-export`
- `lockdown-mode`
- `manage-topology`
- `metrics-read`
- `modify-acl`
- `password-reset`

- `permit-get-password-policy-state-issues`
- `privilege-change`
- `server-restart`
- `server-shutdown`
- `soft-delete-read`
- `stream-values`
- `unindexed-search`
- `update-schema`

The privileges not granted to root users by default include:

- `bypass-pw-policy`
- `bypass-read-acl`
- `jmx-read`
- `jmx-write`
- `jmx-notify`
- `permit-externally-processed-authentication`
- `permit-proxied-mschapv2-details`
- `proxied-auth`

You can change the set of default root privileges to add or remove values as necessary. This requires the `config-read`, `config-write`, and `privilege-change` privileges, and either the `bypass-acl` privilege or sufficient permission granted by the access control configuration to change the server's configuration.

### Assigning additional privileges for administrators

#### Steps

- To allow access to the Tasks backend, set up a global access control instruction (ACI) using `dsconfig` that allows access to members of an Administrators group.

Example:

```
$ dsconfig set-access-control-handler-prop \
  --add 'global-aci:(target="ldap:///cn=tasks") (targetattr="*|+")(
    version 3.0; acl "Access to the tasks backend for
    administrators";
    allow (all) groupdn="ldap:///
    cn=admin,ou=groups,dc=example,dc=com";) '
```

### Assigning privileges to normal users and individual root users

You can grant privileges to normal users on an individual basis.

Add the `ds-privilege-name` operational attribute to the user's entry with the names of the desired privileges. For example, the following change grants the `proxied-auth` privilege to the `uid=proxy,dc=example,dc=com` account.

```
dn: uid=proxy,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: proxied-auth
```

The user making this change must have the `privilege-change` privilege, and the server's access control configuration must also allow the requester to write to the `ds-privilege-name` attribute in the target user's entry.

You can use the same method to grant root users privileges that aren't included in the set of default root privileges. You can also remove default root privileges from root users by prefixing the name of the

privilege to remove with a minus sign. For example, the following change grants a root user the `jmx-read` privilege in addition to the set of default root privileges and removes the `server-restart` and `server-shutdown` privileges.

```
dn: cn=Sync Root User,cn=Root DNs,cn=config
changetype: modify
add: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: -server-restart
ds-privilege-name: -server-shutdown
```

#### Note:

Because root user entries exist in the configuration, this update requires the `config-read` and `config-write` privileges in addition to the `privilege-change` privilege.

### Disabling privileges

Although the privilege subsystem in the PingDirectory Server is a powerful feature, it might break some applications if they expect to perform an operation requiring a privilege that they do not have.

In the majority of these cases, you can assign the necessary privilege manually to the account used by that application. However, if this workaround isn't sufficient, or if you need to remove a particular privilege, such as allowing anyone to access information through Java Management Extensions (JMX) without requiring the `jmx-read` privilege, then you can disable privileges on an individual basis.

The `disabled-privilege` property in the global configuration object controls the set of disabled privileges. By default, no privileges are disabled. If a privilege is disabled, then the server behaves as if all users have that privilege.

### Working with proxied authorization

The Directory Server supports the Proxied Authorization Control (RFC 4370) to allow an authorized LDAP client to authenticate to the server as another user.

Typically, LDAP servers are deployed as backend authentication systems that store user credentials and authorization privileges necessary to carry out an operation. Single sign-on (SSO) systems can retrieve user credentials from the Directory Server and then issue permissions that allow the LDAP client to request operations under the identity as another user. The proxied authorization control allows client applications to securely process requests without binding or re-authenticating to the server for every operation.

The Directory Server supports the proxied authorization v1 and v2 request controls. The proxied authorization v1 request control is based on early versions of the `draft-weltman-ldapv3-proxy` Internet draft and is available primarily for legacy systems. You should use the proxied authorization v2 request control based on RFC 4370.

The proxied authorization v2 control requests that the associated operation is performed as if it had been requested by another user. You can use this control in conjunction with `add`, `delete`, `compare`, `extended`, `modify`, `modify DN`, and `search` requests. In such case, the associated operation processes under the authority of the specified authorization identity rather than the identity associated with the client connection, such as the user as whom that connection is bound. Specify the target authorization identity for this control as an `authzid` value, either with `dn:`, followed by the distinguished name of the target user or `u:`, followed by the user name.

#### Note:

Because of the security risks when using the proxied authorization control, most directory servers enforce strict restrictions on users that can request this control. If a user attempts to use the proxied

authorization v2 request control without the sufficient permission, the server returns a failure response with the `AUTHORIZATION_DENIED` result code.

## Configuring proxied authorization

### About this task

Configuring proxied authorization requires a combination of access control instructions (ACIs) and the `proxied-auth` privilege to the entry that will perform operations as another user.

#### Note:

You cannot use the `cn=Directory Manager` root DN as a proxying DN.

### Steps

1. Open a text editor and create a user entry that will request operations as another user. Include the `proxied-auth` privilege. Save the file as `add-user.ldif`.

#### Example:

In this example, the user entry `uid=clientApp` will request operations as `uid=admin,dc=example,dc=com`.

```
dn: ou=Applications,dc=example,dc=com
objectClass: top
objectClass: organizationalUnit
objectClass: extensibleObject
ou: Admins
ou: Applications

dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
givenName: Client
uid: clientApp
cn: Client App
sn: App
userPassword: password
ds-privilege-name: proxied-auth
```

2. Add the file using `ldapmodify`.

#### Example:

```
$ bin/ldapmodify --defaultAdd --filename add-user.ldif
```

- To allow the target, open a text editor and create an LDIF file to assign an ACI to that branch so that the client app user can access it as a proxy auth user. Add the file using the `ldapmodify`.

The client application targets a specific subtree in the Directory Information Tree (DIT) for its operations. For example, a client might need access to an accounts subtree to retrieve customer information while another client might need access to another subtree, such as a subscriber subtree.

Example:

In this example, the client application targets the `ou=People,dc=example,dc=com` subtree.

#### Note:

The ACI should be on a single line of text. The example shows the ACI over multiple lines for readability.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
    userdn="ldap:///uid=clientApp,ou=Applications,dc=example,dc=com");
```

- Run a search to test the configuration using the bind DN `uid=clientApp` and the `proxyAs` option.

Prefix `dn:` to the proxying entry or `u:` to the user name.

Example:

The `uid=clientApp` binds to the server and proxies as `uid=admin` to access the `ou=People,dc=example,dc=com` subtree.

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)" "
```

## Restricting proxy users

The Directory Server provides a set of operational attributes that restrict the proxied authorization capabilities of a client application and its proxyable target entry.

When present in an entry, the Directory Server evaluates each operational attribute together to form a whitelist of potential users that can be proxied. If none of those attributes are present, the user can potentially proxy as anyone.

The Directory Server supports a two-tier provision system that can restrict specific users for proxied authorization:

- The first tier is a set of `ds-auth-may-proxy-as-*` operational attributes on the client entry that binds to the server and carries out operations under the identity of another user.
- The second tier is a set of `ds-auth-is-proxyable-*` operational attributes on the user entry that defines whether access is allowed, prohibited, or required through proxied authorization. If proxied authorization is allowed or required, the attributes define which client entries can proxy as the user.

## Proxying operational attributes

For example, the following command demonstrates the client application `uid=clientApp` requesting to search the `ou=People,dc=example,dc=com` branch as the user `uid=admin`.

```
ldapsearch --bindDN uid=clientApp,dc=example,dc=com \
--bindPassword password \
--proxyAs uid=admin,dc=example,dc=com \
--baseDN ou=People,dc=example,dc=com \
"(object-class=*)
```

At bind, the Directory Server evaluates the list of users in the `uid=clientApp` entry based on the presence of any `ds-auth-may-proxy-as-*` attributes.

In the previous figure, the `uid=clientApp` entry has a `ds-auth-may-proxy-as` attribute with a value of `uid=admin`, meaning the client app user can proxy only as the `uid=admin` account.

Next, the server confirms that `uid=admin` is in the list of proxyable users and then evaluates the `ds-auth-is-proxyable-*` attributes present in the `uid=admin` entry. These attributes determine the list of restricted users that either are allowed, prohibited, or required to proxy as the `uid=admin` entry. In this case, the `uid=admin` entry has the `ds-auth-is-proxyable` attribute with a value of `required`, meaning the entry can only be accessed by means of proxied authorization.

The `uid=admin` entry also has the `ds-auth-is-proxyable-by` attribute with a value of `uid=clientApp`, meaning it can only be requested by the `uid=clientApp` entry. When both sets of attributes have been satisfied, the `uid=clientApp` can bind to the server as the authenticated user.

Next, the Directory Server performs access control instruction (ACI) evaluation on the branch and determines if the requested user has access rights to the branch. If the `uid=clientApp` entry can access the branch, the search request is processed.

#### About the `ds-auth-may-proxy-as-*` operational attributes

The Directory Server first evaluates the list of potential users that can be proxied for the authenticated user depending on the presence of the `ds-auth-may-*` operational attributes in the entry.

These operational attributes are multi-valued and are evaluated together if all are present in an entry:

##### `ds-auth-may-proxy-as`

Specifies the user distinguished names (DNs) that the associated user can proxy as. For example, you can specify in the `uid=clientApp` entry that it can proxy operations as `uid=admin` and `uid=agent1`.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as: uid=admin,dc=example,dc=com
ds-auth-may-proxy-as: uid=agent1,ou=admins,dc=example,dc=com
```

##### `ds-auth-may-proxy-as-group`

Specifies the group DNs and its group members that the associated user can proxy as. For example, you can specify that the potential users that the `uid=clientApp` entry can proxy as are those members who are present in the group `cn=Agents,ou=Groups,dc=example,dc=com`. This attribute is multi-valued, so you can specify more than one group. Nested static and dynamic groups are also supported.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as-group: cn=Agents,ou=Groups,dc=example,dc=com
```

`ds-auth-may-proxy-as-url`

Specifies the DN's that are returned based on the criteria defined in an LDAP URL that the associated user can proxy as. For example, the attribute specifies that the client can proxy as those entries that match the criteria in the LDAP URL. This attribute is multi-valued, so you can specify more than one LDAP URL.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as-url: ldap:///ou=People,dc=example,dc=com??sub?
(l=austin)
```

### About the `ds-auth-is-proxyable-*` operational attributes

After the Directory Server evaluates the list of users that the authenticated user can proxy as, the server checks to see if the requested authorized user is in the list.

If the requested authorized user is present in the list, then the server continues processing the proxable attributes in the entry. If the requested authorized user is not present in the list, the bind fails.

The operational attributes on the proxying entry are as follows:

`ds-auth-is-proxyable`

Specifies whether the entry is proxyable or not. Possible values are:

`allowed`

Operations can be proxied as this user.

`prohibited`

Operations can't be proxied as this user.

`required`

The account cannot authenticate directly but can only be accessed by some form of proxied authorization.

`ds-auth-is-proxyable-as`

Specifies any users allowed to use this entry as a target of proxied authorization.

`ds-auth-is-proxyable-as-group`

Specifies any groups allowed to use this entry as a target of proxied authorization. Nested static and dynamic groups are also supported.

`ds-auth-is-proxyable-as-url`

Specifies the LDAP URLs that are used to determine any users that are allowed to use this entry as a target of proxied authorization.

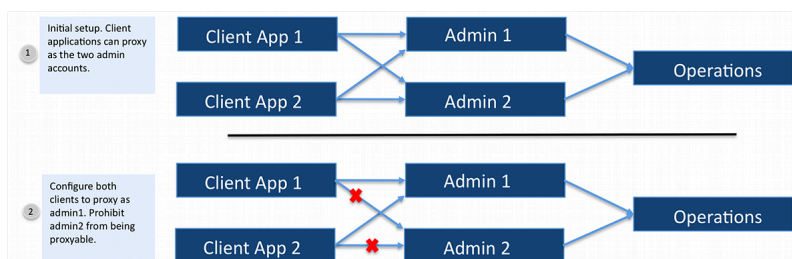

### Restricting proxied authorization for specific users

Use the following example scenario with proxied users to restrict proxied authorization.

About this task

To illustrate how the proxied authorization operational attributes work, set up a simple example where two LDAP clients, `uid=clientApp1` and `uid=clientApp2` and `uid=admin1` and `uid=admin2`. Add the , can freely proxy two administrator accounts, `ds-auth-may-proxy-as-*` and `ds-auth-is-proxyable-*` attributes to these entries to restrict how each account can use proxied authorization.

For example, the two client applications can continue to proxy the `uid=admin1` account but the `uid=admin2` account are no longer able to be used as a proxied entry.

## Proxy Users Example Scenario

### Steps

1. Set up two user entries, `uid=clientApp1`, can freely proxy two administrator accounts, and `uid=clientApp2`, with the `proxied-auth` privilege assigned to them.

The user entries will proxy as the `uid=admin1` and `uid=admin2` accounts to access the `ou=People,dc=example,dc=com` subtree.

- a. Open a text editor and create an LDIF file.
- b. Add the file using the `ldapmodify` tool.

Example:

#### Note:

In this example, ... indicates that other attributes present in the entry are not included for readability purposes.

```
dn: uid=clientApp1,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth

dn: uid=clientApp2,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
```

2. Assign the access control instruction (ACI) for each client application to the subtree, `ou=People,dc=example,dc=com`.

#### Note:

ACIs should be on one line of text. The following example displays ACIs over multiple lines for readability.

Example:

```
dn: ou=People,dc=example,dc=com
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
      userdn="ldap:///
uid=clientApp1,ou=Applications,dc=example,dc=com");
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
```

```
userdn="ldap:///
uid=clientApp2,ou=Applications,dc=example,dc=com");)
```

### 3. Run a search for each entry.

Example:

In this example, assume that there are two admin accounts, `admin1` and `admin2`, that have full access rights to user attributes. You should be able to proxy as the `uid=admin1` and `uid=admin2` entries to access the subtree for both clients.

```
$ bin/ldapsearch --port 1389 \
--bindDN "uid=clientApp1,ou=Applications,dc=example,dc=com" \
--bindPassword password \
--proxyAs "dn:uid=admin1,dc=example,dc=com" \
--baseDN ou=People,dc=example,dc=com \
"(objectclass=*)"

$ bin/ldapsearch --port 1389 \
--bindDN "uid=clientApp2,ou=Applications,dc=example,dc=com" \
--bindPassword password \
--proxyAs "dn:uid=admin2,dc=example,dc=com" \
--baseDN ou=People,dc=example,dc=com \
"(objectclass=*)"
```

### 4. Limit the proxied authorization capabilities for each client application.

In the following example, the `ds-auth-may-proxy-as` attribute specifies that `uid=clientApp1` can proxy as the `uid=admin1` entry.

- a. Open a text editor and create the following LDIF file.
- b. Update the `uid=clientApp1` entry to add the `ds-auth-may-proxy-as` attribute.

**Note:**

`ds-auth-may-proxy-as` is multi-valued.

- c. Save the file and add it using `ldapmodify`.

Example:

```
dn: uid=clientApp1,ou=Applications,dc=example,dc=com
changetype: modify
add: ds-auth-may-proxy-as
ds-auth-may-proxy-as: uid=admin1,dc=example,dc=com
```

### 5. Repeat the previous step for the `uid=clientApp2` entry, but specify the `ds-auth-may-proxy-as-url` attribute.

The client entry can proxy as any distinguished name (DN) that matches the LDAP URL.

Example:

```
dn: uid=clientApp2,ou=Applications,dc=example,dc=com
changetype: modify
add: ds-auth-may-proxy-as-url
ds-auth-may-proxy-as-url: ldap:///dc=example,dc=com??sub?(uid=admin*)
```

6. To illustrate the `ds-auth-proxyable-by-group` attribute, create a group of client applications that has `uid=clientApp1` and `uid=clientApp2` as its `uniquemembers`.

Example:

This example sets up a static group using the `groupOfUniqueNames` object class.

```
dn: ou=Groups,dc=example,dc=com
objectClass: top
objectClass: organizationalunit
ou: groups

dn: cn=Client Applications,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
cn: Client Applications
ou: groups
uniquemember: uid=clientApp1,ou=Applications,dc=example,dc=com
uniquemember: uid=clientApp2,ou=Applications,dc=example,dc=com
```

7. Update the `uid=admin1` entry to provide the DN that it can be proxied as.
  - a. Open a text editor and create the following LDIF file.
  - b. Use the `ds-auth-is-proxyable` to make the `uid=admin1` a required proxyable entry, meaning that it can only be accessed by some form of proxied authorization.
  - c. Use the `ds-auth-is-proxyable-by` attribute to specify each DN that can proxy as `uid=admin1`.
  - d. Save the LDIF file and add it using `ldapmodify`.

Example:

```
dn: uid=admin1,dc=example,dc=com
changetype: modify
add: ds-auth-is-proxyable
ds-auth-is-proxyable: required
-
add: ds-auth-is-proxyable-by
ds-auth-is-proxyable-by: ou=clientApp1,ou=Applications,dc=example,dc=com
ds-auth-is-proxyable-by: ou=clientApp2,ou=Applications,dc=example,dc=com
-
add: ds-auth-is-proxyable-by-group
ds-auth-is-proxyable-by-group: cn=Client
Applications,ou=Groups,dc=example,dc=com
-
add: ds-auth-is-proxyable-by-url
ds-auth-is-proxyable-by-url: ldap:///ou=Applications,dc=example,dc=com??
sub?(uid=clientApp*)
```

**Note:**

The example includes all three types of `ds-auth-is-proxyable-by-*` attributes as an illustration, but only one type of attribute is necessary if they all target the same entries.

8. Prohibit proxying for the `uid=admin2` entry.
  - a. Open a text editor and create the following LDIF file.
  - b. Set the `ds-auth-is-proxyable` attribute to prohibited.
  - c. Save the LDIF file and add it using `ldapmodify`.

Example:

```
dn: uid=admin2,dc=example,dc=com
changetype: modify
```

```
add: ds-auth-is-proxyable
ds-auth-is-proxyable: prohibited
```

9. Run a search using the proxied account.
  - a. To return a successful operation, run a search with `uid=clientApp1` or `uid=clientApp2` that proxies as `uid=admin1`.
  - b. To return an unsuccessful operation, run a search for `uid=clientApp1` that proxies as `uid=admin2`.

Example:

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp1,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin2,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)" "
```

Result:

The operation is unsuccessful because `uid=admin2` does not match the list of potential entries that can be proxied. The `ds-auth-may-proxy-as-*` attributes specify that the client can only proxy as `uid=admin1`.

```
One of the operational attributes (ds-auth-may-proxy-as,
ds-auth-may-proxy-as-group, ds-auth-may-proxy-as-url) in user entry
'uid=clientApp1,ou=Applications,dc=example,dc=com' does not allow
that user to be proxied as user 'uid=admin2,dc=example,dc=com'
```

```
Result Code: 123 (Authorization Denied)
```

```
Diagnostic Message: One of the operational attributes (ds-auth-may-proxy-
as,
ds-auth-may-proxy-as-group, ds-auth-may-proxy-as-url) in user entry
'uid=clientApp1,ou=Applications,dc=example,dc=com' does not allow that
user to be proxied as user 'uid=admin2,dc=example,dc=com'
```

10. Run another search using `uid=clientApp2`, which attempts to proxy as `uid=admin2`.

Example:

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp2,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin2,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)" "
```

Result:

The operation is unsuccessful because the `ds-auth-is-proxyable:prohibited` operational attribute states that `uid=admin2` is not available for proxied authorization.

```
The 'ds-auth-is-proxyable' operational attribute
in user entry 'uid=admin2,dc=example,dc=com' indicates that
user may not be accessed via proxied authorization
```

```
Result Code: 123 (Authorization Denied)
```

```
Diagnostic Message: The 'ds-auth-is-proxyable' operational
attribute in user entry 'uid=admin2,dc=example,dc=com' indicates
that user may not be accessed via proxied authorization
```

## Working with parameterized ACIs

The Directory Server supports the use of parameterized access control instructions (ACIs) to control access to subtrees with homogenous administrative group or user patterns, which can be used in multi-tenant deployments.

A single parameterized ACI can take the place of specifying identical ACIs on each tenant's subtree. For example, consider the following parameterized ACI.

```
(target="ldap:///o=($1),dc=example,dc=com") (version 3.0; acl \
"Subtree Admin Group members may search for and read entries in their
subtree."; allow \
(search, read) groupdn="ldap:///cn=Subtree Admin
Group,ou=groups,o=($1),dc=example,dc=com";)
```

This parameterized ACI enables:

- Members of a group with the distinguished name (DN) "cn=Subtree Admin Group,ou=groups,o=Customers, dc=example,dc=com" to search for and read entries in the "o=Customers, dc=example,dc=com" subtree.
- Members of a group with the DN "cn=Subtree Admin Group,ou=groups,o=Partners, dc=example,dc=com" to search for and read entries in the "o=Partners, dc=example,dc=com" subtree

The same access is granted for any substitution value for the (\$1) parameter variable. If an operation tries to read the uid=user.1,o=acme,dc=example,dc=com entry, this ACI is considered. This ACI would allow a read action if the operation's user is a member of the cn=Subtree Admin Group,ou=groups,o=acme,dc=example,dc=com group.

You can replace attribute values from the target DN with different variables, (\$#), and then reference those variables in the group DN or user DN. Construct the string representation of a parameter variable as follows:

1. An open parenthesis
2. A dollar sign
3. A positive integer
4. A closing parenthesis

Consider the following example.

```
"population=($2),ou=Populations,environment=($1),ou=Environments,o=Acme"
```

The (\$2) variable is the population ID in the DN of the target entry, and (\$1) is the environment ID in the DN of the target entry. Those values from the target entry's DN are substituted into the group DN or user DN value.

Parameter variables present in a parameterized ACI's target will be associated with the actual values from the resource DN. Each actual value will be substituted for its respective parameter variable in the ACI's target and group bind rule DN's when performing access control on the resource entry.

Parameter variables can be used in multiple relative distinguished names (RDNs) in a parameterized target. A given RDN can have at most one parameter variable as its attribute value. A given parameter variable can appear only once in the parameterized target.

The following values are examples of valid parameterized target DN's:

- ou=(\$1),dc=example,dc=com
- population=(\$2),ou=Populations,environment=(\$1),ou=Environments,o=Acme
- o=(\$1) (for a global ACI)

An ACI on an entry only applies to that entry's subtree. If an ACI with a parameterized target is stored on an entry, that entry's DN must appear in a non-parameterized form as the rightmost RDN of

the parameterized target's DN. For example, if an ACI with a parameterized target is stored on the `dc=example,dc=com` entry, that parameterized target must end in `dc=example,dc=com` in a non-parameterized form. Global ACIs do not have this restriction. Each global ACI can have parameter variables in any or all of its parameterized target's RDNs.

Additional restrictions for parameterized targets include:

- They cannot be pattern ACIs, meaning they cannot contain wildcards (\*).
- RDNs that are parameterized must be single-valued. For example, a given parameterized RDN cannot consist of two or more type-value pairs joined by +.

## \$attr.attrName macro

The `($attr.attrName)` macro extracts a value from a specified attribute in the target entry rather than extracting a value from a field with the same number in the target distinguished name (DN).

For example, `($attr.description)` is replaced with the value of the `description` attribute in the target entry. If there are multiple values for the specified attribute, then multiple actualized DN's are produced for the bind DN, and the first matching actualized DN is used.

The `($attr.attrName)` macro expands only the attribute's value so that you can extract values from the target DN and build relative distinguished names (RDNs) with different attribute names and types. Because the `($attr.attrName)` macro extracts only the attribute's value, you can combine it with a type other than what is in the target DN.

## Managing the Schema

---

This section is a summary of the supported schema components on PingDirectory Server and procedures to extend the schema with new element definitions.

### About the schema

A schema is the set of directory server rules that define the structures, contents, and constraints of a directory information tree (DIT).

The schema guarantees that any new data entries or modifications meet and conform to these predetermined set of definitions. It also reduces redundant data definitions and provides a uniform method for clients or applications to access its Directory Server objects.

PingDirectory Server includes a default set of read-only schema files that define the core properties for the Directory Server. The Administrative Console provides a Schema Editor to view existing schema definitions and add new custom schema elements to your DIT.

#### Note:

Any attempt to alter a schema element defined in a read-only file or add a new schema element to a read-only file results in an `Unwilling to Perform` result.

### About the Schema Editor

The Administrative Console provides a user-friendly graphical editor with tabs to manage any existing schema components related to the directory information tree (DIT).

The list of existing schema components that can be managed includes:

- Object classes
- Attributes
- Matching rules
- Attribute syntaxes

- Schema utilities

The following list describes the tabs of the Schema Editor page:

- The **Object Classes** and **Attribute Types** tabs enable viewing existing definitions as well as adding, modifying, or removing custom schema elements.
- The **Matching Rules** and **Attribute Syntaxes** tabs are read-only and provide a comprehensive listing of all of the elements necessary to define new schema elements.
- The **Schema Utilities** tab provides a schema validator that allows you to load a schema file or perform a cut-and-paste operation on the schema definition to verify that it meets the proper schema and ASN.1 formatting rules.
- The **Utilities** tab supports schema file imports by first checking for proper syntax compliance and generating any error message if the definitions do not meet specification.

LDAP Schema ▾

The screenshot shows the 'LDAP Schema' page with the 'Object Classes' tab selected. The interface includes a search bar, a 'Modifiable Only' checkbox, and a dropdown menu for 'All Schema Files'. Below is a table listing various schema elements:

Name	Type	Modifiable	Description	File	Actions
account	Structural	No	-	00-core.ldif	Actions ▾
alias	Structural	No	-	00-core.ldif	Actions ▾
applicationEntity	Structural	No	-	00-core.ldif	Actions ▾
applicationProcess	Structural	No	-	00-core.ldif	Actions ▾
authPasswordObject	Auxiliary	No	authentication password mix in class	03-rl3112.ldif	Actions ▾
automount	Structural	No	Automount information	04-rl2307bis.ldif	Actions ▾
automountMap	Structural	No	-	04-rl2307bis.ldif	Actions ▾
bootableDevice	Auxiliary	No	A device with boot parameters; device SI structural class	04-rl2307bis.ldif	Actions ▾
glrDistributionPoint	Structural	No	-	00-core.ldif	Actions ▾
callEntry	Auxiliary	No	-	03-rl2739.ldif	Actions ▾
certificationAuthority	Auxiliary	No	-	00-core.ldif	Actions ▾
certificationAuthority-V2	Auxiliary	No	-	00-core.ldif	Actions ▾

### Example Schema Editor Page

The Schema Editor provides two views for each definition:

- The **Properties View** that breaks down the schema definition by its properties and shows any inheritance relationships among the attributes.
- The **LDIF View** that shows the equivalent schema definition in ASN.1 format, which includes the proper text spacing required for each schema element.

## Default Directory Server schema files

PingDirectory Server stores its schema as a set of LDIF files for a Directory Server instance in the `<server-root>/config/schema` directory. Directory Server reads the schema files in alphanumeric order at startup in the following order:

1. The `00-core.ldif` file
2. The `01-pwpolicy.ldif` file
3. Remaining files

You should name custom schema files so that they are loaded in last. For example, custom schema elements could be saved in a file labeled `99-user.ldif` that loads after the default schema files are read at startup.

The Directory Server then uses the schema definitions to determine any violations that might occur during **add**, **modify**, or **import** requests. Clients applications check the schema (matching rule definitions) to determine the assertion value algorithm used in comparison or search operations.

The default set of schema files are present at installation and should not be modified. Modifying the default schema files could result in an inoperable server.

The schema files have the following descriptions.

### Default Schema Files

Schema Files	Description
00-core.ldif	Governs the Directory Server's core functions
01-pwpolicy.ldif	Governs password policies
02-config.ldif	Governs the Directory Server's configuration
03-changelog.ldif	Governs the Directory Server's change log
03-rfc2713.ldif	Governs Java objects
03-rfc2714.ldif	Governs Common Object Request Broker Architecture (CORBA) object references
03-rfc2739.ldif	Governs calendar attributes for vCard
03-rfc2926.ldif	Governs Server Location Protocol (SLP) mappings to and from LDAP schemas
03-rfc2985.ldif	Governs PKCS #9 public-key cryptography
03-rfc3112.ldif	Governs LDAP authentication passwords
03-rfc3712.ldif	Governs printer services
03-uddiv3.ldif	Governs web services registries of Service Oriented Architecture (SOA) components
04-rfc2307bis.ldif	Governs mapping entities from TCP/IP and UNIX into X.500 entries

## Extending the Directory Server schema

PingDirectory Server stores its schema as LDIF files in the `<server-root>/config/schema` directory.

At startup, the Directory Server reads the schema files in alphanumeric order starting with `00-core.ldif` and ending with any custom schema definition files, such as `99-user.ldif`, if present.

You can extend the schema to include additional customizations necessary for your Directory Server data using one of the following methods:

- Using the Schema Editor

This method is the easiest and quickest way to set up a schema definition and have it validated for the correct ASN.1 formatting. The Editor lets you define your schema properties, load your custom file, or perform a cut-and-paste operation on a new schema element. If any errors exist in the file, the Schema Editor generates an error message if the schema definitions do not pass compliance.

- Using a custom schema file

You can create a custom schema file with your new definitions using a text editor, save it as `99-user.ldif`, and then import the file using the Schema Editor or the `ldapmodify` tool. You must

name the custom LDIF file with a high two-digit number prefix, so that the Directory Server reads the file after the core schema files are read at startup. For example, you can name the file `99-myschema.ldif`.

**Note:**

For more information on the requirements for naming each file, see the next section, [General tips on extending the schema](#) on page 767.

- Using the command line

If you have a small number of additions, you can extend the schema over LDAP and from the command line using the `ldapmodify` tool. The Directory Server writes the new schema changes to a file such as `99-user.ldif` in the `<server-root>/config/schema` directory. However, this method can be cumbersome because schema definitions require strict adherence to text spacing and white space characters.

### General tips on extending the schema

Consider the following points when extending the schema:

- Never modify the default schema files because doing so could damage the Directory Server's processing capabilities.
- Define all attributes before they can be used in an object class. If you are using the Schema Editor to add new schema elements, use the `Quick Add Attributes` option when defining new object classes.
- Define the parent object class before creating object classes that inherit from the parent.
- You must name custom schema files according to the following syntax:
  1. Begin with exactly two digits.
  2. Follow the two digits with a non-digit character.
  3. Follow the non-digit character with a zero or more characters.
  4. End in `.ldif`.

**Note:**

The two digits don't need to be followed by a dash ("-").

Any files that do not meet this criteria are ignored and either a `NOTICE` or `SEVERE_WARNING` message is logged.

Any file in the `<server-root>/config/schema` directory with a name that starts with "." or ends with a tilde (~), `.swp`, or `.tmp` generates a `NOTICE` message indicating that temporary files will be ignored. Any other file that does not meet the naming criteria generates a `SEVERE_WARNING` message indicating that it will be ignored.

- Define custom attributes and object classes in one file. Typically, this file is the `99-user.ldif`. You can specify a different file name that the Directory Server writes to using the `X-SCHEMA-FILE` element and the file name in the definition, as in the following example.

```
add: attributeTypes attributeTypes: ( 1.3.6.1.4.1.32473.3.1.9.1
  NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'Directory Server Example'
  X-SCHEMA-FILE '99-custom.ldif' )
```

- In the white space characters in the schema definitions, `WSP` means zero or more space characters, and `SP` means one or more space characters. The LDIF specification states that LDIF parsers should ignore exactly one space at the beginning of each continuation line because continuation lines must begin with a space character.

If you define a new schema definition with each keyword on a separate continuation line, you should add two spaces before an element keyword to guarantee correct formatting. For example, the following attribute definition has two spaces before the keywords `NAME`, `SUP`, and `X-ORIGIN`.

```
attributeTypes: ( 2.5.4.32 NAME 'owner' SUP distinguishedName X-ORIGIN
  'RFC 4519' )
```

- In a replicated topology, any new schema additions are replicated to other replication servers to their respective Schema backend. The additions are written to the file specified by the `X-SCHEMA-FILE` extension or written to `99-user.ldif` if no file is specified.

## About managing attribute types

An attribute type determines the important properties related to an attribute, such as specifying the matching and syntax rules used in value comparisons. An attribute description consists of an attribute type and a set of zero or more options.

Options are short, case-insensitive text strings that differentiate between attribute descriptions. For example, the LDAPv3 specification defines only one type of option, the tagging option, that can be used to tag language options, such as `cn;lang-de;lang-sp` or binary data, such as `userCertificate;binary`. You can also extend the schema by adding your own attribute definitions.

Attributes have the following properties:

- Attributes can be user attributes that hold information for client applications, or operational attributes used for administrative or server-related purposes.

### Tip:

To specify the purpose of the attribute, use the `USAGE` element.

- Attributes are multi-valued by default. Multi-valued means that attributes can contain more than one value within an entry.

### Tip:

If the attribute should contain at most one value within an entry, include the `SINGLE-VALUE` element.

- Attributes can inherit properties from a parent attribute as long as they both have the same `USAGE`, and the child attribute has the same `SYNTAX`, or its `SYNTAX` allows values that are a subset of the values allowed by the `SYNTAX` of the parent attribute. For example, the surname (`sn`) attribute is a child of the name attribute.

## Attribute type definitions

New attribute types don't require server code extensions if the provided matching rules and attribute syntaxes are used in the definitions.

Administrators can create new attributes using the Schema Editor, which stores the definition in a file in the `<server-root>/config/schema` directory. For more information, see [Extending the Directory Server Schema](#).

The formal specification for attribute types is provided in RFC 4512, section 4.1.2 as follows.

```
AttributeTypeDescription = "(" wsp; Left parentheses followed by a white
  space
  numericoid
  ; Required numeric object identifier
```

```

[ sp "NAME" sp qdescrs ]           ; Short name descriptor as alias for the
  OID
[ sp "DESC" sp qdstring ]         ; Optional descriptive string
[ sp "OBSOLETE" ]                 ; Determines if the element is active
[ sp "SUP" sp oid ]               ; Specifies the supertype
[ sp "EQUALITY" sp oid ]          ; Specifies the equality matching rule
[ sp "ORDERING" sp oid ]          ; Specifies ordering matching rule
[ sp "SUBSTR" sp oid ]            ; Specifies substrings matching rule
[ sp "SYNTAX" sp oidlen ]         ; Numeric attribute syntax with minimum
  upper bound
                                   ; length expressed in {num}
[ sp "SINGLE-VALUE" ]              ; Specifies if the attribute is single
  valued in
                                   ; the entry
[ sp "COLLECTIVE" ]                ; Specifies if it is a collective
  attribute
[ sp "NO-USER-MODIFICATION" ]     ; Not modifiable by external clients
[ sp "USAGE" sp usage ]           ; Application usage
extensions wsp ")"                ; Extensions followed by a white space and
  ")"
usage = "userApplications" /      ; Stores user data
  "directoryOperation" /         ; Stores internal server data
  "distributedOperation" /       ; Stores operational data that must be
  synchronized
                                   ; across servers
  "dSAOperation"                ; Stores operational data specific to a
  server and
                                   ; should not be synchronized across
  servers

```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512.

```

extensions = /
"X-ORIGIN" /                       ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /                   ; Specifies which schema file contains the
  definition
"X-APPROX" /                         ; Specifies the approximate matching rule
"X-ALLOWED-VALUE" /                ; Explicitly specifies the set of allowed values
"X-VALUE-REGEX" /                   ; Specifies the set of regular expressions to
  compare against
                                   ; attribute values to determine acceptance
"X-MIN-VALUE-LENGTH" /              ; Specifies the minimum character length for
  attribute values
"X-MAX-VALUE-LENGTH" /              ; Specifies the maximum character length for
  attribute values
"X-MIN-INT-VALUE" /                 ; Specifies the minimum integer value for the
  attribute
"X-MAX-INT-VALUE" /                 ; Specifies the maximum integer value for the
  attribute
"X-MIN-VALUE-COUNT" /               ; Specifies the minimum number of allowable values
  for the
                                   ; attribute
"X-MAX-VALUE-COUNT" /               ; Specifies the maximum number of allowable values
  for the
                                   ; attribute
"X-READ-ONLY"                       ; True or False. Specifies if the file that
  contains the
                                   ; schema element is marked as read-only in the
  server
                                   ; configuration.

```

## Basic properties of attributes

The following table details the standard elements in schema definition.

### Basic Properties of Attributes

Attributes	Description
Name	The globally unique name
Description	An optional definition that describes the attribute and its contents The LDIF equivalent is <code>DESC</code> .
OID	The object identifier assigned to the schema definition You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
Syntax	The attribute syntax used For example, the <code>userPassword</code> attribute uses the User Password Syntax whereas the <code>authPassword</code> attribute uses the Authentication Password Syntax.
Parent	The schema definition's parent or supertype, if any The analogous LDIF equivalent is <code>SUP</code> .
Multivalued	Specifies if the attribute can appear more than once in its containing object class
Required By Class	Specifies any object classes that require the attribute
Allowed By Class	Specifies any object classes that can optionally use the attribute
Value Restrictions	Specifies any restriction on the value of the attribute

The Additional Properties table details auxiliary information associated with the attribute.

Attributes	Description
Aliases	Any shortform alias names, if any You can have any number of shortform names as long as they are all unique. The analogous LDIF equivalent appears as the secondary element with the <code>NAME</code> element. For example, <code>NAME, sn, surname</code> .
Origin	The origin of the schema definition Typically, it could refer to a specific RFC or company.
Stored in File	Specifies the schema file that stores the definition in the <code>&lt;server-root&gt;/config/schema</code> folder

Attributes	Description
Usage	<p>The intended use of the attribute</p> <p>The choices are:</p> <ul style="list-style-type: none"> <li>▪ userApplications</li> <li>▪ directoryOperation</li> <li>▪ distributedOperation</li> <li>▪ dSAOperation</li> </ul>
User-Modifiable	Specifies if the attribute can be modified by an authorized user
Obsolete	Specifies if the schema definition is obsolete or not
Matching Rules	Specifies the associated matching rules for the attribute

### Viewing attributes

The Schema Editor displays all of the attribute types on your directory server instance.

It shows the basic properties that are required elements in addition to the extra properties that are allowed within the attribute definition.

### Viewing attribute types using the Schema Editor

Before you begin

Ensure that the Directory Server instance is running.

About this task

To view attribute types using the Schema Editor:

Steps

1. Start the Administrative Console.
2. In the main menu, select **Schema**.
3. In the **Schema Editor**, click the **Attribute Types** tab.

- Click a specific attribute to view its definition.

In the **Object Class** window, view the attribute properties.

Example:

To follow this example, click the `account` attribute.

The screenshot shows a window titled "Object Class: account". It is divided into two main sections: "Basic Properties" and "Advanced Properties".

**Basic Properties:**

- Name: account
- Description: -
- OID: 0.9.2342.19200300.100.4.5
- Parent: top | Show Inheritance
- Type: Structural
- Stored in File: 00-core.ldf
- Required Attributes: uid, objectClass (+ top)
- Optional Attributes: description, hood, l, o, ou, seeAlso

**Advanced Properties:**

- Origin: RFC 4524
- Obsolete: No

At the bottom, there are buttons for "Close", "View as LDIF...", and "Copy As...".

- To see the equivalent attribute definition in ASN.1 format, click the **View as LDIF** button.

## Viewing attribute types over LDAP

### Steps

- To view an operational attribute, run `ldapsearch`.

Example:

This example uses `ldapsearch` to view the multi-valued operational attribute `attributeTypes`, which publishes the definitions on the Directory Server.

#### Note:

The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" attributeTypes
```

## Viewing a specific attribute type over LDAP

### Steps

- To search for a specific attribute, run `ldapsearch` with the `--dontWrap` option and use the `grep` command.

Example:

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base --dontWrap "(objectclass=*)" \
  attributeTypes | grep 'personalTitle'
```

## Creating a new attribute over LDAP

The following sections demonstrate how to add a schema element over LDAP.

You can create your own schema file or type the schema from the command line.

### Note:

Make sure you're aware of text spacing and ASN.1 formatting.

## Adding a new attribute to the schema over LDAP

### Steps

1. In a text editor, create an LDIF file with the new attribute definition.

Example:

In this example, the LDIF file is named `myschema.ldif`.

```
dn: cn=schema
changetype: modify
add: attributeTypes
attributeTypes: ( contractorStatus-OID NAME 'contractorStatus'
EQUALITY booleanMatch
SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
SINGLE-VALUE
USAGE userApplications
X-ALLOWED-VALUES ( 'Y' 'N' 'y' 'n' )
X-ORIGIN 'PingDirectory Server Example' )
```

2. To add the attribute, run `ldapmodify`.

Example:

```
$ bin/ldapmodify --filename myschema.ldif
```

3. To verify the addition, display the attribute using `ldapsearch`.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
--dontwrap "(objectclass=*)" attributeTypes | grep 'contractorStatus'
```

4. To view the custom schema file, go to `<server-root>/config/schema/99-user.ldif`.

Result:

For this example, you see the following details:

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( contractorStatus-OID
NAME 'contractorStatus'
EQUALITY booleanMatch
SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
SINGLE-VALUE
USAGE userApplications
X-ORIGIN 'PingDirectory Server Example' )
```

## Adding constraints to attribute types

About this task

The Directory Server provides attribute type extensions that constrain the values for the associated attribute using the `DirectoryString` attribute syntax.

To constrain the values for an attribute:

### Steps

- Use the `DirectoryString` attribute syntax.

Example:

The following example schema definition includes two `attributeType` definitions for `myAttr1` and `myAttr2`:

- The first definition constrains the values for the attribute `myAttr1` to `'foo'`, `'bar'`, and `'baz'`.
- The second definition constrains the minimum allowable length for `myAttr2` to 1 and the maximum allowable length to 5.

```
attributeTypes: (1.2.3.4
  NAME 'myAttr1'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  X-ALLOWED-VALUES ( 'foo' 'bar' 'baz' ))
attributeTypes: ( 1.2.3.5
  NAME 'myAttr2'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  X-MIN-VALUE-LENGTH '1'
  X-MAX-VALUE-LENGTH '5' )
```

## Managing object classes

Object classes are sets of related information objects that form entries in a directory information tree (DIT).

The Directory Server uses the schema to do the following:

- Define the entries.
- Specify the position of the entries in a DIT.
- Control the operations of the server.

You can also extend the schema by adding your own schema definitions.

Object classes have the following general properties:

- Object classes must have a globally unique name or identifier.
- Object classes specify the required and allowed attributes in an entry.
- Object classes can inherit the properties and the set of allowed attributes from its parent object classes, which might also be part of a hierarchical chain derived from the top abstract object class.
- Object classes that are defined in PingDirectory Server can be searched using the `objectClasses` operational attribute.

### Note:

The Directory Server also has a special entry called the subschema subentry, which provides information about the available schema elements on the server.

### Object classes types

Based on [RFC 4512](#), object classes can be a combination of three different types:

## Abstract object classes

Used as the base object class from which structural or auxiliary classes inherit its properties.

This inheritance is a one-way relationship because abstract object classes cannot be derived from structural or auxiliary classes. The most common abstract object class is `top`, which defines the highest level object class in a hierarchical chain of object classes.

## Structural object classes

Define the basic attributes in an entry and define where an entry can be placed in a directory information tree (DIT).

All entries in a DIT belong to one structural object class. Structural object classes can inherit properties from other structural object classes and from abstract object classes to form a chain of inherited classes. For example, the `inetOrgPerson` structural object class inherits properties from the `organizationalPerson` structural class, which inherits from another object class, `person`.

## Auxiliary object classes

Used together with structural object classes to define additional sets of attributes required in an entry.

The auxiliary object class cannot form an entry alone but must be present with a structural object class. Auxiliary object classes cannot derive from structural object classes or vice-versa. They can inherit properties from other auxiliary classes and from abstract classes.

## Object class definition

You can specify new object classes with existing schema components that don't require additional server code extensions for their implementation. To create new object classes, use the Schema Editor, which manages schema in the `<server-root>/config/schema` directory. For more information, see [Extending the Directory Server Schema](#).

RFC 4512, section 4.1.1, defines the following object class definition.

```
ObjectClassDescription = "(" wsp; Left parenthesis followed by a white space
numericoid                ; Required numeric object identifier
[ sp "NAME" sp qdescrs ]  ; Short name descriptor as alias for the
OID
[ sp "DESC" sp qdstring ] ; Optional descriptive string
[ sp "OBSOLETE" ]         ; Determines if the element is inactive
[ sp "SUP" sp oid ]       ; Specifies the direct superior object
class
[ sp kind ]               ; abstract, structural (default),
auxiliary
[ sp "MUST" sp oids ]     ; Required attribute types
[ sp "MAY" sp oids ]     ; Allowed attribute type
extensions wsp ")"       ; Extensions followed by a white space and
")"

usage = "userApplications" / ; Stores user data
      "directoryOperation" / ; Stores internal server data
      "distributedOperation" / ; Stores operational data that must be
synchronized
      "dSAOperation"      ; across servers
server and                ; Stores operational data specific to a
                           ; should not be synchronized across
servers
```

The following extensions are specific to PingDirectory Server and aren't defined in RFC 4512.

```

extensions = /
"X-ORIGIN" /           ; Specifies where the object class is defined
"X-SCHEMA-FILE" /     ; Specifies which schema file contains the
  definition
"X-READ-ONLY"         ; True or False. Specifies if the file that
  contains
                       ;   the schema element is marked as read-only
                       ;   in the server configuration.

```

**Note:**

Although RFC 4512 allows multiple superior object classes, PingDirectory Server allows at most one superior object class, which is defined by the `SUP` element in the definition.

### Basic object class properties

The Basic Properties table displays the standard elements in schema definition.

Attributes	Description
Name	The globally unique name.
Description	An optional definition that describes the object class and its contents. The analogous LDIF equivalent is <code>DESC</code> .
OID	The object identifier assigned to the schema definition. You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
Parent	The schema definition's hierarchical parent or superior object class, if any. An object class can have one parent.
Type	The type of schema definition, which can be abstract, structural, or auxiliary. The analogous LDIF equivalent is <code>ABSTRACT</code> , <code>STRUCTURAL</code> , or <code>AUX</code> .
Required Attributes	<p>Specifies required attributes with the object class. The analogous LDIF equivalent is <code>MUST</code>.</p> <p> <b>Tip:</b> The Schema Editor marks any inherited attributes from another object class. Double-click an attribute value to take you to the Properties View for that particular attribute.</p>

Attributes	Description
Optional Attributes	Specifies optional attributes that can be used with the object class. The analogous LDIF equivalent is <code>MAY</code> .
	 <b>Tip:</b> The Schema Editor marks any inherited attributes from another object class. Double-click an attribute value to take you to the properties view for that particular attribute.

The Additional Properties table provides auxiliary information associated with the object class.

Attributes	Description
Aliases	Specifies short-form alias names, if any. You could have any number of short-form names as long as they are all unique. The analogous LDIF equivalent appears as the secondary element with the <code>NAME</code> element although most object classes do not have aliases.
Origin	The origin of the schema definition. Typically, it could refer to a specific RFC or company.
Obsolete	Specifies if the schema definition is obsolete or not.
Stored in File	Specifies the schema file that stores the definition in the <code>&lt;server-root&gt;/config/schema</code> folder.

## Viewing object classes

About this task

To view the object classes on your Directory Server, use any of the following:

- The Administrative Console Schema Editor
- LDAP with the `ldapsearch` tool
- A third-party tool

### Note:

The Schema Editor displays all of the object classes on the directory server instance. It shows the basic properties that are required elements and the extra properties that are allowed within the object class.

To view object classes over LDAP:

## Steps

- To view an operational attribute, run `ldapsearch`.

Example:

This example uses `ldapsearch` to view the multi-valued operational attribute `objectClasses`, which publishes the object class definitions on the Directory Server.

### Note:

The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
--dontWrap "(objectclass=*)" objectClasses
```

### Result:

```
dn: cn=schema
objectClasses: ( 2.5.6.0 NAME 'top' ABSTRACT MUST objectClass X-ORIGIN
'RFC 4512' )
objectClasses: ( 2.5.6.1 NAME 'alias' SUP top STRUCTURAL MUST
aliasedObjectName
X-ORIGIN 'RFC 4512' )
objectClasses: ( 2.5.6.2 NAME 'country' SUP top STRUCTURAL MUST c
MAY ( searchGuide $ description ) X-ORIGIN 'RFC 4519' )
...(more output)...
```

## Managing an object class over LDAP

Manage an object class schema element over LDAP by adding a new attribute element to an existing object class. You can create your own schema file or type the schema from the command line. In either case, you must pay special attention to text spacing and ASN.1 formatting.

### Before you begin

Define the attribute you want to add to the custom schema file.

### About this task

The following example procedure adds a predefined attribute, `contractorAddress`, to the custom schema file, then adds it to the `contractor` object class.

## Steps

1. Create and save an LDIF file with the content in the following example.

Example:

In this example, the file is named `contractorAddress-attr.ldif`.

```
dn: cn=schema
changetype: modify

add: attributeTypes attributeTypes: ( contractor-OID NAME
'contractorAddress'
SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
SINGLE-VALUE
USAGE userApplications
X-ORIGIN 'user defined'
X-SCHEMA-FILE '98-custom-schema.ldif' )
X-ORIGINS 'user defined'
```

```
X-SCHEMA-FILE '98-custom-schema.ldif' )
```

2. To add the attribute you defined, run **ldapmodify**.

Example:

In this example, the `contractorAddress` attribute is being added.

```
$ bin/ldapmodify --filename contractorAddress-attr.ldif
```

3. To modify the contractor object class to allow this attribute, create an LDIF file.

When doing this, you are re-adding the updated `objectClass`. The Directory Server handles the proper replacement of the existing object class with the new one.

**Note:**

Ensure that the lines are not wrapped, the `objectClasses` line should be one continuous line.

Example:

In this example, the file is named `contractor-oc.ldif`.

```
dn:cn=schema
changetype: modify
add: objectClasses
objectClasses: ( contractor-OID NAME 'contractor'
DESC 'Contractor status information
SUP top
AUXILIARY MAY ( contractorStatus $ contractorAgency $
contractorAddress )
X-ORIGIN 'Directory Server Example'
X-SCHEMA-FILE '98-custom-schema.ldif' )
```

4. To update the `objectClass`, run **ldapmodify**.

Example:

```
$ bin/ldapmodify --filename contractor-oc.ldif
```

Result: These schema changes are replicated to all servers in the replication topology.

5. To verify the change, view the `config/schema/98-custom-schema.ldif` file on the other servers in the replication topology to ensure that the changes are present.
6. Optional: To add an index for this attribute, run **dsconfig** with the `create-local-db-index` option.

**Note:**

You must do this on each server in your topology unless you have server configuration groups set up.

For more information, see [Configuring Server Groups](#).

Example:

```
$ bin/dsconfig create-local-db-index --backend-name userRoot \
--index-name contractorAddress --set index-type:equality
```

7. Rebuild the index online.

**Note:**

This doesn't affect other indexes or entries because there is no existing data for this attribute on any entry.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index contractorAddress
```

## Creating a new object class using the Schema Editor

The procedures to create a new object class are similar to that of creating a new attribute.

Before you begin

Ensure that any attributes that are part of the new object class are defined before defining the object class.

About this task

To create a new object class:

Steps

1. Start the Administrative Console.
2. From the main menu, select **LDAP Schema**.
3. On the **Schema Editor**, click the **Object Classes** tab, and then click **New**.
4. Enter the properties for the new object class.
5. In the **Attributes** box, filter the types of attributes required for the new object class. Click the right arrow to move it into the **Required** or the **Optional** box.

**Note:**

All custom attributes appear at the bottom of the list in the **Attributes** box.

## Extending the schema using a custom schema file

To add new attributes and object classes to your Directory Server schema, create a custom schema file.

Steps

1. Create an LDIF file with the new attribute extensions using a text editor.

Example:

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
attributeTypes: ( contractorStatus-OID NAME 'contractorStatus'
EQUALITY booleanMatch
SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
SINGLE-VALUE
USAGE userApplications
X-ORIGIN 'Directory Server Example' )
attributeTypes: ( contractorAgency-OID NAME 'contractorAgency'
EQUALITY caseIgnoreMatch
SUBSTR caseIgnoreSubstringsMatch
```

```
SYNTAX 1.3.6.1.4.1.1466.115.121.1.44{256}
SINGLE-VALUE
USAGE userApplications
X-ORIGIN 'PingDirectory Server Example' )
```

2. In the LDIF file you created in step 1, add a new object class definition after the attribute types.

Example:

This example creates an auxiliary object class, `contractor`, that alone cannot be used as an entry.

The object class is used to add supplemental information to the `inetOrgPerson` structural object class. The attributes are all optional for the new object class.

```
objectClasses: ( contractor-OID
  NAME 'contractor'
  DESC 'Contractor status information'
  SUP top
  AUXILIARY
  MAY ( contractorStatus $ contractorAgency )
  X-ORIGIN 'PingDirectory Server Example' )
```

3. Save the file and place it in the `<server-root>/config/schema` directory.

In this example, the file is saved as `99-auxobjclass.ldif`.

4. Load the schema extensions into Directory Server. You have four options:

Choose from:

- Create a task that loads the new extensions into the schema.

The following example creates a task with the ID `add-schema-99-auxobjclass` and adds it using `ldapmodify`.

```
dn: ds-task-id=add-schema-99-auxobjclass,cn=Scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-add-schema-file
ds-task-id: add-schema-99-auxobjclass
ds-task-class-name:
  com.unboundid.directory.server.tasks.AddSchemaFileTask
```

```
ds-task-schema-file-name: 99-auxobjclass.ldif
```

 **Note:**

When using this method, you don't need to restart the server.

- Import the schema file using the Administrative Console Schema Editor.

 **Note:**

When using this method, you don't need to restart the server.

- a. Place the `99-auxobjclass.ldif` file in the `<server-root>/config/schema` directory.
- b. Restart PingDirectory Server.

 **Note:**

The schema file is read at startup.

- Add the schema file using `load-ldap-schema-file`.

```
$ bin/load-ldap-schema-file --schemaFile config/schema 99-
auxobjclass.ldif
```

 **Note:**

When using this method, you don't need to restart the server.

5. Add the new object class and attribute to an existing user entry.

Example:

```
$ bin/ldapmodify
dn: uid=user.9,ou=People,dc=example,dc=com
changetype: modify
add: objectClass
objectClass: contractor
-
add: contractorStatus
contractorStatus: TRUE
```

6. To verify the addition, run `ldapsearch` to display the attribute.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.9)"
contractorStatus
```

Result:

```
dn: uid=user.9,ou=People,dc=example,dc=com
contractorStatus: TRUE
```

## About managing matching rules

Matching rules determine how clients and servers compare attribute values during LDAP requests or operations.

Matching rules are also used in evaluating search filter elements, including distinguished names (DNs) and attributes. They are defined for each attribute based on the following properties:

- **EQUALITY:** two attributes are equal based on case, exact match, and so forth
- **SUBSTR:** assertion value is a substring of an attribute
- **ORDERING:** greater than or equal, less than or equal, and so forth

### Note:

PingDirectory Server supports an `APPROXIMATE` matching rule that compares similar attributes based on fuzzy logic. Attributes that are similar or sound alike are matched. For example, `petersen` would match `peterson`.

### Matching rule definition

New matching rules require additional server code extensions to be implemented on PingDirectory Server.

If you need new matching rules, contact a Ping Identity support representative for assistance.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.3.

```
MatchingRuleDescription = "(" wsp      ; Left parentheses followed by a white
  space
  numericoid                ; Required numeric object identifier
  identifying               ; this matching rule
  [ sp "NAME" sp qdescrs   ; Short name descriptor
  [ sp "DESC" sp qdstring  ; Description
  [ sp "OBSOLETE" ]       ; Specifies if the rule is inactive
  sp "SYNTAX" sp numericoid ; Assertion syntax
  extensions wsp ")"     ; Extensions followed by a white space
  and ")"
```

### Default matching rules

PingDirectory Server provides a large set of matching rules that support a variety of applications.

The default matching rules available for the Directory Server are listed in the table below for each matching rule type:

- Equality matches
- Substring matches
- Ordering matches
- Approximate matches

### Default Matching Rules

Matching Rule/OID	Attribute Syntax/OID	Description
uuidMatch/ 1.3.6.1.1.16.2	UUID/ 1.3.6.1.1.16.1	Compares an asserted UUID with a stored UUID attribute value for equality <a href="#">RFC 4530</a>

Matching Rule/OID	Attribute Syntax/OID	Description
uuidOrderingMatch/ 1.3.6.1.1.16.3	UUID/ 1.3.6.1.1.16.1	Compares the collation order of an asserted UUID with a stored UUID attribute value for ordering  <a href="#">RFC 4530</a>
caseExactIA5Match/ 1.3.6.1.4.1.1466.109.114.1	IA5 String/ 1.3.6.1.4.1.1466.115.121.1.2	Compares an asserted value with an attribute value of International Alphabet 5 (IA5) syntax  <a href="#">RFC 4517</a>
caseIgnoreIA5Match/ 1.3.6.1.4.1.1466.109.114.2	IA5 String/ 1.3.6.1.4.1.1466.115.121.1.2	Compares an asserted value with an attribute value of IA5 syntax  Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space.  <a href="#">RFC 4517</a>
caseIgnoreIA5SubstringsMatch/ 1.3.6.1.4.1.1466.109.114.3	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.5	Compares an asserted substring with an attribute value of IA5 string syntax  Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space.  <a href="#">RFC 4517</a>
authPasswordExactMatch/ 1.3.6.1.4.1.4203.1.2.2	Authentication Password Syntax/ 1.3.6.1.4.1.4203.1.1.2	Authentication password exact matching rule
authPasswordMatch/ 1.3.6.1.4.1.4203.1.2.3	Authentication Password Syntax/ 1.3.6.1.4.1.4203.1.1.2	Authentication password matching rule
ds-mr-double-metaphone-approx/ 1.3.6.1.4.1.30221.1.4.1	Directory String/ 1.3.6.1.4.1.1466.115.121.1.1	Syntax based on the phonetic Double Metaphone algorithm for approximate matching
ds-mr-user-password-exact/ 1.3.6.1.4.1.30221.1.4.2	User Password Syntax/ 1.3.6.1.4.1.30221.1.3.1	User password exact matching rule
ds-mr-user-password-equality/ 1.3.6.1.4.1.30221.1.4.3	User Password Syntax/ 1.3.6.1.4.1.30221.1.3.1	User password equality matching rule

Matching Rule/OID	Attribute Syntax/OID	Description
historicalCsnOrderingMatch/ 1.3.6.1.4.1.30221.1.4.4	1.3.6.1.4.1.30221.1.3.5	Compares the collation order of a historical change sequence number with a historical Change Sequence Number (CSN) attribute value
caseExactIA5SubstringsMatch/ 1.3.6.1.4.1.30221.1.4.902	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.5	Compares an asserted substring with an attribute value of IA5 string syntax <a href="#">RFC 4517</a>
compactTimestampMatch/ 1.3.6.1.4.1.30221.2.4.1	Compact Timestamp/ 1.3.6.1.4.1.30221.2.3.1	Compact Timestamp matching rule
compactTimestampOrderingMatch/ 1.3.6.1.4.1.30221.2.4.2	Compact Timestamp/ 1.3.6.1.4.1.30221.2.3.1	Compares the collation order of a compact timestamp number with an attribute value of Compact Timestamp syntax
objectIdentifierMatch/ 2.5.13.0	OID/ 1.3.6.1.4.1.1466.115.121.1.3	Compares an asserted value with an attribute value of OID syntax <a href="#">RFC 4517</a>
distinguishedNameMatch/ 2.5.13.1	DN/ 1.3.6.1.4.1.1466.115.121.1.1	Compares an asserted value with an attribute value of distinguished name (DN) syntax  Spaces around commas and semicolons are ignored. Spaces around plus and equal signs around relative distinguished name (RDN) components are ignored. <a href="#">RFC 4517.</a>
caseIgnoreMatch/ 2.5.13.2	Directory String/ 1.3.6.1.4.1.1466.115.121.1.1	Compares an asserted value with an attribute value  Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. <a href="#">RFC 4517</a>

Matching Rule/OID	Attribute Syntax/OID	Description
caseIgnoreOrderingMatch/ 2.5.13.3	Directory String/ 1.3.6.1.4.1.1466.115.121.1.10	Compares the collation order of the asserted string with an attribute value of Directory String syntax  Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space.  <a href="#">RFC 4517</a>
caseIgnoreSubstringsMatch/ 2.5.13.4	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.5	Compares an asserted substring value with an attribute value of Directory String syntax  Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space.  <a href="#">RFC 4517</a>
caseExactMatch/ 2.5.13.5	Directory String/ 1.3.6.1.4.1.1466.115.121.1.10	Compares an asserted value with an attribute value of Directory String syntax  <a href="#">RFC 4517</a>
caseExactOrderingMatch/ 2.5.13.6	Directory String 1.3.6.1.4.1.1466.115.121.1.10	Compares the collation order of the asserted string with an attribute value of Directory String syntax  <a href="#">RFC 3698</a>
caseExactSubstringsMatch/ 2.5.13.7	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.5	Compares an asserted substring with an attribute value of Directory String syntax  <a href="#">RFC 3698</a>
numericStringMatch/ 2.5.13.8	Numeric String/ 1.3.6.1.4.1.1466.115.121.1.3	Compares an asserted value with an attribute value of Numeric String syntax. Spaces are ignored when performing these comparisons  <a href="#">RFC 4517.</a>

Matching Rule/OID	Attribute Syntax/OID	Description
numericStringOrderingMatch/ 2.5.13.9	Numeric String/ 1.3.6.1.4.1.1466.115.121.1.30	<p>Compares the collation order of the asserted string with an attribute value of Numeric String syntax</p> <p>Spaces are ignored when performing these comparisons.</p> <p><a href="#">RFC 4517</a></p>
numericStringSubstringsMatch/ 2.5.13.10	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.50	<p>Compares an asserted substring with an attribute value of Numeric String syntax</p> <p>Spaces are ignored when performing these comparisons.</p> <p><a href="#">RFC 4517</a></p>
caseIgnoreListMatch/ 2.5.13.11	Postal Address/ 1.3.6.1.4.1.1466.115.121.1.40	<p>Compares an asserted value with an attribute value, which is a sequence of Directory Strings</p> <p>Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space.</p> <p><a href="#">RFC 4517</a></p>
caseIgnoreListSubstringsMatch/ 2.5.13.12	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.50	<p>Compares the asserted substring with an attribute value, which is a sequence of Directory Strings</p> <p>Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space.</p> <p><a href="#">RFC 3698</a></p>
booleanMatch/ 2.5.13.13	Boolean/ 1.3.6.1.4.1.1466.115.121.1.70	<p>Compares an asserted boolean value with an attribute value of BOOLEAN syntax</p> <p>Returns true if the values are both TRUE or both FALSE.</p> <p><a href="#">RFC 3698</a></p>

Matching Rule/OID	Attribute Syntax/OID	Description
integerMatch/ 2.5.13.14	Integer/ 1.3.6.1.4.1.1466.115.121.1.20	Compares an asserted value with an attribute value of INTEGER syntax <a href="#">RFC 4517</a>
integerOrderingMatch/ 2.5.13.15	Integer/ 1.3.6.1.4.1.1466.115.121.1.20	Compares the collation order of the asserted integer with an attribute value of Integer syntax  Returns true if the attribute value is less than the asserted value.  <a href="#">RFC 3698</a>
bitStringMatch/ 2.5.13.16	Bit String/ 1.3.6.1.4.1.1466.115.121.1.6	Compares an asserted Bit String value with an attribute value of Bit String syntax  <a href="#">RFC 4517</a>
octetStringMatch/ 2.5.13.17	Octet String/ 1.3.6.1.4.1.1466.115.121.1.40	Compares an asserted value with an attribute value of octet string syntax using a byte-for-byte comparison  <a href="#">RFC 4517</a>
octetStringOrderingMatch/ 2.5.13.18	Octet String/ 1.3.6.1.4.1.1466.115.121.1.40	Compares the collation order of the asserted octet string with an attribute value of Octet String syntax  Zero precedes a one bit. Shorter strings precede longer strings.  <a href="#">RFC 3698</a>
octetStringSubstringsMatch/ 2.5.13.19	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58	Compares an asserted substring with an attribute value of octet string syntax using a byte-for-byte comparison  <a href="#">RFC 4517</a>
telephoneNumberMatch/ 2.5.13.20	Telephone Number/ 1.3.6.1.4.1.1466.115.121.1.50	Compares an asserted value with an attribute value of Telephone Number syntax  <a href="#">RFC 4517</a>

Matching Rule/OID	Attribute Syntax/OID	Description
telephoneNumberSubstringsMatch/ 2.5.13.21	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.50	Compares an asserted value with the substrings of an attribute value of Telephone Number String syntax <a href="#">RFC 4517</a>
presentationAddressMatch/ 2.5.13.22	Presentation Address/ 1.3.6.1.4.1.1466.115.121.1.40	Compares an asserted value with an attribute value of Presentation Address syntax <a href="#">RFC 4517</a>
uniqueMemberMatch/ 2.5.13.23	Name and Optional UID/ 1.3.6.1.4.1.1466.115.121.1.30	Compares an asserted value with an attribute value of Unique Member syntax <a href="#">RFC 4517</a>
protocolInformationMatch/ 2.5.13.24	Protocol Information/ 1.3.6.1.4.1.1466.115.121.1.40	Compares an asserted value with an attribute value of Protocol Information syntax <a href="#">RFC 4517</a>
generalizedTimeMatch/ 2.5.13.27	Generalized Time/ 1.3.6.1.4.1.1466.115.121.1.20	Compares an asserted value with an attribute value of Generalized Time syntax <a href="#">RFC 4517</a>
generalizedTimeOrderingMatch/ 2.5.13.28	Generalized Time 1.3.6.1.4.1.1466.115.121.1.20	Compares the collation order of the asserted string with an attribute value of Generalized Time String syntax and case is ignored <a href="#">RFC 4517</a>
integerFirstComponentMatch/ 2.5.13.29	Integer/ 1.3.6.1.4.1.1466.115.121.1.20	Equality matching rules for subschema attributes between an Integer syntax and the value syntax <a href="#">RFC 4517</a>
objectIdentifierFirstComponentMatch/ 2.5.13.30	OID/ 1.3.6.1.4.1.1466.115.121.1.30	Equality matching rules for subschema attributes between an OID syntax and the value syntax <a href="#">RFC 4517</a>

Matching Rule/OID	Attribute Syntax/OID	Description
directoryStringFirstComponentMatch/ 2.5.13.31	Directory String/ 1.3.6.1.4.1.1466.115.121.1.1	Compares an asserted Directory String value with an attribute value of type SEQUENCE whose first component is mandatory and of type Directory String  Returns true if the attribute value has a first component whose value matches the asserted Directory String using the rules of caseIgnoreMatch.  <a href="#">RFC 3698</a> .
wordMatch/ 2.5.13.32	Directory String/ 1.3.6.1.4.1.1466.115.121.1.1	Compares an asserted word with any word in the attribute value for equality  <a href="#">RFC 3698</a>
keywordMatch/ 2.5.13.33	Directory String/ 1.3.6.1.4.1.1466.115.121.1.1	Compares an asserted value with any keyword in the attribute value for equality  <a href="#">RFC 3698</a>

### Basic matching rule properties

The following table describes the standard elements in a matching rule schema definition.

Attributes	Description
Name	Specifies the descriptive and unique name of the element
Description	Specifies an optional definition that describes the matching rule The analogous LDIF equivalent is DESC.
OID	Specifies the globally unique object identifier assigned to the schema definition You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
Type	Specifies the type of matching rule: <ul style="list-style-type: none"> <li>▪ Equality</li> <li>▪ Ordering</li> <li>▪ Substring</li> <li>▪ Approximate</li> </ul>
Syntax	Specifies the matching rule syntax
Used by Attributes	Specifies any attributes that use the corresponding matching rule

## Viewing matching rules

To view the matching rules on your Directory Server, use the Schema Editor, LDAP with `ldapsearch`, or a third-party tool.

About this task

To view matching rules over LDAP:

### Steps

- To view the `matchingRules` attribute, run `ldapsearch`.

Example:

The following example uses `ldapsearch` to view a multi-valued operational attribute, `matchingRules`, which publishes the definitions on the Directory Server.

#### Note:

The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" matchingRules
```

## About managing attribute syntaxes

The attribute type definition has a `SYNTAX` element, or attribute syntax, that specifies how the data values for the attribute are represented.

The syntax can be used to define a large range of data types necessary for client applications. An attribute syntax uses the Abstract Syntax Notation One (ASN.1) format for its definitions.

### Attribute syntax definition

New attribute syntaxes require additional code to be implemented on PingDirectory Server.

If you need new syntax definitions, contact Ping Identity support for assistance.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.5.

```
SyntaxDescription = "(" wsp
  numericoid          ; Object identifier
  [ sp "DESC" sp qdstring ] ; Description
  extensions wsp ")" ; Extensions followed by a white space and ")"
```

### Default attribute syntaxes

PingDirectory Server supports a large set of Attribute Syntax rules for applications.

The default Attribute Syntax rules available for the directory server are listed in the following table.

LDAP Syntax	OID	Description
UUID	1.3.6.1.1.16.1	128-bit (16 octets) Universally Unique Identifier (UUID) used for Uniform Resource Names as defined in <a href="#">RFC 4122</a>  For example, a4028c1a-f36e-11da-bala-04112154bd1e

LDAP Syntax	OID	Description
Attribute Type Description	1.3.6.1.4.1.1466.115.1	Syntax for the AttributeTypeDescription rule based on <a href="#">RFC 4517</a>
Binary	1.3.6.1.4.1.1466.115.1	Strings based on Basic Encoding Rules (BER) or Distinguished Encoding rules (DER)  For example, an X.509 digital certificate or LDAP messages are BER encoded
Bit String	1.3.6.1.4.1.1466.115.1	Sequence of binary digits based on <a href="#">RFC 4517</a>  For example, '0010111'B
Boolean	1.3.6.1.4.1.1466.115.1	TRUE or FALSE
Certificate	1.3.6.1.4.1.1466.115.1	BER/DER-encoded octet strings based on an X.509 public key certificate as defined in <a href="#">RFC 4523</a>
Certificate List	1.3.6.1.4.1.1466.115.1	BER/DER-encoded octet string based on an X.509 certificate revocation list as defined in <a href="#">RFC 4523</a>
Certificate Pair	1.3.6.1.4.1.1466.115.1	BER/DER-encoded octet string based on an X.509 public key certificate pair as defined in <a href="#">RFC 4523</a>
Country String	1.3.6.1.4.1.1466.115.1	Two character country code specified in ISO 3166  For example, US, CA, and so forth   <b>Note:</b> The current implementation for Country String: <ul style="list-style-type: none"> <li>Only verifies that values are two printable characters, where the set of printable characters is defined in <a href="#">RFC 2252</a>.</li> <li>Does not check that the value is a valid ISO 3166 country code.</li> </ul>
DN	1.3.6.1.4.1.1466.115.1	Distinguished name of an entry as defined in <a href="#">RFC 4514</a>

LDAP Syntax	OID	Description
Delivery Method	1.3.6.1.4.1.1466.115.1	Sequence of services in preference order by which an entity receives messages as defined in <a href="#">RFC 4517</a>  For example, videotext \$ telephone
Directory String	1.3.6.1.4.1.1466.115.1	String of one or more characters from the Universal Character Set (UCS) using UCS Transformation Format 8 (UTF-8) encoding of the string
DIT Content Rule Description	1.3.6.1.4.1.1466.115.1	DITContentRuleDescription as defined in <a href="#">RFC 4517</a>
DIT Structure Rule Description	1.3.6.1.4.1.1466.115.1	DITStructureRuleDescription as defined in <a href="#">RFC 4517</a>
Enhanced Guide	1.3.6.1.4.1.1466.115.1	Combination of attribute types and filter operators to be used to construct search filters as defined in <a href="#">RFC 4517</a>  For example, person#(sn\$EQ)#oneLevel
Facsimile Telephone Number	1.3.6.1.4.1.1466.115.1	Fax telephone number on the public switched telephone network as defined in <a href="#">RFC 4517</a>
Fax	1.3.6.1.4.1.1466.115.1	Image generated using Group 3 fax process as defined in <a href="#">RFC 4517</a>
Generalized Time	1.3.6.1.4.1.1466.115.1	String representing data and time as defined in <a href="#">RFC 4517</a> YYYYMMDDHHMMSS[.fraction][(+ -HHMM) Z]  For example, 201103061032, 201103061032-0500, or 201103061032Z (Z indicates Coordinated Universal Time)
Guide	1.3.6.1.4.1.1466.115.1	Attribute types and filter operators as defined in <a href="#">RFC 4517</a>
IA5 String	1.3.6.1.4.1.1466.115.1	String of zero or more characters from the International Alphabet 5 (IA5) character set as defined in <a href="#">RFC 4517</a>
Integer	1.3.6.1.4.1.1466.115.1	String representations of integer values  For example, the character string 1234 represents the number 1234 as defined in <a href="#">RFC 4517</a>
JPEG	1.3.6.1.4.1.1466.115.1	Image in JPEG File Interchange Format (JFIF) as defined in <a href="#">RFC 4517</a>

LDAP Syntax	OID	Description
Matching Rule Description	1.3.6.1.4.1.1466.115.1.1.1.1	MatchingRuleDescription as defined in <a href="#">RFC 4512</a>
Matching Rule Use Description	1.3.6.1.4.1.1466.115.1.1.1.2	Attribute types to which a matching rule is applied in an extensibleMatch search filter  <a href="#">RFC 4511</a>
Name and Optional UID	1.3.6.1.4.1.1466.115.1.1.1.3	Distinguished name and an optional unique identifier that differentiates identical distinguished names (DNs) as defined in <a href="#">RFC 4517</a>  For example, uid=jsmith,ou=People,dc=example,dc=com#'0111'B
Name Form Description	1.3.6.1.4.1.1466.115.1.1.1.4	NameFormDescription as defined in <a href="#">RFC 4512</a>
Numeric String	1.3.6.1.4.1.1466.115.1.1.1.5	Sequence of one or more numerals and spaces as defined in <a href="#">RFC 4517</a>  For example, 14 848 929 102
Object Class Description	1.3.6.1.4.1.1466.115.1.1.1.6	ObjectClassDescription as defined in <a href="#">RFC 4512</a>
OID	1.3.6.1.4.1.1466.115.1.1.1.7	ObjectIdentifier as defined in <a href="#">RFC 4512</a>
Other Mailbox	1.3.6.1.4.1.1466.115.1.1.1.8	Specifies an electronic mailbox as defined in <a href="#">RFC 4517</a>  For example, otherMailbox = google \$user@gmail.com
Octet String	1.3.6.1.4.1.1466.115.1.1.1.9	Sequence of zero or more octets (8-bit bytes) as defined in <a href="#">RFC 4517</a>
Postal Address	1.3.6.1.4.1.1466.115.1.1.1.10	Strings of characters that form a multi-line address in a physical mail system. Each component is separated by a \$  For example, 1234 Main St.\$Austin, TX 78744\$USA
Protocol Information	1.3.6.1.4.1.1466.115.1.1.1.11	Undefined
Presentation Address	1.3.6.1.4.1.1466.115.1.1.1.12	String encoded OSI presentation address as defined in <a href="#">RFC 1278</a>  For example, TELEX+00728722+RFC-1006+03+10.0.0.6

LDAP Syntax	OID	Description
Printable String	1.3.6.1.4.1.1466.115.1	String of one or more printable ASCII alphabetic, numeric, and punctuation characters as defined in <a href="#">RFC 4517</a>
RFC3672 Subtree Specification	1.3.6.1.4.1.1466.115.1	Syntax based on subtree specification as defined as <a href="#">RFC 3672</a>
Supported Algorithm	1.3.6.1.4.1.1466.115.1	Octet string based on the LDAP-encoding for a supported algorithm value that results from the BER encoding of a SupportedAlgorithm ASN.1 value
Telephone Number	1.3.6.1.4.1.1466.115.1	String of printable international telephone number representations in E.123 format as defined in <a href="#">RFC 4517</a>  For example, +1 512 904 5525
Teletex Terminal Identifier	1.3.6.1.4.1.1466.115.1	Identifier and telex terminal as defined in <a href="#">RFC 4517</a>
Telex Number	1.3.6.1.4.1.1466.115.1	String representing the telex number, country code, and answerback code as defined in <a href="#">RFC 4517</a>  For example, 812374, ch, ehhg
UTC Time	1.3.6.1.4.1.1466.115.1	Character string representing the data and time in UTC Time format as defined as <a href="#">RFC 4517</a> : YMMDDHHMM[SS] [(+ -HHMM)   Z], where Z is the coordinated universal time.  For example, 0903051035Z, 0903051035-0500
LDAP Syntax Description	1.3.6.1.4.1.1466.115.1	Syntax Description as defined in <a href="#">RFC 4512</a>
Substring Assertion	1.3.6.1.4.1.1466.115.1	Syntax for assertion values in an extensible match as defined in <a href="#">RFC 4517</a>
Authentication Password Syntax	1.3.6.1.4.1.4203.1.1.2	Encoded password storage syntax as defined in <a href="#">RFC 3112</a>  For example, the syntax specifies the storage scheme in brackets: <storage-scheme>\$<auth component>\$<auth value>  For example, SSHA\$xdezWRqgyJk=\$egDEFDXvdeeEnXUEIDPnd39dkpe=

LDAP Syntax	OID	Description
User Password Syntax	1.3.6.1.4.1.30221.1.3	Encoded password storage syntax as defined in <a href="#">RFC 2307</a>  For example, the syntax specifies the storage scheme in brackets: {SSHA}XaljOF0ii3fOwCrU1klgBpWFayqSYs+5W1pMnw==
Relative Subtree Specification	1.3.6.1.4.1.30221.1.3	Similar to the <a href="#">RFC 3672</a> subtree specification except it uses an LDAP search filter as the specification filter
Absolute Subtree Specification	1.3.6.1.4.1.30221.1.3	Syntax for a subset of entries in a subtree based on <a href="#">RFC 3672</a>
Sun-defined Access Control Information	1.3.6.1.4.1.30221.1.3	Syntax for access control instructions used in Sun Directory Servers
Compact Timestamp	1.3.6.1.4.1.30221.2.3	Syntax based on Compact Timestamp ISO 8601 format  For example, 20110306T102532

### Basic attribute syntax properties

The following table provides a description of the standard elements in an attribute syntax.

Attributes	Description
<b>Name</b>	Specifies the descriptive and unique name of the element
<b>Description</b>	Indicates an optional definition that describes the attribute syntax The analogous LDIF equivalent is <code>DESC</code> .
<b>OID</b>	Specifies the globally unique object identifier assigned to the schema definition
<b>Used by Attributes</b>	Indicates any attributes that use the corresponding attribute syntax

### Viewing attribute syntaxes

To view the attribute syntaxes on your Directory Server, use the Schema Editor, LDAP with `ldapsearch`, or a third-party tool.

About this task

To view attribute syntaxes over LDAP:

## Steps

- To view the Directory Server's published list of attribute syntaxes, run **ldapsearch** using the `ldapSyntaxes` attribute.

Example:

The following example uses **ldapsearch** to view the Directory Server's published list of attribute syntaxes using the multi-valued operational attribute, `ldapSyntaxes`, which publishes the definitions on the Directory Server.

### Note:

The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base "(objectclass=*)" ldapSyntaxes
```

## Using the Schema Editor utilities

The Schema Editor provides a **Schema Utilities** tab that enables importing new schema elements from a file and checking schema compliance.

### About this task

If you are importing a schema file, the system automatically checks for compliance before the import. If the definition doesn't meet schema compliance, the system displays an error message. However, you should check if your file is compliant with your schema prior to importing it.

To check schema compliance using the Schema Editor:

### Steps

1. Start the Administrative Console.
2. In the main menu, click **LDAP Schema**.
3. In the Schema Editor, click the **Schema Utilities** tab.
4. Add your schema definition using one of two methods:  
Choose from:
  - To have the system check an LDIF file, click **Import Schema Elements** and select a file to upload.
  - Copy and paste a new schema definition into the field.
5. Click **Validate Entries**.

Result: If there is a problem with your definition, an error message is generated.

## Modifying a schema definition

You can only edit schema definitions in Directory Server that are read-write. The schema elements indicated by the **Modifiable** column in the Schema Editor's tables can be modified.

### Before you begin

Ensure that your Directory Server instance is running.

### About this task

To modify a schema definition:

### Steps

1. Start the Administrative Console.
2. In the main menu, click **Schema**.
3. On the Schema Editor, click the **Object Classes** tab.
4. Select the object class that you want to modify, and then click **Actions # Edit**.  
Result: The **Edit** dialog box appears.
5. Make your changes and click **OK**.

## Deleting a schema definition

You can only delete schema definitions in Directory Server that are read-write. In general, you can only remove schema definitions in the **Custom** folder of the Schema Editor.

### Before you begin

Ensure that your Directory Server instance is running.

### About this task

Ensure that the schema element you are deleting is not currently in use.

To delete a schema definition:

### Steps

1. Start the Administrative Console.
2. In the main menu, click **Schema**.
3. On the **Schema Editor**, click the **Object Classes** tab.
4. Select the object class that you want to remove, and then click **Actions # Delete**.  
Result: The **Confirmation** dialog box opens.
5. To delete the schema element, click **Yes**.

## Managing schema checking

PingDirectory Server provides full support for parsing all schema elements and provides access to all of its components.

By default, the Directory Server enables schema checking for all operations, especially when importing data to the server or when modifying entries using the `ldapmodify` tool. Any schema violations generate an error message to standard output.

### Viewing the schema checking properties

#### Steps

- To view the schema checking property, run `dsconfig` with the `get-global-configuration-prop` option.

Example:

```
$ bin/dsconfig get-global-configuration-prop \
  --property check-schema
```

## Disabling schema checking

Although you can use the `dsconfig` tool to disable the schema checking, it's not recommended.

### About this task

This feature only applies to public backends. Schema checking is enforced on private backends, such as changes to the configuration, schema, task, and others. An admin action alert is generated if you attempt to disable schema checking using `dsconfig` in interactive or non-interactive mode. The alert provides alternatives to disabling schema checking.

### Steps

1. To disable the `check-schema` property, run `dsconfig` with the `set-global-configuration-prop` option.

Example:

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
  --set check-schema:false
```

Result:

The system generates an admin action alert that provides alternate options to disabling schema checking.

```
One or more configuration property changes require administrative action
or
confirmation/notification.
```

Those properties include:

- \* `check-schema`: Schema checking should only be disabled as a last resort since disabling schema checking harms performance and can lead to unexpected behavior in the server as well as the applications that access it. There are less severe options for addressing schema issues:
  1. Update the data to conform to the server schema.
  2. Modify the server schema to conform to the data. Contact support before modifying the server's default schema.
  3. Change the `single-structural-objectclass-behavior` property to allow entries to have no structural object class or multiple structural object classes.
  4. Change the `invalid-attribute-syntax-behavior` property to allow attribute values to violate their attribute syntax.
  5. Change the `allow-zero-length-values` property of the Directory String Attribute Syntax configuration to allow attributes with this syntax to have a zero length value.

```
Continue? Choose 'no' to return to the previous step (yes / no) [yes]:
```

2. To continue the process of disabling the schema checking instead of following one of the alternate options, press Enter.

## Managing matching rule uses

Matching rule use definitions map certain attribute types with a matching rule definition for extensible match filters.

Extensible match filters allow clients to search using distinguished name (DN) components, such as (`ou:dn:=engineering`), or using an OID number, such as (`cn:1.2.3.4:=Sam Carter`). The matching rule use attribute publishes those attribute types and matching rule combinations, which can be used in extensible match assertions.

Typically, you define a matching rule use that isn't normally specified in the attribute type definition. You can create new matching rule uses from the existing schema definitions by adding a custom schema file in the `<server-root>/config/schema` directory.

### Matching rule use definitions

Matching rule uses can be specified with existing schema components and don't require additional code for implementation.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.4.

```
MatchingRuleUseDescription = "(" wsp
numericoid                  ; Object identifier
[ sp "NAME" sp qdescrs ]   ; Short name descriptor
[ sp "DESC" sp qdstring ]  ; Description
[ sp "OBSOLETE" ]         ; Specifies if the rule use is inactive
sp "APPLIES" sp oid       ; Attribute types
extensions wsp ")"        ; Extensions followed by a white space and ")"
```

The following extensions are specific to PingDirectory Server and aren't defined in RFC 4512.

```
extensions = /
"X-SCHEMA-FILE" /         ; Specifies which schema file contains the
  definition
"X-READ-ONLY"             ; True or False. Specifies if the file that
  contains
  the                      ; the schema element is marked as read-only in
                           ; server configuration.
```

### Viewing matching rule uses

About this task

A matching rule use lists the attribute types that are suitable for use with an `extensibleMatch` search filter.

## Steps

- To view the Directory Server's published list of matching rule uses that use the operational attribute `matchingRuleUse`, run `ldapsearch`.

### Note:

The multi-valued operational attribute `matchingRuleUse` publishes the definitions on the Directory Server, if any. The attribute is stored in the subschema subentry.

### Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" matchingRuleUse
```

## Managing DIT content rules

Directory information tree (DIT) content rules provide a way to precisely define what attributes might be present in an entry based on its structural object class without specifically creating a new object class definition.

The DIT content rules can define the following:

- Mandatory and optional attributes that entries contain
- The set of auxiliary object classes that entries can be part of
- Any optional attributes from the structural and auxiliary object classes that are prohibited from being present in the entries

### DIT content rule definitions

DIT content rules can be specified with existing schema components and don't require additional code for implementation.

On PingDirectory Server, only one DIT content rule can be defined for an entry in the structural object class.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.6.

```
DITContentRuleDescription = "(" wsp
numericoid                 ; Object identifier of the structural object
  class the rule applies to
[ sp "NAME" sp qdescrs ]   ; Short name descriptor
[ sp "DESC" sp qdstring ]  ; Description
[ sp "OBSOLETE" ]         ; Specifies if the rule is inactive
[ sp "AUX" sp oids ]      ; List of allowed auxiliary object classes
[ sp "MUST" sp oids ]     ; List of required attributes
[ sp "MAY" sp oids ]      ; List of allowed attributes in the entry
[ sp "NOT" sp oids ]      ; List of prohibited attributes in the entry
extensions wsp ")"        ; Extensions followed by a white space and ")"
```

The following extensions are specific to PingDirectory Server and aren't defined in RFC 4512.

```
extensions = /
"X-ORIGIN" /              ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the
  definition
"X-READ-ONLY"            ; True or False. Specifies if the file that
  contains
                          ; the schema element is marked as read-only in
                          ; the server configuration.
```

## Viewing DIT content rules

### Steps

- To view the `dITContentRules` attribute, run `ldapsearch`.

#### Note:

`dITContentRules` is a multi-valued operational attribute that publishes the definitions on the Directory Server, if any. The attribute is stored in the subschema subentry.

#### Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" dITContentRules
```

## Managing name forms

Name forms define how entries can be named based on their structural object class.

Specifically, name forms specify the structural object class you are naming as well as the mutually-exclusive set of required and allowed attributes to form the relative distinguished names (RDNs) of the entries. Each structural object class can be associated with at most one name form definition.

### Name form definitions

Name forms can be specified with existing schema components and don't require additional code for implementation.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.7.2.

```
NameFormDescription = "(" wsp
numericoid           ; object identifier
[ sp "NAME" sp qdescrs ] ; short name descriptor
[ sp "DESC" sp qdstring ] ; description
[ sp "OBSOLETE" ]    ; not active
sp "OC" sp oid       ; structural object class
sp "MUST" SP oids    ; attribute types
[ sp "MAY" sp oids ] ; attribute types
extensions wsp ")"   ; extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory Server and aren't defined in RFC 4512.

```
extensions = /
"X-ORIGIN" /           ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /     ; Specifies which schema file contains the
  definition
"X-READ-ONLY"         ; True or False. Specifies if the file that
  contains
                       ; the schema element is marked as read-only in
                       ; the server configuration.
```

## Viewing name forms

### Steps

- To view the `nameForms` attribute, run `ldapsearch`.

#### Note:

`nameForms` is a multi-valued operational attribute that publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

#### Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
"(objectclass=*)" nameForms
```

## Managing DIT structure rules

Directory information tree (DIT) structure rules define which entries might be superior or subordinate to other entries in the DIT.

Together with name forms, DIT structure rules determine how relative distinguished names (RDNs) are added together to make up distinguished names (DNs). Because DITs don't have a global standard and are specific to a company's implementation, each DIT structure rule associates a name form with an object class and specifies each structure rule with an integer rule identifier, instead of an OID number. The identifier defines its relationship, either superior or subordinate, to another object class. If no superior rules are specified, the DIT structure rule applies to the root of the subtree.

### DIT structure rule definition

DIT structure rules can be specified with existing schema components and don't require additional code for implementation.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.7.1.

```
DITStructureRuleDescription = "(" wsp
ruleid                       ; object identifier
[ sp "NAME" sp qdescrs ]     ; short name descriptor
[ sp "DESC" sp qdstring ]    ; description
[ sp "OBSOLETE" ]           ; specifies if the rule is inactive
sp "FORM" sp oid             ; OID or name form with which the rule is
associated
[ sp "SUP" ruleids ]         ; Superior rule IDs
extensions wsp ")"          ; extensions followed by a white space and ")"
```

The following extensions are specific to PingDirectory Server and are not defined in RFC 4512.

```
extensions = /
"X-ORIGIN" /                 ; Specifies where the rule is defined
"X-SCHEMA-FILE" /           ; Specifies which schema file contains the
definition
"X-READ-ONLY"                ; True or False. Specifies if the file that
contains
                             ; the schema element is marked as read-only in
                             ; the server configuration.
```

## Viewing DIT structure rules

### Steps

- To view the `dITStructureRules` attribute, run `ldapsearch`.

#### Note:

`dITStructureRules` is a multi-valued operational attribute that publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

#### Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" dITStructureRules
```

## About managing JSON attribute values

PingDirectory Server supports a JSON object attribute syntax that can be used for attribute types whose values are JSON objects. The syntax requires that each value of this type is a valid JSON object.

The following is an example schema definition.

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( jsonAttr1-OID NAME 'jsonAttr1' DESC 'test json attribute
  support' EQUALITY jsonObjectExactMatch SYNTAX 1.3.6.1.4.1.30221.2.3.4 USAGE
  userApplications )
objectClasses: ( jsonObjectClass-OID NAME 'jsonObjectClass' AUXILIARY MAY
  jsonAttr1 )
```

#### Note:

You should always specify the `EQUALITY` matching rule as `jsonObjectExactMatch` in the schema definition. Using the `jsonObjectFilterExtensibleMatch` isn't valid in this case.

The `jsonObjectExactMatch` and `jsonObjectFilterExtensibleMatch` matching rules are provided to filter equality matching rule JSON object syntax. The following three additional matching rules are used in conjunction with `jsonObjectExactMatch` and provide support for customizing the way that the server treats case sensitivity in JSON field names and in string values:

- `jsonObjectCaseSensitiveNamesCaseSensitiveValues`
- `jsonObjectCaseInsensitiveNamesCaseInsensitiveValues`
- `jsonObjectCaseInsensitiveNamesCaseSensitiveValues`

The `jsonObjectExactMatch` equality matching rule is used in evaluating equality filters in **search** operations, and for matching performed against JSON object attributes for **add**, **compare**, and **modify** operations. It determines whether two values are logically-equivalent JSON objects. The field names used in both objects must match exactly, although fields may appear in different orders. The values of each field must have the same data types. The order of elements in arrays is considered significant. Substring or approximate matching isn't supported.

The `jsonObjectFilterExtensibleMatch` matching rule can perform more powerful matching against JSON objects. The assertion values for these extensible matching filters should be JSON objects that

express the constraints for the matching. These JSON object filters are described in detail in the Javadoc documentation for the LDAP SDK for Java. Although the LDAP SDK can facilitate searches with this matching rule, these searches can be issued through any LDAP client API that supports extensible matching.

The following are example searches using the `jsonObjectFilterExtensibleMatch` rule with available filter types:

"equals" filter type

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com
-D "cn=Directory Manager" -w password
'(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
"equals", "field" : ["stuff", "onetype", "name"], "value" : "John
Doe" })'
```

"containsField" filter type

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com
-D "cn=Directory Manager" -w password
'(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
"containsField", "field" : "age", "expectedType" : "number" })'
```

"greaterThan" filter type

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com
-D "cn=Directory Manager" -w password
'(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
"greaterThan", "field" : "age", "value" : 26, "allowEquals" : true})'
```

## Configuring JSON attribute constraints

PingDirectory Server can define a number of constraints for the fields included in JSON objects stored in values of a specified attribute type.

Defining constraints on JSON object fields allows administrators to set requirements on what values a JSON field may take to ensure consistency across entries.

Constraints that can be placed on a JSON field include:

- Requiring values of the field to have a specified data type.
- Indicating whether the field is required or optional.
- Indicating whether the field can have multiple values in an array. If a field is permitted to have array values, restrictions can also be placed on the number of elements that can be present in the array.
- Indicating whether the field can have a value that is the null primitive as an alternative to values of the indicated data type.
- Restricting values of string fields to a predefined set of values that match a given regular expression or to a length specified by the user.
- Restricting values of numeric fields with upper and lower bounds.

### Note:

Only new entries are subject to the new constraints. Existing data that doesn't match newly-defined JSON constraints can still be decoded and managed by the server. Attempts to alter existing entries with non-compliant JSON objects might require fixing those objects to conform to the new constraints.

The global configuration properties that define schema constraints for JSON objects are `create-json-attribute-constraints` and `create-json-field-constraints` in **dsconfig**. In **dsconfig** interactive, under advanced settings, the menu options are `JSON Attribute Constraints` and `JSON Field Constraints`.

Configuration properties for each include:

#### **attribute-type**

The name or object identifier of the attribute type with which the definition is associated. This attribute type must have the JSON object syntax. **attribute-type** is the naming attribute for the configuration entry.

#### **allow-unnamed-fields**

A Boolean value that indicates whether JSON objects, used as the values of attributes of the associated type, can include fields that are not referenced in the `attribute-value-constraints` object. The default value is `true`.

If **allow-unnamed-fields** is `true` JSON objects can have fields that are not referenced, and no constraints are imposed on those fields. If **allow-unnamed-fields** is `false`, JSON objects can only have the defined fields.

#### **Note:**

Unless a schema definition is configured with `allow-unnamed-fields` set to `false`, only information about fields whose values should be indexed or tokenized is required. To ensure that clients cannot store invalid values, you should define any other expected fields. .

As with the standard LDAP schema, JSON schema constraints are enforced for any changes made after the constraints are defined. If there are already JSON values in the data before a JSON schema is defined for that attribute type, or before changes are made, values that already exist might violate those constraints. JSON schema constraints are also enforced for data provided in an LDIF import, and entries containing JSON objects that violate these constraints are rejected.

### **JSON Field Constraints**

Property	Description
<code>field</code>	Specifies the path to the target field as a string with periods to separate levels of hierarchy.  If any field name in the hierarchy includes a period, then that period must be escaped with a backslash.

Property	Description
value-type	<p>Specifies the expected data type for the target field.</p> <p>The available values are:</p> <p>any</p> <p>The target field can have any value.</p> <p>boolean</p> <p>The target field must have a value of <code>true</code> or <code>false</code>.</p> <p>integer</p> <p>The target field must have a number that can be exactly represented as an integer.</p> <p>null</p> <p>The target field must have a value of <code>null</code>.</p> <p>number</p> <p>The target field must have a value that represents a valid JSON number.</p> <p>object</p> <p>The target field must have a value that represents a valid JSON object. The <code>allowed-fields</code> array can contain additional elements that define constraints for the fields.</p> <p>string</p> <p>The target field must have a value that represents a valid JSON string.</p>
is-required	<p>Specifies whether the target field is required to be present.</p> <p>If the target field is present, its value must be either <code>true</code> or <code>false</code>. If it is absent, a default of <code>false</code> is assumed.</p>
is-array	<p>Indicates whether the target field can be an array.</p> <p>If the value can be an array, all of the elements of the array must be of the type specified in the <code>value-type</code> field. The field constraint can be present with a value of one of the single strings listed below. If the constraint is absent, a value of <code>prohibited</code> is assumed.</p> <p>Values are:</p> <p>required</p> <p>The target field must be an array with zero or more values of the specified type and must not be a single value of the specified type.</p> <p>optional</p> <p>The target field can be an array with zero or more values of the specified type, or it can be a single value of the specified type.</p> <p>prohibited</p> <p>The target field must not be an array and can only be a single value of the specified type.</p>

Property	Description
<code>allow-null-value</code>	<p>Specifies whether the target field can have a value of <code>null</code> as an alternative to the specified <code>value-type</code>.</p> <p>If the field constraint is present, <code>allows-null-value</code>'s value must be either <code>true</code> or <code>false</code>. If the constraint is absent, a default of <code>false</code> is assumed. <code>allow-null-value</code> has no effect if the <code>value-type</code> is <code>null</code>.</p>
<code>allow-empty-object</code>	<p>Specifies whether empty objects are permitted if the value of the target field is a JSON object or an array of JSON objects.</p> <p>If the field constraint is present, the value must be either <code>true</code>, where the object can have zero or more fields, or <code>false</code>, where the object can have one or more fields. If the constraint is absent, a default of <code>false</code> is assumed.</p>
<code>index-values</code>	<p>Specifies whether values of the target field should be indexed in backends.</p> <p>If the field constraint is present, the value must be either <code>true</code> (the field should be indexed) or <code>false</code> (the field should not be indexed). If the constraint is absent, a default of <code>false</code> is assumed. If <code>true</code>, the <code>value-type</code> must be <code>boolean</code>, <code>integer</code>, <code>null</code>, or <code>string</code>.</p>
<code>index-entry-limit</code>	<p>Specifies the maximum number of entries in which a particular value can appear before the entry ID list for that value is no longer maintained.</p> <p>If the field constraint is present, the value must be an integer greater than or equal to 1. If the constraint is absent, the server uses the default index entry limit for the associated backend. This is only applicable if <code>index-values</code> is <code>true</code>.</p>
<code>prime-index</code>	<p>Specifies whether backends should prime the contents of the JSON index database into memory when they are opened.</p> <p>This is ignored if the backend's <code>prime-all-indexes</code> property has a value of <code>true</code>.</p>
<code>cache-mode</code>	<p>Specifies the cache mode to use for the contents of the JSON index database.</p> <p>If the value is not specified, the backend's default cache mode is used. If a cache mode of <code>cache-keys-only</code> is configured, priming only loads the internal nodes into memory for the index. If <code>no-caching</code> is configured, no priming is performed for the index.</p>
<code>tokenize-values</code>	<p>Specifies whether values of the target field should be tokenized in backends.</p> <p>If the field constraint is present, the value is either <code>true</code> (field values should be tokenized) or <code>false</code> (field values should not be tokenized). If the constraint is absent, a value of <code>false</code> is assumed. If <code>true</code>, the <code>value-type</code> must be <code>string</code>.</p>
<code>allowed-values</code>	<p>Specifies an explicit set of values allowed in the target field .</p> <p>If the field constraint is present, the value must be an array of strings. Any attempt to use a value not in this array for the associated field is rejected. <code>allowed-values</code> can only be used with a <code>value-type</code> of <code>string</code>. If the constraint is absent, any value can be used as long as it satisfies all other defined constraints.</p>

Property	Description
<code>allowed-value-regular-expression</code>	<p>Specifies a regular expression that the target field must match</p> <p>If the field constraint is present, the value must be a single string or an array of strings representing valid regular expressions (which might require escaping to represent in JSON). Any attempt to use a value that does not match one of the provided regular expressions is rejected. <code>allowed-value-regular-expression</code> can only be used with a <code>value-type</code> of <code>string</code>. If the constraint is absent, values are not required to match any regular expression.</p>
<code>minimum-numeric-value</code>	<p>Specifies the lower bound for values of the target field</p> <p>If the field constraint is present, the value must be a single number and can be an integer. Any attempt to use a value that is less than this number is rejected. <code>minimum-numeric-value</code> can only be used with a <code>value-type</code> of <code>integer</code> or <code>number</code>. If the constraint is absent, no minimum numeric value applies.</p>
<code>maximum-numeric-value</code>	<p>Specifies the upper bound for values of the target field</p> <p>If the field constraint is present, the value must be a single number and can be an integer. Any attempt to use a value that is greater than this number is rejected. <code>maximum-numeric-value</code> can only be used with a <code>value-type</code> of <code>integer</code> or <code>number</code>. If the constraint is absent, no maximum numeric value applies.</p>
<code>minimum-value-length</code>	<p>Specifies the minimum number of characters allowed for values of the target field</p> <p>If the field constraint is present, the value must be an integer. Any attempt to use a value with fewer characters than this number is rejected. <code>minimum-value-length</code> can only be used with a <code>value-type</code> of <code>string</code>. If the constraint is absent, no minimum length applies.</p>
<code>maximum-value-length</code>	<p>Specifies the maximum number of characters allowed for values of the target field</p> <p>If the field constraint is present, the value must be an integer. Any attempt to use a value with more characters than this number is rejected. <code>maximum-value-length</code> can only be used with a <code>value-type</code> of <code>string</code>. If the constraint is absent, no maximum length applies.</p>
<code>minimum-value-count</code>	<p>Specifies the minimum number of elements that must be present in an array</p> <p>If the field constraint is present, the value must be an integer. Any attempt to use an array with fewer elements is rejected. <code>minimum-value-count</code> can only be used with an <code>is-array</code> value of <code>required</code> or <code>optional</code>. If the constraint is absent, no minimum array value count applies.</p>
<code>maximum-value-count</code>	<p>Specifies the maximum number of elements that must be present in an array</p> <p>If the field constraint is present, the value must be an integer. Any attempt to use an array with more elements is rejected. <code>maximum-value-count</code> can only be used with an <code>is-array</code> value of <code>required</code> or <code>optional</code>. If the constraint is absent, no maximum array value count applies.</p>

When writing JSON objects in a local database backend, field names and JSON primitive values of `null`, `true`, and `false` are always tokenized. Integers are either tokenized or compacted using their two's

complement representation. Other numbers are stored using string representations. Array and object sizes are compacted, and their contents are compacted based on their data types.

String values are tokenized and match a recognizable format, including:

- Dates and times in common generalized time and ISO 8601 formats
- UUIDs in which the alphabetic characters are either all uppercase or all lowercase
- Strings of at least 12 bytes that are a valid base64 encoding
- Strings of at least 6 bytes that are a valid hexadecimal encoding, in which the alphabetic characters are either all uppercase or all lowercase

## Adding constraints to JSON attributes

About this task

To create and configure JSON attribute constraints:

Steps

- Run `dsconfig` with the `create-json-attribute-constraints` option.

Example:

In this example, a JSON attribute constraint is defined on the `appjson` attribute type. This constrains values of the `appjson` attribute to be JSON objects. Because `allow-unnamed-fields` is set to `false`, those JSON objects can only have fields for which there is a corresponding JSON field constraints definition.

### Note:

`appjson` is meant to be replaced by the name of the user's desired attribute type, as defined in the directory schema. For more information, see [About managing JSON attribute values](#) on page 804.

```
$ bin/dsconfig create-json-attribute-constraints \
  --attribute-type appjson \
  --set enabled:true \
  --set allow-unnamed-fields:false
```

Example:

In this example, a JSON field constraint object is defined for the `email.verified` field. The `email.verified` field must be present and must take a boolean value.

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type appjson \
  --json-field email.verified \
  --set value-type:boolean \
  --set is-required:true \
  --set index-values:false \
  --set tokenize-values:false \
  --set allow-null-value:true
```

Example:

In this example, a JSON field constraint object is defined for the `email.type` field. The `email.type` field must be present and must take a value of `home`, `work`, or `other`.

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type appjson \
  --json-field email.type \
```

```
--set value-type:string \
--set is-required:true \
--set index-values:false \
--set tokenize-values:true \
--set allowed-value:home \
--set allowed-value:other \
--set allowed-value:work \
--set allow-null-value:false
```

#### Example:

In this example, a JSON field constraint is defined for the `email.value` field. The `email.value` field must be present and must take a string value that matches the specified regular expression.

```
$ bin/dsconfig create-json-field-constraints \
--attribute-type appjson \
--json-field email.value \
--set value-type:string \
--set is-required:true \
--set index-values:true \
--set tokenize-values:false \
--set prime-index:true \
--set allow-null-value:true \
--set maximum-value-length:256 \
--set minimum-value-length:1 \
--set allowed-value-regular-expression:[-_]+\.\w\d]+@w+\.\w{2,5}
```

## Managing password policies

---

The PingDirectory Server provides a flexible password policy system to assign, manage, or remove password policies for root and non-root users.

The password policy contains configurable properties for password expiration, failed sign-on attempts, account lockout, and other aspects of password and account maintenance on the Directory Server. The Directory Server also provides a global configuration option and a per-user privilege feature that disables parts of the password policy evaluation for production environments that don't require a password policy.

### Viewing password policies

Password policies enforce rules that ensure that access to data is not compromised through negligent password practices.

The PingDirectory Server provides mechanisms to create and maintain password policies that determine:

- Whether passwords should expire
- Whether users are allowed to modify their own passwords
- Whether too many failed authentication attempts should result in an account lockout

Many other options are available to fully configure a password policy for your PingData Platform system.

The Directory Server provides three out-of-the-box password policies that you can apply to your entries or as templates for configuring customized policies:

#### Default password policy

The default password policy is automatically applied to all users although it is possible to use an alternate password policy on a per-user basis.

#### Root password policy

The root password policy is enforced for the default root user, which uses a stronger password storage scheme (PBKDF2 instead of the salted 256-bit SHA-2 scheme) and requires that a root user provide their current password to select a new password.

### Secure password policy

The secure password policy provides a more secure option than the default policy that makes use of a number of features, including password expiration, account lockout, last sign-on time and last sign-on IP address tracking, password history, and a number of password validators.

#### CAUTION:

Using the Secure password policy as-is might notably increase write load in the server by requiring updates to password policy state attributes in user entries and by requiring users to change passwords more frequently. In environments where write throughput is a concern (including environments spread across multiple data centers requiring replication over a WAN), it might be useful to consider whether the policy should be updated to reduce the number of required entry updates.

## Viewing password policies

### About this task

To view the list of password policies configured on the Directory Server:

### Steps

- Do one of the following:  
Choose from:
  - Run the `dsconfig` tool in either interactive or non-interactive mode.
  - Use the Administrative Console.

### Example:

The following example demonstrates the process for obtaining a list of defined password policies in non-interactive mode.

```
$ bin/dsconfig list-password-policies
```

### Result:

```

Password Policy      : Type : password-attribute : default-password-
storage-scheme
-----:-----:-----:-----
Default Password Policy : generic : userpassword      : Salted 256-bit
SHA-2
Root Password Policy  : generic : userpassword      : PBKDF2
Secure Password Policy : generic : userpassword      : PBKDF2

```

## Viewing a specific password policy

### About this task

To view a specific password policy:

## Steps

- Do one of the following:  
Choose from:
  - Run the `dsconfig` tool.
  - Use the Administrative Console.

### Example:

This example uses `dsconfig` to view the default password policy that applies to all uses for which no specific policy is configured.

```
$ bin/dsconfig get-password-policy-prop \
  --policy-name "Default Password Policy"
```

### Result:

Property	: Value(s)
description	: -
password-attribute	: userpassword
default-password-storage-scheme	: Salted SHA-1
deprecated-password-storage-scheme	: -
password-validator	: -
account-status-notification-handler	: -
allow-user-password-changes	: true
password-change-requires-current-password	: false
force-change-on-add	: false
force-change-on-reset	: false
password-generator	: Random Password Generator
require-secure-authentication	: false
require-secure-password-changes	: false
min-password-age	: 0s
max-password-age	: 0s
max-password-reset-age	: 0s
password-expiration-warning-interval	: 5d
expire-passwords-without-warning	: false
allow-expired-password-changes	: false
grace-login-count	: 0s
lockout-failure-count	: 0s
lockout-duration	: 0s
lockout-failure-expiration-interval	: 0s
require-change-by-time	: -
last-login-time-attribute	: ds-pwp-last-login-time
last-login-time-format	: -
previous-last-login-time-format	: -
idle-lockout-interval	: 0s
password-history-count	: 0s
password-history-duration	: 0s

## About the password policy properties

The Directory Server provides a number of configurable properties that you can use to control password policy behavior.

### Note:

To view a description of each of the password policy properties, see the Ping Identity Directory Server Configuration Reference that is bundled with the PingDirectory Server.

Some of the most notable properties include:

`allow-user-password-changes`

Specifies whether users can change their own passwords. If a user attempts to change their own password, then the server consults this property for the user's password policy and ensures that the access control handler allows the user to modify the configured password attribute.

`default-password-storage-scheme`

Specifies the names of the password storage schemes that are used to encode clear-text passwords for this password policy.

`enable-debug`

When enabled, is used to debug password policy interaction. This property should be used in addition to the server's debug framework with a relevant debug target.

`force-change-on-add`

Specifies whether users are required to change their passwords upon first authenticating to the Directory Server after their account is created.

`force-change-on-reset`

Specifies whether users are required to change their passwords after they're reset by an administrator. An administrator is a user who has the `password-reset` privilege and the appropriate access control instruction to allow modification of other users' passwords.

`idle-lockout-interval`

Specifies the maximum length of time that an account can remain idle (the associated user does not authenticate to the server) before that user is locked out. For accounts that don't have a last sign-on time value, the password changed time or the account creation time is used. If that information is not available, then the user isn't allowed to authenticate.

 **Note:**

The server should be allowed to run for a period of time with last sign-on time tracking enabled, such as values for both `last-login-time-attribute` and `last-login-time-format` properties to ensure that users have a last sign-on time before enabling idle account lockout.

`lockout-duration`

Specifies the length of time that an account is locked after too many authentication failures. The value of this attribute is an integer followed by a unit of seconds, minutes, hours, days, or weeks. A value of 0 seconds indicates that the account must remain locked until an administrator resets the password.

`lockout-failure-count`

Specifies the maximum number of times that a user can attempt to bind with the wrong password before that user's account becomes locked either temporarily (in which case the account is automatically unlocked after a configurable length of time) or permanently (in which case an administrator must reset the user's password before the account is used again). For example, if the value is set to 3, the user is locked out after three failed attempts, even if a fourth attempt is made with the correct password.

`max-password-age`

Specifies the maximum length of time that a user can continue to use the same password before they must choose a new one. The value can be expressed in seconds (s), minutes (m), hours (h),

days (d), or weeks (w). You can specify a minimum length of time before the user can change the password.

#### `password-change-requires-current-password`

Specifies whether users must include their current password when changing their password. This applies for both password changes made with the password modify extended operation as well as simple modify operations targeting the password attribute. In the latter case, if the current password is required then the password modification must remove the current value and add the desired new value (providing both the current and new passwords in the clear rather than using encoded representations).

#### `password-expiration-warning-interval`

Specifies the length of time before a user's password expires that they receive notification about the upcoming expiration (either through the password policy or password expiring response controls). The value can be expressed in seconds (s), minutes (m), hours (h), days (d), or weeks (w).

#### `password-retirement-behavior`

Specifies the behavior of a password that is allowed a retirement period before becoming invalid. You can use this setting by application service accounts that require a transition period while updating passwords. This is disabled by default.

#### `password-validator`

Specifies the names of the password validators that are used with the associated password storage scheme. The password validators are invoked when a user attempts to provide a new password to determine whether the new password is acceptable.

#### `require-secure-authentication`

Indicates whether users with the associated password policy are required to authenticate in a secure manner. This can mean either using a secure communication channel between the client and the server, or using a Simple Authentication and Security Layer (SASL) mechanism that doesn't expose the credentials.

#### `require-secure-password-changes`

Indicates whether users with the associated password policy are required to change their password in a secure manner that does not expose the credentials.

#### Note:

As an alternative to account lockout, you can set a **`failed-bind-response-delay`** configuration property on the LDAP connection handler to instruct the server to introduce a delay (such as one second) into the process of returning a response to an unsuccessful bind operation.

Delaying the response to a failed bind only affects the connection on which the bind was attempted, and still limits the rate at which a malicious client can try to guess a user's password. However, it won't affect other attempts to authenticate as that user on other connections, so the legitimate user can still authenticate with the correct password.

## Access log

You can configure the server to maintain a recent sign-on history for both successful and failed sign-on attempts.

You can maintain this history by count or duration, and you can configure the history separately for successful and failed sign-on attempts. Each record in the sign-on history contains the following:

- The time of the sign-on attempt
- The client IP address

- The authentication method
- The reason for failure for failed attempts

You can collapse information about multiple similar attempts on the same date to avoid flooding the history for accounts that bind frequently. Records have an additional attempt count that tracks the number of attempts with the same client IP address, authentications method, and failure reason on the same date. You can configure the server to maintain each attempt separately, or to only update the history at most once per day.

Recent sign-on history is disabled by default. You can enable and configure the recent sign-on history in password policy. You can retrieve sign-on history with the `get recent login history` control, available in the LDAP SDK or with the `ldapsearch` and `ldapmodify` commands. The recent sign-on history is also available in the `ds-pwp-state-json` JSON attribute, the password policy state extended operation, and the `manage-account` command-line tool.

You can enable and configure the recent sign-on history with the following password policy configuration properties:

**maximum-recent-login-history-successful-authentication-count**

The maximum number of records that the server maintains about recent successful authentications.

**maximum-recent-login-history-successful-authentication-duration**

The maximum length of time for which the server maintains information about recent successful authentications.

**maximum-recent-login-history-failed-authentication-count**

The maximum number of records that the server maintains about recent failed authentication attempts.

**maximum-recent-login-history-failed-authentication-duration**

The maximum length of time for which the server maintains information about recent failed authentication attempts.

**recent-login-history-similar-attempt-behavior**

The behavior that the server exhibits for cases in which a user makes multiple authentication attempts on the same date in which all of the fields in the record other than the timestamp (`client-ip-address`, `authentication-method`, and potentially `failure-reason`) match.

Possible values for this property include the following:

**collapse-similar-attempts-on-the-same-date**

Indicates that the server only maintains one record for any given date with the same values for all non-timestamp fields, and it uses the `additional-attempt-count` field to keep track of the number of additional attempts that were collapsed into the same record. The timestamp field for that record reflects the most recent attempt on that date.

This is the default behavior.

**maintain-every-attempt**

Indicates that the server maintains a separate record for every attempt, regardless of how similar it is to a previous attempt although duplicate attempts within the same millisecond might not be preserved.

For more information, see [Replication considerations](#) on page 818.

**update-at-most-once-per-day**

Indicates that the server only maintains one record for any given date with the same values for all non-timestamp fields. This can help reduce the number of writes needed to maintain

a recent sign-on history, but the value of the timestamp field might not accurately reflect the timestamp of the most recent attempt.

None of these properties are defined by default. If at least one of these properties is defined, the server maintains a recent sign-on history within the specified constraints.

If both the `maximum-recent-login-history-successful-authentication-count` and `maximum-recent-login-history-successful-authentication-duration` properties are defined, the server uses the more-restrictive value that applies to a given user. This is also true for the `maximum-recent-login-history-failed-authentication-count` and `maximum-recent-login-history-failed-authentication-duration` properties. For example, if you configure the password policy to maintain a successful count of 10 and a successful duration of 30 days, then a user who successfully authenticates on more than 10 dates in a 30-day period would be capped at 10 records. A user who authenticates less frequently would only have records for however many attempts they made within those 30 days.

The server can collapse multiple authentication attempts from the same date into a single record if other fields in the record (`client-ip-address`, `authentication-method`, and potentially `failure-reason`) match. This caps the number of records that are maintained if you want to maintain records by duration rather than count. Because multiple records can be generated for the same user on the same date, if something is different (such as a different IP address or authentication method), there is technically no limit to the number of records that can be generated when using only a duration-based cap. To mitigate this, you can specify a maximum count to place an upper bound on what information the server maintains for a given user.

The password policy state for a given user is only updated when that user attempts to authenticate to the server. A user might have records in their entry for authentication attempts that occurred outside of the maximum duration if they have not made any authentication attempt within that duration.

If you configure the server to maintain recent sign-on history for successful authentication attempts, then it keeps a record of the most recent attempt even if the attempt occurs outside of the maximum duration.

#### Note:

If the `recent-login-history-similar-attempt-behavior` is set to `update-at-most-once-per-day`, it keeps an attempt from the same date as the most recent attempt.

If you configure the server to maintain a history of failed attempts, then it provides information about the most recent failed attempt even if it is older than the maximum duration.

If you configure the password policy to maintain a recent sign-on history, the `ds-pwp-state-json` virtual attribute includes a `recent-login-history` field whose value is a JSON object with the same representation used in the `get recent login history` response control. It can also include the following additional fields that provide information about related configuration in the password policy:

- `maximum-recent-login-history-successful-authentication-count`
- `maximum-recent-login-history-successful-authentication-duration-seconds`
- `maximum-recent-login-history-failed-authentication-count`
- `maximum-recent-login-history-failed-authentication-duration-seconds`

The password policy state extended operation provides support for two additional operations:

- An operation you can use to retrieve the recent sign-on history. The value returned in this operation is a JSON object in the same format as used in the `get recent login history` response control and the `ds-pwp-state-json` virtual attribute.
- An operation that you can use to clear the `get recent login history` for a user.

### Replication considerations

Each sign-on attempt is maintained as a separate attribute value to avoid the potential for data loss as a result of replication propagation delay.

If a record of all sign-on attempts was maintained within a single JSON object, the object written on one server would not reflect concurrent attempts made on other servers, and replication would only use what it perceives to be the most recent value rather than attempting to merge the values.

It is possible that information about one or more attempts made around the same time could be lost. This includes the following cases:

- If the server is not configured to collapse information about multiple similar attempts, then it will not record information about multiple similar attempts made within the same millisecond because that would result in duplicate attribute values.
- If the server is configured to collapse information about multiple similar attempts, then concurrent modifications (especially on different servers) might cause the `additional-attempt-count` value to be incremented to the same value on each of those servers.

#### Note:

If the concurrent attempts occur within the same millisecond, then only one of them is preserved and any others are lost. If the attempts do not occur within the same millisecond, then you can infer the correct value during internal processing, but there might still be corner cases in which the server loses information about one or more attempts.

### Get Recent Login History control

You can use a pair of request and response controls to obtain the recent sign-on history.

The request control, which has an OID of 1.3.6.1.4.1.30221.2.5.61 and no value, can be included in a bind request to indicate that the server should return the recent sign-on history in the bind response. This is provided in the response control, which has an OID of 1.3.6.1.4.1.30221.2.5.62 and a value containing only the string representation of a JSON object with the recent sign-on history.

The JSON object will have one or both of two top-level fields:

#### successful-attempts

This field is present if the server is configured to maintain a history of successful attempts, and its value is an array of JSON objects with information about those successful attempts.

In particular, each of those objects contains the following fields, as used in the `ds-pwp-recent-login-history-json` attribute:

- `timestamp`
- `client-ip-address`
- `authentication-method`
- `additional-attempt-count`

#### failed-attempts

This field is present if you configure the server to maintain a history of failed attempts, and its value is an array of JSON objects with information about these failed attempts.

In particular, each of those objects contains the following fields, as used in the `ds-pwp-recent-login-history-json` attribute:

- `timestamp`
- `client-ip-address`
- `authentication-method`
- `failure-reason`

- `additional-attempt-count`

The response control is only returned if the server is configured to maintain a recent sign-on history. When provided, the elements of the arrays are arranged in chronological order from most-recent to least-recent.

The UnboundID LDAP SDK for Java provides support for these controls, including enhanced support for retrieving information from the response control value. By ensuring that the request control does not have a value and that the response control value is a simple string, this information is readily accessible to applications using other APIs.

## Modifying an existing password policy

Modify an existing password policy to meet your company's requirements.

About this task

### Tip:

Keep your password policies synchronized across all PingDirectory Server and Directory Proxy Server instances.

To modify the configuration for any defined password policy:

Steps

- Choose one of the following methods:  
Choose from:
  - Run the `dsconfig` tool in interactive or non-interactive mode.
  - Use the administrative console.

Example:

The following example sets some of the properties presented in the previous section for the default password policy using `dsconfig`.

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "max-password-age:90 days" \
  --set "password-expiration-warning-interval:14 days" \
  --set "lockout-failure-count:3" \
  --set "password-history-count:6"
```

## Creating new password policies

You can create new password policies that meet your organization's requirements.

You can create any number of password policies in the Directory Server using either the `dsconfig` tool (in interactive or non-interactive mode) or the Administrative Console.

## Creating a new password policy

### Steps

- To create a new password policy:  
Choose from:
  - Run **dsconfig** in interactive or non-interactive mode.
  - Use the administrative console.

### Example:

This example demonstrates creating a new policy using **dsconfig** in non-interactive mode.

```
$ bin/dsconfig create-password-policy \
--policy-name "Demo Password Policy" \
--set "password-attribute:userpassword" \
--set "default-password-storage-scheme:Salted SHA-256" \
--set "force-change-on-add:true" \
--set "force-change-on-reset:true" \
--set "password-expiration-warning-interval:2 weeks" \
--set "max-password-age:90 days" \
--set "lockout-duration:24 hours" \
--set "lockout-failure-count:3" \
--set "password-change-requires-current-password:true"
```

## Assigning a password policy to an individual account

### About this task

Rather than a user automatically inheriting the default password policy, you can assign a user to a particular password policy by including the `ds-pwp-password-policy-dn` operational attribute in that user's entry with a value equal to the distinguished name (DN) of the desired password policy for that user. This operational attribute is explicitly included in a user's entry, or generated by a virtual attribute, which makes it easy to apply a custom password policy to a set of users based on a flexible set of criteria.

### Steps

1. Create an LDIF file that adds the `ds-pwp-password-policy-dn` attribute with the password policy DN you want to assign to that user.

### Example:

This example creates the file `assign.ldif` with the following contents.

```
dn: uid=user.1,ou=People,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Demo Password Policy,cn>Password
Policies,cn=config
```

2. To apply the modification to the user's entry, run **ldapmodify**.

### Example:

For this example, the file used is `assign.ldif`.

```
$ bin/ldapmodify --filename assign.ldif
```

## Assigning a password policy using a virtual attribute

### About this task

You can automatically assign a custom password policy for a set of users using a virtual attribute. You can configure the virtual attribute so that it uses a range of criteria for selecting the entries for which the virtual attribute should appear.

### Steps

1. Create an LDIF file, which you can use to add a group to the server.

Example:

```
dn: ou=Groups,dc=example,dc=com
objectClass: organizationalunit
objectClass: top
ou: Groups

dn: cn=Engineering Managers,ou=groups,dc=example,dc=com
objectClass: groupOfUniqueNames
objectClass: top
cn: Engineering Managers
uniqueMember: uid=user.0,ou=People,dc=example,dc=com ou: groups
```

2. To add the entries to the server, run the **ldapmodify** tool.

Example:

```
$ bin/ldapmodify --defaultAdd --filename groups.ldif
```

3. To create a virtual attribute, run **dsconfig**.

Example:

This virtual attribute adds the **ds-pwp-password-policy-dn** attribute with a value of **cn=Demo Password Policy,cn=Password Policies,cn=config** to the entries for all users that are members of the **cn=Engineering Managers,ou=Groups,dc=example,dc=com** group.

```
$ bin/dsconfig create-virtual-attribute \
  --name "Eng Mgrs Password Policy" \
  --type user-defined \
  --set "description:Eng Mgrs Grp PWPolicy" \
  --set enabled:true \
  --set attribute-type:ds-pwp-password-policy-dn \
  --set "value:cn=Demo Password Policy,cn=Password Policies,cn=config" \
  --set "group-dn:cn=Engineering Managers,ou=Groups,dc=example,dc=com"
```

4. To verify that a user in the group contains the assigned password policy distinguished name (DN), run the **ldapsearch** tool.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
  ds-pwp-password-policy-dn
```

Result:

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Demo Password Policy,cn=Password
Policies,cn=config
```

## Deleting a password policy

You can delete a password policy with the `dsconfig` tool running in interactive or non-interactive mode.

About this task

### Note:

You can also use the administrative console to delete a password policy.

Steps

- To delete a password policy, run the `dsconfig` command with the `delete-password-policy` subcommand.

Example:

```
$ bin/dsconfig delete-password-policy \
  --policy-name "Demo Password Policy"
```

## Modifying a user's password

There are two primary ways to change user passwords in the Directory Server:

- Perform a modify operation which replaces the value of the password attribute (often `userPassword`).

### Note:

In some configurations, when a user attempts to change their own password, it might be necessary to perform the modification by removing the password value and adding the desired new value to demonstrate that the user knows the current password value.

- Use the password modify extended operation to change the password.

### Note:

If a user is changing their own password, it might be necessary to provide the current password value. If the new password is acceptable to all configured password validators, the server provides a new password, or it can automatically generate a new password for the user.

### Note:

Regardless of the mechanism used to change the password, all password values should be provided in cleartext rather than pre-encoded, and the user must have sufficient access control rights to update the password attribute in the target user's entry.

When one user attempts to change the password for another user, the requester must have the `password-reset` privilege.

## Validating a password

About this task

A new password is valid if it:

- Meets the server's password requirements

- Is assigned a password policy
- Passes user authentication

The server can display requirements for a password change to users. You can use the `get-password-quality-requirements` extended operation to retrieve information about the requirements, which you can forward to an end user before an attempted password change. You can also use these requirements to enable client-side validation so that any password problems can be identified before it is sent to the server. The password validation details request control can be included in an `add` or `modify` request, or a `password modify` extended request, to identify which validation requirements were not met by the password provided in the request.

You can configure password validators with user-friendly messages that describe the password requirements, and error messages that display if a proposed password does not satisfy those requirements. The server will automatically generate these messages if they are not provided in the configuration.

Password properties include the following:

`bind-password-validator`

Specifies which validators to invoke on bind.

`password-validator`

Specifies which validators to invoke during a password change.

`minimum-bind-password-validation-frequency`

Specifies how frequently the server should validate a user's password during bind. Although you can specify that the password should be validated during each bind, it's probably sufficient to only do so periodically (for example, once a week or once a month).

`bind-password-validation-failure-action`

Specifies the action the server should take if a user's password fails validation. By default, the account is placed in a "must change password" state where the user is allowed to bind, but any other operations the user attempts fail until the user changes their password. Alternatively, the account can be locked so that the password needs to be reset by an administrator, or the server can generate an account status notification to recommend that the user choose a new password.

## Steps

1. Create a password validator.

### Note:

Password validator properties include `validator-requirement-description` and `validator-failure-messages`.

### Example:

The following is a simple password validator configuration that requires passwords to contain a minimum of five characters and lists custom validator messages.

```
$ dsconfig create-password-validator \
--validator-name "Minimum 5 Characters Password Validator" \
--type length-based --set enabled:true \
--set "validator-requirement-description:The password must contain
at least 5 characters." \
--set "validator-failure-message:The password did not contain
at least 5 characters." \
--set min-password-length:5
```

- To make the newly created password validator take effect, assign it to a password policy.

Example:

```
$ dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Minimum 5 Characters Password Validator"
```

- To validate the password, authenticate as a user.

**Note:**

When a user authenticates, password validation processing is performed so that the server has access to the user's clear-text password.

## Retiring a password

About this task

An account password can be retired and rotated out of service instead of being invalidated. Retiring a password enables a new password to be assigned to an account while keeping the original password valid for a period of time to enable a transition. This is useful for application service accounts that require uninterrupted authentication with the server.

Steps

- To enable password retirement, set the `password-retirement-behavior` and `maximum-retired-password-age` properties in the password policy configuration.
- To manually retire an account password or purge a password that has been retired, run the `ldapmodify` and `ldappasswordmodify` tools with subcommands `-- retireCurrentPassword` and `--purgeCurrentPassword`.

**Note:**

To use these commands on an account, enable the `password-retirement-behavior` subcommand on the password policy that governs the account.

## Changing a user's password using the Modify operation

Steps

- Use `ldapmodify` to change a user's password by replacing the `userPassword` attribute.

Example:

```
$ bin/ldapmodify
dn: uid=user.0,ou=People,dc=example,dc=com
changetype: modify
replace: userPassword
userPassword: newpw
```

## Changing a user's password using the Password Modify extended operation

About this task

To request that the Password Modify extended operation be used to modify a user's password:

## Steps

- Run the `ldappasswordmodify` tool.

Example:

```
$ bin/ldappasswordmodify --authzID
dn:uid=jdoe,ou=People,dc=example,dc=com \
--newPassword newpw
```

## Using an automatically-generated password

### Steps

- To automatically generate a new password for a user, run the `ldappasswordmodify` tool.

Example:

```
$ bin/ldappasswordmodify --authzID "u:user.1"
```

Result:

```
The LDAP password modify operation was successful
Generated Password: fbi27oqy
```

## Enabling YubiKey authentication

Users can authenticate with YubiKey devices, which generate secure one-time passcodes (OTPs) with the `UNBOUNDID-YUBIKEY-OTP SASL` mechanism.

A YubiKey device generates a different password for every authentication attempt, and that OTP is sent to a validation service to ensure that it is genuine and has not been used in an earlier authentication attempt.

### Note:

It is possible to use the OTP as the only proof of identity, but you should combine it with a static password as a form of two-factor authentication.

YubiKey authentication requires:

- Server configuration and the addition of this capability to a user entry
- Configuration of a client ID and API key to use when communicating with the validation service

### Note:

The API key is a shared secret between the YubiKey validation service and the client that is interacting with it and is used when generating digital signatures so that both the server and the YubiKey validation service can ensure that the peer server is genuine.

All server and user entry configuration details are available in the [Security Guide](#).

## Enabling social sign-on

You can enable authentication involving credentials that do not reside in, or cannot be forwarded to or validated by, the Directory Server (such as social sign-on through Facebook, Google, or Twitter) with the `UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION SASL` mechanism.

The bind request does not include any credentials, and authentication with this mechanism does not actually change the state of the underlying client connection. The server behaves as if the bind request included the retain identity request control, whether or not that control was included.

Bind requests using this mechanism can include any request controls that are permitted with other bind requests. If the externally-processed authentication is successful, the client can include the `get password policy state issues request control` in the bind request to obtain information about any password policy state issues that might cause the Directory Server authentication attempt to fail. You can include the `password policy request control` to obtain certain password policy state warnings and errors or to look for the password expired or password expiring controls in the bind response.

## Managing user accounts

Manage user accounts with the `manage-account` tool.

About this task

The Directory Server provides a user management utility, the `manage-account` tool, that provides a means to quickly view and manipulate a number of password and account policy properties for a user or group of users.

PingDirectory Server also hosts the Self Service Account Manager project at <https://github.com/pingidentity/ssam>, which is a customizable web application that allows users to perform their own account registration, profile updates, and password changes.

### Note:

The project is for testing and development purposes and is not a supported PingDirectory Server application.

Steps

- Unlock a user account with the `manage-account` tool.
- To enable a disabled account, contact the administrator for assistance.

### Note:

Password resets are not used.

## Returning the password policy state information

Steps

- To get information about the account's password policy, run the `manage-account` tool.

Example:

```
$ bin/manage-account get-all \
  --targetDN uid=user.1,ou=People,dc=example,dc=com
```

Result:

```
Password Policy DN: cn=Demo Password Policy,cn>Password
Policies,cn=config
Account Is Disabled: false
Account Expiration Time:
Seconds Until Account Expiration:
Password Changed Time: 19700101000000.000Z
Password Expiration Warned Time:
Seconds Until Password Expiration: 1209600
Seconds Until Password Expiration Warning: 0
Authentication Failure Times:
```

```

Seconds Until Authentication Failure Unlock:
Remaining Authentication Failure Count: 3
Last Login Time:
Seconds Until Idle Account Lockout:
Password Is Reset: false
Seconds Until Password Reset Lockout:
Grace Login Use Times:
Remaining Grace Login Count: 0
Password Changed by Required Time:
Seconds Until Required Change Time:
Password History:

```

## Determining whether an account is disabled

### Steps

- To determine whether a user's account has been disabled, run the **manage-account** tool with the `get-account-is-disabled` subcommand.

Example:

```

$ bin/manage-account get-account-is-disabled \
  --targetDN uid=user.1,ou=People,dc=example,dc=com

```

Result:

If the account has been disabled, you receive the following message.

```
Account Is Disabled: true
```

## Disabling an account

### Steps

- To disable a user's account, run the **manage-account** tool.

Example:

```

$ bin/manage-account set-account-is-disabled \
  --operationValue true --targetDN uid=user.1,ou=People,dc=example,dc=com

```

Result:

You receive the following message.

```
Account Is Disabled: true
```

## Enabling a disabled account

### Steps

- To enable a user's account, run the **manage-account** tool with the `clear-account-is-disabled` subcommand.

Example:

```

$ bin/manage-account clear-account-is-disabled \
  --targetDN uid=user.1,ou=People,dc=example,dc=com

```

Result:

You receive the following message.

```
Account Is Disabled: false
```

## Assigning the manage-account access privileges to non-root users

Assign access rights to the non-root admin user.

### About this task

Non-root users, such as `uid=admin`, with admin right privileges require access control permission to interact with certain password policy operational attributes when using the `manage-account` tool.

For example, the presence of the `ds-pwp-account-disabled` operational attribute in an entry determines that the entry is disabled. If the non-root admin user does not have the access privilege to read or interact with the `ds-pwp-account-disabled` operational attribute, the `manage-account` tool might report that the account is active. An account is considered active if the `ds-pwp-account-disabled` operational attribute does not exist in the entry or if the admin user does not have permission to see it.

### Steps

1. Create a non-root user admin account, such as `uid=admin,dc=example,dc=com`.
  - a. Grant the `password-reset` privilege to the account.

For more information, see steps 1 and 6 in the [Setting up a single administrator account](#) section in [Configuring Administrators](#).

2. To view the account status for an account, run the `manage-account` tool.

Example:

```
$ bin/manage-account get-all \
  --targetDN uid=user.0,ou=People,dc=example,dc=com
```

Result:

The system displays the following information for the account.

```
Password Policy DN:  cn=Default Password Policy,cn=Password
Policies,cn=config
Account Is Disabled:  false
Account Expiration Time:
Seconds Until Account Expiration:
Password Changed Time:  19700101000000.000Z
Password Expiration Warned Time:
Seconds Until Password Expiration:
Seconds Until Password Expiration Warning:
Authentication Failure Times:
Seconds Until Authentication Failure Unlock:
Remaining Authentication Failure Count:
Last Login Time:
Seconds Until Idle Account Lockout:
Password Is Reset:  false
Seconds Until Password Reset Lockout:
Grace Login Use Times:
Remaining Grace Login Count:  0
Password Changed by Required Time:
Seconds Until Required Change Time:
Password History:
```

3. Grant access control privileges to an account.
