> When you run the `manage-profile replace-profile` tool with an SDK extension included in the new profile, the tool invokes the `setup` command.
>
> The `manage-profile replace-profile` tool can update the server version when needed. It can also directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to `dsconfig`.

Server profiles in a pets service model

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server. Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new pet server has been set up with a server profile, `manage-profile replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see About the manage-profile tool.

Topology-management tools

Because PingDirectory server topology-management tools like `dsreplication` and `remove-defunct-server` feature internal retries, external deployment automation scripts are not required to incorporate retries. This approach mitigates transient failures and makes servers more robust in automated environments.

To support this approach, `dsreplication` and `remove-defunct-server` include a `--retryTimeoutSeconds` option, which specifies a timeout value for the entire command. If the command fails, it is retried until the timeout value is reached. The command is not aborted if the timeout expires mid-execution, so it is guaranteed to be executed at least once. The default value of zero indicates the command does not have a timeout and is not retried upon initial failure.

The `remove-defunct-server tool` can also be used to complete the following tasks:

- Remove an online server.

  Because a server runs as a container's main process, and because shutting down a server re-spins the container, this task was impossible to complete in deployment automation environments that use containers. Automation scripts often resorted to hacks like impersonating an offline server by taking down the LDAP connection handler. In environments where security concerns prevented the use of LDAP, removing an online server was never an option.

Copyright © 2025 Ping Identity Corporation

- Remove servers without forcing a topology primary when you do not have a quorum majority of online severs.

  The topology registry uses a primary-secondary architecture in which all write requests are chained through a single write-primary. When a primary could not be nominated, the topology becomes read-only. To work around this issue, a single server had to be forced as a primary to apply changes.

- Remove servers concurrently.

The `--ignoreOnline` option can be used to remove an online server, and the `--retryTimeoutSeconds` option can be used to increase robustness in concurrent environments.

Finally, `dsreplication enable` provides internal support for a seed server before the replication topology exists. To prevent the creation of separate islands of replicating servers when simultaneously enabling replication on multiple hosts with a topology JSON file, the server that appears first in lexicographical order in the topology JSON file is designated as the seed server. When enabling replication on the seed server itself with the topology JSON file, it stops and returns a `ERROR_SEED_AND_TARGET_SERVER_ARE_THE_SAME` code. This precaution avoids deadlocking a `dsreplication` process when replication is invoked concurrently. On the seed server itself, deployment automation scripts can treat this code as being successful.

Deployment automation

Automated workflows help shift the deployment process from a pets service model to a cattle service model. The primary tools that are required to manage the replication topology are `dsreplication` and `remove-defunct-server`.

Another key to every topology-management workflow is the `topology.json` file, which represents the intended state of the topology at any time. An administrator should create this file manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.

The following code shows an example `topology.json` file:

Copyright © 2025 Ping Identity Corporation

```
{
  "serverInstances" : [
    {
      "instanceName" : "ds-0",
      "hostname" : "ds-0.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-1",
      "hostname" : "ds-1.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-2",
      "hostname" : "ds-2.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-3",
      "hostname" : "ds-3.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    ...
  ]
}
```

The remaining sections in this chapter describe the deployment automation that is necessary to satisfy the following workflows:

- **Setting up the initial topology**
- **Initializing data on all servers**
- **Replacing crashed instances and scaling up**

Copyright © 2025 Ping Identity Corporation

- Scaling down
- Rolling updates

Consistent network identifiers are required for each server instance. Additionally, we strongly recommend persistent storage for all server bits. The required level of automation changes slightly when this recommendation is not followed, as noted in each section.

Setting up the initial topology

About this task

The `server.uuid` file in the server's `config` directory indicates whether the server is being set up initially or being updated.

> **Note**
>
> If you're not using persistent storage, set up a new server and skip step 3. If you are using persistent storage, start on step 3.

For more information about server profiles, see Server profiles.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation.

   When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using `manage-topology export`.

2. To install and configure a server instance, run the `manage-profile` command with the `setup` option.

   Example:

   ```
   manage-profile setup \
     --profile /path/to/server-profile \
     --profileVariablesFile /path/to/instance-specific-variables.properties
   ```

3. If you're using persistent storage, replace the current server profile. Otherwise, proceed to step 4. To replace the current profile, run the `manage-profile replace-profile` command from a second, extracted server install package on the same host as the existing server.

   Example:

   ```
   manage-profile replace-profile \
     --profile /path/to/server-profile \
     --profileVariablesFile /path/to/instance-specific-variables.properties
     --serverRoot /path/to/existing/server
   ```

4. To enable replication within the topology, run `dsreplication` with the `enable` option.

   Example:

Copyright © 2025 Ping Identity Corporation

```
dsreplication enable \
  --topologyFilePath /path/to/topology.json \
  --retryTimeoutSeconds 120
```

5. To initialize the replication data, run `dsreplication` with the `initialize` option.

   Example:

```
dsreplication initialize \
  --topologyFilePath /path/to/topology.json
```

Prefer topology administrator accounts over root users

In PingDirectory server, administrative accounts can be placed in any of three places.

- They can be created as root users. These accounts exist in the configuration (after `cn=Root DNs,cn=config`) and are not synchronized across server instances. If you want to use root accounts across multiple servers, then you must create the account in each server and keep it up to date across all of them. Root user accounts can optionally automatically inherit a default set of privileges, and you can also explicitly grant and revoke privileges as needed.
- They can be created as topology administrators. These accounts also exist in the configuration (after `cn=Topology Admin Users,cn=topology,cn=config`), and these accounts are automatically synchronized between server instances within the same topology. Topology administrators can also automatically inherit a default set of privileges, and you can also explicitly grant or revoke privileges.
- They can be created in the user data. These accounts will be replicated across all directory servers and they can be used to authenticate to PingDirectory and PingDirectoryProxy servers, but they cannot be used to authenticate to PingDataSync or PingDataMetrics servers. They cannot automatically inherit a default set of privileges, but you can explicitly grant privileges to them as needed. Accounts created in the user data can also be unavailable if the backend containing that data is offline, such as when performing an online restore, replica initialization, or LDIF import.

We recommend using topology administrator accounts over root users or accounts created in the user data. Topology administrators have all of the same capabilities as root users, and their accounts are also automatically synchronized across all servers in the topology so there is no need to apply the same change across multiple servers.

See the `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file for more information about creating topology administrator accounts. The contents of the `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file are shown below:

Copyright © 2025 Ping Identity Corporation

```
# Although setup automatically creates an initial root user account that can
# be used to manage the server, we strongly recommend creating a separate
# account for each administrator rather than using a single shared account.
# This offers several benefits, including:
#
# * It is easier to determine which administrator performed a given action.
# * There is no need to share credentials or coordinate password changes.
# * It is easier to use strong authentication options like certificates or
#   two-factor mechanisms.
# * You can customize the level of access that each administrator has.
#
# We also recommend creating topology admin user accounts rather than root
# user accounts.  If you create a root user account, then it is only created
# in that one instance.  If you create a topology admin user, then that
# account will be available in all instances in the topology.
#
# Because administrative accounts are very powerful, they are high-priority
# targets for attackers to try to compromise.  They should be required to have
# strong credentials, and you may wish to require that they use strong
# authentication mechanisms (see other dsconfig batch files for configuring
# password validators and other password policy features).  You may also want
# to give them usernames that are not likely to be guessed by an attacker,
# even if they know information about the individuals administering the
# service.  For example, you may not want to use their name in the DN or
# username, choosing instead something that is less predictable or even
# completely random like a UUID.
#
# Once each administrator has their own account, we recommend that you disable
# or remove the initial root user created during setup.  See the
# disable-or-remove-the-initial-root-user.dsconfig batch file for more
# information about that.

#
# NOTE:  Do not edit this file directly.  Changing this file could prevent it
# from being updated during a server upgrade.  If you want to alter the
# dsconfig commands below before applying the configuration changes, copy this
# file to another directory and edit that copy.
#

# Create a new topology administrator account.  In this example, the user will
# be able to read the configuration but will not be allowed to update it, and
# will be given the bypass-read-acl privilege rather than bypass-acl, which
# only ensures they will be able to read entries but they will not be
# permitted to update them unless permitted by the server's access control
# configuration.  They will also only be permitted to communicate with the
# server over a secure connection, and they will only be permitted to
# authenticate with the EXTERNAL or UNBOUNDID-TOTP mechanisms.
dsconfig create-topology-admin-user \
     --user-name "[USER_NAME]" \
     --set "password:[PASSWORD]" \
     --set "first-name:[FIRST_NAME]" \
     --set "last-name:[LAST_NAME]" \
     --set "user-id:[USER_NAME]" \
     --set inherit-default-root-privileges:true \
```

Copyright © 2025 Ping Identity Corporation

```
    --set privilege:bypass-read-acl \
    --set privilege:-bypass-acl \
    --set privilege:-config-write \
    --set search-result-entry-limit:0 \
    --set time-limit-seconds:0 \
    --set look-through-entry-limit:0 \
    --set idle-time-limit-seconds:0 \
    --set require-secure-authentication:true \
    --set require-secure-connections:true \
    --set "allowed-authentication-type:SASL EXTERNAL" \
    --set "allowed-authentication-type:SASL UNBOUNDID-TOTP"
```

Initializing data on all servers

About this task

Skip this step if you are using one of the following methods to load data during the initial setup:

- Each server instance imports the same user data from one or more LDIF backup files
- Data is synchronized from another source, such as an Active Directory server, to all servers
- No data is imported initially

Data must be imported and available on a single server only. Servers that do not feature user data must be initialized reliably and quickly. NOTE: The absence of user data during the initial setup does not prevent the the environment from being set up correctly.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the **`manage-topology export`** subcommand.
2. Import data into one of the server instances, as follows:

   ```
   import-ldif --backendID userRoot \
     --ldifFile userData0.ldif \
     --ldifFile userData1.ldif
   ```

3. Initialize data on each server by using this server as the initial source:

   ```
   dsreplication initialize \
     --topologyFilePath /path/to/topology.json \
     --retryTimeoutSeconds 120
   ```

   For the sake of simplicity, other **`dsreplication`** options are not shown.

Copyright © 2025 Ping Identity Corporation

Replacing crashed instances and scaling up

About this task

The automation for this scenario is identical to the automation for Setting up the initial topology.

Scaling down

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. If the server is not present in the topology JSON file, remove it from the topology, as follows:

   ```
   remove-defunct-server --topologyFilePath /path/to/topology.json \
     --ignore-online \
     --serverInstanceName instance-name
     --retryTimeoutSeconds 120
   ```

   For the sake of simplicity, LDAP bind options are omitted.

Rolling updates

About this task

The presence of the file `server.uuid` in the PingDirectory server's `config` directory indicates whether the server is being set up initially or being updated.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. Extract the new server bits to a directory.
3. From the same directory's `bin` directory, replace the new server profile, as follows:

   ```
   manage-profile replace-profile \
     --profile /path/to/server-profile \
     --profileVariablesFile /path/to/instance-specific-variables.properties \
     --serverRoot /path/to/existing/server
   ```

Troubleshooting the PingDirectory server

The PingDirectory server provides a highly-reliable service that satisfies your company's objectives. However, if problems do arise (whether from issues in the server itself or a supporting component, like the JVM, operating system, or hardware), then it is essential to be able to diagnose the problem quickly to determine the underlying cause and the best course of action to take towards resolving it.

This chapter provides information about how to perform this analysis to help ensure that the problem is resolved as quickly as possible. This chapter presents the following information:

PingDirectory server gauges

The PingDirectory server provides a number of built-in gauges to monitor server performance. These gauges are listed in the following table:

Gauge Namee	Enabled by default?	Description
Active Cleaner Threads (Percent)	true	Monitors the percentage of database cleaner threads that are active in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the `list-backends` command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends can be included or excluded from monitoring by specifying its backend ID in the include resource and exclude resource properties respectively. To keep the database from growing on disk, database cleaner threads copy database information from older, mostly obsolete database files to new database files. At a single point in time, 100% of the cleaner threads might be active, but when averaged over time, the percentage of active cleaner threads should remain relatively low. Even environments that sustain a very high write load do not typically see an average cleaner percent busy over 50%. If the percentage exceeds 90% for over an hour, it is a sign that the database cleaner is not progressing and the act of cleaning is producing as much garbage as it cleans. This typically occurs in environments that are not fully cached, and have not given sufficient memory to the database cache. Either increase the memory available to the database cache (by increasing the JVM size or increasing the `db-cache-percent` setting on the backend) or reduce the `db-cleaner-min-utilization` setting, which reduces the burden on the cleaner thread(s).
Authentication Failure Rate	false	Rate of LDAP bind failures per second. A high rate of failures might indicate a misconfigured client application or a malicious attack.

Copyright © 2025 Ping Identity Corporation

Gauge Namee	Enabled by default?	Description
Available File Descriptors	true	Monitors the number of file descriptors available to the server process. The server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. The number of file descriptors that the server will use can be configured by either using a `NUM_FILE_DESCRIPTORS` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as `NUM_FILE_DESCRIPTORS=12345`. If these are not set, the default of 65535 is used. Running out of available file descriptors can lead to unpredictable behavior and severe system instability.
Certificate Expiration (Days)	true	Monitors the expiration dates of key server certificates. A server certificate expiring can cause server unavailability, degradation, or loss of key server functionality. Certificates nearing the end of their validity should be replaced as soon as possible. See the status tool, or Status in the Administrative Console, for more information about server certificates and how they are managed.

Copyright © 2025 Ping Identity Corporation

Gauge Namee	Enabled by default?	Description
Changelog Database Target Size (Percent)	true	Monitors the size of a changelog database on disk relative to the configured `target-database-size` value for the Replication Server changelog and the LDAP Changelog Backend (cn=changelog). The resource identifier indicates the changelog environment that is being monitored. The server aims to keep the disk usage of the changelog to between 95% and 100% of the target-database-size value. The most common reason that the server exceeds this limit is that there are no more changes that are old enough to purge. This is controlled with the replication-purge-delay setting on the Replication Server configuration object and the `changelog-maximum-age` setting on the 'changelog' Backend configuration object. If this is the case, the effective-purge-delay monitor attribute will match the configured purge delay. To eliminate the alarm in this case reduce the purge delay or increase the target-database-size value. Another reason that the disk usage could exceed this limit is that an export-ldif or online backup of the corresponding backend is running since database files on disk cannot be deleted while this operation is in progress. In practice, this will not occur unless the purge delay and target-database-size setting are configured to very small values and/or the backup is throttled with the `--maxMegabytesPerSecond` option so that it takes an especially long time to complete. The final reason that the limit could be exceeded is that the target-database-size setting is unreasonably small like less than one gigabyte.
Cleaner Backlog (Number Of Files)	true	Monitors the cleaner backlog in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the `list-backends` command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends can be included or excluded from monitoring by specifying its backend ID in the include resource and exclude resource properties respectively. The backlog is the number of database files that need to be cleaned to reach the target level of utilization. The value over time should stay close to zero. If it remains high or continues to grow, then consider updating the backend configuration to increase the `db-num-cleaner-threads` setting or reduce the `db-cleaner-min-utilization` setting. Temporary spikes in cleaner backlog are common during rebuild-index, export-ldif, and backup operations. The backlog should decrease automatically once these commands complete.

Copyright © 2025 Ping Identity Corporation

Gauge Namee	Enabled by default?	Description
CPU Usage (Percent)	true	Monitors server CPU use and provides an averaged percentage for the interval defined. The monitored resource is the host system's CPU, which does not include a resource identifier. If CPU use is high, check the server's current workload and other processes on this system and make any needed adjustments. Reducing the load on the system will lead to better response times.
Database Cache Full (Percent)	true	Monitors the percentage capacity of the database cache currently populated with entries, per backend. The resource identifier for this gauge is a backend ID. Use the `list-backends` command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends can be included or excluded from monitoring by specifying its backend ID in the include-resource and exclude-resource properties respectively. Server performance can drop off dramatically when the database cache can no longer hold the entire data set. Most deployments are designed to keep the database cache usage comfortably within the configured limits. If this server is intentionally disk-bound, this gauge should be disabled.
Disk Busy (Percent)	true	Monitors disk busy percentage over the update interval. This gauge requires that the Host System Monitor Provider be enabled and that any monitored disks be registered using the disk-devices property of that Monitor Provider. The resource identifier for this gauge is the disk device name. Use the `iostat` command or a similar system utility to see a list of disk device names. A separate gauge monitor entry will be created for each monitored disk. High disk usage might be indicative of a directory server whose database cache and/or JVM heap size are not large enough to contain the entire data set.
HTTP Processing (Percent)	true	Monitors the percentage of time that request handler threads spend processing HTTP requests. This percentage represents the inverse of the server's ability to handle new requests without queueing.

Copyright © 2025 Ping Identity Corporation

Gauge Namee	Enabled by default?	Description
JVM Memory Usage (Percent)	true	Monitors the percentage of Java Virtual Machine memory that is in use. This value naturally fluctuates due to garbage collection, so the minimum value within an interval is reported since it is a better indication of overall memory growth. When the memory usage exceeds 90%, this should be reported to customer support since the server is either misconfigured or has a memory leak. As memory usage approaches 100%, the server is more and more likely to experience garbage collection pauses, which leave the server unresponsive for a long time. Restarting the server is likely the only remedy for this situation. Prior to restarting the server, please run collect-support-data and capture the output of 'jmap -histo ' to provide to customer support. The pid of the server can be found from `/logs/server.pid`.
LDAP Operation Average Response Time (Milliseconds)	false	Monitors the average response time across all LDAP operations processed by this server since it was started. There is no resource identifier associated with this gauge. The monitored resource is overall response time of all LDAP operations processed by this server since it was started. High response times can be indicative of a number of factors including a disk-bound server, network latency, or misconfiguration. Enabling the Stats Logger plugin might help isolate problems. See the administration guide for more information on common problems and solutions.
LDAP Operations Failed (Percent)	false	Monitors the percentage of all LDAP operations processed by this server that have failed since it was started. There is no resource identifier associated with this gauge. The monitored resource is overall number of failed LDAP operations processed by this server since it was started. A high percentage of failed operations might indicate misconfiguration of a client or server in a topology.
License Expiration (Days)	true	Monitors the expiration date of the product license. An expired license will cause warnings to appear in the server's logs and in the status tool output. Request a license key through the Ping Identity licensing website https://www.pingidentity.com/en/account/request-license-key.html or contact sales@pingidentity.com. Use the dsconfig tool to update the License configuration's license key property.

Copyright © 2025 Ping Identity Corporation

Gauge Namee	Enabled by default?	Description
Memory Usage (Percent)	false	Monitors the percentage of memory use averaged over the update interval defined. The monitored resource is the host system's memory use, which does not have a resource identifier. Some operating systems, including Linux, use the majority of memory for file system cache, which is freed as applications need it. If memory use is high, check the applications that are running on the server.
Purge Expired Data Backlog (Number of Entries)	true	Monitors the backlog of entries that need to be purged by a Purge Expired Data Plugin. The resource identifier for this gauge is the name of the configured plugin. Increasing the max-updates-per-second configuration property on the plugin can increase the rate that the plugin purges expired data. It might also be necessary to refine the search that the plugin performs to be more efficient.
Recent Changes Database-to-JVM Heap Size Ratio (Percent)	true	The recent changes database keeps a number of recent changes made by update operations in changelog change entry form. This database is used by replication and the changelog backends, and unexpected growth affects server start time, memory consumption and space on disk. The ratio of the recent changes database to the overall heap size is used to track the impact on memory consumption. If you expect large changes and the server isn't experiencing issues, increase the alarm threshold. After processing large changes the alarm should clear itself, if not, it might necessary to perform an export and re-import of the data to resolve the issue.

Copyright © 2025 Ping Identity Corporation

Gauge Namee	Enabled by default?	Description
Replication Conflict Growth Rate	false	Growth rate of the number of unresolved conflicts per second over the update interval. The resource identifier for this gauge is the base DN of the replica. Use the `dsreplication status` command to see a list of replicated base DNs. A separate gauge monitor entry will be created for each monitored replica. Replicas can be included or excluded from monitoring by specifying a replication base DN in the include resource and exclude resource properties respectively. Updates to directory server entries in a replication topology can happen independently, since replication guarantees only eventual consistency, not strong consistency. The eventual consistency model means that conflicting changes can be applied at different directory server instances. In most cases, the directory server is able to resolve these conflicts automatically and in a consistent manner. However, in some scenarios, manual administrative action is required. Attention should be paid to the origin of client write requests to prevent conflicts.
Replication Connection Status	false	Indicates the connection status of remote replication servers this servers replication topology. The 'cn=schema' backend as well as the local replication server, are excluded using the include-filter property. For all other remote servers in the topology, separate monitor entries will be created per server and replication base DN. The resource identifier for this gauge is a concatenated string containing the data set name, the host and port of the replication server and the replication server ID. A replicated data set depends upon the availability of servers replicating the data. So long as there are other replicas available in a replication topology, a single replica being unavailable should not affect the overall performance of the replication topology. However, unavailable replicas can increase the likelihood of data loss or performance degradation.

Copyright © 2025 Ping Identity Corporation

Gauge Namee	Enabled by default?	Description
Replication Latency (Milliseconds)	false	Average amount of time it takes a modification on one replica to propagate and commit on another replica, in milliseconds. The resource identifier for this gauge is the base DN of the replica. Use the `dsreplication status` command to see a list of replicated base DNs. A separate gauge monitor entry will be created for each monitored replica. Replicas can be included or excluded from monitoring by specifying its base DN in the include-resource and exclude-resource properties respectively. Replication latency can be reported as high after the server starts, if the global configuration property startup-min-replication-backlog-count is not set. That property limits the number of outstanding changes any replica can have before the server will complete the startup process and begin accepting connections. This limits how out of the sync the server is at start up.
Replication Purge Delay (Hours)	true	For the replication server indicates the effective purge delay. In order to protect against missing changes the effective purge delay should be large enough to accommodate servers that have been offline as well as the need to restore from backups.
Replication Servers Available	false	Strong Encryption Not Available
Strong Encryption Not Available	true	The JVM does not appear to support strong encryption algorithms, like 256-bit AES. The server will fall back to using weaker algorithms, like 128-bit AES. To enable support for strong encryption, update your JVM to a newer version that supports it by default, or install or enable the unlimited encryption strength jurisdiction policy files in your Java installation.

Copyright © 2025 Ping Identity Corporation

Gauge Namee	Enabled by default?	Description
Undeletable Database Files (Percent)	true	Monitors the percentage of undeletable database files in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the `list-backends` command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends can be included or excluded from monitoring by specifying its backend ID in the include resource and exclude resource properties respectively. The percentage of undeletable database files tracks the percentage of database files that have been cleaned but cannot be deleted because they are being used by a database maintenance operation. This could be a separate, offline process such as export-ldif or verify-index, or it could be a task running within the server such as a backup or replication initialization. A small percentage of undeletable files is expected when these commands are running, but a high percentage could indicate that one of these operations is having problems and should be canceled and restarted to avoid the database growing too large on disk.
Work Queue Size (Number Of Requests)	true	Number of requests in the server's work queue waiting to be processed, averaged over the update interval. There is no resource identifier associated with this gauge. The monitored resource is the server's work queue. If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available.

Working with the collect-support-data tool

The PingDirectory server provides a significant amount of information about its current state including any problems that it has encountered during processing. If a problem occurs, the first step is to run the `collect-support-data` tool in the `bin` directory. The tool aggregates all relevant support files into a zip file that administrators can send to your authorized support provider for analysis. The tool also runs data collector utilities, such as `jps`, `jstack`, and `jstat` plus other diagnostic tools, and bundles the results in the zip file.

The tool may only archive portions of certain log files to conserve space, so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

The data collected by the `collect-support-data` tool varies between systems. However, the tool always tries to get the same information across all systems for the target PingDirectory server. The data collected includes the configuration directory, summaries and snippets from the `logs` directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

Copyright © 2025 Ping Identity Corporation

Server commands used in the collect-support-data tool

The following presents a summary of the data collectors that the `collect-support-data` tool archives in zip format. If an error occurs during processing, you can re-run the specific data collector command and send the results to your authorized support provider.

Data Collector	Description
status	Runs `status -F` to show the full version information of the PingDirectory server (Unix, Windows).
server-state	Runs `server-state` to show the current state of the PingDirectory server process (Unix, Windows).

JDK commands used in the collect-support-data tool

Data Collector	Description
jps	Java Virtual Machine Process status tool. Reports information on the JVM (Linux, Windows, Mac OS).
jstack	Java Virtual Machine Stack Trace. Prints the stack traces of threads for the Java process (Linux, Windows, Mac OS).
jstat	Java Virtual Machine Statistics Monitoring Tool. Displays performance statistics for the JVM (Linux, Windows, Mac OS).
jinfo	Displays the Java configuration information for the Java process (Linux, Windows, Mac OS).

Linux commands used in the collect-support-data tool

Data Collector	Description
tail	Displays the last few lines of a file. Tails the `/var/logs/messages` directory.
uname	Prints system, machine, and operating system information.
ps	Prints a snapshot of the current active processes.
df	Prints the amount of available disk space for file systems in 1024-byte units.

Copyright © 2025 Ping Identity Corporation

Data Collector	Description
cat	Concatenates the following files and prints to standard output: • `/proc/cpuinfo` • `/proc/meminfo` • `/etc/hosts` • `/etc/nsswitch.conf` • `/etc/resolv.conf`
netstat	Prints the state of network interfaces, protocols, and the kernel routing table.
ifconfig	Prints information on all interfaces.
uptime	Prints the time the server has been up and active.
dmesg	Prints the message buffer of the kernel.
vmstat	Prints information about virtual memory statistics.
iostat	Prints disk I/O and CPU utilization information.
mpstat	Prints performance statistics for all logical processors.
pstack	Prints an execution stack trace on an active processed specified by the pid.
top	Prints a list of active processes and how much CPU and memory each process is using.

MacOS commands used in the collect-support-data tool

Data Collector	Description
uname	Prints system, machine, and operating system information.
uptime	Prints the time the server has been up and active.
ps	Prints a snapshot of the current active processes.
system_profiler	Prints system hardware and software configuration.
vm_stat	Prints machine virtual memory statistics.
tail	Displays the last few lines of a file. Tails the `/var/log/system.log` directory.
netstat	Prints the state of network interfaces, protocols, and the kernel routing table.
ifconfig	Prints information on all interfaces.
df	Prints the amount of available disk space for file systems in 1024-byte units.

Copyright © 2025 Ping Identity Corporation

Data Collector	Description
sample	Profiles a process during an interval.

Invoking the collect-support-data tool as an administrative task

You can invoke `collect-support-data` as an administrative task, including as a recurring task that can be automatically invoked on a regular basis.

For more information, see About recurring tasks and task chains.

Available tool options

The `collect-support-data` tool has some important options that you should be aware of:

- --noLdap. Specifies that no effort should be made to collect any information over LDAP. This option should only be used if the server is completely unresponsive or will not start and only as a last resort.
- --pid {pid}. Specifies the ID of an additional process from which information is to be collected. This option is useful for troubleshooting external server tools and can be specified multiple times for each external server, respectively.
- --sequential. Use this option to diagnose "Out of Memory" errors. The tool collects data in parallel to minimize the collection time necessary for some analysis utilities. This option specifies that data collection should be run sequentially as opposed to in parallel. This action has the effect of reducing the initial memory footprint of this tool at a cost of taking longer to complete.
- --reportCount {count}. Specifies the number of reports generated for commands that supports sampling (for example, `vmstat`, `iostat`, or `mpstat`). A value of 0 (zero) indicates that no reports will be generated for these commands. If this option is not specified, it defaults to 10.
- --reportInterval {interval}. Specifies the number of seconds between reports for commands that support sampling (for example, `mpstat`). This option must have a value greater than 0 (zero). If this option is not specified, it default to 1.
- --maxJstacks {number}. Specifies the number of jstack samples to collect. If not specified, the default number of samples collected is 10.
- --collectExpensiveData. Specifies that data on expensive or long running processes be collected. These processes are not collected by default, because they will impact the performance of a running server.
- --comment {comment}. Provides the ability to submit any additional information about the collected data set. The comment will be added to the generated archive as a README file.
- --includeBinaryFiles. Specifies that binary files be included in the archive collection. By default, all binary files are automatically excluded in data collection.
- --adminPassword {adminPassword}. Specifies the global administrator password used to obtain `dsreplication status` information.
- --adminPasswordFile {adminPasswordFile}. Specifies the file containing the password of the global administrator used to obtain `dsreplication status` information.
- --outputPath. Specifies the path (and optionally, the name) for the support data archive file. If the path specifies a filename, the archive is written to that file. If the path specifies a directory, the file is written into that directory with a server-generated name.

Copyright © 2025 Ping Identity Corporation

- --useRemoteServer. Invokes the tool against a remote server instance and streams the output and resulting support data archive back to the client. This option can be especially useful when the server instance is running in a container because it might otherwise be difficult to invoke commands or access files in that container. See also: --proxyToServerAddress and --proxyToServerPort.
- --proxyToServerAddress and --proxyToServerPort. Use these options with --useRemoteServer to indicate that the support data archive should be retrieved from a server that is not directly accessible but can be accessed through a PingDirectoryProxy server.

Running the collect-support-data tool

Steps

1. Go to the server root directory.
2. Use the `collect-support-data` tool. Make sure to include the host, port number, bind DN, and bind password.

   Example:

   ```
   $ bin/collect-support-data --hostname 127.0.0.1 --port 389 \
     --bindDN "cn=Directory Manager" --bindPassword secret
   ```

3. Email the zip file to your Authorized Support Provider.

PingDirectory server troubleshooting information

The PingDirectory server has a comprehensive default set of log files and monitor entries that are useful when troubleshooting a particular server problem.

Error log

By default, this log file is available at `logs/errors` below the server install root and it provides information about warnings, errors, and other significant events that occur within the server. A number of messages are written to this file on startup and shutdown, but while the server is running there is normally little information written to it. In the event that a problem does occur, however, the server writes information about that problem to this file.

The following is an example of a message that might be written to the error log:

```
[11/Apr/2011:10:31:53.783 -0500] category=CORE severity=NOTICE msgID=458887 msg="The Directory Server has
started successfully"
```

The category field provides information about the area of the server from which the message was generated. Available categories include ACCESS_CONTROL, ADMIN, ADMIN_TOOL, BACKEND, CONFIG, CORE, DSCONFIG, EXTENSIONS, PROTOCOL, SCHEMA, JEB, SYNC, LOG, PLUGIN, PROXY, QUICKSETUP, REPLICATION, RUNTIME_INFORMATION, TASK, THIRD_PARTY, TOOLS, USER_DEFINED, UTIL, and VERSION.

Copyright © 2025 Ping Identity Corporation

The severity field provides information about how severe the server considers the problem to be. Available severities include:

- DEBUG – Used for messages that provide verbose debugging information and do not indicate any kind of problem. Note that this severity level is rarely used for error logging, because the server provides a separate debug logging facility.
- INFORMATION – Used for informational messages that can be useful from time to time but are not normally something that administrators need to see.
- MILD_WARNING – Used for problems that the server detects, which can indicate something unusual occurred, but the warning does not prevent the server from completing the task it was working on. These warnings are not normally something that should be of concern to administrators.
- MILD_ERROR – Used for problems detected by the server that prevented it from completing some processing normally but that are not considered to be a significant problem requiring administrative action.
- NOTICE – Used for information messages about significant events that occur within the server and are considered important enough to warrant making available to administrators under normal conditions.
- SEVERE_WARNING – Used for problems that the server detects that might lead to bigger problems in the future and should be addressed by administrators.
- SEVERE_ERROR – Used for significant problems that have prevented the server from successfully completing processing and are considered important.
- FATAL_ERROR – Used for critical problems that arise which might leave the server unable to continue processing operations normally.

The messages written to the error log can be filtered based on their severities in two ways. First, the error log publisher has a `default-severity` property, which can be used to specify the severity of messages logged regardless of their category. By default, this includes the NOTICE, SEVERE_WARNING, SEVERE_ERROR, and FATAL_ERROR severities.

You can override these severities on a per-category basis using the `override-severity` property. If this property is used, then each value should consist of a category name followed by an equal sign and a comma-delimited set of severities that should be logged for messages in that category. For example, the following override severity would enable logging at all severity levels in the PROTOCOL category:

```
protocol=debug,information,mild-warning,mild-error,notice,severe-warning,severe-error,fatal-error
```

Note that for the purposes of this configuration property, any underscores in category or severity names should be replaced with dashes. Also, severities are not inherently hierarchical, so enabling the DEBUG severity for a category will not automatically enable logging at the INFORMATION, MILD_WARNING, or MILD_ERROR severities.

The error log configuration can be altered on the fly using tools like `dsconfig`, the Administrative Console, or the LDIF connection handler, and changes will take effect immediately. You can configure multiple error logs that are active in the server at the same time, writing to different log files with different configurations. For example, a new error logger can be activated with a different set of default severities to debug a short-term problem, and then that logger can be removed after the problem is resolved, so that the normal error log does not contain any of the more verbose information.

Copyright © 2025 Ping Identity Corporation

server.out log

The `server.out` file holds any information written to standard output or standard error while the server is running. Normally, it includes a number of messages written at startup and shutdown, as well as information about any administrative alerts generated while the server is running. In most cases, this information is also written to the error log. The `server.out` file can also contain output generated by the JVM. For example, if garbage collection debugging is enabled, or if a stack trace is requested via "kill -QUIT" as described in a later section, then output is written to this file.

Debug log

The debug log provides a means of obtaining information that can be used for troubleshooting problems but is not necessary or desirable to have available while the server is functioning normally. As a result, the debug log is disabled by default, but it can be enabled and configured at any time.

Some of the most notable configuration properties for the debug log publisher include:

- enabled – Indicates whether debug logging is enabled. By default, it is disabled.
- log-file – Specifies the path to the file to be written. By default, debug messages are written to the `logs/debug` file.
- default-debug-level – Specifies the minimum log level for debug messages that should be written. The default value is "error," which only provides information about errors that occur during processing (for example, exception stack traces). Other supported debug levels include warning, info, and verbose. Note that unlike error log severities, the debug log levels are hierarchical. Configuring a specified debug level enables any debugging at any higher levels. For example, configuring the info debug level automatically enables the warning and error levels.
- default-debug-category – Specifies the categories for debug messages that should be written. Some of the most useful categories include caught (provides information and stack traces for any exceptions caught during processing), database-access (provides information about operations performed in the underlying database), protocol (provides information about ASN.1 and LDAP communication performed by the server), and data (provides information about raw data read from or written to clients).

As with the error and access logs, multiple debug loggers can be active in the server at any time with different configurations and log files to help isolate information that might be relevant to a particular problem. NOTE: Enabling one or more debug loggers can have a significant impact on server performance. We recommend that debug loggers be enabled only when necessary, and then be scoped so that only pertinent debug information is recorded.

Debug targets can be used to further pare down the set of messages generated. For example, you can specify that the debug logs be generated only within a specific class or package. If you need to enable the debug logger, you should work with your authorized support provider to best configure the debug target and interpret the output.

Replication repair log

The replication repair log is written to `logs/replication` by default and records information about processing performed by the replication repair service. This log is used to resolve replication conflicts that can arise. For example, if the same entry is modified at the same time on two different systems, or if an attempt is made to create entries with the same DN at the same time on two different systems, the PingDirectory server records these events.

Copyright © 2025 Ping Identity Corporation

Config audit log and the configuration archive

The configuration audit log provides a record of any changes made to the server configuration while the server is online. This information is written to the `logs/config-audit.log` file and provides information about the configuration change in the form that can be used to perform the operation in a non-interactive manner with the `dsconfig` command. Other information written for each change includes:

- Time that the configuration change was made.
- Connection ID and operation ID for the corresponding change, which can be used to correlate it with information in the access log.
- DN of the user requesting the configuration change and the method by which that user authenticated to the server.
- Source and destination addresses of the client connection.
- Command that can be used to undo the change and revert to the previous configuration for the associated configuration object.

In addition to information about the individual changes that are made to the configuration, the server maintains complete copies of all previous configurations. These configurations are provided in the `config/archived-configs` directory and are gzip-compressed copies of the `config/config.ldif` file in use before the configuration change was made. The file names contain timestamps that indicate when that configuration was first used.

Access and audit log

The access log provides information about operations processed within the server. The default access log file is written to `logs/access`, but multiple access loggers can be active at the same time, each writing to different log files and using different configurations.

By default, a single access log message is generated, which combines the elements of request, forward, and result messages. If an error is encountered while attempting to process the request, then one or more forward-failed messages can also be generated.

```
[01/Jun/2011:11:10:19.692 -0500] CONNECT conn=49 from="127.0.0.1" to="127.0.0.1"
  protocol="LDAP+TLS" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.764 -0500] BIND RESULT conn=49 op=0 msgID=1 version="3"
  dn="cn=Directory Manager" authType="SIMPLE" resultCode=0 etime=0.401
  authDN="cn=Directory Manager,cn=Root DNs,cn=config" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.769 -0500] SEARCH RESULT conn=49 op=1 msgID=2
  base="ou=People,dc=example,dc=com" scope=2 filter="(uid=1)" attrs="ALL"
  resultCode=0 etime=0.549 entriesReturned=1
[01/Jun/2011:11:10:19.788 -0500] DISCONNECT conn=49 reason="Client Unbind"
```

Each log message includes a timestamp indicating when it was written, followed by the operation type, the connection ID (which is used for all operations processed on the same client connection), the operation ID (which can be used to correlate the request and response log messages for the operation), and the message ID used in LDAP messages for this operation.

The remaining content for access log messages varies based on the type of operation being processed, and whether it is a request or a result message. Request messages generally include the most pertinent information from the request, but generally omit information that is sensitive or not useful.

Copyright © 2025 Ping Identity Corporation

Result messages include a `resultCode` element that indicates whether the operation was successful or if failed and an `etime` element that indicates the length of time in milliseconds that the server spent processing the operation. Other elements that might be present include the following:

- origin=replication – Operation that was processed as a result of data synchronization (for example, replication) rather than a request received directly from a client.
- message – Text that was included in the `diagnosticMessage` field of the response sent to the client.
- additionalInfo – Additional information about the operation that was not included in the response sent back to the client.
- authDN – DN of the user that authenticated to the server (typically only included in bind result messages).
- authzDN – DN of an alternate authorization identify used when processing the operation (for example, if the proxied authorization control was included in the request).
- authFailureID – Unique identifier associated with the authentication failure reason (only included in non-successful bind result messages).
- authFailureReason – Information about the reason that a bind operation failed that might be useful to administrators but was not included in the response to the client for security reasons.
- responseOID – OID included in an extended response returned to the client.
- entriesReturned – Number of matching entries returned to the client for a search operation.
- unindexed=true – Indicates that the associated search operation could not be sufficiently processed using server indexes and a significant traversal through the database was required.

Note that this is not an exhaustive list, and elements that are not listed here can also be present in access log messages. The LDAP SDK for Java provides an API for parsing access log messages and provides access to all elements that they can contain.

The server provides a second access log implementation called the audit log, which is used to provide detailed information about write operations (add, delete, modify, and modify DN) processed within the server. If the audit log is enabled, the entire content of the change is written to the audit log file (which defaults to `logs/audit`) in LDIF form.

The server also provides a very rich classification system that can be used to filter the content for access log files. This can be helpful when debugging problems with client applications, because it can restrict log information to operations processed only by a particular application (for example, based on IP address and/or authentication DN), only failed operations, or only operations taking a long time to complete, etc.

Setup log

The `setup` tool writes a log file providing information about the processing that it performs. By default, this log file is written to `logs/setup.log` although a different name may be used if a file with that name already exists, because the `setup` tool has already been run. The full path to the setup log file is provided when the `setup` tool has completed.

Copyright © 2025 Ping Identity Corporation

Tool log

Many of the administrative tools provided with the server (for example, `import-ldif`, `export-ldif`, `backup`, `restore`, etc.) can take a significant length of time to complete write information to standard output or standard error or both while the tool is running. They also write additional output to files in the `logs/tools` directory (for example, `logs/tools/ import-ldif.log`). The information written to these log files can be useful for diagnosing problems encountered while they were running. When running using the server tasks interface, log messages generated while the task is running can alternately be written to the server error log file.

je.info and je.config files

The primary datastore used by the PingDirectory server is the Oracle Berkeley DB Java Edition (JE). The PingDirectory server provides two primary sources of information about processing within the database.The first is logging performed by the JE code itself, and is written into the

`je.info.0` file in the server containing the database files (for example, `db/userRoot/je.info.0`). In the event of a problem within JE itself, useful information about the nature of the problem may be written to this log. The level of information written to this log file is controlled by the `db-logging-level` property in the backend configuration object. It uses the standard Java logging framework for logging messages, so the standard SEVERE, WARNING, INFO, CONFIG, FINE, FINER, and FINEST levels are available.

The second is configuration information used when opening the database environment. When the backend database environment is opened, then the PingDirectory server will also write a file named `je.config` in the server containing the database files (for example, `db/userRoot/je.config`) with information about the configuration used.

LDAP SDK debug log

This log can be used to help examine the communication between the PingDirectory server and the PingDirectoryProxy server. It contains information about exceptions that occur during processing, problems establishing and terminating network connections, and problems that occur during the reading and writing of LDAP messages and LDIF entries. You can configure the types of debugging that should be enabled, the debug level that should be used, and whether debug messages should include stack traces. As for other file-based loggers, you can also specify the rotation and retention policies.

About the monitor entries

While the server is running, it generates a significant amount of information available through monitor entries. Monitor entries are available over LDAP in the `cn=monitor` subtree. The types of monitor entries that are available include:

- General Monitor Entry (cn=monitor) – Provides a basic set of general information about the server.
- Active Operations Monitor Entry (cn=Active Operations,cn=monitor) – Provides information about all operations currently in progress in the server.
- Backend Monitor Entries (cn={id} Backend,cn=monitor) – Provides information about the backend, including the number of entries, the base DN(s), and whether it is private.
- Client Connections Monitor Entry (cn=Client Connections,cn=monitor) – Provides information about all connections currently established to the server.
- Connection Handler Monitor Entry (cn={name},cn=monitor) – Provides information about the configuration of each connection handler and the client connections established to it.

Copyright © 2025 Ping Identity Corporation

- Database Environment Monitor Entries (cn={id} Database Environment,cn=monitor) – Provides statistics and other data from the Oracle Berkeley DB Java Edition database envi- ronment used by the associated backend.
- Disk Space Usage Monitor Entry (cn=Disk Space Usage,cn=monitor) – Provides information about the amount of usable disk space available to server components.
- JVM Memory Usage Monitor Entry (cn=JVM Memory Usage,cn=monitor) – Provides information about garbage collection activity, the amount of memory available to the server, and the amount of memory consumed by various server components.
- JVM Stack Trace Monitor Entry (cn=JVM Stack Trace,cn=monitor) – Provides a stack trace of all threads in the JVM.
- LDAP Statistics Monitor Entries (cn={name} Statistics,cn=monitor) – Provides information about the number of each type of operation requested and bytes transferred over the connection handler.
- Processing Time Histogram Monitor Entry (cn=Processing Time Histogram,cn=monitor) – Provides information about the number or percent of operations that completed in various response time categories.
- SSL Context Monitor Entry (cn=SSL Context,cn=monitor) – Provides information about the available and supported SSL Cipher Suites and Protocols on the server.
- System Information Monitor Entry (cn=System Information,cn=monitor) – Provides information about the underlying JVM and system.
- Version Monitor Entry (cn=Version,cn=monitor) – Provides information about the server version.
- Work Queue Monitor Entry (cn=Work Queue,cn=monitor) – Provides information about the state of the server's work queue, including the number of operations waiting on worker threads and the number of operations that have been rejected because the queue became full.

PingDirectory server troubleshooting tools

The Server provides a set of tools that can also be used to obtain information for diagnosing and solving problems.

Server version information

If it becomes necessary to contact your authorized support provider, then it will be important to provide precise information about the version of the PingDirectory server software that is in use. If the server is running, then this information can be obtained from the "`cn=Version,cn=monitor`" entry. It can also be obtained using the command:

```
$ bin/status --fullVersion
```

This command outputs a number of important pieces of information, including:

- Major, minor, point and patch version numbers for the server.
- Source revision number from which the server was built.
- Build information including build ID with timestamp, OS, user, Java and JVM version for the build.
- Auxiliary software versions: Jetty, JZlib, SNMP4j (SNMP4J, Agent, Agentx), Groovy, LDAP SDK for Java, and the Server SDK.

Copyright © 2025 Ping Identity Corporation

LDIF connection handler

The PingDirectory server provides an LDIF connection handler that provides a way to request operations that don't require any network communication with the server. This can be particularly helpful if a configuration problem or bug in the server has left a connection handler unusable, or if all worker threads are busy processing operations.

The LDIF connection handler is enabled by default and looks for LDIF files in the `config/auto-process-ldif` directory. This directory doesn't exist by default, but if you create it and place an LDIF file in it that contains one or more changes to be processed, the LDIF connection handler applies those changes.

Any changes that can be made over LDAP can be applied through the LDIF connection handler. It is primarily intended for administrative operations like updating the server configuration or scheduling tasks, although other types of changes (including changes to data contained in the server) can be processed. As the LDIF file is processed, a new file is written with comments for each change providing information about the result of processing that change.

dbtest tool

The **`dbtest`** tool provides a utility that can be used to obtain general information about the data in a backend database. The tool dumps information about entries or keys, and raw data from the database. It can also find keys that have exceeded the entry limit.

For example, the following command can be used to dump a list of all keys in the `objectClass.equality` that have exceeded the entry threshold:

```
$ bin/dbtest dump-database-container \
  --backendID userRoot \
  --baseDN "dc=example,dc=com" \
  --databaseName objectClass.equality \
  --onlyExceedingLimit
```

On a large database, many **`dbtest`** operations may take a long time to complete, since every record in the associated database is examined. Use the database name option to list a specific database. The following command displays information about the uid.equality database in the `dc=example,dc=com` entry container in the userRoot backend.

```
$ bin/dbtest list-database-containers -n userRoot -b "dc=example,dc=com" -d uid.equality
```

Index key entry limit

Indexes have keys that maintain a list of matching entries, up to the index entry limit. When that limit is reached, the key will not contain or maintain that list, and will just maintain a count of matching entries. To determine if index keys are approaching their limit, use either the **`dbtest`** tool or the **`verify-index`** tool.

While the **`dbtest`** tool can be used to gather general imformation, the **`verify-index`** tool provides statistical data about the percent of entries covered by the keys.

For example, the following command can be used to retrieve a list of keys that have exceeded the entry threshold:

Copyright © 2025 Ping Identity Corporation

```
$ bin/verify-index \
  --baseDN dc=example,dc=com \
  --listKeysExceedingIndexEntryLimit
```

The following is a sample of the data returned:

```
[12:06:05]  Checked 6003 entries and found 0 error(s) in 2 seconds (average rate 2453.2/sec)
[12:06:05]  Statistics for records that have exceeded the entry limit:
[12:06:05]  The st.equality index has 48 such record(s) limit=100 min=103 max=152 median=118
[12:06:05]  1. or (152 entries / 2.53% of all entries)
[12:06:05]  2. ma (132 entries / 2.20% of all entries)
 .....
[12:06:05]  The id2subtree index has 2 such record(s) limit=4000 min=6000 max=6002 median=6001
[12:06:05]  1. 1 => dc=example,dc=com (6002 entries / 99.98% of all entries)
 .....
[12:06:05]  The id2children index has 1 such record(s) limit=4000 min=6000 max=6000 median=6000
[12:06:05]  1. 2 => ou=People,dc=example,dc=com (6000 entries / 99.95% of all entries)
[12:06:05]  The objectClass.equality index has 4 such record(s) limit=4000 min=6001 max=6003 median=6001
[12:06:05]  1. top (6003 entries / 100.00% of all entries)
 .....
```

Embedded profiler

If the PingDirectory server appears to be running slowly, then it is helpful to know what operations are being processed in the server. The JVM Stack Trace monitor entry can be used to obtain a point-in-time snapshot of what the server is doing, but in many cases, it might be useful to have information collected over a period of time.

The embedded profiler is configured so that it is always available but is not active by default so that it has no impact on the performance of the running server. Even when it is running, it has a relatively small impact on performance, but it is recommended that it remain inactive when it is not needed. It can be controlled using the `dsconfig` tool or the Administrative Console by managing the "Profiler" configuration object in the "Plugin" object type, available at the standard object level. The `profile-action` property for this configuration object can have one of the following values:

- start – Indicates that the embedded profiler should start capturing data in the background.
- stop – Indicates that the embedded profiler should stop capturing data and write the information that it has collected to a `logs/profile{timestamp}` file.
- cancel – Indicates that the embedded profiler should stop capturing data and discard any information that it has collected.

Any profiling data that has been captured can be examined using the `profiler-viewer` tool. This tool can operate in either a text-based mode, in which case it dumps a formatted text representation of the profile data to standard output, or it can be used in a graphical mode that allows the information to be more easily understood.

Invoking the profile viewer in text-based mode

Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z
```

Invoking the profile viewer in GUI mode

Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option. To invoke GUI mode, add the option `--useGUI`.

  Example:

  ```
  $ bin/profile-viewer --fileName logs/profile.20110101000000Z --useGUI
  ```

Oracle Berkeley DB Java Edition utilities

The Oracle Berkeley DB Java Edition (JE) itself provides a number of utilities that can be used for performing various types of low-level debugging in the database environment. These utilities should generally not be used unless you are advised to do so by your authorized support provider, but they provide access to information about the underlying database environment that is not available through any other means.

Troubleshooting resources for Java applications

Because the Server is written entirely in Java, it is possible to use standard Java debugging and instrumentation tools when troubleshooting problems with the PingDirectory server. In many cases, obtaining the full benefit of these tools requires access to the server source code. These Java tools should be used under the advisement of your authorized support provider.

Java troubleshooting tools

The Java Development Kit provides a number of very useful tools to obtain information about Java applications and diagnosing problems. These tools are not included with the Java Runtime Environment (JRE), so the full Java Development Environment (JDK) should always be installed and used to run the Server.

jps

The `jps` tool is a Java-specific version of the UNIX `ps` tool. It can be used to obtain a list of all Java processes currently running and their respective process identifiers. When invoked by a non-root user, it will list only Java processes running as that user. When invoked by a root user, then it lists all Java processes on the system.

This tool can be used to see if the PingDirectory server is running and if a process ID has been assigned to it. This process ID can be used in conjunction with other tools to perform further analysis.

This tool can be run without any arguments, but some of the more useful arguments that include:

- -v – Includes the arguments passed to the JVM for the processes that are listed.
- -m – Includes the arguments passed to the main method for the processes that are listed.
- -l – (lowercase L). Include the fully qualified name for the main class rather than only the base class name.

Copyright © 2025 Ping Identity Corporation

jstack

The `jstack` tool is used to obtain a stack trace of a running Java process, or optionally from a core file generated if the JVM happens to crash. A stack trace can be extremely valuable when trying to debug a problem, because it provides information about all threads running and exactly what each is doing at the point in time that the stack trace was obtained.

Stack traces are helpful when diagnosing problems in which the server appears to be hung or behaving slowly. Java stack traces are generally more helpful than native stack traces, because Java threads can have user-friendly names (as do the threads used by the Server), and the frame of the stack trace may include the line number of the source file to which it corresponds. This is useful when diagnosing problems and often allows them to be identified and resolved quickly.

To obtain a stack trace from a running JVM, use the command:

```
jstack {processID}
```

where {processID} is the process ID of the target JVM as returned by the `jps` command. To obtain a stack trace from a core file from a Java process, use the command:

```
jstack {pathToJava} {pathToCore}
```

where `{pathToJava}` is the path to the java command from which the core file was created, and `{pathToCore}` is the path to the core file to examine. In either case, the stack trace is written to standard output and includes the names and call stacks for each of the threads that were active in the JVM.

In many cases, no additional options are necessary. The "`-l`" option can be added to obtain a long listing, which includes additional information about locks owned by the threads. The "`-m`" option can be used to include native frames in the stack trace.

jmap

The `jmap` tool is used to obtain information about the memory consumed by the JVM. It is very similar to the native `pmap` tool provided by many operating systems. As with the `jstack` tool, `jmap` can be invoked against a running Java process by providing the process ID, or against a core file , like:

```
jmap {processID}
jmap {pathToJava} {pathToCore}
```

Some of the additional arguments include:

- -dump:live,format=b,file=filename – Dump the live heap data to a file that can be examined by the `jhat` tool
- -heap – Provides a summary of the memory used in the Java heap, along with information about the garbage collection algorithm in use.
- -histo:live – Provides a count of the number of objects of each type contained in the heap. If the "`:live`" portion is included, then only live objects are included; otherwise, the count include objects that are no longer in use and are garbage collected.

Copyright © 2025 Ping Identity Corporation

jhat

The `jhat` (Java Heap Analysis Tool) utility provides the ability to analyze the contents of the Java heap. It can be used to analyze a heap dump file, which is generated if the PingDirectory server encounters an out of memory error (as a result of the "`-XX:+HeapDumpOnOutOfMemoryError`" JVM option) or from the use of the `jmap` command with the "`-dump`" option.

The `jhat` tool acts as a web server that can be accessed by a browser in order to query the contents of the heap. Several predefined queries are available to help determine the types of objects consuming significant amounts of heap space, and it also provides a custom query language (OQL, the Object Query Language) for performing more advanced types of analysis.

The `jhat` tool can be launched with the path to the heap dump file, like:

```
jhat /path/to/heap.dump
```

This command causes the `jhat` web server to begin listening on port 7000. It can be accessed in a browser at `http://localhost:7000` (or `http://address:7000` from a remote system). An alternate port number can be specified using the "`-port`" option, like:

```
jhat -port 1234 /path/to/heap.dump
```

To issue custom OQL searches, access the web interface using the URL `http://localhost:7000/oql/` (the trailing slash must be provided). Additional information about the OQL syntax may be obtained in the web interface at `http://localhost:7000/oqlhelp/`.

jstat

The `jstat` tool is used to obtain a variety of statistical information from the JVM, much like the `vmstat` utility that can be used to obtain CPU utilization information from the operating system. The general manner to invoke it is as follows:

```
jstat {type} {processID} {interval}
```

The `{interval}` option specifies the length of time in milliseconds between lines of output. The `{processID}` option specifies the process ID of the JVM used to run the PingDirectory server, which can be obtained by running `jps` as mentioned previously. The `{type}` option specifies the type of output that should be provided. Some of the most useful types include:

- -class – Provides information about class loading and unloading.
- -compile – Provides information about the activity of the JIT complex.
- -printcompilation – Provides information about JIT method compilation.
- -gc – Provides information about the activity of the garbage collector.
- -gccapacity – Provides information about memory region capacities.

Copyright © 2025 Ping Identity Corporation

Java diagnostic information

In addition to the tools listed in the previous section, the JVM can provide additional diagnostic information in response to certain events.

JVM crash diagnostic information

If the JVM itself should happen to crash for some reason, then it generates a fatal error log with information about the state of the JVM at the time of the crash. By default, this file is named `hs_err_pid{processID}.log` and is written into the base directory of the PingDirectory server installation. This file includes information on the underlying cause of the JVM crash, information about the threads running and Java heap at the time of the crash, the options provided to the JVM, environment variables that were set, and information about the underlying system.

Troubleshooting resources in the operating system

The underlying operating system also provides a significant amount of information that can help diagnose issues that impact the performance and the stability of the PingDirectory server. In some cases, problems with the underlying system can be directly responsible for the issues seen with the server, and in others system, tools can help narrow down the cause of the problem.

Identifying problems with the underlying system

If the underlying system itself is experiencing problems, it can adversely impact the function of applications running on it. To look for problems in the underlying system view the system log file (`/var/log/messages` on Linux). Information about faulted or degraded devices or other unusual system conditions are written there.

Examining CPU utilization

Observing CPU utilization for the server process and the system as a whole provides clues as to the nature of the problem.

System-Wide CPU utilization

To investigate CPU consumption of the system as a whole, use the `vmstat` command with a time interval in seconds, like:

```
vmstat 5
```

The specific output of this command varies between different operating systems, but it includes the percentage of the time the CPU was spent executing user-space code (user time), the percentage of time spent executing kernel-space code (system time), and the percentage of time not executing any code (idle time).

Copyright © 2025 Ping Identity Corporation

If the CPUs are spending most of their time executing user-space code, the available processors are being well-utilized. If performance is poor or the server is unresponsive, it can indicate that the server is not optimally tuned. If there is a high system time, it can indicate that the system is performing excessive disk and/or network I/O, or in some cases, there can be some other system-wide problem like an interrupt storm. If the system is mostly idle but the server is performing poorly or is unresponsive, there can be a resource constraint elsewhere (for example, waiting on disk or memory access, or excessive lock contention), or the JVM can be performing other tasks like stop-the-world garbage collection that cannot be run heavily in parallel.

Per-CPU utilization

To investigate CPU consumption on a per-CPU basis, use the `mpstat` command with a time interval in seconds, like:

```
mpstat 5
```

On Linux systems, it might be necessary to add "`-P ALL`" to the command, like:

```
mpstat -P ALL 5
```

Among other things, this shows the percentage of time each CPU has spent in user time, system time, and idle time. If the overall CPU utilization is relatively low but `mpstat` reports that one CPU has a much higher utilization than the others, there might be a significant bottleneck within the server or the JVM might be performing certain types of garbage collection which cannot be run in parallel. On the other hand, if CPU utilization is relatively even across all CPUs, there is likely no such bottleneck and the issue might be elsewhere.

Per-process utilization

To investigate CPU consumption on a per-process basis, use a command such as the `top` utility on Linux. If a process other than the Java process used to run the PingDirectory server is consuming a significant amount of available CPU, it might be interfering with the ability of the server to run effectively.

Examining disk utilization

If the underlying system has a very high disk utilization, it can adversely impact server performance. It could delay the ability to read or write database files or write log files. It could also raise concerns for server stability if excessive disk I/O inhibits the ability of the cleaner threads to keep the database size under control.

The `iostat` tool can be used to obtain information about the disk activity on the system.

On Linux systems, `iostat` should be invoked with the "`-x`" argument, like:

```
iostat -x 5
```

Copyright © 2025 Ping Identity Corporation

A number of different types of information will be displayed, but to obtain an initial feel for how busy the underlying disks are, look at the "%util" column on Linux. This field shows the percentage of the time that the underlying disks are actively servicing I/O requests. A system with a high disk utilization likely exhibits poor server performance.

If the high disk utilization is on one or more disks that are used to provide swap space for the system, the system might not have enough free memory to process requests. As a result, it might have started swapping blocks of memory that have not been used recently to disk. This can cause very poor server performance. It is important to ensure that the server is configured appropriately to avoid this condition. If this problem occurs on a regular basis, then the server is likely configured to use too much memory. If swapping is not normally a problem but it does arise, then check to see if there are any other processes running, which are consuming a significant amount of memory, and check for other potential causes of significant memory consumption (for example, large files in a `tmpfs` file system).

Examining process details

There are a number of tools provided by the operating system that can help examine a process in detail.

ps

The standard `ps` tool can be used to provide a range of information about a particular process. For example, the command can be used to display the state of the process, the name of the user running the process, its process ID and parent process ID, the priority and nice value, resident and virtual memory sizes, the start time, the execution time, and the process name with arguments:

```
ps -fly -p {processID}
```

Note that for a process with a large number of arguments, the standard `ps` command displays only a limited set of the arguments based on available space in the terminal window.

pstack

The `pstack` command can be used to obtain a native stack trace of all threads in a process. While a native stack trace might not be as user-friendly as a Java stack trace obtained using `jstack`, it includes threads that are not available in a Java stack trace. For example, the command displays those threads used to perform garbage collection and other housekeeping tasks. The general usage for the `pstack` command is:

```
pstack {processID}
```

Copyright © 2025 Ping Identity Corporation

dbx / gdb

A process debugger provides the ability to examine a process in detail. Like `pstack`, a debugger can obtain a stack trace for all threads in the process, but it also provides the ability to examine a process (or core file) in much greater detail, including observing the contents of memory at a specified address and the values of CPU registers in different frames of execution. The GNU debugger `gdb` is widely-used on Linux systems.

Note that using a debugger against a live process interrupts that process and suspends its execution until it detaches from the process. In addition, when running against a live process, a debugger has the ability to actually alter the contents of the memory associated with that process, which can have adverse effects. As a result, it is recommended that the use of a process debugger be restricted to core files and only used to examine live processes under the direction of your authorized support provider.

pfiles / lsof

To examine the set of files that a process is using (including special types of files, like sockets), you can use a tool such as `lsof` on Linux systems. For example:

```
lsof -p {processID}
```

Tracing process execution

If a process is unresponsive but is consuming a nontrivial amount of CPU time, or if a process is consuming significantly more CPU time than is expected, it might be useful to examine the activity of that process in more detail than can be obtained using a point-in-time snapshot. For example, if a process is performing a significant amount of disk reads and/or writes, it can be useful to see which files are being accessed. Similarly, if a process is consistently exiting abnormally, then beginning tracing for that process just before it exits can help provide additional information that cannot be captured in a core file (and if the process is exiting rather than being terminated for an illegal operation, then no core file may be available).

This can be accomplished using the `strace` tool on Linux. For example:

```
strace -f -p {processID}
```

Consult the `strace` manual page for additional information.

Problems with SSL communication

Enable TLS debugging in the server to troubleshoot SSL communication issues:

Copyright © 2025 Ping Identity Corporation

```
$ dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
  --set debug-level:verbose \
  --set include-throwable-cause:true
```

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true \
  --set default-debug-level:disabled
```

In the `java.properties` file, add `-Djavax.net.debug=ssl` to the `start-server` line, and run `bin/dsjavaproperties` to make the option take effect on a scheduled server restart.

Examining network communication

Because the server is a network-based application, it can be valuable to observe the network communication that it has with clients. The server itself can provide details about its interaction with clients by enabling debugging for the protocol or data debug categories, but there can be a number of cases in which it is useful to view information at a much lower level. A network sniffer, like the tcpdump tool on Linux, can be used to accomplish this.

There are many options that can be used with these tools, and their corresponding manual pages will provide a more thorough explanation of their use. However, to perform basic tracing to show the full details of the packets received for communication on port 389 with remote host 1.2.3.4, the following command can be used on Linux:

```
tcpdump -i {interface} -n -XX -s 0 host 1.2.3.4 and port 389
```

It does not appear that the `tcpdump` tool provides support for LDAP parsing. However, it is possible to write capture data to a file rather than displaying information on the terminal (using "`-w {path}`" with `tcpdump`), so that information can be later analyzed with a graphical tool like Wireshark, which provides the ability to interpret LDAP communication on any port.

Note that enabling network tracing generally requires privileges that are not available to normal users and therefore can require root access.

Common problems and potential solutions

This section describes a number of different types of problems that can occur and common potential causes for them.

General troubleshooting methodology

When a problem is detected, the following general methodology to isolate the problem are recommended.

1. Run the `bin/status` tool or look at the server status in the Administrative Console. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts.

Copyright © 2025 Ping Identity Corporation

2. Look in the server logs. In particular, view the following logs:
    - logs/errors
    - logs/failed-ops
    - logs/expensive-ops
3. Use system commands, such as `vmstat` and `iostat` to determine if the server is bottle-necked on a system resource like CPU or disk throughput.
4. For performance problem (especially intermittent ones like spikes in response time), enabling the `periodic-stats-logger` can help to isolate problems, because it stores important server performance information on a per-second basis. The `periodic-stats-logger` can save the information in a csv-formatted file that can be loaded into a spreadsheet. The information this logger makes available is very configurable. You can create multiple loggers for different types of information or a different frequency of logging (for example, hourly data in addition to per-second data). For more information, see "Profiling Server Performance Using the Periodic Stats Logger".
5. For replication problem, run `dsreplication status` and look at the `logs/replication` file.
6. For more advanced users, run the `collect-support-data` tool on the system, unzip the archive somewhere, and look through the collected information. This is often useful when administrators most familiar with the Data Platform do not have direct access to the systems where the production servers are running. They can examine the `collect-support-data` archive on a different server. For more information, see Using the Collect Support Data Tool.

> **Important**
>
> Run the `collect-support-data` tool whenever there is a problem whose cause is not easily identified, so that this information can be passed back to your authorized support provider before corrective action can be taken.

The server will not run setup

If the `setup` tool does not run properly, some of the most common reasons include the following.

A suitable Java environment is not available

The server requires that Java be installed on the system and made available to the server, and it must be installed prior to running `setup` . If the `setup` tool does not detect that a suitable Java environment is available, it will refuse to run.

To ensure that this does not happen, the `setup` tool should be invoked with an explicitly-defined value for the *JAVA_HOME* environment variable that specifies the path to the Java installation that should be used. For example:

```
env JAVA_HOME=/ds/java ./setup
```

If this still does not work for some reason, then it can be that the value specified in the provided *JAVA_HOME* environment variable can be overridden by another environment variable. If that occurs, try the following command, which should override any other environment variables that can be set:

Copyright © 2025 Ping Identity Corporation

```
env UNBOUNDID_JAVA_HOME="/ds/java" UNBOUNDID_JAVA_BIN="" ./setup
```

Oracle Berkeley DB Java Edition is not available

If the version of the server that you are using was not provided with the Oracle Berkeley DB Java Edition library, then it must be manually downloaded and the appropriate JAR file placed in the `lib` directory before running setup. See the `lib/downloading-je.txt` file for instructions on obtaining the appropriate library.

Unexpected arguments provided to the JVM

If the `setup` script attempts to launch the java command with an invalid set of Java arguments, it might prevent the JVM from starting. By default, no special options are provided to the JVM when running setup, but this might not be the case if either the *JAVA_ARGS* or *UNBOUNDID_JAVA_ARGS* environment variable is set. If the `setup` tool displays an error message that indicates that the Java environment could not be started with the provided set of arguments, then invoke the following command before trying to re-run `setup`:

```
unset JAVA_ARGS UNBOUNDID_JAVA_ARGS
```

The server has already been configured or used

The `setup` tool is only intended to provide the initial configuration for the server. It refuses to run if it detects that the `setup` tool has already been run, or if an attempt has been made to start the server prior to running the `setup` tool. This protects an existing server installation from being inadvertently updated in a manner that could harm an existing configuration or data set.

If the server has been previously used and if you want to perform a fresh installation, it is recommended that you first remove the existing installation, create a new one and run `setup` in that new installation. However, if you are confident that there is nothing of value in the existing installation (for example, if a previous attempt to run `setup` failed to complete successfully for some reason but it will refuse to run again), the following steps can be used to allow the `setup` program to run:

- Remove the `config/config.ldif` file and replace it with the `config/update/config.ldif.{revision}` file containing the initial configuration.
- If there are any files or subdirectories below the `db` directory, then remove them.
- If a `config/java.properties` file exists, then remove it.
- If a `lib/setup-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) exists, then remove it.

Copyright © 2025 Ping Identity Corporation

The server will not start

If the server does not start, then there are a number of potential causes.

The server or other administrative tool is already running

Only a single instance of the server can run at any time from the same installation root. If an instance is already running, then subsequent attempts to start the server will fail. Similarly, some other administrative operations can also prevent the server from being started. In such cases, the attempt to start the server should fail with a message like:

```
The Diretory Server could not acquire an exclusive lock on file
/ds/the/locks/server.lock: The exclusive lock requested for file
/ds/the/locks/ server.lock was not granted, which indicates
that another process already holds a shared or exclusive lock on that
file. This generally means that another instance of this server is already
running
```

If the server is not running (and is not in the process of starting up or shutting down) and there are no other tools running that could prevent the server from being started, and the server still believes that it is running, then it is possible that a previously-held lock was not properly released. In that case, you can try removing all of the files in the `locks` directory before attempting to start the server.

If you wish to have multiple instances running at the same time on the same system, then you should create a completely separate installation in another location on the file system.

There is not enough memory available

When the server is started, the JVM attempts to allocate all memory that it has been configured to use. If there is not enough free memory available on the system, then the server generates an error message that indicates that the server could not be started with the specified set of arguments. Note that it is possible that an invalid option was provided to the JVM (as described below), but if that same set of JVM arguments has already been used successfully to run the server, then it is more likely that the system does not have enough memory available.

There are a number of potential causes for this:

- If the amount of memory in the underlying system has changed (for example, system memory has been removed, or if the server is running in a zone or other type of virtualized container and a change has been made to the amount of memory that container will be allowed to use), then the server might need to be re-configured to use a smaller amount of memory than had been previously configured.
- Another process running on the system is consuming a significant amount of memory so that there is not enough free memory available to start the server. If this is the case, then either terminate the other process to make more memory available for the server, or reconfigure the server to reduce the amount of memory that it attempts to use.

Copyright © 2025 Ping Identity Corporation

- The server was just shut down and an attempt was made to immediately restart it. In some cases, if the server is configured to use a significant amount of memory, then it can take a few seconds for all of the memory that had been in use by the server, when it was previously running, to be released back to the operating system. In that case, run the `vmstat` command and wait until the amount of free memory stops growing before attempting to restart the server.
- If the system is configured with one or more memory-backed file systems, verify whether any large files might be consuming a significant amount of memory in any of those locations. If so, remove them or relocate them to a disk-based file system.
- For Linux systems only, if a mismatch exists between the huge pages setting for the JVM and the huge pages reserved in the operating system.

If nothing else works and there is still not enough free memory to allow the JVM to start, then as a last resort, try rebooting the system.

An invalid Java Environment or JVM option was used

If an attempt to start the server fails with an error message indicating that no valid Java environment could be found, or indicates that the Java environment could not be started with the configured set of options, then you should first ensure that enough memory is available on the system as described above. If there is a sufficient amount of memory available, then other causes for this error can include the following:

- The Java installation that was previously used to run the server no longer exists (for example, an updated Java environment was installed and the old installation was removed). In that case, update the `config/java.properties` file to reference to path to the new Java installation and run the `bin/dsjavaproperties` command to apply that change.
- The Java installation used to run the server has been updated and the server is trying to use the correct Java installation but one or more of the options that had worked with the previous Java version no longer work with the new version. In that case, it is recommended that the server be re-configured to use the previous Java version, so that it can be run while investigating which options should be used with the new installation.
- If an *UNBOUNDID_JAVA_HOME* or *UNBOUNDID_JAVA_BIN* environment variable is set, then its value might override the path to the Java installation used to run the server as defined in the `config/java.properties` file. Similarly, if an *UNBOUNDID_JAVA_ARGS* environment variable is set, then its value might override the arguments provided to the JVM. If this is the case, then explicitly unset the *UNBOUNDID_JAVA_HOME*, *UNBOUNDID_JAVA_BIN*, and *UNBOUNDID_JAVA_ARGS* environment variables before trying to start the server.

Note that any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration. If a problem with the previous Java configuration prevents the `bin/dsjavaproperties` tool from running properly, then it can be necessary to remove the `lib/set-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) and invoke the `bin/dsjavaproperties` tool with an explicitly-defined path to the Java environment, like:

```
env UNBOUNDID_JAVA_HOME=/ds/java bin/dsjavaproperties
```

Copyright © 2025 Ping Identity Corporation

An invalid command-line option was provided

There are a small number of arguments that are provided when running the `bin/start-server` command, but in most cases, none are required. If one or more command-line arguments were provided for the `bin/start-server` command and any of them is not recognized, then the server provides an error message indicating that an argument was not recognized and displays version information. In that case, correct or remove the invalid argument and try to start the server again.

The server has an invalid configuration

If a change is made to the server configuration using an officially-supported tool like `dsconfig` or the administrative console, the server should validate that configuration change before applying it. However, it is possible that a configuration change can appear to be valid at the time that it is applied, but does not work as expected when the server is restarted. Alternately, a change in the underlying system can cause a previously-valid configuration to become invalid.

In most cases involving an invalid configuration, the server displays (and writes to the error log) a message that explains the problem, and this can be sufficient to identify the problem and understand what action needs to be taken to correct it. If for some reason the startup failure does not provide enough information to identify the problem with the configuration, then look in the `logs/config-audit.log` file to see what recent configuration changes have been made with the server online, or in the `config/archived-configs` directory to see if there might have been a recent configuration change resulting from a direct change to the configuration file itself that was not made through a supported configuration interface.

If the server does not start as a result of a recent invalid configuration change, then it can be possible to start the server using the configuration that was in place the last time that the server started successfully (for example, the "last known good" configuration). This can be achieved using the `--useLastKnownGoodConfig` option:

```
$ bin/start-server --useLastKnownGoodConfig
```

Note that if it has been a long time since the last time the server was started and a number of configuration changes have been made since that time, then the last known good configuration can be significantly out of date. In such cases, it can be preferable to manually repair the configuration.

If there is no last known good configuration, if the server no longer starts with the last known good configuration, or if the last known good configuration is significantly out of date, then manually update the configuration by editing the `config/config.ldif` file. In that case, you should make sure that the server is offline and that you have made a copy of the existing configuration before beginning. You might wish to discuss the change with your authorized support representative before applying it to ensure that you understand the correct change that needs to be made.

> **Note**
>
> In addition to manually-editing the configuration file, you can look at previous archived configurations to see if the most recent one works. You can also use the **`ldif-diff`** tool to compare the configurations in the archive to the current configuration to see what is different.

Copyright © 2025 Ping Identity Corporation

You do not have sufficient permissions

The server should only be started by the user or role used to initially install the server. In most cases, if an attempt is made to start the server as a user or role other than the one used to create the initial configuration, then the server will fail to start, because the user will not have sufficient permissions to access files owned by the other user, such as database and log files. However, if the server was initially installed as a non-root user and then the server is started by the root account, then it can no longer be possible to start the server as a non-root user because new files that are created would be owned by root and could not be written by other users.

If the server was inadvertently started by root when it is intended to be run by a non-root user, or if you wish to change the user account that should be used to run the server, then it should be sufficient to simply change ownership on all files in the server installation, so that they are owned by the user or role under which the server should run. For example, if the server should be run as the "ds" user in the "other" group, then the following command can be used to accomplish this (invoked by the root user):

```
chown -R ds:other /ds/the
```

The server has crashed or shut itself down

You can first check the current server state by using the `bin/server-state` command. If the PingDirectory server was previously running but is no longer active, then the potential reasons include the following:

- The PingDirectory server was shut down by an administrator. Unless the server was forcefully terminated (for example, using "kill -9"), then messages are written to the `error` and `server.out` logs explaining the reason for the shutdown.
- The PingDirectory server was shut down when the underlying system crashed or was rebooted. If this is the case, then running the `uptime` command on the underlying system shows that it was recently booted.
- The PingDirectory server process was terminated by the underlying operating system for some reason (for example, the out of memory killer on Linux). If this happens, then a message will be written to the system error log.
- The PingDirectory server decided to shut itself down in response to a serious problem that had arisen. At present, this should only occur if the server has detected that the amount of usable disk space has become critically low, or if significant errors have been encountered during processing that left the server without any remaining worker threads to process operations. If this happens, then messages are written to the `error` and `server.out` logs (if disk space is available) to provide the reason for the shutdown.
- The JVM in which the PingDirectory server was running crashed. If this happens, then the JVM should dump a fatal error log (a `hs_err_pid{processID}.log` file) and potentially a core file.

In the event that the operating system itself crashed or terminated the process, then you should work with your operating system vendor to diagnose the underlying problem. If the JVM crashed or the server shut itself down for a reason that is not clear, then contact your authorized support provider for further assistance.

Copyright © 2025 Ping Identity Corporation

Conditions for automatic server shutdown

All PingDirectory servers will shut down in an out of memory condition, a low disk space error state, or for running out of file descriptors. The server will enter lockdown mode on unrecoverable database environment errors, but can be configured to shutdown instead with this setting:

```
$ dsconfig set-global-configuration-prop \
            --set unrecoverable-database-error-mode:initiate-server-shutdown
```

The server won't accept client connections

You can first check the current server state by using the `bin/server-state` command. If the server doesn't appear to be accepting connections from clients, then potential reasons include the following:

- The server isn't running.
- The underlying system on which the server is installed isn't running.
- The server is running but isn't reachable as a result of a network or firewall configuration problem. If that is the case, then connection attempts should time out rather than be rejected.
- If the server is configured to allow secure communication via SSL or StartTLS, then a problem with the key manager and/or trust manager configuration can cause connections to be rejected. If that is the case, then messages should be written to the server access log for each failed connection attempt.
- If the server has been configured with a maximum allowed number of connections, then it can be that the maximum number of allowed client connections are already established. If that is the case, then messages should be written to the server access log for each rejected connection attempt.
- If the server is configured to restrict access based on the address of the client, then messages should be written to the server access log for each rejected connection attempt.
- If a connection handler encounters a significant error, then it can stop listening for new requests. If this occurs, then a message should be written to the server error log with information about the problem. Another solution is to restart the server. A third option is to restart the connection handler using the LDIF connection handler to make it available again. To do this, create an LDIF file that disables and then re-enables the connection handler, create the `config/auto-process-ldif` directory if it doesn't already exist, and then copy the LDIF file into it.

The server is unresponsive

You can first check the current server state by using the `bin/server-state` command. If the server process is running and appears to be accepting connections but does not respond to requests received on those connections, then potential reasons for this behavior include:

Copyright © 2025 Ping Identity Corporation

If it appears that the problem is with the server software or the JVM in which it is running, then you need to work with your authorized support provider to fully diagnose the problem and determine the best course of action to correct it.

- If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available. If this is the case, then a stack trace obtained using the `jstack` command shows that all of the worker threads are busy and none of them are waiting for new requests to process.

  A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the `ldapsearch` command for example, use the `--useAdministrativeSession` option. The requester must have the `use-admin-session` privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

  > **Note**
  >
  > If all of the worker threads are tied up processing the same operation for a long time, the server will also issue an alert that it might be deadlocked, which might not actually be the case. All threads might be tied up processing unindexed searches.

- If a request handler is stuck performing some expensive processing for a client connection, then other requests sent to the server on connections associated with that request handler is forced to wait until the request handler is able to read data on those connections. If this is the case, then only some of the connections can experience this behavior (unless there is only a single request handler, in which it will impact all connections), and stack traces obtained using the `jstack` command shows that a request handler thread is continuously blocked rather than waiting for new requests to arrive. Note that this scenario is a theoretical problem and one that has not appeared in production.
- If the JVM in which the server is running is not properly configured, then it can be forced to spend a significant length of time performing garbage collection, and in severe cases, could cause significant interruptions in the execution of Java code. In such cases, a stack trace obtained from a `pstack` of the native process should show that most threads are idle but at least one thread performing garbage collection is active. It is also likely that one or a small number of CPUs is 100% busy while all other CPUs are mostly idle. The server will also issue an alert after detecting a long JVM pause (due to garbage collection). The alert will include details of the pause.
- If the JVM in which the server is running has hung for some reason, then the `pstack` utility should show that one or more threads are blocked and unable to make progress. In such cases, the system CPUs should be mostly idle.
- If a network or firewall configuration problem arises, then attempts to communicate with the server cannot be received by the server. In that case, a network sniffer like `snoop` or `tcpdump` should show that packets sent to the system on which the server is running are not receiving TCP acknowledgement.
- If the system on which the server is running has become hung or lost power with a graceful shutdown, then the behavior is often similar to that of a network or firewall configuration problem.

Copyright © 2025 Ping Identity Corporation

The server is slow to respond to client requests

If the server is running and does respond to clients, but clients take a long time to receive responses, then the problem can be attributable to a number of potential problems. In these cases, use the Periodic Stats Logger, which is a valuable tool to get per-second monitoring information on the server. The Periodic Stats Logger can save the information in `.csv` format for easy viewing in a spreadsheet. For more information, see *Profiling server performance using the Periodic Stats Logger*. The potential problems that cause slow responses to client requests are as follows:

- The server is not optimally configured for the type of requests being processed, or clients are requesting inefficient operations. If this is the case, then the access log should show that operations are taking a long time to complete and they will likely be unindexed. In that case, updating the server configuration to better suit the requests, or altering the requests to make them more efficient, could help alleviate the problem. In this case, view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second. You can also run the `bin/status` command or view the status in the Administrative Console to see the server's Work Queue information (also see the next bullet point).
- The server is overwhelmed with client requests and has amassed a large backlog of requests in the work queue. This can be the result of a configuration problem (for example, too few worker thread configured), or it can be necessary to provision more systems on which to run the server software. Symptoms of this problem appear similar to those experienced when the server is asked to process inefficient requests, but looking at the details of the requests in the access log show that they are not necessarily inefficient requests. Run the `bin/status` command to view the Work Queue information. If everything is performing well, you should not see a large queue size or a server that is near 100% busy. The %Busy statistic is calculated as the percentage of worker threads that are busy processing operations.

  ```
             --- Work Queue ---
             : Recent : Average : Maximum
  -----------:--------:---------:--------
  Queue Size : 10   : 1       : 10
  % Busy     : 17     : 14      : 100
  ```

  You can also view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second.
- The server is not configured to fully cache all of the data in the server, or the cache is not yet primed. In this case, `iostat` reports a very high disk utilization. This can be resolved by configuring the server to fully cache all data, and to load database contents into memory on startup. If the underlying system does not have enough memory to fully cache the entire data set, then it might not be possible to achieve optimal performance for operations that need data which is not contained in the cache. For more information, see Disk-Bound Deployments.
- If the JVM is not properly configured, then it will need to perform frequent garbage collection and periodically pause execution of the Java code that it is running. In that case, the server error log should report that the server has detected a number of pauses and can include tuning recommendations to help alleviate the problem.
- If the server is configured to use a large percentage of the memory in the system, then it is possible that the system has gotten low on available memory and has begun swapping. In this case, `iostat` should report very high utilization for disks used to hold swap space, and commands like `cat /proc/meminfo` on Linux can report a large amount of swap memory in use. Another cause of swapping is if swappiness is not set to 0 on Linux. For more information, see Disable File System Swapping.

Copyright © 2025 Ping Identity Corporation

- If another process on the system is consuming a significant amount of CPU time, then it can adversely impact the ability of the server to process requests efficiently. Isolating the processes (for example, using processor sets) or separating them onto different systems can help eliminate this problem.

The server returns error responses to client requests

If a large number of client requests are receiving error responses, then view the `logs/failed-ops` log, which is an access log for only failed operations. The potential reasons for the error responses include the following:

- If clients are requesting operations that legitimately should fail (for example, they are targeting entries that do not exist, are attempting to update entries in a way that would violate the server schema, or are performing some other type of inappropriate operation), then the problem is likely with the client and not the server.
- If a portion of the PingDirectory server data is unavailable (for example, because an online LDIF import or restore is in progress), then operations targeting that data will fail. Those problems will be resolved when the backend containing that data is brought back online. During the outage, it might be desirable to update PingDirectoryProxy servers or load balancers or both to route requests away from the affected server. As of PingDirectory version 3.1 or later, the PingDirectory server will indicate that it is in a degraded status and the PingDirectoryProxy server will route around it.
- If the PingDirectory server work queue is configured with a maximum capacity and that capacity has been reached, then the server begins rejecting all new requests until space is available in the work queue. In this case, it might be necessary to alter the server configuration or the client requests or both, so that they can be processed more efficiently, or it might be necessary to add additional server instances to handle some of the workload.
- If an internal error occurs within the server while processing a client request, then the server terminates the connection to the client and logs a message about the problem that occurred. This should not happen under normal circumstances, so you will need to work with your authorized support provider to diagnose and correct the problem.
- If a problem is encountered while interacting with the underlying database (for example, an attempt to read from or write to disk failed because of a disk problem or lack of available disk space), then it can begin returning errors for all attempts to interact with the database until the backend is closed and re-opened and the database has been given a change to recover itself. In these cases, the `je.info.*` file in the database directory should provide information about the nature of the problem.

The server must disconnect a client connection

If a client connection must be disconnected due to the expense of the client's request, such as an unindexed search across a very large database, perform the following:

- Find the client's connection ID by looking in the `cn=Active Operations,cn=monitor monitor` entry.

```
$ bin/ldapsearch -baseDN cn=monitor "cn=active operations" \
  --bindDN "cn=directory manager"  \
  --bindPassword password
```

- The monitor entry will contain attribute values for `operation-in-progress`, which look like an access log message. Look for the value of `conn` in the client request that should be disconnected. In the following example, the client to be disconnected is requesting a search for `(description=expensive)`, which is on connection 6.

Copyright © 2025 Ping Identity Corporation

```
dn: cn=Active Operations,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-active-operations-monitor-entry
objectClass: extensibleObject
cn: Active Operations
num-operations-in-progress: 2
operation-in-progress: [15/Dec/2014:10:55:35 -0600] SEARCH conn=6 op=3 msgID=4
     clientIP="10.8.4.21" authDN="cn=app1,ou=applications,dc=example,dc=com" base="dc
     =example,dc=com" scope=wholeSubtree filter="(description=expensive)" attrs="A
     LL" unindexed=true
operation-in-progress: [15/Dec/2014:10:56:11 -0600] SEARCH conn=7 op=1 msgID=2
     clientIP="127.0.0.1" authDN="cn=Directory Manager,cn=Root DNs,cn=config" base="c
     n=monitor" scope=wholeSubtree filter="(cn=active operations)" attrs="ALL"
     num-persistent-searches-in-progress: 0
```

- With the connection ID value, create a file with the following contents, named `disconnect6.ldif`.

```
dn: ds-task-id=disconnect6,cn=scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-disconnect
ds-task-disconnect-connection-id: 6
ds-task-id: disconnect6
ds-task-class-name: com.unboundid.directory.server.tasks.DisconnectClientTask
```

- This LDIF file represents a task entry. The connection ID value 6 is assigned to `ds-task-disconnect-connection-id`. The value for `ds-task-id` value does not follow a specific convention. It must be unique among other task entries currently cached by the server.
- Disconnect the client and cancel the associated operation by adding the task entry to the server:

```
$ bin/ldapmodify --filename disconnect6.ldif  \
  --defaultAdd --bindDN "cn=directory manager" \
  --bindPassword password
```

The server is experiencing problems with replication

If replication does not appear to be functioning properly, then first check the `dsreplication status` command, which shows all of the servers that are replicating and whether they are back-logged or not. Next, you can check the server error log, replication repair log, and replication monitor entries may provide information about the nature of the underlying problem. Potential reasons that replication may not be functioning as expected include the following:

- Replication has not yet been configured between systems or has been disabled.
- If a server has been offline for a period of time or has fallen far enough behind such that it is missing changes, which are no longer present in any of the replication databases, then that server must be re-initialized with an up-to-date copy of the data from another server.

Copyright © 2025 Ping Identity Corporation

- If the environment is comprised of a heterogeneous set of systems, then it is possible that some of the systems might not be able to keep up with the maximum throughput achieved by other servers in the topology. In such cases, the slower servers might not be fast enough to remain in sync with the other servers in the environment.
- If the environment contains systems in multiple data centers and the network links between the data centers are insufficient for the volume of changes that must be processed, then servers might not be able to remain in sync under a high volume of changes.
- A network or firewall configuration problem has arisen, which prevents or interferes with communication between servers.
- An internal problem within the server has caused replication to stop functioning properly. The PingDirectory server logs the event in the error log in this case. Run the `collect-support-data` tool, so that the details of the problems can be passed to your authorized support provider. Then, try restarting the server.

How to regenerate the server ads-certificate

At setup time, the server generates a private key and certificate for use when secure communication between servers is required. This certificate, `ads-certificate`, is stored in `config/ads-truststore` and should typically remain unchanged for the life of the server deployment. If the need arises for a new ads-certificate to be created, say because the server-root has been copied to a new host, then the private key and certificate will be recreated by the startup process if the `config/ads-truststore` and `config/ads-truststore.pin` files are first manually removed while the server is offline. Note that if replication is enabled, the server must have replication disabled before regeneration of the ads-certificate.

For example, the server allows easy copying of its installation, which can then be used to install another server instance. If a server (ldap1.example.com:389) is enabled with its own copy (ldap2.example.com:389), `dsreplication` will exit with the following error message:

```
Replication cannot be enabled between servers ldap1.example.com:389 and ldap2.example.com:389
because they are using the same instance key.
```

The solution is to stop the server, remove `config/adstruststore` and `config/adstruststore.pin` and re-start the server. Upon startup, a new `adstruststore`, containing the server's instance key, will be generated. Then, you can re-run `dsreplication enable` to set up replication between the two servers.

The server behaves differently from Sun/Oracle

After migrating from a Sun/Oracle configuration to a PingDirectory server, follow the tuning procedures in Configuring the PingDirectory server for Oracle compatibility if the PingDirectory server behaves differently from the Sun/Oracle server.

Troubleshooting ACI evaluation

The server provides the ability to collect debug information related to ACI evaluation for any operation by enabling the Debug ACI Logger. The Debug ACI Logger is highly configurable and can be scoped to trace very specific request operations in order to narrow on any ACI issue that might arise in the field. Parameters for non-request operations, such as `log-connects`, `log-disconnects`, `log-security-negotiation`, `log-results`, `log-assuance-completed`, `log-search-entries`, `log-search-references`, `log-intermediate-responses` are set to `false` by default and should remain so.

Copyright © 2025 Ping Identity Corporation

Here is an example to enable the Debug ACI Logger:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Debug ACI Logger" \
  --set enabled:true
```

Using this debug tracer is often more efficient by limiting the output using request and result criteria to match specific types of operations. An example result criteria for operations that fail due to insufficient access rights can be added to the logger as follows:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Debug ACI Logger" \
  --set "result-criteria:Insufficient Access Rights"
```

Once the logger is enabled, all matching operations begin writing ACI evaluation traces to the log file. The amount of information is quite large for each evaluation that is done. However, this information is useful if there is an ACI issue that is difficult to resolve. Most operations result in multiple "ACI DEBUG" traces in the log, since it usually requires multiple ACI rights to perform an operation, each of which requires a separate evaluation. In particular, you can expect a lot of debug tracing when dealing with ACIs for controls, extended operations, and proxied authorization.

The ACI DEBUG traces contain the following pieces of information:

- Operation. Specifies a dump of the operation object that you can use to correlate to the original request operation.
- ACI Container. Specifies the context of the ACI evaluation being performed.
- Client Entry. Specifies an LDIF dump of the client request access.
- Resource Entry. Specifies an LDIF dump of the target resource.
- isProxiedAuth. Specifies if the client is attempting to proxy as another user.
- Original Auth. Specifies the original client DN if authorization is currently via the proxy.
- Rights. Specifies a list of the ACI rights being requested on the resource entry.
- Control. Specifies the OIDs when evaluating ACIs for a control.
- ExtOp. Specifies the OIDs when evaluating ACIs for an extended operation.
- ACI Canidates. Specifies a list of all the ACIs known to this operation, sorted by origin.
- Applicable ACIs. Specifies a list of ACIs relevant to the current evaluation. These ACIs are separated by type into "Denies" and "Allows".
- Deny ACI Evaluations. Specifies the results of evaluating each "deny" ACI. If any of these evaluate to TRUE, then the operation will be denied.
- Allow ACI Evaluations. Specifies the results of evaluating each "allow" ACI. At least one of these must evaluate to "TRUE" or the operation will be denied.

Copyright © 2025 Ping Identity Corporation

For users with the `bypass-acl` privilege, the Debug ACI Logger will not provide any ACI debug tracing since evaluations are not done for those operations. However, you will see the following trace if you have ACI debugging enabled (`debug-aci-enabled` is set to TRUE) for those operations:

```
Bypassing ACL Evaluation for Operation
```

To avoid unnecessary tracing of these operations, the "Debug ACI Logger" uses a "Client Connection Criteria" called "Clients subject to Access Control" that excludes requests from users with the `bypass-acl` privilege. It is recommended that you create and use your own criteria which specifically targets the clients that you are trying to debug in order to make analyzing the tracing output easier.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Restricted Clients" \
  --type simple \
  --set none-included-user-privilege:bypass-acl
```

Note

Do not use Result Criteria with the Debug ACI Logger. Result criteria is evaluated after ACIs, so it will not be taken into consideration for this type of debugging.

Problems with the administrative console

If a problem arises when trying to use the administrative console, then potential reasons for the problem may include the following:

- The web application container used to host the console is not running. If an error occurs while trying to start it, then consult the logs for the web application container.
- If a problem occurs while trying to authenticate to the web application container, then make sure that the target PingDirectory server is online. If it is online, then the access log may provide information about the reasons for the authentication failure.
- If a problem occurs while attempting to interact with the PingDirectoryProxy server instance using the administrative console, then the access and error logs for that PingDirectory server instance might provide additional information about the underlying problem.

Problems with the administrative console: JVM memory issues

Console runs out of memory (PermGen). An inadequate PermSize setting in the server, while hosting web applications like the Administrative Console may result in errors like this in the error log:

Copyright © 2025 Ping Identity Corporation

```
[02/Mar/2016:07:50:27.017 -0600] threadID=2 category=UTIL
    severity=SEVERE_ERROR msgID=-1 msg="The server experienced an unexpected
    error. Please report this problem and include this log file.
    OutOfMemoryError: PermGen space
    ()\ncom.unboundid.directory.server.core.DirectoryServer.uncaughtException
    (DirectoryServer.java:15783)\njava.lang.ThreadGroup.uncaughtException
    (ThreadGroup.java:1057)\njava.lang.ThreadGroup.uncaughtException
    (ThreadGroup.java:1052)\njava.lang.ThreadGroup.uncaughtException
    (ThreadGroup.java:1052)\njava.lang.Thread.dispatchUncaughtException
    (Thread.java:1986)\nBuild revision: 22496\n"
```

This is only relevant for servers running Java 7.

Problems with the HTTP Connection Handler

When problems with the HTTP Connection Handler occur, first look at the HTTP connection handler log to diagnose the issue. The following section shows HTTP log examples when various errors occur.

- Failed Request Due to a Non-Existent Resource. The server receives a status code 404, which indicates the server could not match the URI.

```
[15/Mar/2012:17:39:39 -0500] RESULT requestID=0 from="10.2.1.113:52958"
method="GET" url="https://10.2.1.113:443/Aleph/Users/uid=user.1,ou=people,
dc=example,dc=com" requestHeader="Host: x2270-11.example.lab"
requestHeader="Accept: / " requestHeader="User-Agent: curl/7.21.6
(i386-pc-centos2.10) libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22
libssh2/1.2.7" authorizationType="Basic" statusCode=404 etime=81.484
responseContentLength=103 responseHeader="Access-Control-Allow-Credentials:true"
responseContentType="application/json"
```

- Failed Request due to a Malformed Request Body. The server receives a status code 400, which indicates that the request had a malformed syntax in its request body.

```
[15/Mar/2012:17:47:23-0500] RESULT requestID=10 from="10.2.1.113:55284"
method="POST" url="https://10.2.1.113:443/Aleph/Users" requestHeader="Host:
x2270-11.example.lab" requestHeader="Expect: 100-continue"
requestHeader="Accept: / " requestHeader="Content-Type: application/json"
requestHeader="User-Agent: curl/ 7.21.6 (i386-pc-centos2.10) libcurl/7.21.6
OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22 libssh2/1.2.7" authorizationType="Basic"
requestContentType="application/json" requestContentLength=5564 statusCode=400
etime=15.272 responseContentLength=133 responseContentType="application/json"
```

- Failed Request due to an unsupported HTTP method. The server receives a status code 405, which indicates that the specified method (e.g., "PATCH") in the request line is not allowed for the resource identified in the URI.

Copyright © 2025 Ping Identity Corporation

```
[15/Mar/2012:17:48:59-0500] RESULT requestID=11 from="10.2.1.113:55763"
method="PATCH" url="https://10.2.1.113:443/Aleph/Users" requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: / " requestHeader="Content-Type:
application/json" requestHeader="User-Agent: curl/7.21.6 (i386-pc-centos2.10)
libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22 libssh2/1.2.7"
authorization-Type="Basic" requestContentType="application/json" statusCode=405
etime=6.807 responseContentLength=0 responseHeader="Allow: POST, GET, OPTIONS, HEAD"
```

- Failed Request due to an Unsupported Media Type. The server receives a status code 415, which indicates that the request entity is in a format that is not supported by the requested resource.

```
[15/Mar/2012:17:44:45-0500] RESULT requestID=4 from="10.2.1.113:54493"
method="POST" url="https://10.2.1.113:443/Aleph/Users" requestHeader="Host:

Virtual process size on RHEL6 Linux is much larger than the heap

Red Hat Linux introduced a change in glib 2.11 that creates larger per-thread address spaces aligned at 64MB. This change results in a virtual process size much larger than those seen in previous versions of `glibc`. This is not considered a bug by RedHat, as noted in https://bugzilla.redhat.com/show_bug.cgi?id=640286, and does not affect the physical memory needed by the server process. To see the version of `glibc` on your system, use the command `yum info glibc`.

Providing information for support cases

If a problem arises that you are unable to fully diagnose and correct on your own, then contact your authorized support provider for assistance. To ensure that the problem can be addressed as quickly as possible, be sure to provide all of the information that the support personnel may need to fully understand the underlying cause by running the `collect-support-data` tool, and then sending the generated zip file to your authorized support provider. It is good practice to run this tool and send the ZIP file to your authorized support provider before any corrective action has taken place.

Copyright © 2025 Ping Identity Corporation

Command-line tools

The server provides a full suite of command-line tools necessary for administration. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

Available command-line tools

Review a list of available command-line tools and their descriptions.

PingDirectory provides the following command-line tools, which you can run in interactive, non-interactive, or script mode.

Tools Help

For	Use this option	Example
Information about arguments and subcommands Usage examples	`--help`	`dsconfig --help`
A list of subcommands	`--help-subcommands`	`dsconfig --help-subcommands`
More information about a subcommand	`--help` with the subcommand	`dsconfig list-log-publishers --help`

Command-Line Tools

`audit-data-security`	Invoke data security audit processing in order to identify potential risks or other notable security characteristics contained in directory data. This tool schedules an internal task with the server that examines all or a subset of entries in the server, writing a series of reports on potential risks with the data. Reports are written to the output directory organized by backend name and audit items. The list of available auditors can be obtained using `dsconfig list-data-security-auditors --advanced --property name`. Either the `--includeAuditor` or the `--excludeAuditor` arguments may be used to limit the scope of the audit. Additionally, the entries scanned can be limited by specifying the backends to scan, or by specifying an LDAP filter that is used to selected entries to be processed. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.

Copyright © 2025 Ping Identity Corporation

`authrate`	Perform repeated authentications against the PingDirectory server, where each authentication consists of a search to find a user followed by a bind to verify the credentials for that user.
`backup`	Back up one or more directory server backends. Each backend backup is stored in a separate backend backup directory. A backend backup directory may contain multiple backups of the backend. Each backend backup directory contains a `backup.info` file providing information about each backup in the directory and an archive file for each backup. The name of the archive file includes both the backend ID and the backup ID. The backup ID may be provided to the backup command, or an ID is generated from a current timestamp. Each backup can be optionally compressed, encrypted, hashed or signed. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the directory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`base64`	Encode raw data using the base64 algorithm or decode base64-encoded data back to its raw representation.
`check-replication-domains`	Scan the `replicationChanges` database for all known replication domains and identify any obsolete replicas still listed as part of a topology. Run this tool before upgrading replicated topologies to help avoid lockdown mode. Learn more about Discovering obsolete replicas.
`collect-support-data`	Collect and package system information useful in troubleshooting problems. The information is packaged as a zip archive that can be sent to a technical support representative. Information collected may include configuration files, server monitor entries, portions of log files, JVM thread stack dumps, system metrics, and other data that may be helpful in diagnosing problems, understanding server performance, or otherwise assisting with support requests. Although the tool will do its best to obscure or omit sensitive data, and the entire archive may be encrypted if you desire, you may wish to review the resulting support data archive to ensure verify its contents. Further, the archive will include a summary of any potential problems or concerns that are identified in the course of collecting the support data.

Copyright © 2025 Ping Identity Corporation

`config-diff`	Compares directory server configurations and produces a `dsconfig` batch file needed to bring the source inline with the target. Its uses include comparing multiple servers for configuration differences, producing a batch file to reconfigure a server from scratch from the out-of-the-box configuration, and comparing a local server against an expected configuration. Both the source and the target configurations can be retrieved over LDAP, accessed from the local server's file system, extracted from a specific file, or retrieved from every server in a configuration server group. Also, with the exception of accessing a configuration from a specific file, the source and/or target configurations can be compared as they existed at any point in the past, including the baseline, pre-installation configuration. Some configuration differences (those that will always differ between instances, like instance-name) are excluded by default to reduce the amount of spurious output, but these can be included by specifying the `--includeExpectedDifferences` command. Further differences can be excluded with the `--exclude` option. This tool attempts to generate a batch file that can be applied to the source server without any errors. However, there are some edge case configurations that the tool is not sophisticated enough to handle. For example, it cannot handle two peer configuration objects that would require swapping values for a property (for example, evaluation-order-index) that must be unique within the server. It will still generate a `dsconfig` batch file that includes these changes, but they might be rejected by the server. In these rare cases, the batch file can be hand edited so that it can be applied to a running server or it can be applied with the server shut down using `dsconfig --offline`.
`create-rc-script`	Create a Run Control (RC) script that you can use to start, stop, and restart the PingDirectory server on UNIX-based systems.
`create-systemd-script`	Create a systemd script to start and stop the PingDirectory server on Linux-based systems. Each local DB backend has a root container, identified by backend ID. Each root container has an entry container for each base DN in the backend, identified by base DN. Each entry container has a number of database containers that store entries, attribute indexes and system indexes. The dbtest command allows the contents of root containers, entry containers and database containers to be inspected.
`dbtest`	Inspect the contents of the PingDirectory server local DB backends that store their information in Berkeley DB Java Edition databases. Only backends of type local DB can be inspected by this tool. Each local DB backend has a root container, identified by backend ID. Each root container has an entry container for each base DN in the backend, identified by base DN. Each entry container has a number of database containers that store entries, attribute indexes and system indexes. The `dbtest` command allows the contents of root containers, entry containers and database containers to be inspected.

Copyright © 2025 Ping Identity Corporation

`deliver-one-time-password`	Generate and deliver a one-time password to a user through some out-of-band mechanism. That password can then be used to authenticate via the UNBOUNDID-DELIVERED-OTP SASL mechanism.
`deliver-password-reset-token`	Generate and deliver a single-use token to a user through some out-of-band mechanism. The user can provide that token to the password modify extended request in lieu of the user's current password in order to select a new password.
`dsconfig`	View and edit the PingDirectory server configuration. This utility offers three primary modes of operation, the interactive mode, the non-interactive mode and batch mode. The interactive mode supports viewing and editing the configuration via an intuitive, menu driven environment. Running `dsconfig` in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the server. To start `dsconfig` in interactive command-line mode, simply invoke the `dsconfig` shell script or batch file without any arguments. The `dsconfig` non-interactive command-line mode provides a simple way to make arbitrary changes to the PingDirectory server by invoking it on the command-line. If you want to use administrative scripts to automate the configuration process, then run the `dsconfig` command in non-interactive mode. The `dsconfig` tool provides a batching mechanism that reads multiple `dsconfig` invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting in that it minimizes LDAP connections and JVM invocations that normally occur with each `dsconfig` call. You can view the `logs/config-audit.log` file to review the configuration changes made to the PingDirectory server and use them in the batch file.

Copyright © 2025 Ping Identity Corporation

`dsjavaproperties`	Configure the JVM arguments used to run the PingDirectory server and associated tools. The options managed by this tool are stored in `config/java.properties`. Typically you should not edit that file directly but rather run this tool specifying `--jvmTuningParameter` arguments to customize JVM options appropriate for this system. It is necessary however that this tool be run in the event that `config/java.properties` must be edited by hand. Note that the changes will only apply to this PingDirectory server installation. No modifications will be made to your environment variables. Memory and other settings for the tool JVMs including the start-server tool can be tuned during initialization by specifying one or more instances of the `--jvmTuningParameter` option when invoking this tool. Supported values are as follows: • `NONE` Explicitly specify no parameters • `AGGRESSIVE` This system is dedicated to running only this server. The amount of memory allocated to this server will be computed accordingly • `SEMI_AGGRESSIVE` This system is shared by multiple server processes. The amount of memory allocated to this server will be computed accordingly If no parameters are specified the parameters specified by the previous invocation of this tool or setup will be used. Use the `NONE` option to explicitly specify no parameters.
`dsreplication`	Manage data replication between two or more PingDirectory server instances. For replication to work, you must first enable replication using the `enable` option. Then, you initialize the contents of one of the servers with the contents of the other using the 'initialize' subcommand.
`dump-dns`	Obtain a listing of all of the DNs for all entries below a specified base DN in the PingDirectory server.
`encode-password`	Encode user passwords with a specified storage scheme or determine whether a given clear-text value matches a provided encoded password.
`encrypt-file`	Encrypt or decrypt data using a key generated from a user-supplied passphrase, a key generated from an encryption settings definition, or a key shared among servers in the topology. The data to be processed can be read from a file or standard input, and the resulting data can be written to a file or standard output. You can use this command to encrypt and subsequently decrypt arbitrary data, or to decrypt encrypted backups, LDIF exports, and log files generated by the server.
`encryption-settings`	Manage the server encryption settings database. More information about the cipher algorithms and transformations available for use may be found in the Java Cryptography Architecture Reference Guide, as well as the Standard Algorithm Name Documentation for your chosen JDK implementation used by this server.

Copyright © 2025 Ping Identity Corporation

`enter-lockdown-mode`	Request that the PingDirectory server enter lockdown mode, during which it only processes operations requested by users holding the `lockdown-mode` privilege. While in lockdown mode, the PingDirectory server rejects all requests from users that do not hold the lockdown-mode privilege.
`export-ldif`	Export data from the PingDirectory server backend in LDIF form. To export data from a remote PingDirectory server, the server must be running and connection parameters must be supplied. You can specify options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The data may be appended to an existing file instead of overwriting it, and the output may be optionally compressed. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`export-reversible-passwords`	Requests that the server export entries from a specified backend in LDIF form, including clear-text representations of any passwords encoded with a reversible storage scheme. Include the following arguments to configure the output of the tool: **`--filter`** The export only includes entries matching the specified filter. **`--exportNonReversiblePasswords`** The export includes entries with non-reversible passwords. **`--exportEntriesWithoutPasswords`** The export includes entries that don't have passwords. **`--includeAdditionalAttribute`** The exported entries include the specified attribute(s) in addition to the user's DN and password. You can use `"*"` to include all user attributes and `"+"` to include all operational attributes. **`--includeVirtualAttributes`** The exported entries include the values of virtual attributes in addition to real attributes. This tool can only be used over a secure connection and when authenticated as a user with the `permit-export-reversible-passwords` privilege. The server encrypts the output using a key generated from either a user-supplied passphrase or an encryption settings definition.

Copyright © 2025 Ping Identity Corporation

`extract-data-recovery-log-changes`	Extract changes matching a given set of criteria from a PingDirectory server audit log so that they can be replayed (for example, as part of a disaster recovery process) or reverted (for example, to back out changes made in error). This tool is designed to be used in conjunction with the server's data recovery log files (in the logs/data-recovery directory). It may be used in conjunction with other audit log files, but for best results, the logger should be configured to operate in reversible form, to include the requester DN and IP address, and to include information about any intermediate client control that may have been provided in the request. This tool must not be used with a log file that the server may update while the tool is running, or that may have some content stored in an unwritten buffer (which is especially likely if the log is compressed or encrypted). To use this tool with the server online, you should only specify a log file that has already been rotated to ensure that no more writes will be made to that file. If necessary, you may use the rotate-log tool to force the current active file to be rotated. To use this tool to revert an inappropriate set of changes, run it with '--direction revert' and an additional set of arguments that identify which changes should be reverted (for example, based on the address of the client, the authorization DN of the requester, the time frame in which the changes were applied, etc.). To use this tool to replay changes that were previously applied (for example, after restoring an old backup or importing an old LDIF file), run it with `--direction replay` and an appropriate set of arguments to select the desired set of changes. Also, make sure to use `dsreplication pre-external-initialization` before performing the restore or import and applying the changes, and then use `dsreplication post-external-initialization` after the changes have been applied. See the PingDirectory Server Administration Guide for additional information. This tool will extract changes from the selected log file (and any previously rotated files, unless the --doNotFollowRotationChain argument is provided) and output them in LDIF change format. If the `--outputFile` argument is provided, then the changes will be written to that file; otherwise, they will be written to standard output. If changes are to be written to a file, then the output will be compressed if the input files were compressed (unless the `--doNotCompressOutput` argument was provided), and the output will be encrypted if the input files were encrypted (unless `--doNotEncryptOutput` was provided). You may wish to first run the tool without specifying an output file so that you can verify that the selected changes are correct. Once you are certain that the appropriate changes have been selected, then you can use a tool like `ldapmodify` or `parallel-update` to apply those changes to the server.
`generate-totp-shared-secret`	Generate a shared secret that you can use to generate time-based one-time password (TOTP) authentication codes for use in authenticating with the UNBOUNDID-TOTP SASL mechanism or with the validate TOTP password extended operation.
`identify-references-to-missing-entries`	This tool may be used to identify entries containing one or more attributes which reference entries that do not exist. This may require the ability to perform unindexed searches and/or the ability to use the simple paged results control.

Copyright © 2025 Ping Identity Corporation

`identify-unique-attribute-conflicts`	This tool may be used to identify unique attribute conflicts. That is, it may identify values of one or more attributes which are supposed to exist only in a single entry but are found in multiple entries.
`import-ldif`	Import LDIF data into a PingDirectory server backend. Connection parameters are not required when importing to a local PingDirectory server that is not running. However, connection parameters are required if the server is remote, or if it is running locally and it is inconvenient to have to stop it for the import. You can use the options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The input file may be compressed. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`indent-ldap-filter`	Parse a provided LDAP filter string and display it a multiline form that makes it easier to understand its hierarchy and embedded components. If possible, it might also simplify the provided filter in certain ways (for example, by removing unnecessary levels of hierarchy, like an AND embedded in an AND).
`ldap-debugger`	Intercept and decode LDAP communication.

Copyright © 2025 Ping Identity Corporation

`ldap-diff`	**Compare the contents of two LDAP servers.** **The `ldap-diff` tool outputs the difference between data stored in two LDAP servers into an LDIF file. This file could be used with the `ldapmodify` command to bring the source directory server in sync with the target directory server. The specific entries to compare can be controlled with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. Specific attributes can also be excluded by prepending a `^` character to the attribute. On Windows operating systems, excluded attributes must be quoted, for example, `"^attrToExclude"`. When retrieving entries from a PingDirectory server, the @objectClassName notation can be used to compare only attributes that are defined for a given objectclass.** **This command can be used on servers actively being modified, without reporting false positives due to replication delays, by checking differing entries multiple times. By default, it will re-check each differing entry twice, pausing two seconds between checks. These settings can be configured with the `--numPasses` and `--secondsBetweenPass` options. The output is formatted so that delete operations come first, modify operations come next, and add operations come last. This gives the best chance that the resulting output file can be used to bring the source server into sync with the target server without causing any conflicts. This takes into account attribute uniqueness constraints as well as that child entries must be deleted before parents and parents must be added before children.** **The directory user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the PingDirectory server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry:** • `ds-cfg-default-root-privilege-name: unindexed-search` • `ds-cfg-default-root-privilege-name: bypass-acl` • `ds-rlim-size-limit: 0` • `ds-rlim-time-limit: 0` • `ds-rlim-idle-time-limit: 0` • `ds-rlim-lookthrough-limit: 0` **For servers from other vendors, consult their documentation for configuring the proper privileges.** **The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For directories that contain tens of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by `ldap-diff` can be customized by editing the `ldap-diff.java-args` setting in the `config/java.properties` file and running the `dsjavaproperties` command.**

Copyright © 2025 Ping Identity Corporation

`ldap-result-code`	Display and query LDAP result codes. This tool may be used to list all known defined LDAP result codes, retrieve the name of the result code with a given integer value, or search for all result codes with names containing a given substring. At most one of the `--list`, `--int-value`, and `--search` arguments may be provided. If none of them is provided, then the --list option will be chosen by default.
`ldapcompare`	Perform compare operations in an LDAP PingDirectory server. Compare operations can be used to efficiently determine whether a specified entry has a given value. The exit code for this tool will indicate whether processing was successful or unsuccessful, and to provide a basic indication of the reason for unsuccessful attempts. By default, it will use an exit code of zero (which corresponds to the LDAP 'success' result) if all compare operations completed with a result code of either 'compare false' or 'compare true' (integer values 5 and 6, respectively), but if the `--useCompareResultCodeAsExitCode` argument is provided, only one compare assertion is performed, and it yields an exit code of 'compare false' or 'compare true', then the numeric value for that result code will be used as the exit code. If any error occurs during processing, then the exit code will be a nonzero value that reflects the first error result that was encountered. The attribute type and assertion value to use for the compare operations will typically be provided as the first unnamed trailing argument provided on the command line. It should be formatted with the name or OID of the target attribute type followed by a single colon and the string representation of the assertion value. Alternatively, the attribute name or OID may be followed by two colons and the base64-encoded representation of the assertion value, or it may be followed by a colon and a less-than symbol to indicate that the assertion value should be read from a file (in which case the exact bytes of the file, including line breaks, will be used as the assertion value). The DNs of the entries to compare may either be provided on the command line as additional unnamed trailing arguments after the provided attribute-value assertion, or they may be read from a file whose path is provided using the --dnFile argument. If the attribute-value assertion is provided on the command line as an unnamed trailing argument, then the same assertion will be performed for all operations. If multiple types of assertions should be performed, then you may use the `--assertionFile` argument to specify the path to a file containing both attribute-value assertions and entry DNs.
`ldapdelete`	Apply a set of add, delete, modify, and/or modify DN operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the `ldifFile` argument. Change records must be separated by at least one blank line.
`ldapmodify`	Apply a set of add, delete, modify, and/or modify DN operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the `ldifFile` argument. Change records must be separated by at least one blank line.

Copyright © 2025 Ping Identity Corporation

`ldappasswordmodify`	Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in RFC 3062), a standard LDAP modify operation, or an Active Directory-specific modification. Unless the password change method is explicitly specified (using the --passwordChangeMethod argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password change method will be selected, using a regular LDAP modify to update the unicodePwd attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute. Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in RFC 3062), a standard LDAP modify operation, or an Active Directory-specific modification. Unless the password change method is explicitly specified (using the --passwordChangeMethod argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password change method will be selected, using a regular LDAP modify to update the unicodePwd attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute. The new password to set for the user may be specified in one of several ways. It may be directly provided on the command line, read from a specified file, interactively prompted from the user, or automatically generated by this tool. If the new password is not specified using any of those methods, and if the password is to be updated using the password modify extended operation, then the new password field of the request will be left blank to indicate that the server should generate a new password for the user and include it in the response to the client. If no new password is specified and some other password change method is selected, then the tool will exit with an error. The current password for the user may also be specified. This is optional, although some servers may require a user to provide their current password when setting a new one. If a current password is provided (whether given as a command-line argument, read from a specified file, or interactively requested from the user), and if a regular LDAP modify operation is used to change the password, then the resulting modify request will include a delete of the current value and an add of the new value. If no current password is provided, then the modify request will replace any existing password(s) with the new value.

Copyright © 2025 Ping Identity Corporation

`ldapsearch`	Process one or more searches in an LDAP directory server. The criteria for the search request can be specified in a number of different ways, including providing all of the details directly via command-line arguments, providing all of the arguments except the filter via command-line arguments and specifying a file that holds the filters to use, or specifying a file that includes a set of LDAP URLs with the base DN, scope, filter, and attributes to return.
`ldif-diff`	Compare the contents of two files containing LDIF entries. The output will be an LDIF file containing the add, delete, and modify change records needed to convert the data in the source LDIF file into the data in the target LDIF file. This tool works best with small LDIF files because it reads the entire contents of the source and target LDIF files into memory so they can be quickly compared. If you encounter an out of memory error while running the tool, you may need to increase the amount of memory available to the JVM used to invoke it. The amount of memory available to the JVM may be customized by invoking the JVM with the `-Xms` and `-Xmx` arguments (which specify the initial and maximum amounts of memory that it may use, respectively). These arguments should be immediately followed (without any intervening space) by an integer and a unit to specify the amount of memory that may be used. The unit may be either `m` to indicate that the size is in megabytes, or `g` to indicate that it is in gigabytes. For example, `-Xms512m` indicates that the JVM should be given an initial heap size of 512 megabytes, while `-Xmx2g` indicates that it should be given a maximum heap size of two gigabytes. When invoking the `ldif-diff` tool included in the installation of a Ping Identity server product, you may edit the `config/java.properties` file to specify the arguments to use when invoking the JVM. After modifying the file, run the `dsjavaproperties` tool to ensure that those changes will be used for subsequent tool invocations.

Copyright © 2025 Ping Identity Corporation

`ldifmodify`	Apply a set of changes (including add, delete, modify, and modify DN operations) to a set of entries contained in an LDIF file. The changes will be read from a second file (containing change records rather than entries), and the updated entries will be written to a third LDIF file. Unlike `ldapmodify`, the `ldifmodify` command cannot read the changes to apply from standard input. All of the change records will be read into memory before processing begins, so it is important to ensure that the tool is given enough memory to hold those change records. However, it will only operate on a single source entry at a time, so the size of the source LDIF file does not significantly impact the amount of memory that the tool requires. Note that the tool will attempt to correctly handle multiple changes affecting the same entry. However, because it only operates on one entry at a time, it cannot always behave in exactly the same way as if it were applying the changes over LDAP to a server populated with the source LDIF file. For example, it is not possible to reject an attempt to delete an entry that has subordinates, so any delete will be treated as a subtree delete. Further, not all types of modify DN change records are supported. In particular, modify DN change records are not permitted if they target any entry that has been targeted by a previous change record (for example, renaming an entry that was created by a previous add change record). Finally, it cannot perform other types of validation, like ensuring that all of the necessary superior entries exist when adding a new entry, or ensuring that a modify DN will not introduce a conflict with an existing entry.
`ldifsearch`	Search one or more LDIF files to identify entries matching a given set of criteria.
`leave-lockdown-mode`	Request that the PingDirectory server leave lockdown mode and resume normal operation. While in lockdown mode, the PingDirectory server rejects all requests from users that do not hold the lockdown-mode privilege. Note that the PingDirectory server may place itself in lockdown mode under certain conditions (for example, if it detects a security problem like a malformed access control rule that may have otherwise resulted in exposure of sensitive data).
`list-backends`	List the backends and base DNs configured in the PingDirectory server.
`load-ldap-schema-file`	Loads the schema definitions contained in a specified LDIF file into the schema for a running server. This tool may only be used in conjunction with a server instance running on the local system.
`make-ldif`	Generate LDIF data based on a definition in a template file. See the server's `config/MakeLDIF` directory for example template files. In particular, the `examples-of-all-tags.template` file shows how to use all of the tags for generating values.

Copyright © 2025 Ping Identity Corporation

`manage-account`	Retrieve or update information about the current state of a user account. Processing will be performed using the password policy state extended operation, and you must have the password-reset privilege to use this extended operation.
`manage-certificates`	Manage certificates and private keys in a JKS, PKCS #12, PKCS #11, or BCFKS key store.
`manage-extension`	Install or update PingDirectory server extension bundles. An extension bundle is a package of extension(s) that utilize the Server SDK to extend the functionality of the PingDirectory server. Extension bundles are installed from a zip archive or file system directory. The server will be restarted if running to activate the extension(s).
`manage-profile`	Generate, compare, install, and replace server profiles. Server profiles define a format for the configuration of a server, including `dsconfig`, initial DIT, setup arguments, server SDK extensions, and other files. These are combined into one concrete structure. This tool provides subcommands that can be used to generate a new profile from an existing server, to set up a new server, and to replace an existing server's profile with a different profile. A template server profile file structure can be found in the resource/ directory.
`manage-tasks`	Access information about pending, running, and completed tasks scheduled in the PingDirectory server.
`manage-topology`	Tool to manage the topology registry. The topology registry is a branch of the configuration DIT (cn=Topology,cn=config). It stores all metadata about server instances, including their instance and listener certificates, secret keys, server groups and administrative user accounts. In addition, it also stores information about the replication topology (replication server ID and replication domain ID) when replication is enabled among servers in a Directory topology. Last but not least, it stores the license key required to install the server. Changes to the topology registry on one server are automatically mirrored to other servers in the topology. The `dsconfig` tool, configuration API or the management console may be used to make changes to the topology registry. This tool allows some additional capability such as exporting the contents of the registry as a JSON file.
`migrate-ldap-schema`	Migrate schema information from an existing LDAP server into a PingDirectory server instance. This tool may be used to migrate schema information from an existing LDAP server into this PingDirectory server instance. The source server may be any standards-compliant LDAPv3 server. All attribute type and objectclass definitions which are contained in the source LDAP server but not in the target PingDirectory server instance will be either added to the target instance or written to a schema file.

Copyright © 2025 Ping Identity Corporation

`migrate-sun-ds-config`	Update an instance of the PingDirectory server to match the configuration of an existing Sun Java System Directory Server 5.x, 6.x, or 7.x. This tool may be used to compare the configuration of Sun Java System Directory Server 5.x, 6.x, or 7.x and PingDirectory server instances in order to identify any differences and update the PingDirectory server configuration to more closely match that of the Sun server instance.
`modrate`	Perform repeated modifications against an LDAP directory server.
`move-subtree`	Move all entries in a specified subtree from one server to another.
`oid-lookup`	Search the OID registry to retrieve information about items that match a given OID or name. The string to use to search the OID registry should be provided as an unnamed trailing argument. All items in the OID registry will be examined, and any items that contain the provided string in its OID, name, type, origin, or URL will be matched. If no search string is provided, the entire OID registry will be displayed.
`parallel-update`	Use multiple concurrent threads to apply a set of add, delete, modify, and modify DN operations read from an LDIF file. As with other tools like `ldapmodify`, changes in the LDIF file to be processed should be ordered such that if there are any dependencies between changes (for example, if one add change record creates a parent entry and another add change record creates a child of that parent), prerequisite changes come before the changes that depend on them. When this tool is preparing to process a change, it will determine whether the new change depends on any other changes that are currently in progress, and if so, will delay processing that change until its dependencies have been satisfied. If a change does not depend on any other changes that are currently being processed, then it can be processed in parallel with those changes. This tool will keep track of any changes that fail in a way that indicates they succeed if re-tried later (for example, an attempt to add an entry that fails because its parent does not exist, but its parent may be created later in the set of LDIF changes), and can optionally re-try those changes after processing is complete. Any changes that are not retried, as well as changes that still fail after the retry attempts, will be written to a rejects file with information about the reason for the failure so that an administrator can take any necessary further action upon them.

Copyright © 2025 Ping Identity Corporation

`populate-composed-attribute-values`	Populate entries in one or more backends with attribute values generated by one or more composed attribute plugins. This tool uses the configuration from a specified set of composed attribute plugin instances to identify which entries to update and what changes to apply. It may be used as an alternative to exporting the data to LDIF and re-importing to ensure that existing entries have an appropriate set of composed attribute values. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`profile-viewer`	View information in data files captured by the PingDirectory server profiler. Profiler data files are generated by the Profiler plugin. To create these data files, set the profile-action attribute of the Profiler configuration object to 'start' to begin collection. Set the `profile-action` attribute to `stop` to end collection and have the plugin write the file to `logs/profile`.{timestamp}.
`re-encode-entries`	Re-encode all or a specified portion of the entries in a local DB backend. This tool may be used to initiate a task that will cause a local DB backend to re-encode all or a specified subset of the entries that it contains. The contents of the entries will not be altered, but this provides a useful mechanism for applying significant changes to the way that entries are actually stored in the backend (for example, to apply encoding changes if a feature like data encryption or uncached attributes or entries is enabled). This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.

Copyright © 2025 Ping Identity Corporation

`rebuild-index`	Rebuild index data within a backend based on the Berkeley DB Java Edition. Note that this tool uses different approaches to rebuilding indexes based on whether it is running in online mode (as a task) rather than with the server offline. Running in offline mode will often provide significantly better performance and require significantly less database cleaning, particularly for indexes containing keys that match a large number of entries and have high index entry limit and exploded index entry threshold values. Also note that rebuilding an index with the server online will prevent the server from using that index while the rebuild is in progress, so some searches may behave differently while a rebuild is active than when it is not. An index must be rebuilt if the database already contains data when the index is configured. The backend containing the provided base DN must be a local DB backend. The types of indexes that can be rebuilt include attribute indexes, VLV indexes, and JSON field indexes. **Note** PingDirectory does not support the rebuilding of system indexes, regardless of whether the rebuild is attempted online or offline. If you need to rebuild a system index, you must export the backend to LDIF and re-import it. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`register-yubikey-otp-device`	Registers a YubiKey OTP device with the PingDirectory server for a specified user so that the device may be used to authenticate that user in conjunction with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. Alternately, it may be used to deregister one or more YubiKey OTP devices for a user so that they may no longer be used to authenticate that user.
`reload-http-connection-handler-certificates`	Reload HTTPS Connection Handler certificates. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.

Copyright © 2025 Ping Identity Corporation

`remove-attribute-type-from-schema`	Safely remove an attribute type definition from the server schema. The tool will perform an appropriate set of validation before actually removing the attribute type from the schema. The below conditions must be satisfied before the attribute type may be removed. • The requester must have the update-schema privilege. • The attribute type must not be referenced by any other schema element. • The attribute type must not be defined in any schema file that is included with the PingDirectory server. Only custom attribute types may be removed from the schema. • The attribute type must not be referenced in the server configuration (for example, it must not be indexed by any backend). • The attribute type must not be present in any entry that exists in any backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
remove-backup	Safely remove a backup from the specified PingDirectory server backend. This tool deletes the specified backup archive and updates the backup descriptor accordingly. As an alternative to removing a specific backup, you can automatically remove backups outside of specified count or age criteria. The `--retainFullBackupCount` argument can be used to indicate that the specified number of full backups should be retained, and any other full backups in the directory are eligible to be removed. The `--retainFullBackupAge` argument can be used to indicate that any full backups older than the specified age are eligible to be removed.
`remove-defunct-server`	Remove a server from this server's topology. This tool will remove the specified server from the topology. In general, the `uninstall` tool should be used to remove a server from the topology. The `remove-defunct-server` tool should only be used if a prior attempt to uninstall a server was unsuccessful or the system where the server was installed is no longer available, leaving the server permanently inaccessible from the topology. If the defunct server is online and is able to reach other servers in the topology, running remove-defunct-server from it will cleanly remove it from the topology. If it cannot reach the other servers, then remove-defunct-server must also be run from one of the online servers.

Copyright © 2025 Ping Identity Corporation

`remove-object-class-from-schema`	Safely remove an object class definition from the server schema. The tool will perform an appropriate set of validation before actually removing the object class from the schema. The below conditions must be satisfied before the object class may be removed. • The requester must have the update-schema privilege. • The object class must not be referenced by any other schema element. • The object class must not be defined in any schema file that is included with the PingDirectory server. Only custom object classes may be removed from the schema. • The object class must not be referenced in the server configuration. • The object class must not be present in any entry that exists in any backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`replace-certificate`	Replace the listener certificate for this PingDirectory server instance.
`restore`	Restore a backup of a PingDirectory server backend. Only one backend may be restored at a time by the restore command. The PingDirectory server should be stopped unless task connection options are supplied for a running server. You can list the backups contained in a particular backend backup directory. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`revert-update`	Revert this server package's most recent update.
`review-license`	Review and/or indicate your acceptance of the license agreement defined in `legal/LICENSE.txt`.

Copyright © 2025 Ping Identity Corporation

`rotate-log`	Trigger the rotation of one or more log files. If the file argument is provided one or more times to specify the target log file paths, then only those log files will be rotated. If the file argument is not given, then the server will trigger rotation for all supported log files. You must have the config-read and config-write privileges to run this tool, and you must have the necessary access control rights to create and monitor entries in the task backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`sanitize-log`	Sanitize the contents of a server log file to remove potentially sensitive information while still attempting to retain enough information to make it useful for diagnosing problems or understanding load patterns. The sanitization process operates on fields that consist of name-value pairs. The field name is always preserved, but field values might be tokenized or redacted if they might include sensitive information. Supported log file types include the file-based access, error, sync, and resync logs, as well as the operation timing access log and the detailed HTTP operation log. Sanitize the audit log using the `scramble-ldif` tool.
`schedule-exec-task`	Schedule an exec task to run a specified command in the server. To run an exec task, a number of conditions must be satisfied: the server's global configuration must have been updated to include `com.unboundid.directory.server.tasks.ExecTask` in the set of allowed-task values, the requester must have the `exec-task` privilege, and the command to execute must be listed in the `exec-command-whitelist.txt` file in the server's `config` directory. The absolute path (on the server system) of the command to execute must be specified as the first unnamed trailing argument to this program, and the arguments to provide to that command (if any) should be specified as the remaining trailing arguments. The server root is used as the command's working directory, so any arguments that represent relative paths are interpreted as relative to that directory.
`search-and-mod-rate`	Perform repeated searches against an LDAP directory server and modify each entry returned.
`search-logs`	Search across log files to extract lines matching the provided patterns, like the `grep` command-line tool. The benefits of using this tool over `grep` are its ability to handle multiline log messages, extract log messages within a given time range, and the inclusion of rotated log files.
`searchrate`	Perform repeated searches against an LDAP directory server.
`server-state`	View information about the current state of the PingDirectory server process.
`set-delegated-admin-aci`	Request that the PingDirectory server assign appropriate ACI for configured delegated administrators of the Delegated Admin API.

Copyright © 2025 Ping Identity Corporation

`setup`	Perform the initial setup for a server instance. This tool features both interactive and non-interactive modes for accepting the product license terms and initially configuring a server instance.
`start-server`	Start the PingDirectory server.
`status`	Display basic server information. This tool prints information about the server, such as version, connection handlers, and data sources. Some information may not be available if the server is not running, or if authentication credentials are missing or do not have sufficient privileges, or if the invoking user does not have sufficient file system access rights.
`stop-server`	Stop or restart the server. This tool is used to stop or restart the local instance of the server (by omitting LDAP connection options), or a remote server (by interacting with it over LDAP). In addition, this tool is used to schedule the server for shutdown at a later time using the server's task interface.
`subtree-accessibility`	List or update the set of subtree accessibility restrictions defined in the PingDirectory server.
`sum-file-sizes`	Calculate the sum of the sizes for a set of files. This tool is used to find the sum of the sizes of one or more files. If any of the files specified is a directory then it will be recursively processed.
`summarize-access-log`	Examine one or more access log files to display a number of metrics about operations processed within the server.
`transform-ldif`	Apply one or more changes to entries or change records read from an LDIF file, writing the updating records to a new file. This tool can apply a variety of transformations, including scrambling attribute values, redacting attribute values, excluding attributes or entries, replacing existing attributes, adding new attributes, renaming attributes, and moving entries from one subtree to another.
`uninstall`	Uninstall the PingDirectory server. This tool removes the entire server or individual server components from the file system. If this server is a member of a replication topology, you must first remove references to this server in the other servers using the `dsreplication disable` command.
`update`	Update a deployed server so its version matches the version of this package.

Copyright © 2025 Ping Identity Corporation

`validate-acis`	This tool may be used to validate a set of access control definitions contained in an LDAP server (including Sun/Oracle DSEE instances) or an LDIF file to determine whether they are acceptable for use in the PingDirectory server. Note that output generated by this tool will be LDIF, but each entry in the output will have exactly one ACI, so entries which have more than one ACI will appear multiple times in the output with different ACI values.
`validate-file-signature`	Validate file signatures. For best results, file signatures should be validated by the same instance used to generate the file. However, it might be possible to validate signatures generated on other instances in a replicated topology.
`validate-ldap-schema`	Validate an LDAP schema read from one or more LDIF files.
`validate-ldif`	Validate the contents of an LDIF file against the server schema.
`verify-index`	Verify that indexes in a backend using the Berkeley DB Java Edition are consistent with the entry data contained in the database.
`watch-entry`	Launch a window to watch an LDAP entry for changes. If the entry changes, the background of modified attributes will temporarily be red. Attributes can be modified as well. This tool is primarily intended to demonstrate replication or synchronization functionality.

Saving options in a file

The PingDirectory server supports the use of a tools properties file (`config/tools.properties`) to simplify command-line invocations by reading in a set of options for each tool from a text file.

Properties files are convenient when quickly testing the PingDirectory server in multiple environments.

Each property takes the form of a name-value pair that defines predetermined values for a tool's options.

The PingDirectory server supports the following types of properties:

- Default properties that apply to all command-line utilities
- Tool-specific properties

Creating a tools properties file

You can set properties that apply to all tools or are tool-specific. These properties serve as defaults for the command-line options they represent.

Steps

1. Use a text editor to open the default tools properties file (`config/tools.properties)` or a different properties file.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If you use a file other than `config/tools.properties`, invoke the tool with the `--propertiesFilePath` option to specify the path to your properties file.

2. Set or change properties that apply to all tools.

   Use the standard Java properties file format (name=value) to set properties. For example, the following properties define a set of Lightweight Directory Access Protocol (LDAP) connection parameters.

   ```
   hostname=server1.example.com
   port=1389
   bindDN=cn=Directory\ Manager
   bindPassword=secret
   baseDN=dc=example,dc=com
   ```

   > **Note**
   >
   > Properties files do not allow quotation marks of any kind around values.
   > Escape spaces and special characters.
   > Whenever you specify a path, do not use `~` to refer to the home directory. The server does not expand the `~` value when read from a properties file.

3. Set or change properties that apply to specific tools.

   Tool-specific properties start with the name of the tool followed by a period. These properties take precedence over properties that apply to all tools. The following example sets two ports: one that applies to all tools (`port=1389`) and a tool-specific one that `ldapsearch` uses instead (`ldapsearch.port=2389`).

   ```
   hostname=server1.example.com
   port=1389
   ldapsearch.port=2389
   bindDN=cn=Directory\ Manager
   ```

4. Save your changes and close the file.

Evaluation of command-line options and file options

You can specify options for a command-line tool on the command line, in a properties file, or both.

Options you specify on a tool's command line take priority over options in a properties file.

Consider the following scenarios.

Command-line options	Server uses ...
No command-line options	The options in the default `<server-root>/config/tools.properties` file.

Copyright © 2025 Ping Identity Corporation

Command-line options	Server uses ...
Command-line options other than the `--propertiesFilePath <my-properties-file>` option	The command-line options, which take priority if the options are also in the `<server-root>/config/tools.properties` file. The file options for options that are only in the default `<server-root>/config/tools.properties` file.
Only the `--propertiesFilePath <my-properties-file>` option	The options in `<my-properties-file>`.
The `--propertiesFilePath <my-properties-file>` option and other command-line options	The command-line options, which take priority if the options are also in `<my-properties-file>`. The file options for options that are only in `<my-properties-file>`.
The `--noPropertiesFile` option and other command-line options	Only the options you specify on the command line, ignoring the default properties file.

Example

Consider this example properties file that is saved as `<server-root>/bin/tools.properties`:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

The server checks command-line options and file options to determine the options to use, as explained below.

- All options presented with the tool on the command line take precedence over any options in a properties file.

  In the following example, the command runs with the options specified on the command line (`--port` and `--baseDN`). With the `port` value both on the command line and in the properties file, the command-line value takes priority. The command uses the `bindDN` and `bindPassword` values specified in the properties file.

  ```
  $ bin/ldapsearch --port 2389 --baseDN ou=People,dc=example,dc=com \
    --propertiesFilePath bin/tools.properties "(objectclass=*)"
  ```

- If you specify the properties file using the `--propertiesFilePath` option and no other command-line options, the server uses only the options in the specified properties file:

  ```
  $ bin/ldapsearch --propertiesFilePath bin/tools.properties \
    "(objectclass=*)"
  ```

- If you do not specify any command-line options, the server attempts to locate the default properties file in the following location:

Copyright © 2025 Ping Identity Corporation

```
<server-root>/config/tools.properties
```

By moving your `tools.properties` file from `<server-root>/bin` to `<server-root>/config`, you do not have to specify the `--propertiesFilePath` option. That change shortens the previous command to the following command:

```
$ bin/ldapsearch "(objectclass=*)"
```

dsconfig batch files">

Sample `dsconfig` batch files

The `config/sample-dsconfig-batch-files` directory contains `dsconfig` batch files that you can use to configure various aspects of the server. For example, these files can enable additional security capabilities or take advantage of features that might require customization from one environment to another.

Each file includes comments that describe the purpose and benefit of its configuration change. You can choose which of the changes you want to apply.

You need to customize some of the batch files to provide values that might vary from one environment to another. To apply a batch file that requires changes, copy it to another directory and edit the copy. Leave the files in the `config/sample-dsconfig-batch-files` directory unchanged so that they can be updated when you upgrade the server. To specify the path to the file that contains the changes to apply, use the `dsconfig` tool (`bin/dsconfig` on UNIX-based systems or `bat\dsconfig.bat` on Windows) with the `--batch-file` argument.

You should also provide the arguments needed to connect and authenticate to the server. The `--no-prompt` argument ensures that the tool does not block while waiting for input if any necessary arguments are missing. Consider this example.

```
bin/dsconfig --hostname localhost \
  --port 636 --useSSL --trustStorePath config/truststore \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPasswordFile admin-password.txt \
  --batch-file config/hardening-dsconfig-batch-files/reject-insecure-request.dsconfig \
  --no-prompt
```

Running task-based tools

The PingDirectory server has a Tasks subsystem that allows you to schedule basic operations, such as `backup`, `restore`, `rotate-log`, `schedule-exec-task`, `stop-server`, and others. All task-based tools require the `--task` option that explicitly indicates the tool is to run as a task rather than in offline mode.

The following table shows the options that you can use for task-based operations:

Copyright © 2025 Ping Identity Corporation

Options for task-based operations

Option	Description
`--task`	Indicates that the tool is invoked as a task. The `--task` option is required. If you invoke a tool as a task without this `--task` option, then a warning message is displayed stating that it must be used. If the `--task` option is provided but the tool was not given the appropriate set of authentication arguments to the server, then an error message is displayed and the tool exits with an error.
`--start <startTime>`	Indicates the date and time, expressed in the format 'YYYYMMDDhhmmss', when the operation is to start. A value of '0' causes the task to be scheduled for immediate execution. After the scheduled run, the tool exits immediately.
`--dependency <taskID>`	Specifies the ID of a task upon which this task depends. A task does not start execution until all its dependencies have completed execution. You can use this option multiple times in a single command.
`--failedDependencyAction <action>`	Specifies the action this task takes if one of its dependent tasks fail. Valid action values are: • `CANCEL` (the default) - Cancels the task. • `DISABLE` - Disables the task so that it is not eligible to run until you manually enable it again. • `PROCESS` - Runs the task.
`--startAlert`	Generates an administrative alert when the task starts running.
`--errorAlert`	Generates an administrative alert when the task fails to complete successfully.
`--successAlert`	Generates an administrative alert when the task completes successfully.
`--startNotify <emailAddress>`	Specifies an email address to notify when the task starts running. You can use this option multiple times in a single command.
`--completionNotify <emailAddress>`	Specifies an email address to notify when the task completes, regardless of whether it succeeded or failed. You can use this option multiple times in a single command.
`--errorNotify <emailAddress>`	Specifies an email address to notify if an error occurs when this task executes. You can use this option multiple times in a single command.
`--successNotify <emailAddress>`	Specifies an email address to notify when this task completes successfully. You can use this option multiple times in a single command.

Introduction to the PingDirectoryProxy server

This section gives an overview of PingDirectoryProxy features and components.

PingDirectoryProxy is a fast and scalable LDAPv3 gateway for the PingDirectory server. Administrators can configure the PingDirectoryProxy server architecture to control how client requests are routed to backend servers.

Overview of the PingDirectoryProxy features

The following overview describes the PingDirectoryProxy server's features and capabilities.

The PingDirectoryProxy server is a fast, scalable, and easy-to-use LDAP proxy server that provides high availability and additional security for the PingDirectory server while remaining largely invisible to client applications. From a client perspective, request processing is the same, whether communicating with the PingDirectory server directly or going through the PingDirectoryProxy server.

The PingDirectoryProxy server provides the following features:

High availability

The PingDirectoryProxy server allows you to transparently fail over between servers if a problem occurs as well as ensuring that the workload is balanced across the topology. If a client does not support following referrals, the server can follow them on the client's behalf.

Data mapping and transformation

The PingDirectoryProxy server can perform distinguished name (DN) mapping and attribute mapping to allow clients to interact with the server using older names for directory content. It allows clients to continue working when they would not be able to work directly with the PingDirectory server, either because of changes that have occurred at the data layer or to inherent design limitations in the clients.

Horizontal scalability and performance

Reads can be horizontally scaled using load balancing. In large data centers, if the data set is too large to be cached or to provide horizontal scalability for writes, the PingDirectoryProxy server can automatically split the data across multiple systems. This feature allows the PingDirectoryProxy server to improve scalability and performance of the PingDirectory server environment.

Load balancing and failover

You can spread the workload across multiple directory servers in a large data center using load-balancing algorithms. Load balancing is also useful when a server becomes degraded or non-responsive because client process requesting directs to a different server.

Security and access control

The PingDirectoryProxy server can add additional firewall capabilities as well as constraints and filtering to help protect the PingDirectory server from attacks. You can use a PingDirectoryProxy server in a DMZ as opposed to allowing clients to directly access the PingDirectoryProxy server in the internal network or providing the data in the DMZ. It can help provide secure access to the data and you can define what actions clients are allowed to do. For example, you can prevent clients from making modifications to data when connected through a VPN no matter what their identity or permissions.

Tracking of operations across the environment

In the past, administrators have complained that when they see a request in the access log they have no idea where it came from and cannot track it back to a particular client. The PingDirectoryProxy server contains controls that allow administrators to track requests back to the client that issued them. Whenever the PingDirectoryProxy server forwards a request to the PingDirectory server, it includes a control in the request so that the PingDirectory server's access log has the IP address of the client, address and connection ID of the PingDirectory server. In the response back to the client, it similarly includes information about the PingDirectory server that processed the request, such as the connection ID and operation ID. This feature makes it easier for administrators to monitor in their environment.

Monitoring and management tools

Because the PingDirectoryProxy server uses many of the components of PingDirectory, it can leverage them to provide protocol support, logging, management tools for configuration and monitoring, and schema. You can use the DataMetricsServer, the `dsconfig` tool, and the administrative console to manage the PingDirectoryProxy server.

Overview of the PingDirectoryProxy server components and terminology

This section describes each PingDirectoryProxy server component in more detail.

The PingDirectoryProxy server provides the following components and functionalities for the proxy capabilities:

- Locations

Copyright © 2025 Ping Identity Corporation

- LDAP External Servers
- LDAP Health Checks
- Load-Balancing Algorithms
- Data Transformations
- Request Processors
- Server Affinity Providers
- Subtree Views
- Connection Pools
- Client Connection Policies
- Entry Balancing

About locations

You can assign a location to the PingDirectoryProxy server and each of the backend LDAP external servers for routing requests and failover response preferences.

Locations define a group of servers with similar response time characteristics. Each location consists of a name and an ordered list of preferred failover locations. These locations can determine how to route requests so that the server forwards requests to the PingDirectoryProxy server in the same data center over those in remote locations.

For example, a deployment consists of three data centers, one in New York, one in Chicago, and one in Los Angeles. In the New York data center, applications that reside in this data center prefer communicating with directories in this data center. If none of the servers are available, it prefers to failover to the data center in Chicago rather than the data center in Los Angeles, so the New York location contains an ordered list in which the Chicago location is preferred over the Los Angeles data center for failover.

Follow these guidelines for assigning locations in the PingDirectoryProxy server:

- If you have multiple data centers, assign a separate location for each one.
- In most environments, all PingDirectoryProxy server instances should have the same configuration except for the attribute that specifies the location of the server itself.

Learn more about Configuring locations.

About LDAP external servers

PingDirectoryProxy allows you to configure different types of LDAP external servers.

You can configure information about the directory server instances accessed by PingDirectoryProxy. The default configuration for each type is tuned to be the best possible configuration for each.

The configuration information includes the following:

- Server connection information, such as IP address, port, and security layer

Copyright © 2025 Ping Identity Corporation

- Location
- Authentication information
- Methods for authenticating and authorizing clients
- Server-specific health checks
- Types of operations allowed

  For example, some LDAP external servers might allow only reads and others allow reads and writes so that the PingDirectoryProxy server can recognize this and accommodate it.

For more information about configuring LDAP external servers, see Configuring LDAP external servers.

About LDAP health checks

LDAP health checks provide information about the status and availability of LDAP external servers. Configure the PingDirectoryProxy server health checks that work best for your environment.

PingDirectoryProxy provides the following health checks:

Measure the response time for searches and examine the entry contents

The health check might retrieve a monitoring entry from a server and base the health check result on whether the entry was returned, how long it took to be returned, and whether the value of the returned entry matches what was expected.

Monitor the replication backlog

If a server falls too far behind in replication, then the PingDirectoryProxy server can stop sending requests to it. A server is classified as `degraded` or `unavailable` if the threshold is reached for the number of missing changes, the age of the oldest missing change, or both.

Consume Directory Server administrative alerts

If the PingDirectory server indicates there is a problem, such as an index that must be rebuilt, then it flags itself as `degraded` or `unavailable`. When the PingDirectoryProxy server detects this, it stops sending requests to the server. The PingDirectoryProxy server detects administrative alerts as soon as they are issued by maintaining an LDAP persistent search for changes within the `cn=alerts` branch of the PingDirectory server.

When the PingDirectoryProxy server is notified by the PingDirectory server of a new alert, it immediately retrieves the base `cn=monitor` entry of the PingDirectory server. If this entry has a value for the `unavailable-alert-type` attribute, then the PingDirectoryProxy server considers it unavailable. If this entry has a value for the `degraded-alert-type` attribute, then the PingDirectoryProxy server considers it `degraded`. Clients of the PingDirectoryProxy server can use a similar mechanism to detect and react when server flags itself as `degraded` or `unavailable`.

Monitor the busyness of the server

If a server becomes too busy, you can mark it as `degraded` or `unavailable` so that less heavily-loaded servers are preferred.

Copyright © 2025 Ping Identity Corporation

Results

The health check results contain the following server states:

`Available`

Completely accessible for use.

`Degraded`

The server can be used if necessary but has a condition which can make it less desirable than other servers. For example, it is slow to respond or has fallen behind in replication.

`Unavailable`

Completely unsuitable for use. For example, the server is offline or is missing critical data.

Health check results include a numeric score that has a value between 1 and 10. This score helps rank servers with the same state. For example, two servers are available and one has a score of 8 and the other a score of 7, you can configure the PingDirectoryProxy server to prefer the server with the higher score.

The results of health checks are made available to the load-balancing algorithms to help determine where to send requests. The PingDirectoryProxy server attempts to use servers with a state of `available` before trying servers with a state of `degraded`. It never attempts to use servers with a state of `unavailable`.

Some load-balancing algorithms also take the health check score into account, such as the health-weighted load-balancing algorithm that prefers servers with higher scores over those with lower scores. You should configure the algorithms that work best for you environment.

Frequency

The PingDirectoryProxy server periodically invokes health checks to monitor each LDAP external server and initiates health checks in response to failed operations. It checks the health of the LDAP external servers at intervals configured in the LDAP server's `health-check-frequency` property. The PingDirectoryProxy server contains safeguards to ensure that only one health check is in progress at any time against a backend server to avoid affecting its ability to process other requests.

To associate a health check with an LDAP external server and set the health check frequency, you must configure the `health-check` and `health-check-frequency` properties of the LDAP external server.

For more information about configuring the properties of the external server, see Configuring an external server using `dsconfig`.

Server states and search response times

In some cases, an LDAP health check defines different sets of criteria for promoting and demoting the state of a server. A `degraded` server might need to meet more stringent requirements to be reclassified as `available` than originally for it to be considered `degraded`.

If response time is used in the process of determining the health of a server, then the PingDirectoryProxy server might have a faster response time threshold for transitioning a server from `degraded` back to `available` than the threshold used to consider it `degraded` in the first place. This threshold difference helps avoid cases in which a server repeatedly transitions between the two states because it is operating near the threshold.

Copyright © 2025 Ping Identity Corporation

For example, the health check used to measure search response time is configured to mark any server as `degraded` when the search response time is greater than 1 second. You can configure that the response time must be less than 500 ms before the server is made available again so that the PingDirectoryProxy server does not flip back and forth between `available` and `degraded`.

For more information about configuring health checks, see Configuring server health checks.

About load-balancing algorithms

Load-balancing algorithms determine which server in a set of similar servers to use to process a client request.

The PingDirectoryProxy server provides the following load-balancing algorithms:

Fewest operations

Forwards request to the backend server with the fewest operations currently in progress.

Single server

Sends requests to the same server and doesn't attempt to fail over to another server if the target server is unavailable.

Weighted

Administrators explicitly assign numeric weights to individual servers or sets of servers to control how likely they are to be selected for processing requests relative to other servers.

Health-based weighting

Uses the health check score to assign weights to each of the servers so that a server with a higher score gets a higher percentage of the traffic than a server with a lower score. The proportion of traffic received is the difference between their health check scores.

Failover

Sends requests to a given server first. If that server fails, then the request sends to another specified server as specified in the ordered failover server list.

Learn more about Configuring load balancing.

Algorithm criteria

The algorithm takes the following criteria into account:

Location of the server

Servers in the same location as the PingDirectoryProxy server are preferred over those in alternate locations.

Health of the server

Servers that are `available` are preferred over those that are `degraded`. In some cases, the health check score can be used to further differentiate between servers with the same health check state.

Copyright © 2025 Ping Identity Corporation

Route requests consistency

Requests from a single client can be consistently routed to the same PingDirectoryProxy server instance to avoid problems such as propagation delay from replication.

Operation retries

Retries the operation in an alternate server if the request fails or the operation times out. You can control if the retry is allowed and, if so, how many times to retry and the time out interval.

Proxy transformations

Proxy transformations are used to rewrite requests and responses as they pass through the PingDirectoryProxy server. Proxy data transformations are helpful for clients that use an old schema or that contain a hard-coded schema.

Use the PingDirectoryProxy server proxy transformations to:

- Provide a distinghuished name (DN) and attribute mapping altering both requests to the server as well as responses from the server.

  For example, a client sends a request to `o=example.com` even though the directory server handling the request uses `dc=example,dc=com`. The PingDirectoryProxy server can transparently remap the request so that the server can process it and map it back to the original DN of the client request when the value is returned.

- Alternatively, if a client tries to use the attribute `userID`, the PingDirectoryProxy server can map it to `uid` before sending the request on to the backend LDAP server. The PingDirectoryProxy server then remaps the response to `userID` when the value is returned.

- Suppress a specified attribute so that it is never returned to clients. Also, it can cause the server to reject requests which target that particular attribute.

- Prevent entries that match a given search filter from being returned to clients.

For more information about configuring proxy transformations, see Configuring proxy transformations.

About request processors

A request processor encapsulates the logic for handling an operation, ensuring that a given operation is handled appropriately.

The request processor can:

- Process the operation directly

- Forward the request to another server

- Hand off the request to another request processor

PingDirectoryProxy server request processors can be used to forward certain controls, including the batch transaction control and the LDAP join control. The batch transaction control must target a single Berkeley DB backend. For more information about the controls, see LDAP SDK for Java documentation.

PingDirectoryProxy provides the following types of request processors:

Copyright © 2025 Ping Identity Corporation

Proxying request processors

Forwards operations received by the PingDirectoryProxy server to other LDAP external servers.

Entry-balancing request processors

Splits data across multiple servers. They determine which set of servers are used to process a given operation. They then hand off operations to proxying request processors so that requests can be forwarded to one of the servers in the set.

Failover request processors

Perform ordered failover between other types of request processors, sometimes with different behavior for different types of operations.

Learn more about Configuring request processors.

About server affinity providers

The PingDirectoryProxy server supports the ability to forward a sequence of requests to the same external server if specific conditions are met, called server affinity.

Use the server affinity provider to establish an affinity to a particular backend server for certain operations.

The following provider configurations and server affinity methods are available in the PingDirectoryProxy server:

Client connection Server Affinity

Requests from the same client connection consistently route to the same backend server.

Client IP address Server Affinity

All requests coming from the same client system consistently route to the same backend server.

Bind DN Server Affinity

All requests from the same user consistently route to the same backend server.

For information about configuring server affinity, see Configuring server affinity.

About subtree views

A subtree view can be used to make a portion of the directory information tree (DIT) available to a client by associating a request processor with a base distinguished name (DN).

A subtree views allow you to route operations concerning one set of data to a particular set of data sources and operations concerning another set of data to another set of data sources. Multiple subtree views are involved in processing a request, such as searches that have a scope that is larger than the subtree view.

The subtree view includes using a single base DN to identify the portion of the DIT. They might have hierarchical relationships: for example, one subtree view is configured for `dc=example,dc=com` and another for `ou=People,dc=example,dc=com`.

Copyright © 2025 Ping Identity Corporation

For information about configuring a subtree view, see Configuring subtree views.

About the connection pools

PingDirectoryProxy maintains either one or two connection pools to the backend server, depending on the type of backend server you use.

PingDirectoryProxy maintains either one pool for all types of operations or two separate pools for processing bind and non-bind operations from clients. When PingDirectoryProxy establishes connections, it authenticates them using the authentication mechanism defined in the configuration of the external server.

These connections are re-used for all types of operations forwarded to the backend server. You can configure the bind distinguished name (DN) and password in the PingDirectoryProxy server.

When a client sends a bind request to the PingDirectoryProxy server, the server looks at the type of bind request that was sent:

- If the bind request is a SASL bind request, authentication is processed by the PingDirectoryProxy server itself and does not forward to the backend server, however, the PingDirectoryProxy server can use information contained in the backend server as needed.
- If the bind request is a simple bind request, and the bind DN is within the scope of data supplied by the backend server, the PingDirectoryProxy server forwards the client request to the backend server so that it uses the credentials provided by the client.

Regardless of the authentication method the client uses, the PingDirectoryProxy server remembers the identity of the client after the authentication completes. For any subsequent requests sent by that client, the server uses the configured authorization method to identify the client to the backend server.

Even though the operation is forwarded over a connection that is authenticated as a user defined in the PingDirectoryProxy server configuration, the request processes through the backend server under the authority of the end client.

About client connection policies

Client connection policies define the general behavior the server exhibits when communicating with a set of clients.

Each policy contains the following:

- A set of connection criteria that define which client is associated with the policy based on information the server has about the client, including:
  - Client address
  - Protocol used
  - Secure communication mechanism
  - Location of the client's entry in the PingDirectoryProxy server
  - Contents of the client's entry

  These criteria are the same as those used for filtered logging. For example, different client connection policies could be established for different classes of users, such as root and non-root users.

Copyright © 2025 Ping Identity Corporation

- A set of constraints on the type of operations a client can request. You can specify whether a particular type of operation is allowed for clients.

  For some operation types, such as extended operations, you can allow only a particular subset of an operation type, such as a particular extended operation.

- A set of subtree views that define information about the parts of the directory information tree (DIT) the client can access.

When a client connection is established, only one client connection policy is applied. If the criteria for several policies match the same client connection, the evaluation order index is used as a tiebreaker. If no policy matches, the client connection is terminated. If the client binds, changing its identity, or uses StartTLS to convert from an insecure connection to a secure connection, then the connection is evaluated again to determine if it matches the same or a different client connection policy. The connection is terminated if it no longer matches any policy.

Learn more about Client connection policy configuration.

About entry balancing

Entry balancing allows you to automatically spread entries below a common parent among multiple sets of directory servers for improved scalability and performance.

Entry balancing can take advantage of a global index. A global index is an in-memory cache used for quickly determining which set or sets of servers to use to process a request based on the entry distinguished names (DNs) and attribute values.

For information about configuring entry balancing, see Deploying an entry-balancing proxy configuration.

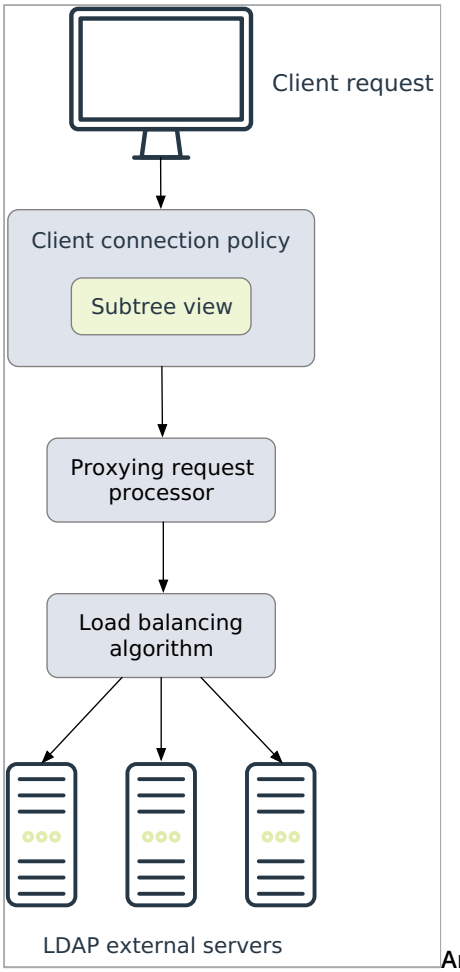
Server component architecture

This section provides an overview of the process flow between the PingDirectory server components for a simple proxy deployment and an entry-balancing deployment.

Architecture of a simple PingDirectory server deployment

A simple PingDirectory server deployment is illustrated in the following figure.

Copyright © 2025 Ping Identity Corporation



An illustration of the process flow of a simple PingDirectory Proxy server deployment. The process starts with a client request represented by a person at a desktop computer. The flow moves with a series of down arrows between boxes in the order described in the topic text. The last step of the process is represented by three servers lined up side-by-side

Processing steps

1. A client request is initiated.
2. The client connection policy processes the client request.
3. The client connection policy contains a subtree view, which defines the portion of the directory information tree (DIT) available to clients and determines if the DIT is available.
4. After the PingDirectory server determines that the DIT is available, it passes the request to the request processor, which defines the logic for processing the request.
5. The request processor passes the request to a load-balancing algorithm, which determines the server in a set of servers responsible for handling the request.
6. The request is passed to the LDAP external server.

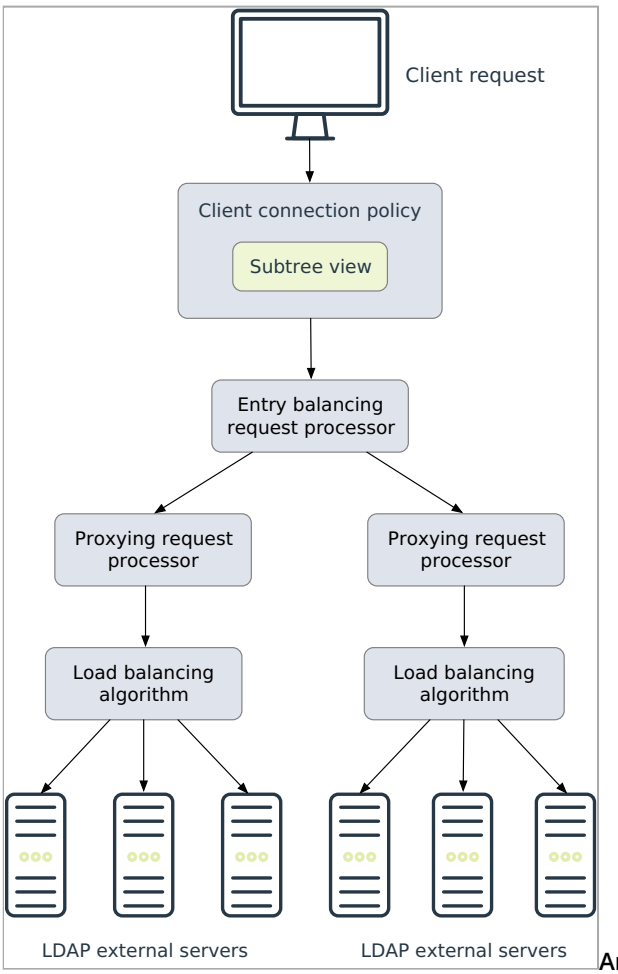
Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The LDAP external server contains properties that define the server's location in a topology and the health checks used to determine if the server is functioning properly.
> This information can be used by the load-balancing algorithm for determining how to route requests.

Architecture of an entry-balancing PingDirectory server deployment

Entry balancing is used when the data set is too large to fully cache on a single server or when the write performance requirements of an environment are higher than can be achieved with a single replicated set of servers. In such cases, the data can be split across multiple sets of servers, increasing the memory available for caching and the overall write performance in proportion to the number of server sets.

The following figure shows how a client request is treated in an entry-balancing PingDirectory server deployment.



An illustration of the process flow of an entry-balancing PingDirectory server deployment. The process starts with a client request represented by a person at a desktop computer. The flow moves with a series of down arrows splitting in two directions and forming two separate flows between boxes in the order described in the topic text. The last step of the process for each of the two separate flows is represented by three servers lined up side-by-side

1. A client request is initiated.
2. The client connection policy processes the client request.

Copyright © 2025 Ping Identity Corporation

3. The client connection policy contains a subtree view, which determines how the PingDirectoryProxy server communicates with a set of clients. It contains a subtree view that represents the base distinguished name (DN) for the entire deployment. The data set splits beneath this base DN.
4. The PingDirectory server passes the request to the entry-balancing request processor.

   The entry-balancing request processor contains a global attribute index property, which helps the request processor determine which server set contains the entry and how to properly route the request. It also contains a placement algorithm, which helps it select the server set in which to place new entries created by add requests.
5. The entry-balancing request processor has beneath it multiple proxying request processors that handle multiple unique sets of data.
6. The proxying request processors passes the request to a load-balancing algorithm, which determines which LDAP external server should handle the request.

   > **Note**
   >
   > As with a simple proxy deployment, this LDAP external server contains properties that define the server's location and the health checks that determine if the server is functioning properly.
7. The request is passed to the LDAP external server.

For information about entry-balancing replication, see Overview of replication in an entry-balancing environment.

PingDirectoryProxy server configuration overview

The following topic provides an overview of the component configurations for your PingDirectoryProxy server deployment.

Configuring locations for your deployment

A location is a collection of servers that share access and latency characteristics. For example, your deployment might include two data centers, one in the east and one in the west. These data centers are configured as two locations in the PingDirectoryProxy server. Each location is associated with a name and an ordered list of failover locations to use if none of the servers in the preferred location are available.

Configuring the PingDirectoryProxy server location

You update the configuration to specify the location of the PingDirectoryProxyserver instance.

Configuring health checks for the LDAP external servers

You configure at what point the PingDirectoryProxy server considers an LDAP external server to be available, of degraded availability, or unavailable. Each health check can be configured to be used automatically for all LDAP external servers or for a specified set of servers.

Configuring the LDAP external servers

You define each of the external directory servers, including the server type. You can configure Ping Identity directory servers, Java System Directory Servers, or generic LDAP servers. You also assign the server-specific health checks configured previously.

Copyright © 2025 Ping Identity Corporation

Configuring the load-balancing algorithm

You configure the load-balancing algorithm that the PingDirectoryProxy server uses to determine which server in a set of similar servers to use to process a client request. The PingDirectoryProxy server provides default algorithms. You can create new algorithms either using an existing algorithm as a template or creating one from scratch.

Configuring the proxying request processor

You configure proxying request processors that forward operations received by the PingDirectoryProxy server to other LDAP external servers.

Configuring subtree views

A subtree view defines the portion of the directory information tree (DIT) available to a client. Each subtree view can be associated with a load-balancing algorithm to help distribute the work load.

Configuring the client connection policy

You configure policies to classify how the PingDirectoryProxy server manages different client connections. The client connection policy can be used to control the types of operations that a client might perform and the portion of the DIT that the client can access. Restrictions configured in a client connection policy take precedence over any capabilities granted by access control or privileges.

Installing the PingDirectoryProxy server

This section describes how to install the PingDirectoryProxy server and includes pre-installation requirements and considerations.

It includes the following sections:

- Before you begin
- Preparing the operating system
- Getting the installation packages
- Signing on to the administrative console
- Ping Identity license keys
- Installing the PingDirectoryProxy server
- PingDirectoryProxy server folder layout

Before you begin

Review requirements and considerations before installing the software and configuring the PingDirectoryProxy objects.

Copyright © 2025 Ping Identity Corporation

> **Important**
>
> Each server deployment requires an execution of `setup`. Duplicating a server-root is not supported. The installation of the server doesn't write or require any data outside of the server-root directory.
> After you run the `setup` tool, do not copy the server-root to another location or system to duplicate the installation because this isn't a supported method of deployment. If a host or file system change is needed, you can move the server-root to another host or disk location.

Make sure a Network Time Protocol (NTP) system is in place so that multi-server environments are synchronized and timestamps are accurate.

System requirements

The PingDirectory server requires certain software packages to operate properly.

For optimal performance, the server requires Java for 64-bit architectures. To view the minimum required Java version, contact your authorized support provider for the latest supported software versions.

> **Tip**
>
> Implement a Network Time Protocol (NTP) system so that multi-server environments are synchronized and timestamps are accurate.

The following system requirements are qualified and certified to be compatible with the PingDirectory server.

Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software are suspected of causing issues.

CPU and memory

When sizing an instance of the PingDirectory server, provide at least the following minimum specs:

- 2 processor cores
- 4 GB of RAM

You can find more information about memory allocation in Memory allocation and database cache or Finding the optimal heap size (requires authentication).

Running PingDirectory on Amazon Web Services (AWS)

To take advantage of snapshots for backing up any important files, install the PingDirectory server on an Elastic Block Store (EBS) file system. You should also move any databases, logs, and other files to a high-performance file system that's separate from the rest of the server image and create an S3 bucket for storing backups, schema, and other artifacts.

The following guidelines and considerations apply to AWS environments:

- PingDirectory does not support the Elastic File System (EFS) for database persistence. For the best performance, use the local SSD.
- Using network load balancers (NLBs) can lead to severed connections, which could cause issues that are difficult to diagnose.

Copyright © 2025 Ping Identity Corporation

Platforms

The PingDirectory, PingDirectoryProxy, PingDataSync, and PingDataMetrics servers support the following operating systems for installation and deployment:

- **Amazon Linux 2**
- **Canonical Ubuntu 18.04 LTS and 20.04 LTS**
- **CentOS 7.7 and 8.1**
- **Microsoft Windows Server 2016 and 2019**
- **Oracle Linux**
  - **Release 7 up to 7.9**
  - **Release 8 up to 8.6**
- **Red Hat Enterprise Linux ES**
  - **Release 7 up to 7.9**
  - **Release 8 up to 8.6**
  - **Release version 9.0**
- **SUSE Linux Enterprise 12 SP5 and 15 SP3**

> **Important**
>
> The PingDirectory suite of products has been tested with the default configurations of all operating system components. Customized implementations or installed third-party plugins from your organization might affect the deployment of this product.

Docker

To deploy the PingDirectory server using Docker, you must have a supported version of Docker.

The following versions of Docker are supported:

- **Docker 20.10.9**

Learn more in the pingidentity/pingdirectory Docker image and the Ping Identity DevOps documentation.

> **Note**
>
> Only the PingDirectory server software is licensed under Ping Identity's end user license agreement, and any other software components contained within the image are liensed solely under the terms of the applicable open source or third-party license.
> Ping Identity accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

Copyright © 2025 Ping Identity Corporation

Java Runtime Environment

You must have one of the following versions of the Java Development Kit installed prior to installing the server:

- Oracle JDK 8 64-bit
- Oracle JDK 11 LTS 64-bit
- Oracle JDK 17
- OpenJDK 8 64-bit
- OpenJDK 11 and 17
- Corretto 8, 11, and 17

Important

Refer to the following with regard to Java support:

- Due to the number of supported JDK variants, we do not explicitly list all of them here. The criteria for supported JDKs are:
  - They must be built from the OpenJDK codebase.
  - They must use the HotSpot JIT compiler. They cannot use OpenJ9 or other JIT implementations.
- PingDataMetrics doesn't support Java 17.
- The Java Support Policy applies to your Java Runtime Environment (JRE).

Browsers

The following browsers are supported by the PingDirectory server administrative console:

- Chrome
- Firefox
- Edge

Defining a naming strategy for server locations

The various objects defined in the PingDirectoryProxy server are specific to a particular location.

Location names can define a grouping of PingDirectoryProxy products based on physical proximity.

A location is usually associated with a single data center location. During the installation, assign a location to each server for optimal inter-server behavior. The location assigned to a server within Global Configuration can be referenced by components within the server as well as processes external to the server to satisfy "local" versus "remote" decisions used in replication, load balancing, and failover.

Installing Java

About this task

Copyright © 2025 Ping Identity Corporation

For optimized performance, the PingDirectoryProxy server requires Java for 64-bit architectures. You can view the minimum required Java version on your Customer Support Center portal or contact your authorized support provider for the latest software versions supported.

Even if your system already has Java installed, you can create a separate Java installation for use by the PingDirectoryProxy server to ensure that updates to the system-wide Java installation do not inadvertently impact the PingDirectoryProxy server. This setup requires that you download the 64-bit version of the Java Development Kit (JDK) instead of the Java Runtime Environment (JRE).

Steps

1. Go to the Oracle download site.
2. Click JDK Download.
3. On the download page, select the download file for your operating system and accept the license agreement to start the download.

Preparing the operating system

You should make the following changes to your operating system depending on the production environments on which the PingDirectoryProxy server will run:

- Configure the file descriptor limits
- Enable the server toPre listen on privileged ports (Linux)
- Set the file system flushes
- Disable file system swapping
- About editing OS-level environment variables
- Install sysstat and pstack (RedHat)
- Install dstat (SUSE Linux)
- Omit vm.overcommit_memory
- Manage system entropy
- Set file system event monitoring (inotify)
- Tune the I/O scheduler

Configuring the file descriptor limits

The operating system default file descriptor limits restrict the number of PingDirectory server connections. Change the descriptor limits to allow more connections.

About this task

Copyright © 2025 Ping Identity Corporation

The PingDirectory server allows for an unlimited number of connections by default, but the file descriptor limit on the operating system restrict the number of connections. Many Linux distributions have a default file descriptor limit of 1024 per process, which might be too low for the server if it needs to handle a large number of concurrent connections.

If the operating system relies on `systemd`, see the Linux operating system documentation for instructions on setting the file descriptor limit.

After you set the operating system limit, you can configure the number of file descriptors that the server will use either by using a `NUM_FILE_DESCRIPTORS` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as `NUM_FILE_DESCRIPTORS=12345`. If these are not set, the operating system uses the default of 65535 descriptors. This is an optional change you can make if you want to ensure that the server shuts down safely prior to reaching the file descriptor limit.

Steps

1. Display the current `fs.file-max` limit of the system.

   ```
   sysctl fs.file-max
   ```

   The `fs.file-max` limit is the maximum server-wide file limit you can set without tuning the kernel parameters in the `proc` file system.

2. Edit the `/etc/sysctl.conf` file.

   If there is a line that sets the value of the `fs.file-max` property, make sure that its value is set to at least 1.5 times the per-process limit.

   If there is no line that sets a value for this property, add the following to the end of the file:

   ```
   fs.file-max = 100000
   ```

   > **Note**
   >
   > 100000 is just an example here. Specify a value of at least 1.5 times the per-process limit.

3. Display the current hard limit of the system.

   ```
   ulimit -aH
   ```

   The `open files (-n)` value is the maximum number of open files per process limit.

   The value should be set to at least 65535.

4. Edit the `/etc/security/limits.conf` file.

   If the file has lines that set the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines before `#End of file`, making certain to insert a tab between the columns.

Copyright © 2025 Ping Identity Corporation

```
*   soft   nofile   65535
*   hard   nofile   65535
```

Note

The number of open file descriptors is limited by the physical memory available to the host. You can determine this limit with the following command.
+

```
cat /proc/sys/fs/file-max
```

If the `file-max` value is significantly higher than the 65535 limit, consider increasing the file descriptor limit to between 10% and 15% of the system-wide file descriptor limit. For example, if the `file-max` value is 810752, you could set the file descriptor limit to 100000. If the `file-max` value is lower than 65535, the host is likely not sized appropriately.

5. **Reboot your system, and then use the `ulimit` command to verify that the file descriptor limit is set to 65535.**

```
# ulimit -n
```

Result

Note

For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits.

```
/etc/security/limits.d/20-nproc.conf

 Add or edit the following lines if they do not already exist:

*          soft    nproc     65536
*          soft    nofile    65536
*          hard    nproc     65536
*          hard    nofile    65536
root       soft    nproc     unlimited
```

Enabling the server to listen on privileged ports (Linux)

For your convenience, enable the server to listen on privileged ports while running as a non-root user.

About this task

Linux systems have a mechanism called capabilities that is used to grant specific commands the ability to do things that are normally only allowed for a root account:

- **The `setcap` command assigns capabilities to an application.**
- **The `cap_net_bind_service` capability enables a service to bind a socket to privileged ports (port numbers less than 1024).**

Copyright © 2025 Ping Identity Corporation

Steps

1. If Java is installed in `/ds/java` (and the Java command to run the server is `/ds/java/bin/java`), you can grant the `cap_net_bind_service` capability to the Java binary with the following command.

   ```
   $ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
   ```

2. Create the file `/etc/ld.so.conf.d/libjli.conf` with the path to the directory that contains the `libjli.so` file.

   The java binary needs an additional shared library (`libjli.so`) as part of the Java installation. Because this process imposes stricter limits on where the operating system looks for shared libraries to load for commands that have capabilities assigned, it is also necessary to tell the operating system where to look for this library.

   Example:

   For example, if the Java installation is in `/ds/java`, the contents of that file should be:

   ```
   /ds/java/lib/amd64/jli
   ```

3. To apply the changes, run the following command.

   ```
   $ sudo ldconfig -v
   ```

Setting the file system flushes

Reduce the span between file system flushes to improve PingDirectory server performance.

About this task

By default, Linux servers running the ext3 file system flush the data to disk every five seconds.

Steps

1. If the PingDirectory server is running on a Linux server using the ext3 file system, consider editing the mount options for that file system to include the following command.

   ```
   commit=1
   ```

   This variable changes the flush frequency from five seconds to one second.

2. You should also set the flush frequency in the `/etc/fstab` file.

   Changing the mount command alone does not survive across reboots.

Copyright © 2025 Ping Identity Corporation

Disabling file system swapping

Because file system swapping can interfere with PingDirectory, disable performance tuning tools like `tuned`.

Steps

1. Sign on as the root user.
2. Add the line `vm.swappiness = 0` to the file `/etc/sysctl.conf`.
3. Restart the system to apply the change.
4. (Optional) If you need to tune performance after disabling file system swapping, do the following:
    1. Clone the existing performance profile.
    2. Run `tuned`.
    3. Add the line `vm.swappiness = 0` to the file `/usr/lib/tuned/profile-name/tuned.conf`.
    4. To select the updated profile, run `tuned-adm profile customized_profile`.
    5. Restart the system to apply the changes.

About editing OS-level environment variables

Certain environment variables might affect the PingDirectory server in unexpected ways. This is particularly true for environment variables that are used by the underlying operating system to control how it uses non-default libraries.

For this reason, the PingDirectory server explicitly overrides the values of key environment variables like *<PATH>*, *<LD_LIBRARY_PATH>*, and *<LD_PRELOAD>* to ensure that environment settings used to start the server do not inadvertently impact its behavior.

If you need to edit any of these environment variables, set the values of those variables by manually editing the *<set_environment_vars>* function of the `lib/_script-util.sh` script.

You must stop (`bin/stop-server`) and re-start (`bin/start-server`) the server for the change to take effect.

Installing sysstat and pstack (Red Hat)

If you plan to run PingDirectory on a Red Hat Linux system, install a couple of packages, `sysstat` and `pstack`, that are disabled by default, but are useful for troubleshooting.

About this task

The troubleshooting tool `collect-support-data` uses the `iostat`, `mpstat`, and `pstack` utilities to collect monitoring, performance, and stack trace information on the server's processes.

Steps

- To install `systat` on your Red Hat system, run the following command.

Copyright © 2025 Ping Identity Corporation

```
$ sudo yum install sysstat gdb dstat -y
```

.

Installing dstat (SUSE Linux)

`dstat` is a system monitoring tool that can help you troubleshoot PingDirectory servers on SUSE distributions.

About this task

The `collect-support-data` tool uses the `dstat` utility for system monitoring. `dstat` can be obtained from the OpenSUSE project website. The following process shows how to install the `dstat` utility on SUSE Enterprise Linux 11 SP2.

Steps

1. Sign on as the root user.
2. Add the appropriate repository using the `zypper` tool.
3. Install the `dstat` utility.

```
$ zypper install dstat
```

Omitting vm.overcommit_memory

An improperly configured value for the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file might cause the `setup` or `start-server` tool to fail.

About this task

For Linux systems, the `vm.overcommit_memory` property sets the kernel policy for memory allocations. The default value of 0 indicates that the kernel determines the amount of free memory to grant a `malloc` call from an application. If the property is set to a value other than zero, the operating system might grab too much memory, reducing the amount of available memory for the `setup` or `start-server` tools.

Steps

1. Omit the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file to ensure that enough memory is available for these tools.

Managing system entropy

Linux uses entropy to calculate random data that is used by the system in cryptographic operations.

About this task

Copyright © 2025 Ping Identity Corporation

Some environments with low entropy might have intermittent performance issues with SSL-based communication. This is more typical on virtual machines but can occur in physical instances as well.

Steps

- Monitor the `kernel.random.entropy_avail` in `sysctl` value for best results.

Setting file system event monitoring (inotify)

An event monitoring tool such as `inotify` can be configured for notifying processes about file system events, including file creation, deletion, and updates.

About this task

Linux limits the number of `inotify` watches a user can receive.

Steps

- To increase the limit, edit `etc/sysctl.conf` to add the following line.

```
fs.inotify.max_user_watches = 524288
```

- Run the following command.

```
$ sudo sysctl -w fs.inotify.max_user_watches=524288
```

Tuning the I/O scheduler

Using the correct I/O scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load.

About this task

> **Important**
>
> - For file systems running on an SSD or in a virtualized environment, use the recommended **`noop`** scheduler.
> - For additional considerations related to network attached storage, see Databases on storage area networks, network-attached storage, or running in virtualized environments.
> - For all other systems, use the **`deadline`** scheduler.

The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

Steps

1. To determine which scheduler is configured on your system, run the following command.

Copyright © 2025 Ping Identity Corporation

```
$ cat /sys/block/<block-device>/queue/scheduler
```

2. To change the scheduler on a running system, run the following command.

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

3. To apply the change, restart the system.

Getting the installation packages

Obtain the latest `.zip` release bundle from the PingDirectory downloads page, and extract it to a folder of your choice to begin the installation process.

About this task

The release bundle contains the PingDirectory server's code, tools, and package documentation.

Complete the following steps to unpack the build distribution.

Steps

1. Download the latest `.zip` distribution of the PingDirectory server software.
2. Extract the compressed `.zip` archive file to a directory of your choice.

   Example:

   ```
   $ unzip  {pingdir}-<version>.zip
   ```

   Result:

   You can set up the PingDirectory server.

Ping Identity license keys

License keys are required to install, update, and renew all Ping Identity products.

How to obtain a license

To obtain a license key, contact your account representative or use the Ping Identity licensing portal.

When do you need a license

A license is required for setting up a new single server instance and can be used site-wide for all servers in an environment. Additionally, you must obtain a new license when updating a server to a new major version, such as when upgrading from 7.3 to 8.0. When cloning a server instance with a valid license, you do not need a new license.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The update process displays a prompt for a new license.

How to specify a license

- Specify a license at setup.

  You have these options:

  - Use the `--licenseKeyFile` *<path-to-license>* option with `setup`.
  - Copy the license file to the server root directory and then run the `setup` tool. The tool discovers the license file.

- Specify a license after setup

  Use the administrative console or `dsconfig` (in the Topology section, select License).

  > **Note**
  >
  > Placing the new license file in the server root directory does not work in this case.

How to view the license status

To view the details of a license, including its expiration, you have these options:

- The server's `status` tool
- The administrative console's Status page (On the Monitors tab, search for License.)

License expiration

The server provides a notification as the expiration date approaches.

Before a license expires, obtain a new one and install it by using `dsconfig` or the administrative console.

> **Note**
>
> An expiring license causes alerts and alarms but does not affect the functionality of the product.

Installing the PingDirectoryProxy server

To help administrators install identical proxies, the PingDirectoryProxy server lets you clone a proxy configuration.

About this task

When you deploy PingDirectoryProxy servers in a topology, you generally deploy them in pairs. These pairs have identical configurations except for their host name, port name, and possibly their location.

The following sections describe the `setup` tool in more detail, explaining how to install the first and subsequent directory proxy servers in your topology:

- About the setup tool

Copyright © 2025 Ping Identity Corporation

- Installing the PingDirectoryProxy server in interactive mode
- Installing the first PingDirectoryProxy server in non-interactive mode
- Installing additional PingDirectoryProxy servers in non-interactive mode
- Installing the PingDirectoryProxy server with a truststore in non-interactive mode

Steps

1. To install a PingDirectoryProxy server, run the `setup` tool.
2. To configure the server, run the `create-initial-proxy-config` tool.

   For more information, see Using the create-initial-proxy-config tool.
3. To clone the configuration, run the `setup` tool on subsequent servers and clone the configuration on a peer server.

About the setup tool

The `setup` tool lets you quickly install and configure a stand-alone PingDirectoryProxy server instance.

One of the strengths of the PingDirectoryProxy server is the ease with which you can install a server instance using the `setup` tool.

To install a server instance, run the `setup` tool in one of the following modes:

Interactive command-line mode

Interactive command-line mode prompts for information during the installation process. To start the installation in this mode, run the `setup` command without any options.

Non-interactive command-line mode

Non-interactive command-line mode is designed for setup scripts to automate installations or for command-line usage.

To start the installation in this mode, run `setup` with the `--no-prompt` option as well as the other arguments required to define the appropriate initial configuration.

Perform all installation and configuration steps while signed on to the system as the user or role under which the PingDirectoryProxy server runs.

Installing the PingDirectoryProxy server in interactive mode

The `setup` tool provides an interactive text-based interface to install a PingDirectoryProxy server instance.

Installing the first PingDirectoryProxy server in interactive mode

Steps

1. Change to the server root directory.

Copyright © 2025 Ping Identity Corporation

Example:

```
cd Directory Proxy Server
```

2. Use the `setup` command.

   Example:

   ```
   $ ./setup
   ```

3. Read the Ping Identity End-User License Agreement, and type `yes` to continue.
4. Press Enter to accept the default of `no` in response to adding this new server to an existing topology.

   Example:

   ```
   Would you like to add this server to an existing Directory Proxy Server topology? (yes / no) [no]:
   ```

5. Enter the fully qualified host name for this server, or press Enter to accept the default.
6. Create the initial root user DN for this server, or press Enter to accept the default.
7. Enter and confirm a password for this account.
8. To enable the PingDirectoryProxy server services (Configuration, Documentation, and Directory REST API) and Administrative Console over HTTPS, press Enter to accept the default. After setup, individual services can be enabled or disabled by configuring the HTTPS Connection Handler.
9. Enter the port on which the PingDirectoryProxy server should accept connections from HTTPS clients, press Enter to accept the default.
10. Enter the port on which the PingDirectoryProxy server should accept connections from LDAP clients, press Enter to accept the default.
11. The next two options enable LDAPS and StartTLS. Press Enter to accept the default (yes), or type no. If either are enabled, certificate options are required. To use the Java Keystore or the PKCS#12 keystore, the keystore path and the key PIN are required. To use the PKCS#11 token, only the key PIN is required.
12. Choose a certificate server option:

    Example:

    ```
    Certificate server options:
      1) Generate self-signed certificate (recommended for testing purposes only)
      2) Use an existing certificate located on a Java Keystore (JKS)
      3) Use an existing certificate located on a PKCS#12 keystore
      4) Use an existing certificate on a PKCS#11 token
    ```

13. Choose the desired encryption for backups and log files from the choices provided:

Copyright © 2025 Ping Identity Corporation

Choose from:

- Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments, and you should use the same encryption passphrase when setting up each server in the topology.
- Encrypt data with a key generated from a passphrase read from a file.
- Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
- Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
- Do not encrypt server data.

14. To configure your PingDirectoryProxy server to use entry balancing, type `yes`, or accept the default `no`. In an entry balancing environment, entries immediately beneath the balancing base DN are divided into disjoint subsets. Each subset of data is handled by a separate set of one or more directory server instances, which replicate this subset of data between themselves. Choosing `yes` will enable more memory be allocated to the server and tools.
15. Choose the option for the amount of memory to assign to this server.
16. Enter an option to set up the server with the current configuration, provide new parameters, or cancel.
17. After setup is complete, choose the next configuration option.

Example:

```
This server is now ready for configuration What would you like to do?

   1) Start 'create-initial-proxy-config' to create a basic
      initial configuration (recommended for new users)
   2) Start 'dsconfig' to create a configuration from scratch
   3) Quit

Enter choice [1]:
```

Installing additional PingDirectoryProxy server instances in interactive mode

About this task

The `setup` tool provides an interactive text-based interface to install a PingDirectoryProxy server instance that clones a previously installed PingDirectoryProxy server instance.

Steps

1. Change to the server root directory.

Example:

```
cd Directory Proxy Server
```

Copyright © 2025 Ping Identity Corporation

2. Use the `setup` command.

   Example:

   ```
   $ ./setup
   ```

3. Read the Ping Identity End-User License Agreement, and type `yes` to continue.

4. Enter `yes` in response to add this new server to an existing topology.

   Example:

   ```
   Would you like to add this server to an existing Directory Proxy Server topology? (yes / no) [no]:
   yes
   ```

5. Enter the host name of the PingDirectoryProxy server from which configuration settings are copied during setup.

   Example:

   ```
   Enter the host name of the peer Directory Proxy Server from which you would like
   to copy configuration settings. [proxy.example.com]:
   ```

6. Type the port number of the peer PingDirectoryProxy server from which configuration settings are copied during setup. You can press Enter to accept the default port, which is 389.

   Example:

   ```
   Enter the port of the peer Directory Proxy Server [389]:
   ```

7. Enter the option corresponding to the type of connection you want to use to connect to the peer PingDirectoryProxy server.

   Example:

   ```
   How would you like to connect to the peer Directory Proxy Server?
     1) None
     2) SSL
     3) StartTLS

   Enter choice [1]:
   ```

8. Type the root user DN of the peer PingDirectoryProxy server, or press Enter to accept the default (cn=Directory Manager), and then type and confirm the root user password.

   Example:

   ```
   Enter the manager account DN for the peer Directory Proxy Server [cn=Directory Manager]:
   Enter the password for cn=Directory Manager:
   ```

9. Enter the host name of the new local PingDirectoryProxy server.

Copyright © 2025 Ping Identity Corporation

Example:

```
Enter the fully qualified host name or IP address of the local host [proxy.example.com]:
```

10. Choose the location of your new PingDirectoryProxy server instance or enter a new one.
11. Enter an option to set up the server with the current configuration, provide new parameters, or cancel.
12. After setup is complete, choose the next configuration option.

Installing the first PingDirectoryProxy server in non-interactive mode

Run the setup tool in non-interactive mode to automate the installation process using a script or to run the command directly from the command line.

About this task

The `setup` tool automatically chooses the maximum heap size. You can manually tune the maximum amount of memory devoted to the server's process heap using the `--maxHeapSize` option. The `--maxHeapSize` argument is only valid if the `--entryBalancing` option is also present.

If you are using entry balancing, tune the amount of memory devoted to the PingDirectoryProxy server using the `--entryBalancing` option as follows.

```
--entryBalancing --maxHeapSize 1g
```

The amount of memory allowed when using the `--entryBalancing` option is calculated and depends on the amount of system memory available.

If you already configured a truststore, you can run the `setup` tool to enable security. The following example enables both SSL and StartTLS security. It also specifies a Java Keystore (JKS) and Truststore that define the server certificate and trusted CA. The passwords for the keystore files are defined in the corresponding `.pin` files, where the password is written on the first line of the file. The values in the `.pin` files are copied to the `server-root/config` directory in the `keystore.pin` file.

```
$ env JAVA_HOME=/ds/java ./setup \
   --no-prompt --rootUserDN "cn=Directory Manager" \
   --rootUserPassword "password" --ldapPort 389 \
   --enableStartTLS --ldapsPort 636 \
   --useJavaKeystore /path/to/devkeystore.jks \
   --keyStorePasswordFile /path/to/devkeystore.pin \
   --certNickName server-cert \
   --useJavaTrustStore /path/to/devtruststore.jks \
   --trustStorePasswordFile /path/to/devtruststore.pin \
   --acceptLicense \
   --instanceName ds1 --location Denver
```

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The password to the private key within the keystore is expected to be the same as the password to the keystore. If this is not the case, you can define the private key password within the administrative console or `dsconfig` by editing the Trust Manager Provider standard configuration object.

Steps

1. Run `setup` with the `--no-prompt` option.

   The command uses the default root user distinguished name (DN) (`cn=Director Manager`) with the specified `--rootUserPassword` option. You must include the `--acceptLicense` , `--instanceName` , and `--location` options or the `setup` tool will generate an error message.

```
$ env JAVA_HOME=/ds/java ./setup --no-prompt \
--rootUserDN "cn=Directory Manager" \
--rootUserPassword "password" --ldapPort 389 \
--acceptLicense \
--instanceName ds1 --location Denver
```

Installing additional PingDirectoryProxy servers in non-interactive mode

Run the setup tool in non-interactive mode to automate the installation process using a script or to run the command directly from the command line.

About this task
Steps

1. Run the `setup` tool with the `--no-prompt` option.

```
$ env JAVA_HOME=/ds/java ./setup --no-prompt \
--rootUserDN "cn=Directory Manager" \
--rootUserPassword "password" --ldapPort 1389 \
--localHostName proxy2.example.com \
--peerHostName proxy1.example.com --peerPort 389 \
--peerUseNoSecurity --acceptLicense --instanceName ds1 \
--location austin1
```

Installing the PingDirectoryProxy server with a truststore in non-interactive mode

About this task

If you've already configured a trust store, you can use the `setup` tool to enable security. The following example enables SSL security and specifies a Java KeyStore (JKS) and truststore that define the server certificate and trusted certificate authority (CA). The passwords for the keystore files are defined in the corresponding `.pin` files, where the password displays on the first line of the file. The values in the `.pin` files are copied to the `server-root/config` directory in the `keystore.pin` and `truststore.pin` files.

Copyright © 2025 Ping Identity Corporation

Steps

1. To install a PingDirectoryProxy server with a truststore, run the `setup` tool.

```
$ env JAVA_HOME=/ds/java ./setup \
  --no-prompt --rootUserDN "cn=Directory Manager" \
  --rootUserPassword "password" \
  --ldapPort 389 --ldapsPort 636 \
  --useJavaKeystore /path/to/devkeystore.jks \
  --keyStorePasswordFile /path/to/devkeystore.pin \
  --certNickName server-cert \
  --useJavaTrustStore /path/to/devtruststore.jks \
  --acceptLicense \
  --instanceName ds1 --location Denver

In order to update the trust store, the password must be provided

See 'prepare-external-server --help' for general overview

Testing connection to ds-east-01.example.com:1636 ..... Done
Testing 'cn=Proxy User,cn=Root DNs,cn=config' access .....

Verifying backend 'dc=example,dc=com' ..... Done
```

PingDirectoryProxy server folder layout

After extracting the PingDirectoryProxy server distribution file, a variety of folders and command-line utilities are available.

Directories, Files, or Tools	Description
`License.txt`	Licensing agreement for the PingDirectoryProxy server.
`README`	`README` file that describes the steps to set up and start the PingDirectoryProxy server.
`bak`	Stores the physical backup files used with the `backup` command-line tool.
`bat`	Stores Windows-based command-line tools for the PingDirectoryProxy server.
`bin`	Stores UNIX/Linux-based command-line tools for the PingDirectoryProxy server.
`classes`	Stores any external classes for server extensions.
`collector`	Used by the server to make monitored statistics available to the Data Metrics Server.
`config`	Stores the configuration files for the backends (`admin` , `config`) as well as the directories for messages, schema, tools, and updates.
`docs`	Provides the product documentation.

Copyright © 2025 Ping Identity Corporation

Directories, Files, or Tools	Description
`import-tmp`	Stores temporary imported items.
`ldif`	Stores any LDIF files that you create or import.
`legal-notices`	Stores any legal notices for dependent software used with the PingDirectoryProxy server.
`lib`	Stores any scripts, jar, and library files needed for the server and its extensions.
`locks`	Stores any lock files in the backends.
`logs`	Stores log files for the PingDirectoryProxy server.
`metrics`	Stores the metrics that can be gathered for this server and surfaced in the Data Metrics Server.
`resource`	Stores the management information base (MIB) files for SNMP and can include `ldif` files, `make-ldif` templates, schema files, `dsconfig` batch files, and other items for configuring or managing the server.
`revert-update`	The `revert-update` tool for UNIX/Linux systems.
`revert-update.bat`	The `revert-update` tool for Windows systems.
`setup`	The `setup` tool for UNIX/Linux systems.
`setup.bat`	The `setup` tool for Windows systems.
`scim-data-tmp`	Used to create temporary files containing SCIM request data.
`uninstall`	The `uninstall` tool for UNIX/Linux systems.
`uninstall.bat`	The `uninstall` tool for Windows systems.
`update`	The `update` tool for UNIX/Linux systems.
`update.bat`	The `update` tool for Windows systems.
`Velocity`	Stores any customized Velocity templates and other artifacts, such as CSS, Javascript, and images, or Velocity applications hosted by the server.

Signing on to the administrative console

After you install the server, access the administrative console to verify the configuration and manage the server.

To access the administrative console, go to `https://<host>:<port>/console/login`.

Copyright © 2025 Ping Identity Corporation

<host> is the hostname of the server, and *<port>* is the port on which the server accepts connections from HTTPS clients. This was configured during the install.

The root user distinguished name (DN) or the common name of a root user DN is required to sign on to the administrative console. For example, if the DN created when the server was installed is `cn=Directory Manager`, `directory manager` can be used to sign on to the administrative console.

To run the administrative console in an external container, such as Tomcat, seeDeploying the administrative console.

Uninstalling the server

The server provides an `uninstall` command-line utility for quick removal of the code base.

To uninstall a server instance, run the `setup` tool in interactive command-line, or non-interactive command-line mode.

Interactive command-line mode

Interactive command-line mode is a text-based interface that prompts the user for input. To use this mode, run `bin/uninstall` without any options.

Non-interactive command-line mode

Non-interactive command-line mode suppresses progress information from being written to standard output during processing, except for fatal errors. To run this mode, use the `bin/uninstall` command with the `--no-prompt` option.

> **Note**
>
> For standalone installations with a single server instance, you can also manually remove the server by stopping it and recursively deleting the directory and subdirectories, as in the following example.
>
> ```
> $ rm -rf /ds/PingDirectory
> ```

Uninstalling the server in interactive mode

Interactive mode uses the `uninstall` utility, a text-based, command-line interface to help you remove your server instance.

About this task

If the `uninstall` command-line utility cannot remove all of the server files, the `uninstall` tool generates a message with a list of the files and directories that must be deleted manually. The `uninstall` command must be run as either the root user or the same user (or role) that installed the server.

Steps

1. From the server root directory, run the `uninstall` command-line utility.

   Example:

   ```
   $ ./uninstall
   ```

Copyright © 2025 Ping Identity Corporation

2. Select the components to be removed.

   Choose from:

   - Remove all components - If you want to remove all components, press Enter to accept the default (remove all).
   - Select the components to be removed - If you do not want to remove all components, enter the option to specify the removal of only specific components.

     For each type of server component, press Enter to remove it or enter `no` to keep it.

3. If the server is part of a replication topology, enter `yes` to provide your authentication credentials (Global Administrator ID and password). If you are uninstalling a standalone server, continue to step 6.
4. Enter the Global Administrator ID and password to remove the references to this server in other replicated servers, and then enter or verify the host name or IP address for the server that you are uninstalling.
5. Select how you want to trust the server certificate if you have set up SSL or StartTLS. Press Enter to accept the default.

   Example:

   ```
   How do you want to trust the server certificate for the PingDirectory Server
   on server.example.com:389?

   1) Automatically trust
   2) Use a trust store
   3) Manually validate

   Enter choice [3]:
   ```

6. View the logs for any remaining files and manually remove any remaining files or directories.

   If your server is running, it shuts down before continuing the uninstall process. The uninstall action processes the removal requests before completing.

Uninstalling the server in non-interactive mode

The `uninstall` command-line utility provides a non-interactive method to enter the command with the `--no-prompt` option.

About this task

Another useful argument is the `--forceOnError` option that continues the uninstall process when an error is encountered. If an option is incorrectly entered or if a required option is omitted and the `--forceOnError` option is not used, the command fails and aborts.

Steps

1. From the server root directory, run `uninstall` with the `--remove-all` option to remove all of the PingDirectory server's libraries.

   The optional `--quiet` option suppresses output information.

   Example:

Copyright © 2025 Ping Identity Corporation

The following command assumes that the server is standalone and not part of a replication topology.

```
$ ./uninstall --remove-all --no-prompt --quiet --forceOnError
```

2. If any files or directories remain, manually remove them.

Uninstalling selected components in non-interactive mode

Use the `--backup-files` with the `uninstall` command to remove the server's backup files.

Steps

1. From the server root directory, run `uninstall` with the `--backup-files` option.

   Example:

   ```
   $ ./uninstall --backup-files --no-prompt --quiet --forceOnError
   ```

2. To view the other options available to remove specific components, use the `--help` or `-H` option.

Upgrading the PingDirectoryProxy server

Administrators can use the PingDirectoryProxy server's `update` utility to update the current server code with the latest features and bug fixes.

Software builds of the PingDirectory server are issued periodically and are distributed in `.zip` format. To update the server to a newer version, download the build package, and then extract the new server package on the same host as the server you want to update.

> **Note**
>
> Before upgrading a server, ensure that it is capable of starting without severe or fatal errors. Learn more in Planning your upgrade in the Best Practices Guides.

During the update process, the updater checks a manifest file that contains a MD5 checksum of each file in its original state when installed from `.zip`. Next, it compares the checksum of the new server files to that of the old server. Any files that have different checksums are updated. For files that predates the manifest file generation, the file is backed up and replaced. The updater also logs all file changes in the history directory to tell what files have been changed.

For schema updates, the `update` tool preserves any custom schema definitions (`99-user.ldif`). For any default schema element changes (if any), the updater warns the user about this condition and then creates a patch schema file and copies it into the server's schema directory. For configuration files, the `update` tool preserves the configuration file, `config.ldif`, unless you need to add new configuration options to the PingDirectoryProxy server.

When the updater finishes processing, it checks if the newly updated server starts without any fatal errors. If an error occurs during the update process, the `update` tool reverts the server root instance to the server state prior to the update.

Upgrade overview and considerations

Spring compatibility

For PingDirectory Suite releases prior to 9.0.0.0, Spring configuration properties in the administrative console are not compatible with the most recent console bundled with 9.0.0.0 and later. This is due to major updates to Spring dependencies. Attempting to use these older configuration files will result in the console failing to start.

If you are using older administrative console configuration files, they should be updated. Replace the following excerpt in the old `application.yml` file:

```
spring:
  profiles.active: default
  main.show-banner: false
  thymeleaf.cache: true
  thymeleaf.prefix: classpath:/public/app/
```

with the following:

```
spring:
  profiles.active: default
  web.resources:
    # 1 year. Update the corresponding value in MvcConfig if this changes.
    cache.period: 31536000
    add-mappings: false # use our custom mappings instead of the defaults
  main:
    banner-mode: "OFF"
  thymeleaf:
    prefix: classpath:/public/app/
```

Upgrading servers in a topology

An update to the current server release includes the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts.

Before you begin

Before you can update and migrate the admin backend, the following conditions must be satisfied:

- Run the update tool and provide LDAP authentication options to the peer servers of the server being updated. The `update` tool connects to the peer servers of the server being updated to obtain the necessary information to populate the topology registry.
- On every server in the topology, configure the encryption protocol requested, either plain, TLS, StartTLS, or SASL, for an LDAP connection.
- Ensure the LDAP credentials are present on every server in the topology.

Copyright © 2025 Ping Identity Corporation

- Ensure the users related to the LDAP credentials have permissions to read from the admin backend and the config backend of every server in the topology. For example, you can use a root DN user that has `inherit-default-privileges` set to true, such as the `cn=Directory Manager` user, that exists on every server.
- The instance name is set on every server and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server is uniquely identified by its instance name. After the name is set, it cannot be changed.

> **Tip**
>
> If needed, use the following command to set the instance name of a server prior to the update.
> +
> ```
> $ bin/dsconfig set-global-configuration-prop \
>   --set instance-name:uniqueName
> ```

> **Important**
>
> This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than a 7.x to a 7.x version and is not applicable to any updates to a server version of 8.x or later.

About this task

Upgrade to a server that uses a topology registry to store network configuration, administrator user accounts, and keys information, as well as migrate the information from the previous server version. The following requirements must be met:

- When the first server is being updated, all other servers in the topology are online.
- When updating additional servers, all topology information was obtained from one of the servers that has already been updated.
- The users related to the provided LDAP credentials have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server and is unique across all servers in the topology.

Steps

1. To make clustered configuration changes in a mixed-version cluster, choose one of the following options:

   Choose from:

   - Update each server to the same version.
   - Temporarily split up the cluster by changing the `cluster-name` property on the server instance configuration objects.

     > **Note**
     >
     > Changes to clustered configurations are not allowed in mixed-version clusters. This applies to configuration in the `cn=Cluster,cn=config` subtree and only applies to servers with matching cluster names.

Copyright © 2025 Ping Identity Corporation

2. Make clustered configuration changes again to mirror these changes across the topology.

   Result:

   When all of these conditions are met, the cluster-wide configuration is synchronized on all servers in the topology.

   > **Note**
   >
   > Older versions have some topology configuration under the `cn=cluster,cn=config` JSON attribute and field constraints. These items do not support mirrored cluster-wide configuration data. In an update, avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree primary. If additional configuration steps are needed, see step 4.

3. To synchronize the cluster-wide configuration data across all servers in the topology, run the `config-diff` tool on each pair of servers to determine the differences, and use `dsconfig` to update each instance using the `config-diff` output.

   Example:

   ```
   $ bin/config-diff --sourceHost hostName \
     --sourcePort port \
     --sourceBindDN bindDN \
     --sourceBindPassword password \
     --targetHost hostName \
     --targetPort port \
     --targetBindDN bindDN \
     --targetBindPassword password
   ```

Upgrading the PingDirectoryProxy server

About this task

Assume that an existing version of the PingDirectoryProxy server is stored in the `PingDirectoryProxy-old` directory.

Steps

1. Make a complete, readable backup of the existing system.

   > **Note**
   >
   > Make sure you have a clear backout plan and schedule.

2. Download the latest version of the PingDirectoryProxy software and extract the file.

   Assume the new server is located in the `PingDirectoryProxy-new` directory.

3. Use the `--version` option on any command-line utility to check the version number of the PingDirectoryProxy server instance that you downloaded in step 2.

   Example:

   You should see the latest revision number.

Copyright © 2025 Ping Identity Corporation

```
$ PingDirectoryProxy-new/setup --version PingDirectoryProxy 9.0.0.0
Build 2011043200609Z Revision 9235
```

4. Run the `update` tool of the newly extracted build to update the PingDirectoryProxy server code.

   Use the `--serverRoot` option to specify the PingDirectoryProxy server instance that you're upgrading.

   Example:

   ```
   $ PingDirectoryProxy-new/update --serverRoot PingDirectoryProxy-old
   ```

   > **Note**
   >
   > The PingDirectoryProxy server provides a web-based administrative console for configuring and monitoring the server. If you update the server version, you should also update the administrative console.

   > **Note**
   >
   > You must stop the PingDirectoryProxy server to apply this update.

5. To see which files are changed, go to the `<server-root>/history` directory and open the log file.

   Example:

   The file is labeled with the version number and revision.

   ```
   $ view  <server-root>/history/1272307020420-9.0.0.0.9235/update.log
   ```

Reverting an update

After the server has been updated, you can revert to the last version or one level back using the `revert-update` tool.

About this task

The `revert-update` tool accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the `revert-update` tool multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing the server, you can run the `revert-update` command to revert to its previous state, then run the `revert-update` command again to return to its original state. The following steps detail reverting from 7.x to a version prior to 7.0.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server displays warnings about "offline configuration changes," but they are not critical and do not appear on subsequent start ups.

To revert to the most recent server version:

Steps

- Use `revert-update` in the server root directory to revert back to the most recent version of the server.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ PingDirectory-old/revert-update
```

Next steps

Reverting from the 7.0 version or later to a version earlier than 7.0 using the `revert-update` command might require extra steps. This is also the case when updating or reverting from a version earlier than 6.2.0.2 to a 6.2.0.2 version or later. These steps are listed when the `update` and `revert-update` tool are run as well. Depending on your installation and configuration, you might need to perform one or more of the following tasks:

- When updating or reverting from 6.2.0.2 or later to a version earlier than 6.2.0.2, indexes might need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and rebuild the indexes using the `rebuild-index` tool. The command for recreating an index is in the `Undo` portion of the `logs/config-audit.log` file. To later revert to an older version, delete and recreate those composite indexes again after the revert process completes.
- When updating to 7.x for the first time, instance names must be set for each server in the topology if they were not previously set. This is done with the following `dsconfig` command.

  ```
  $ bin/dsconfig --bindDN "cn=Directory Manager" \
    --bindPassword secret \
    --no-prompt set-global-configuration-prop \
    --set instance-name:<name>
  ```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the `admin` backend. As long as new servers are not added to the topology after this update, you can use the `revert-update` command to return to the previous version. However, if new servers are added, then the restored `admin` backend of this server does not contain information about the new servers, and the local server cannot communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.
- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a version earlier than 7.x, any servers in the topology using the topology portion of the configuration rather than the `admin` backend must know that the reverted server was downgraded to the `admin` backend. To do this, run the following `dsconfig` command on one of the servers that has not been reverted.

  ```
  $ bin/dsconfig set-server-instance-prop \
    --instance-name <Reverted server instance name> \
    --set server-version:<Version to which server is reverted>
  ```

- If the topology does not have a primary server when this command is run, the `revert-update` will not succeed. In this case, you must make one of the remaining updated servers in the topology the primary with the following command. This enables the chosen instance to run the `revert-update` command successfully.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-global-configuration-prop \
  --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions, such as 6.x or earlier. To later revert to an older version, you must export the data to LDIF before performing the reversion. Then, re-import the data after the revert process completes. In addition, you must delete the `changelogDb/` and `db/changelog/` directories in the reverted server root after the revert process completes.

Getting Started with the PingDirectoryProxy server

- Running the server
- Stopping the server
- Scheduling a server shutdown
- Restarting the server
- Running the server as a Microsoft Windows service

Running the server

Run the server as a background or foreground process.

Steps

1. To start the server, run the `bin/start-server` command on UNIX or Linux systems.

   An analogous command is in the `bat` folder on Microsoft Windows systems.

   > **Note**
   >
   > The `bin/start-server` command starts the server as a background process when no options are specified.

2. (Optional) To run the server as a foreground process, use the `bin/start-server` command with the `--nodetach` option.

Starting the server

Start the server using the terminal.

Steps

- To start the server, on the terminal run the following command:

  Example:

```
$ bin/start-server
```

Copyright © 2025 Ping Identity Corporation

Running the server as a foreground process

Use the terminal to run the server as a foreground process.

Steps

1. To launch the server as a foreground process, open the terminal and enter `bin/start-server` with the `--nodetach` option.

   Example:

   ```
   $ bin/start-server --nodetach
   ```

2. To stop the server:

   Choose from:

   - Press `CNTRL+C` in the terminal window where the server is running.
   - Enter `bin/stop-server` command from another terminal window.

Starting the PingDirectoryProxy server at boot time

By default, the server does not start automatically when the system is booted. Instead, you must start it manually with the `bin/start-server` command.

About this task

To configure the server to start automatically when the system boots, use the `create-systemd-script` utility to create a script, or create the script manually.

Steps

1. Create the service unit configuration file in a temporary location, where "ds" is the user running the server.

   Example:

   ```
   $ bin/create-systemd-script \
        --outputFile /tmp/ping-directory-proxy.service \
        --userName ds
   ```

2. As a root user, copy the `ping-directory-proxy.service` configuration file into the `/etc/systemd/system` directory.

3. To read the new configuration file, reload `systemd`.

   Example:

   ```
   $ systemctl daemon-reload
   ```

4. To start the server, run the `start` command.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ systemctl start ping-directory-proxy.service
```

5. To configure the server to start automatically when the system boots, run the `enable` command.

   Example:

   ```
   $ systemctl enable ping-directory-proxy.service
   ```

6. Log out as root.

   To perform this task on an RC system, create the startup script with `bin/create-rc-script` and move it to the `/etc/init.d` directory.

   > **Note**
   >
   > Create symlinks to this script from the /etc/rc3.d directory (starting with an "S" to ensure that the server is started) and /etc/rc0.d directory (starting with a "K" to ensure that the server is stopped).

Stopping the server

The server provides a simple shutdown command, `bin/stop-server`, to stop the server. You can run it manually from the command line or within a script.

About this task

If the server has been configured to use a large amount of memory, then it might take several seconds for the operating system to fully release the memory and make it available again. If you try to start the server too quickly after shutting it down, then the server might fail because the system does not yet have enough free memory. On UNIX systems, run the `vmstat` command and watch the values in the "free" column increase until all memory held by the server is released back to the system.

You can also set a configuration option that specifies the maximum shutdown time a process might take.

Steps

- Use the following command to shut down the server.

  Example:

  ```
  $ bin/stop-server
  ```

Scheduling a server shutdown

Schedule a server shutdown using the `--stopTime YYYYMMDDhhmmss` option.

Steps

- To schedule a server shutdown, use the `bin/stop-server` command with the `--stopTime YYYYMMDDhhmmss` option.

Copyright © 2025 Ping Identity Corporation

The server schedules the shutdown and sends a notification to the `server.out` log file. The following example sets up a shutdown task that is scheduled to be processed on June 6, 2012 at 8:45 A.M. CDT. The server uses the UTC time format if the provided timestamp includes a trailing "Z", for example, 20120606134500Z. The command also uses the `--stopReason` option that writes the reason for the shut down to the logs.

Example:

```
$ bin/stop-server --stopTime 20120606134500Z --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --stopReason "Scheduled offline maintenance"
```

Restarting the server

Restart the server.

About this task

Running this command is equivalent to shutting down the server, exiting the Java Virtual Machine (JVM) session, and then starting up again.

Steps

- Go to the server root directory, and run the **`bin/stop-server`** command with the `-R` or `--restart` options.

  Example:

  ```
  $ bin/stop-server --restart
  ```

Running the server as a Microsoft Windows service

The server can run as a Windows service, which enables you to sign out of a machine without stopping the server.

Registering the server as a Windows service

Register the server as a Windows service using the Windows command prompt.

About this task

Perform the following steps to register the server as a service:

Steps

1. Stop the server with `bin\stop-server`.

   You cannot register a server while it is running.

2. To register the server as a service, from a Windows command prompt, run `bat\register-windows-service.bat`.

3. After registration, start the server from the Windows Services Control Panel or with the `bat\start-server.bat` command.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

Running multiple service instances

Only one instance of a particular service can run at one time.

About this task

Services are distinguished by the `wrapper.name` property in the `<server-root>\config\wrapper-product.conf` file.

Steps

1. To run additional service instances, change the `wrapper.name` property on each additional instance.
2. Add or change descriptions of the service in the `wrapper-product.conf` file.

Deregistering and uninstalling services

To uninstall a service, you must first deregister it.

About this task

While a server is registered as a service, it cannot run as a non-service process or be uninstalled.

Steps

1. To remove the service from the Windows registry, use the `bat\deregister-windows-service.bat` file.
2. To uninstall the server, run the `uninstall.bat` script.

Configuring log files for services

About this task

The log files are stored in `<server-root>\logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or the file reaches its maximum size. Only the last three log files are retained.

Steps

1. These configurations can be changed in the `<server-root>\config\wrapper.conf` file.

Configuring the PingDirectoryProxy server

After you have set up the PingDirectoryProxy server, you can manage your deployment using the configuration framework and management tools.

About the configuration tools

You can access and modify your PingDirectoryProxy server in two ways.

Copyright © 2025 Ping Identity Corporation

Administrative console

The PingDirectoryProxy server provides an administrative console for graphical server management and monitoring. The console functions are equivalent to the `dsconfig` tool for viewing or editing configurations.

All configuration changes using the administrative console are recorded in `logs/config-audit.log`, which also has the equivalent reversion commands if you need to undo a configuration.

`dsconfig` *Command-line tool*

The `dsconfig` tool is a text-based menu-driven interface to the underlying configuration. The tool runs the configuration using three operational modes:

- Interactive command-line mode
- Non-interactive command-line mode
- Batch mode

All configuration changes made using this tool are recorded in `logs/config-audit.log`.

Using the create-initial-proxy-config tool

The `create-initial-proxy-config` tool can be used to initially configure the PingDirectoryProxy server. We strongly recommend that you use the `create-initial-proxy-config` tool for your initial server configuration. This tool prompts you for basic information about your topology, including external servers, their locations, and credentials for communicating with them. Once the configuration is complete, the tool writes the configuration to a `dsconfig` batch file and allows you to apply the configuration to the local PingDirectoryProxy server. The tool assumes the following about your topology:

- All servers are accessible through a single user account. This user account must be a root user that is not generally accessible to clients to avoid inadvertent changes, deletions, or backend server availability issues due to reimporting data.
- All servers support the same type of communication security.
- All external servers are any combination of PingDirectory server, Sun Directory Server, or Red Hat (including Fedora and 389) instances.

If your topology does have these characteristics, you can use the tool to define a basic configuration that is saved to a `dsconfig` batch file. You can then run the `dsconfig` tool to fine-tune the configuration. You can also use this tool to configure an entry balancing configuration, which allows you to automatically spread entries below a common parent among multiple sets of directory servers for improved scalability and performance.

The `create-initial-proxy-config` tool produces a log file called `create-initial-proxy-config.log` that is stored in the local PingDirectoryProxy server's `logs` directory.

You can only run the `create-initial-proxy-config` tool once for the initial configuration of each PingDirectoryProxy server instance. To tune your configuration, use the `dsconfig` tool. When installing a second PingDirectoryProxy server, it will not be necessary to run the `create-initial-proxy-config` tool again, because the PingDirectoryProxy server setup has the ability to clone the settings from an existing Directory Proxy Server.

This section describes how to use this tool to configure a standard PingDirectoryProxy server deployment as well as an entry balancing configuration.

Copyright © 2025 Ping Identity Corporation

Configuring a standard PingDirectoryProxy server deployment

Install a standard PingDirectoryProxy server deployment using the `create-initial-proxy-config` tool.

About this task

> **Note**
>
> Remember that you deploy PingDirectoryProxy servers in pairs. Each pair should be configured identically except for their host name, port, and possibly their location.

Steps

1. After initial installation, select the number to start the `create-initial-proxy-config` tool automatically, or run it manually at the command line from the server root directory, `<server-root>/PingDirectoryProxy`.

```
$ ./bin/create-initial-proxy-config
```

2. If the servers do not meet the displayed configuration requirements, you can enter `no` to quit the process.

```
Some assumptions are made about the topology in order to keep this tool simple:

        1) all servers will be accessible via a single user account
        2) all servers support the same communication security type
        3) all servers are PingDirectoryProxy, Directory Server,
           Java System 5.x, 6.x, or 7.x, or Red Hat (including Fedora and 389)
           directory servers

If your topology does not have these characteristics you can use this tool to define a basic
configuration and then use the 'dsconfig' tool or the Administrative Console to
fine tune the configuration.

Continue? (yes / no) [yes]:
```

3. Enter the distinguished name (DN) for the PingDirectoryProxy server user account, and then enter and confirm the password for this account.

```
Enter the DN of the proxy user account [cn=Proxy User,cn=Root DNs,cn=config]:
Enter the password for 'cn=Proxy User,cn=Root DNs,cn=config':
Confirm the password for 'cn=Proxy User,cn=Root DNs,cn=config':
```

> **Note**
>
> You should not use `cn=Directory Manager` account for communication between the PingDirectoryProxy server and the PingDirectory server.
> For security reasons, the account used to communicate between the PingDirectoryProxy server and the PingDirectory server should not be directly accessible by clients accessing the PingDirectoryProxy server.
> For more information about this account, see Configuring LDAP external servers.

Copyright © 2025 Ping Identity Corporation

4. Specify whether to use secure communication with the PingDirectory server instances.

```
>>>> External Server Communication Security

Specify the type of security that the Directory Proxy Server will use when communicating with
directory server instances:

   1)  None
   2)  SSL
   3)  StartTLS

   b)  back
   q)  quit

Enter choice [1]:
```

5. Enter the base DNs of the PingDirectory server instances that will be accessed through the PingDirectoryProxy server. Press Enter when you have finished specifying the DNs.

```
Enter a base DN of the directory server instances that will be accessed through the Identity Proxy:

    b)  back
    q)  quit

Enter a DN or choose a menu item [dc=example,dc=com]:
```

   The PingDirectoryProxy server will create subtree views using each base DN to define portions of the external servers' directory information tree (DIT) available for client access. You can specify more than one base DN.

6. Specify whether the entries under your defined subtree view will be split across multiple servers in an entry balanced deployment.

   Press Enter to accept the default setting of no.

7. Define a location for your server, such as the name of your data center or the city where the server is located.

```
Enter a location name or choose a menu item: east
```

8. (Optional) If you defined more than one location, specify the location that contains the PingDirectoryProxy server itself.

Copyright © 2025 Ping Identity Corporation

```
Choose the location for this Directory Proxy Server

    1)  east
    2)  west

    b)  back
    q)  quit

Enter choice [1]: 1
```

9. Define the host:port used by the LDAP external servers.

```
Enter a host:port or choose a menu item [localhost:389]: ldap-east-01.example.com:389
```

> **Note**
>
> If you have specified more than one location, you will complete this process for each location.

10. Select the option Yes, and all subsequent servers to indicate that you want the tool to create a proxy user account on all of your LDAP external servers within that location.

```
Would you like to prepare ldap-east-01.example.com:389 for access by the Directory Proxy Server?

    1) Yes
    2) No
    3) Yes, and all subsequent servers
    4) No, and all subsequent servers

Enter choice [1]: 3
```

11. If the proxy user account does not already exist on your LDAP external server, create the account by connecting as `cn=Directory Manager`.

```
Would you like to create or modify root user 'cn=Proxy User' so that it is available for this
Directory Proxy Server? (yes / no) [yes]:
Enter the DN of an account on ldap-east-01.example.com:389 with which to create or manage the
'cn=Proxy
User' account [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':

Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User' privileges ..... Done
Verifying backend 'dc=example,dc=com' ..... Done
```

12. Repeat steps 9-12 for the servers in the other location. When finished, press Enter to finish configuring the location.

13. Review the configuration summary. After you have confirmed that the changes are correct, press Enter to write the configuration.

Copyright © 2025 Ping Identity Corporation

```
>>>> Configuration Summary

  External Server Security:  SSL
  Proxy User DN:             cn=Proxy User,cn=Root DNs,cn=config

  Location east
    Failover Order: west
    Servers: localhost:1636

  Location west
    Failover Order: east
    Servers: localhost:2636

  Base DN: dc=example,dc=com
    Servers: localhost:1636, localhost:2636

    b)  back
    q)  quit
    w)  write configuration file

Enter choice [w]:
```

14. Enter `yes` to apply the configuration changes locally to the PingDirectoryProxy server.

```
This tool can apply the configuration changes to the local Identity Proxy. This requires any
configured Server SDK extensions to be in place. Do you want to do
this? (yes / no) [yes]:
```

> **Note**
>
> If you have any Server SDK extensions, be sure to run the **`manage-extension`** tool first, then press Enter to apply the changes to the PingDirectoryProxy server.

Alternatively, you can quit and run the `dsconfig` batch file at a later time.

Once the changes have been applied, you cannot use the `create-initial-proxy-config` tool to configure this PingDirectoryProxy server again. Use the `dsconfig` tool to modify your configuration instead.

Result

If you open the generated `proxy-cfg.txt` file or the `logs/config-audit.log` file, you see that a configuration element hierarchy has been created, listing locations, health checks, external servers, load-balancing algorithms, request processors, and subtree views.

About the dsconfig configuration tool

The `dsconfig` tool is the text-based management tool used to configure the underlying server configuration.

The `dsconfig` tool has three operational modes: interactive mode, non-interactive mode, and batch mode.

Copyright © 2025 Ping Identity Corporation

The `dsconfig` tool offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, you should keep the server running when you access the configuration for the server to give the user feedback about the validity of the configuration.

Using dsconfig in interactive command-line mode

In interactive mode, the `dsconfig` tool offers a filtering mechanism that only displays the most common configuration elements.

About this task

The user can specify that more expert level objects and configuration properties be shown using the menu system.

Running `dsconfig` in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the PingDirectory server.

Steps

1. To start `dsconfig` in interactive command-line mode, invoke the `dsconfig` script without any arguments.

   Result:

   You are prompted for connection and authentication information to the PingDirectoryProxy server, and then a menu displays the available operation types.

2. To accept the default values, press Enter.

   > **Note**
   >
   > In some cases, a default value is provided in square brackets. For example, [389] indicates that the default value for that field is port 389.

3. To skip the connection and authentication prompts, provide the connection and authentication information using the command-line options of `dsconfig`.

Changing the dsconfig object menu

The purpose of object levels is to present only those properties that an administrator will likely use.

About this task

Because some configuration objects are more likely to be modified than others, the PingDirectory server provides four different object menus that hide or expose configuration objects to the user. The `object` type is a convenience feature designed to improve menu readability.

The following object menus are available:

Basic

Only includes the components that are configured most frequently.

Copyright © 2025 Ping Identity Corporation

Standard

Includes all components in the Basic menu plus other components that might occasionally need to be altered in many environments.

Advanced

Includes all components in the Basic and Standard menus plus other components that might require configuration under special circumstances or that might be harmful if configured incorrectly.

Expert

Includes all components in the Basic, Standard, and Advanced menus plus other components that almost never require configuration, or that could seriously impact the functionality of the server if not properly configured.

To change the `dsconfig` object menu:

Steps

1. Using `dsconfig`, repeat steps 1–6 in Installing the PingDirectory server in interactive mode.
2. On the PingDirectory Server configuration main menu, enter the letter `o` to change the object level.

   Basic objects are displayed by default.
3. Enter a number corresponding to an object level of your choice.

   Choose from:

   - Enter `1` for Basic.
   - Enter `2` for Standard.
   - Enter `3` for Advanced.
   - Enter `4` for Expert.
4. Review the menu at the new object level.

   Additional configuration options for the server components are displayed.

Using dsconfig in non-interactive mode

The `dsconfig` non-interactive command-line mode provides a simple way to make arbitrary changes to the server by invoking it from the command line.

Steps

1. To use administrative scripts to automate configuration changes, run the `dsconfig` command in non-interactive mode.

   Non-interactive mode is convenient for scripting applications.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If you plan to make changes to multiple configuration objects at the same time, then the batch mode might be more appropriate.

2. **Use the `dsconfig` tool to update a single configuration object using command-line arguments to provide all of the necessary information.**

   Example:

   The following shows the general format for the non-interactive command line.

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

> **Note**
>
> The `--no-prompt` argument indicates that you want to use non-interactive mode. The `{sub-command}` is used to indicate which general action to perform. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the PingDirectory server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on your setup. For example, using standard LDAP connections, you can invoke the **`dsconfig`** tool, as shown.
>
> ```
> $ bin/dsconfig --no-prompt list-backends \
>   --hostname server.example.com \
>   --port 389 \
>   --bindDN uid=admin,dc=example,dc=com \
>   --bindPassword password
> ```

3. **If your system uses SASL GSSAPI (Kerberos), invoke `dsconfig` as shown.**

```
$ bin/dsconfig --no-prompt list-backends \
  --saslOption mech=GSSAPI \
  --saslOption authid=admin@example.com \
  --saslOption ticketcache=/tmp/krb5cc_1313 \
  --saslOption useticketcache=true
```

4. **To always display the advanced properties, use the `--advanced` command-line option.**

> **Note**
>
> The `{subcommandArgs}` argument contains a set of arguments specific to the particular subcommand that you want to invoke.
> Global arguments can appear anywhere on the command line, including before the subcommand and after or intermingled with subcommand-specific arguments. The subcommand-specific arguments can appear anywhere after the subcommand.

dsconfig non-interactive mode command">

Copyright © 2025 Ping Identity Corporation

Getting the equivalent `dsconfig` non-interactive mode command

Find the command you want to use in non-interactive command-line mode by looking it up in interactive mode.

Steps

1. Use `dsconfig` in interactive mode to make changes to a configuration, but do not enter the letter `f` to apply the changes.

   To view the equivalent non-interactive command, enter `d`.

   View the equivalent command, and then press Enter to continue.

   Based on an example in the previous section, changes made to the `db-cache-percent` returns the following message.

   ```
   Command line to apply pending changes to this Local DB Backend: dsconfig set-backend-prop --backend-
   name userRoot --set db-cache-percent:40
   ```

   The command does not contain the LDAP connection parameters required for the tool to connect to the host because the command is presumed to be used to connect to a different remote host.

Using dsconfig batch mode

Configure the server in `dsconfig` batch mode.

About this task

The PingDirectory server provides a `dsconfig` batching mechanism that reads multiple `dsconfig` invocations from a file and executes them sequentially.

The batch file provides advantages over standard scripting by minimizing LDAP connections and Java virtual machine (JVM) invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

If a `dsconfig` command has a missing or incorrect argument, the command fails and aborts the batch process without applying any changes to the server. The `dsconfig` command supports a `--batch-continue-on-error` option that instructs `dsconfig` to apply all changes and skip any errors.

You can view the `logs/config-audit.log` file to review the configuration changes made to the server and use them in the batch file. The batch file can have blank lines for spacing and lines starting with a pound sign (#) for comments. The batch file also supports a `\` line continuation character for long commands that require multiple lines.

The server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Oracle to PingDirectory server machines.

Steps

1. Create a text file that lists each `dsconfig` command with the complete set of properties that you want to apply to the server.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The items in this file should be in the same format as those accepted by the **dsconfig** command.
> The batch file can have blank lines for spacing and lines starting with a pound sign (**#**) for comments.
> The batch file also supports a "\" line continuation character for long commands that require multiple lines.

Example:

```
# This  dsconfig  operation creates the exAccountNumber global attribute index.
dsconfig create-global-attribute-index
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--index-name exAccountNumber --set prime-index:true

# Here we create the entry-count placement algorithm with the
# default behavior of adding entries to the smallest backend
# dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name example_com_entry_count
--type entry-counter
--set enabled:true
--set "poll-interval:1 m"

# Note that once the entry-count placement algorithm is created
# and enabled, we can delete the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then delete the
# original round-robin algorithm created during the setup
# procedure.

dsconfig delete-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin
```

2. To read and execute the commands, run `dsconfig` with the `--batch-file` option.

Using the PingDirectory server or the PingDirectoryProxy server with PingFederate OAuth tokens

Configure an access token validator to use PingFederate OAuth tokens with PingDirectory.

Before you begin

You need the following information:

- The runtime engine service port of the PingFederate server, usually 9031
- The client ID of an OAuth 2.0 client configured on the PingFederate server
- The client secret of the OAuth 2.0 client
- The IP address of the PingFederate server

About this task

Copyright © 2025 Ping Identity Corporation

After you configure a PingFederate server to issue OAuth 2 tokens, you must make these tokens compatible with SCIM 2.0 operations on the PingDirectory server or the PingDirectoryProxy server.

This section explains how to set up an access token validator to handle this task.

Steps

1. Register the PingFederate server using the following command.

```
dsconfig create-external-server \
  --server-name PingFederateInstance \
  --type http \
  --set base-url:https://<PingFed IP address>:<PingFed port>  \
  --set hostname-verification-method:allow-all \
  --set "trust-manager-provider:Blind Trust"
```

> **Note**
>
> In this example, the hostname verification method is set to `allow-all` and the Blind Trust manager provider is used for the sake of simplicity. You should not use these settings for production environments.

2. Create the access token validator using the following command.

```
dsconfig create-access-token-validator \
                        --validator-name PingFederateValidator \
  --type ping-federate \
  --set enabled:true \
  --set authorization-server:PingFederateInstance \
  --set client-id:client-id  \
  --set client-secret:client-secret
```

> **Note**
>
> Take the *client-id* and *client-secret* values from the PingFederate OAuth 2 client that will be used with the PingDirectory server or PingDirectoryProxy.

3. Add the access token validator to the SCIM 2 HTTP Servlet configuration with the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set access-token-validator:PingFederateValidator
```

4. Test the validator by sending a GET request to `/scim/v2/ServiceProviderConfig`.

   This endpoint does not require any scopes to access, just a valid bearer token. The sever should return a response similar to the following.

Copyright © 2025 Ping Identity Corporation

```

Topology configuration

Topology configuration enables automatic server grouping and configuration change mirroring. It uses a primary and secondary architecture for mirroring shared data across the topology.

All writes and updates are forwarded to the primary, which forwards them to all other servers. Reads can be served by any server in the group, and servers can be added to an existing topology at installation.

> **Note**
>
> To remove a server from the topology, you must uninstall it with the uninstall tool.

Copyright © 2025 Ping Identity Corporation

Topology primary requirements and selection

A topology primary server receives configuration changes from other servers in the topology, verifies the changes, and then makes the changes available to all connected servers.

When updating, the primary sends a digest of its subtree contents. If the node's digest differs from the primary's, the server node knows it is not synchronized. The servers pull the entire subtree from the primary if they detect that they are not synchronized.

A server detects it is not synchronized with the primary under the following conditions:

- The server's subtree digest differs from the primary's digest at the end of its periodic polling interval.
- One or more servers have been added to or removed from the topology.

The primary of the topology is selected by prioritizing servers based on:

- Minimum supported product version
- Availability
- Server version
- Earliest start time
- Startup UUID (smaller is preferred)

After determining a primary, the topology data is reviewed from all available servers, every five seconds by default, to determine if any new information identifies a better server primary. If a new server can be the primary and no other servers have indicated that they should be the primary, it will communicate its eligibility to the other servers. This ensures that all servers accept the same primary at approximately the same time, within a few milliseconds of each other. If there is no better primary, the initial primary maintains the role.

After the best primary has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that primary.

  The primary server itself is considered while determining this majority.

- There is only a single primary in the entire topology.

If either of these conditions is not met, the topology is without a primary and the peer polling frequency is reduced to 100 milliseconds to find a new primary as quickly as possible. If there is no primary in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as primary with the `force-as-master-for-mirrored-data` option in the Global Configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as primaries, then a `multiple-servers-forced-as-masters` alarm is raised.

Topology components

When you install a server, you can add it to an existing topology, cloning the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

Copyright © 2025 Ping Identity Corporation

Server configuration settings

Configuration settings for the topology are configured in the global configuration and in the config file handler backend. They are topology settings, but they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The global configuration object contains a single topology setting, `force-as-master-for-mirrored-data`. This should be set to `true` on only one of the servers in the topology, and is used only if the topology cannot determine a primary because most of the servers are not available. A server with this setting enabled is assigned the role of primary if no suitable primary can be determined.

The config file handler backend defines three topology `mirrored-subtree` settings:

`mirrored-subtree-peer-polling-interval`

Specifies the frequency at which the server polls its topology peers to identify any changes warranting a new primary selection. A lower value ensures a faster failover, but it also causes more traffic among the peers. The default value is 5 seconds. If no suitable primary is found, the polling frequency adjusts to 100 milliseconds until a new primary is selected.

`mirrored-subtree-entry-update-timeout`

Specifies the maximum length of time to wait for an entry update operation, such as add, delete, modify or modify-dn, to be applied by the primary on all of the servers in the topology. The default is 10 seconds, but updates can take up to twice as long if primary selection is in progress at the time the update operation is received.

`mirrored-subtree-search-timeout`

Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

Topology settings

Topology metadata is stored under the `cn=topology,cn=config` subtree and cluster data is stored under the `cn=cluster,cn=config` subtree. The only setting that can be changed is the cluster name.

Monitor data for the topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to identify changes in the topology.

Topology data includes the following:

- The server ID of the current primary, if the primary is not known
- The instance name of the current primary or if a primary is not set, a description stating why a primary is not set
- A flag indicating which server thinks that it should be the primary
- A flag indicating which server is the current primary
- A flag indicating a server that was forced as primary

Copyright © 2025 Ping Identity Corporation

- The total number of configured peers in the topology group
- The peers connected to this server
- The current availability of this server
- A flag indicating that a server is not synchronized with its primary or another node in the topology if the primary is unknown
- The amount of time in milliseconds that multiple primaries were detected by this server
- The amount of time in milliseconds that no suitable server is found to act as primary
- A SHA-256 digest encoded as a base-64 string for the current subtree contents

The following metrics are included if this server has processed any operations as primary:

- The number of operations processed by this server as primary
- The number of successful operations processed by this server as primary
- The number of operations processed by this server as primary that failed to validate
- The number of operations processed by this server as primary that failed to apply
- The average amount of time taken in milliseconds by this server to process operations as the primary
- The maximum amount of time taken in milliseconds by this server to process an operation as the primary

Using the Configuration API

The PingDirectory server provides a Configuration API when updating the server configuration with LDAP is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers allow the application/json content type.

About this task

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP.

Steps

- To add the extension to one of the server's HTTP Connection Handlers, run the following code.

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:Configuration
```

> **Note**
>
> By default, the extension is enabled for new installations. You can enable the extension for existing deployments.

Result:

Copyright © 2025 Ping Identity Corporation

The API is made available on the HTTPS Connection Handler's host:port in the `/config` context. Due to the potentially sensitive nature of the server's configuration, use the HTTPS Connection Handler for hosting the configuration extension.

Authentication and authorization with the Configuration API

Use this topic for how to make changes for customizing authentication and authorization access with the Configuration API.

Authentication

Clients must use HTTP basic authentication to authenticate to the Configuration API. If the username value is not a distinguished name (DN), then it resolves to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a username. To customize this behavior, either customize the default identity mapper or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. The following code provides an example.

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Configuration \
  --set "identity-mapper:Alternative Identity Mapper"
```

Authorization

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACI.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

The Configuration API and the dsconfig tool relationship

The Configuration API is designed to mirror the **`dsconfig`** tool, using the same names for properties and object types.

Property names are presented as hyphen case in **`dsconfig`** and as camel-case attributes in the API. In API requests that specify property names, case is not important. `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the **`dsconfig list-connection-handlers`** command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a local database backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the **`dsconfig`** tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the System for Cross-domain Identity Management (SCIM) specification. Request specific attributes using the attributes query parameter, whose value must be a comma-delimited list of properties to be returned, such as `attributes=baseDN,description`. You can exclude attributes from responses by specifying the `excludedAttributes` parameter.

Copyright © 2025 Ping Identity Corporation

Configuration API operations supported in REST APIs

HTTP Method	Description	Related dsconfig Example
GET	Lists the properties of an object when used with a path representing an object, such as `/config/global-configuration` or `/config/backends/userRoot`. Can also list objects when used with a path representing a parent relation, such as `/config/backends`.	• `get-backend-prop` • `list-backends` • `get-global-configuration-prop`
POST	Creates a new instance of an object when used with a relation parent path, such as `/config/backends`.	`create-backend`
PUT	Replaces the existing properties of an object. A PUT operation is similar to a PATCH operation, except that the PATCH identifies the difference between an existing target object and a supplied source object. Only those properties in the source object are modified in the target object. The target object is specified using a path, such as `/config/backends/userRoot`.	• `set-backend-prop` • `set-global-configuration-prop`
PATCH	Updates the properties of an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	• `set-backend-prop` • `set-global-configuration-prop`
DELETE	Deletes an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	`delete-backend`

Note

The `OPTIONS` method can also be used to determine the operations permitted for a particular path.
Object names, such as userRoot in the description column, must be URL-encoded for use in the path segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent, %, character. The following URL is for accessing the HTTP Connection Handler object.

```
/config/connection-handlers/http%20connection%20handler
```

```

PATCH example

Modify the Configuration API using the HTTP PATCH method.

The PATCH request body is a JSON object formatted according to the System for Cross-domain Identity Management (SCIM) patch request. The Configuration API supports a subset of possible values for the path attribute that indicates the configuration attribute to modify.

Modify the configuration object's attributes according to the information in the following table, which details the comparable `dsconfig modify-[object]` options to each PATCH request.

Operations and PATCH requests to modify the configuration object's attributes

Operation	PATCH request	Comparable dsconfig modify-[object] options
Set the single-valued `description` attribute to a new value.	`{ "op" : "replace", "path" : "description", "value" : "A new backend." }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --set "description:A new backend"`
Add a new value to the multi-valued `jeProperty` attribute.	`{ "op" : "add", "path" : "jeProperty", "value" : "je.env.backgroundReadLimit=0" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --add je-property:je.env.backgroundReadLimit=0`
Remove a value from a multi-valued property. In this case, path specifies a SCIM filter identifying the value to remove.	`{ "op" : "remove", "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --remove je-property:je.cleaner.adjustUtilization=false`

Copyright © 2025 Ping Identity Corporation

Operation	PATCH request	Comparable dsconfig modify-[object] options
Second operation to remove a value from a multi-valued property, where the `path` specifies both an attribute to modify and a SCIM filter whose attribute is the following value.	`{ "op" : "remove", "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --remove je-property:je.nodeMaxEntries=32`
Option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value.	`{ "op" : "remove", "path" : "id2childrenIndexEntryLimit" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --reset id2childrenIndexEntryLimit`

Example

The following is the full example request.

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json

{
  "schemas" : [ "urn:ietf:params:scim:api:messages:2.0:PatchOp" ],
  "Operations" : [ {
    "op" : "replace",
    "path" : "description",
    "value" : "A new backend."
  }, {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }, {
    "op" : "remove",
    "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
  }, {
    "op" : "remove",
    "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
  }, {
    "op" : "remove",
    "path" : "id2childrenIndexEntryLimit"
  } ]
}
```

Example

The API responds with the entire modified configuration object, which can include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions. The following is an example response.

           that had already hit the previous limit."
      }
    ]
  }
}
```

Configuration API paths

The Configuration API and supported sub-paths are available under the `/config` path.

A full listing of supported sub-paths is available when you access the base `/config/ResourceTypes` endpoint.

```
GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json
```

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted or created. These paths can be differentiated from others by their singular, rather than plural, relation name, such as `global-configuration`.

Copyright © 2025 Ping Identity Corporation

Example

The following sample response is abbreviated.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 520,
  "Resources": [
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "dsee-compat-access-control-handler",
      "name": "DSEE Compat Access Control Handler",
      "description": "The DSEE Compat Access Control
              Handler provides an implementation that uses syntax
              compatible with the Sun Java System Directory Server
              Enterprise Edition access control handler.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/dsee-compat-access-control-handler"
      }
    },
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "access-control-handler",
      "name": "Access Control Handler",
      "description": "Access Control Handlers manage the
              application-wide access control. The server's access
              control handler is defined through an extensible
              interface, so that alternate implementations can be created.
              Only one access control handler may be active in the server
                        at any given time.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/access-control-handler"
      }
    },
    {
 ...
```

The response's `endpoint` elements enumerate all available sub-paths. You can use the path `/config/access-control-handler` in the example to get a list of existing access control handlers and create new ones. You can use a path containing an object name, such as `/config/backends/{backendName}` (where `{backendName}` corresponds to an existing backend like `userRoot`) to obtain an object's properties, update the properties, or delete the object.

Sort and filter objects

The Configuration API supports System for Cross-domain Identity Management (SCIM) parameters for filter, sorting, and pagination.

Copyright © 2025 Ping Identity Corporation

Search operations can specify a SCIM filter to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters, or paging parameters. Include or exclude attributes can be specified in both GET and list operations.

GET Parameter	Description
`filter`	Values can be simple SCIM filters, such as `id eq "userRoot"`, or compound filters like `meta.resourceType eq "Local DB Backend"` and `baseDn co "dc=exmple,dc=com"`.
`sortBy`	Specifies a property value by which to sort.
`sortOrder`	Specifies either `ascending` or `descending` alphabetical order.
`startIndex`	1-based index of the first result to return.
`count`	Indicates the number of results per page.

Update properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH.

With PUT, the server computes the differences between the object in the request with the current version in the server and performs modifications where necessary. The server never removes attributes that are not specified in the request. The API responds with the entire modified object.

Example

Sample request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
  "description" : "A new description."
}
```

Sample response:

    ],
    "primeThreadCount": "2",
    "primeTimeLimit": "0 ms",
    "processFiltersWithUndefinedAttributeTypes": "false",
    "returnUnavailableForUntrustedIndex": "true",
    "returnUnavailableWhenDisabled": "true",
    "setDegradedAlertForUntrustedIndex": "true",
    "setDegradedAlertWhenDisabled": "true",
    "subtreeDeleteBatchSize": "5000",
    "subtreeDeleteSizeLimit": "100000",
    "uncachedId2entryCacheMode": "cache-keys-only",
    "writabilityMode": "enabled"
  }
```

Administrative actions

Updating a property might require an administrative action before changes can take effect.

If you need administrative actions to update a property, the server returns `200 Success`. Any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

Example

For example, changing the `jeProperty` of a backend results in the following:

```
"urn:unboundid:schemas:configuration:messages:2.0": {
    "required-actions": [
      {
       "property": "baseContextPath",
       "type": ""componentRestart",
       "synopsis": "In order for this modification to take effect, the component
                    must be restarted, either by disabling and re-enabling it, or
                    by restarting the server"
      },
      {
        "property": {
        "type": "other",
        "synopsis": "If this limit is increased, then the
                 contents of the backend must be exported to LDIF
                 and re-imported to allow the new limit to be used
                 for any id2children keys that had already hit the
                 previous limit."
      }
    ]
  }
```

Copyright © 2025 Ping Identity Corporation

Updating servers and server groups

You can configure servers as part of a server group so that configuration changes applied to a single server are applied to all servers in a group.

When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query attribute. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `single-server` or `server-group` can be specified.

Example

```
http://localhost:8082/config/backends/userRoot?applyChangeTo=single-server
```

Configuration API responses

Clients of the API should examine the HTTP response code to determine the success or failure of a request.

The following are response codes and their meanings.

Response Code	Description	Response Body
200 Success	The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the `urn:unboundid:schemas:configuration:messages:2.0` object.	List of objects, object properties, or administrative actions
204 No Content	The requested operation succeeded and no further information has been provided, as in the case of a DELETE operation.	None
400 Bad Request	The request contents are incorrectly formatted or a request is made for an invalid API version.	Error summary and optional message
401 Unauthorized	User authentication is required. Some user agents, such as browsers, might respond by prompting for credentials. If the request specified credentials in an Authorization header, they are invalid.	None
403 Forbidden	The requested operation is forbidden, either because the user does not have sufficient privileges or some other constraint, such as an object is edit-only and cannot be deleted.	None
404 Not Found	The requested path does not refer to an existing object or object relation.	Error summary and optional message

Copyright © 2025 Ping Identity Corporation

Response Code	Description	Response Body
409 Conflict	The requested operation could not be performed due to the current state of the configuration. For example, an attempt was made to create an object that already exists, or an attempt was made to delete an object that is referenced by another object.	Error summary and optional message
415 Unsupported Media Type	The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.	None
500 Server Error	The server encountered an unexpected error. Report server errors to Customer Support.	Error summary and optional message

Note

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages can change, and their presence can depend on server configuration. Use the HTTP return code and the context of the request to create a client error message.

Example

The following is an example encoded error message.

```
{
 "schemas": [
   "urn:ietf:params:scim:api:messages:2.0:Error"
 ],
 "status": 404,
 "scimType": null,
 "detail": "The Local DB Index does not exist."
}
```

Managing the Directory REST API

The Directory REST API is the native interface for client access to the PingDirectory server.

About this task

Instead of trying to manage directory hierarchy or require attribute mapping, the Directory REST API provides direct access to directory data in a way that is dynamic, discoverable, and efficient. For more information, see PingDirectory REST API Reference and the Developer portal.

The Directory REST API gives developers who are more comfortable with REST than LDAP access to arbitrary directory data in a way that ensures that directory data remains consistent regardless of whether it is accessed from LDAP or REST.

The Directory API is enabled during server setup. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.

Copyright © 2025 Ping Identity Corporation

Although both the Directory REST API and System for Cross-domain Identity Management (SCIM) provide REST access to directory data, the goals of the two protocols are different. SCIM is useful to generic, external clients that require simple, narrow access to identity data, but because it's a less common standard for identity stores, it might not offer as much functionality or be as user-friendly as the Directory REST API.

The Directory REST API can be used for the following operations.

HTTP operation	Resource endpoint	Description	Allowed query parameters
DELETE	`/directory/v1/{{dn}}`	Delete an entry	Not applicable
GET	`/directory/v1`	Get metadata about the API and server	Not applicable
GET	`/directory/v1/{{dn}}`	Retrieve a single entry	• `expand` • `includeAttributes` • `excludeAttributes`
GET	`/directory/v1/{{dn}}/subtree`	Search an entry's descendants	• `filter` • `searchScope` • `cursor` • `limit` • `includeAttributes` • `excludeAttributes`
GET	`/directory/v1/schemas`	Retrieve the schemas of all available object classes	Not applicable
GET	`/directory/v1/schemas/{objectclass}`	Retrieve schema for a specific object class	Not applicable
GET	`/directory/v1/schemas/_operationalAttributes`	Retrieve schema for operational attributes	Not applicable
GET	`/directory/v1/me`	Alias for retrieving the current user	Not applicable
PATCH	`/directory/v1/{{dn}}`	Modify an entry (add or delete values)	`expand`
POST	`/directory/v1`	Create a new entry	`expand`

Copyright © 2025 Ping Identity Corporation

HTTP operation	Resource endpoint	Description	Allowed query parameters
POST	`/directory/v1/suggestPassword`	Generate a new password suggestion	Not applicable
POST	`/directory/v1/passwordRequirements`	Get password quality requirements	Not applicable
POST	`/directory/v1/{{dn}}/changePassword`	Modify an existing password	Not applicable
PUT	`/directory/v1/{{dn}}`	Modify or rename an entry	`expand` **Important** You can't update a user's `userPassword` or `authPassword` attributes with this operation. Instead, use the `/directory/v1/{{dn}}/changePassword` endpoint to update passwords.

Steps

- Configure the Directory REST API with any of the following properties using `dsconfig`:

Command	Description
`basic-auth-enabled`	Specifies whether users can connect to the service with HTTP basic authentication. If disabled, users need a bearer token. If changed, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled. Basic authentication is enabled by default.
`identity-mapper`	If HTTP basic authentication is enabled, the identity mapper referenced by this distinguished name (DN) must be used to map the user names provided to user entries. By default, an identity mapper is provided, which maps a fully-qualified DN to an entry. For changes to take effect, the server must be restarted, or any HTTP connection handlers referencing this service disabled and re-enabled.

Copyright © 2025 Ping Identity Corporation

Command	Description
`access-token-validator`	Specifies the subset of this server's access token validators (by DN), which can validate bearer authentication tokens. By default, if no validators are specified, then any of the validators on the server can be used. For changes to take effect, the server must be restarted, or any HTTP connection handlers referencing this service disabled and re-enabled.
`access-token-scope`	The scope that must be present in bearer tokens in order to be accepted by this service. If no value is provided, bearer token authentication is disabled, and only basic authentication is used. By default, no value is provided. Changes to this value take effect immediately.
`audience`	A string or URI audience that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, any audience is acceptable. By default, no value is provided. Changes to this value take effect immediately.
`max-page-size`	The maximum number of entries to be returned in one page from the search endpoint. Actual results returned might be lower due to the limit query parameter on the request and the actual number of available results. The value must be an integer between 1 and 1000. The default value is 100. Changes to this value take effect immediately.
`schemas-endpoint-objectclass`	The list of object classes that will be returned by the `/schemas/` endpoint in the REST API. By default, no schemas are returned. Changes to this value take effect immediately.

Example:

The following example uses `dsconfig` to configure an `objectClass` entity:

```
dsconfig set-http-servlet-extension-props --extension-name "Directory REST API" \
  --add schemas-endpoint-objectclass:ubidPerson
```

Configuring server groups

The PingDirectoryProxy server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group.

About this task

After you have set up a server group, you can make an update on one server using `dsconfig`, then apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the `dsconfig` non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using `dsconfig` in interactive command-line mode, you are asked if you want to apply the change to a single server or to all servers in the server group.

You can create an administrative server group using the `dsconfig` tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group, as outlined in Replication Configuration.

The following example procedure adds three PingDirectoryProxy server instances into the server group labeled "group-one".

Steps

1. Create a group called "group-one" using `dsconfig`.

   Example:

   ```
   $ bin/dsconfig create-server-group --group-name group-one
   ```

2. Add any directory server to the server group.

   If you have set up replication between a set of servers, these server entries are created by the `dsreplication enable` command.

   Example:

   ```
   $ bin/dsconfig set-server-group-prop \
     --group-name group-one --add member:server1

   $ bin/dsconfig set-server-group-prop \
     --group-name group-one --add member:server2

   $ bin/dsconfig set-server-group-prop \
     --group-name group-one --add member:server3
   ```

3. Set a global configuration property for each of the servers that should share changes in this group.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --set configuration-server-group:group-one
   ```

4. Test the server group.

Copyright © 2025 Ping Identity Corporation

In this example, enable the log publisher for each directory server in the group "server-group" by using the `--applyChangeTo server-group` option.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
  --applyChangeTo server-group
```

5. View the property on the first directory server instance.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
---------:---------
 enabled : true
```

6. Repeat step 5 on the second and third directory server instances.

7. Test the server group by disabling the log publisher on the first directory server instance by using the `--applyChangeTo single-server`.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:disabled \
  --applyChangeTo single-server
```

8. View the property on the first directory server instance.

The first directory server instance should be disabled.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
---------:---------
 enabled : false
```

Copyright © 2025 Ping Identity Corporation

9. View the property on the second PingDirectory server instance.

   Repeat this step on the third directory server instance to verify that the property is still enabled on that server.

   Example:

   ```
   $ bin/dsconfig get-log-publisher-prop \
     --publisher-name "File-Based Audit Logger" \
     --property enabled
   ```

   Result:

   ```
   Property : Value(s)
   ---------:---------
    enabled : true
   ```

Generating a summary of configuration components

The `config-diff` tool generates a summary of the configuration in a local or remote directory server instance.

About this task

The `config-diff` tool is useful for comparing configuration settings on the server instance when troubleshooting issues or when verifying configuration settings on newly-added servers. The tool can interact with the local configuration regardless of whether the server is running.

Steps

- To generate a summary of configuration components, run `config-diff`

  Example:

  `$ bin/config-diff` generates a summary of a local online server.

- To generate a comparison of the current configuration with the pre-installation configuration, run the following.

  ```
  $ bin/config-diff --sourceLocal \
    --sourceBaseline \
    --targetLocal \
    --exclude differs-after-install \
    --outputFile configuration-steps.dsconfig
  ```

  This comparison ignores any changes that could be made by the installer and writes the output to a file called `configuration-steps.dsconfig`.

  You can use this file as the basis for a script to configure a new server identical to the local server.

- To view other available tool options, run `config-diff --help`.

Configuring server groups

The PingDirectoryProxy server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group.

About this task

After you have set up a server group, you can make an update on one server using `dsconfig`, then apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the `dsconfig` non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using `dsconfig` in interactive command-line mode, you are asked if you want to apply the change to a single server or to all servers in the server group.

You can create an administrative server group using the `dsconfig` tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group, as outlined in Replication Configuration.

The following example procedure adds three PingDirectoryProxy server instances into the server group labeled "group-one".

Steps

1. Create a group called "group-one" using `dsconfig`.

   Example:

   ```
   $ bin/dsconfig create-server-group --group-name group-one
   ```

2. Add any directory server to the server group.

   If you have set up replication between a set of servers, these server entries are created by the `dsreplication enable` command.

   Example:

   ```
   $ bin/dsconfig set-server-group-prop \
     --group-name group-one --add member:server1

   $ bin/dsconfig set-server-group-prop \
     --group-name group-one --add member:server2

   $ bin/dsconfig set-server-group-prop \
     --group-name group-one --add member:server3
   ```

3. Set a global configuration property for each of the servers that should share changes in this group.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --set configuration-server-group:group-one
   ```

4. Test the server group.

Copyright © 2025 Ping Identity Corporation

In this example, enable the log publisher for each directory server in the group "server-group" by using the `--applyChangeTo server-group` option.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
  --applyChangeTo server-group
```

5. View the property on the first directory server instance.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
---------:---------
enabled : true
```

6. Repeat step 5 on the second and third directory server instances.

7. Test the server group by disabling the log publisher on the first directory server instance by using the `--applyChangeTo single-server`.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:disabled \
  --applyChangeTo single-server
```

8. View the property on the first directory server instance.

The first directory server instance should be disabled.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
---------:---------
enabled : false
```

Copyright © 2025 Ping Identity Corporation

9. View the property on the second PingDirectory server instance.

   Repeat this step on the third directory server instance to verify that the property is still enabled on that server.

   Example:

   ```
   $ bin/dsconfig get-log-publisher-prop \
     --publisher-name "File-Based Audit Logger" \
     --property enabled
   ```

   Result:

   ```
   Property : Value(s)
   ---------:---------
   enabled : true
   ```

DNS caching

You can use two global configuration properties to control the caching of host name-to-numeric IP address or DNS lookup results returned from the name resolution services of the underlying operating system.

About this task
Steps

1. To configure these properties, use the `dsconfig` tool.

   Global configuration properties and their descriptions

Global configuration property	Description
network-address-cache-ttl	Sets the Java system property `networkaddress.cache.ttl`, and controls the length of time in seconds that a host name-to-IP address mapping can be cached. By default, it keeps resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.
network-address-outage-cache-enabled	Caches host name-to-IP address results in the event of a DNS outage. By default, this is set to true, meaning name resolution results are cached. Unexpected service interruptions might occur during planned or unplanned maintenance, network outages, or an infrastructure attack. This cache can allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

2. To reduce delays due to unnecessary DNS lookups, follow these recommendations:

   1. Maintain a connection pool in the client app rather than opening new connections for each bind.

Copyright © 2025 Ping Identity Corporation

2. Add appropriate records to DNS, including PTR records.
3. Add `options timeout:1` or `options single-request` in the `/etc/resolv.conf` file.
4. If IPv6 requests are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in server's `config/java.properties` file, so that running `bin/dsjavaproperties` and restarting the server no longer issues IPv6 PTR requests.

IP address reverse name lookups

The directory server performs numeric IP address-to-host name lookups.

Numeric IP address-to-host name lookups

The following are some of the numeric IP address-to-host name lookups:

- Binding to the Directory: Decoding, examining, or evaluating a DNS bind rule
- Logging: Logging information to certain monitors or writing to the error log
- Java Management Extension (JMX): Creating a server socket
- Key Management: Generating a trust store
- Replication Server: Creating an SSL socket
- Replication Session Management: Obtaining a session or performing a handshake with a replication server
- Simple Authentication and Security Layer (SASL) Authentication: Applying configuration changes
- SMTP Alert Handler: Initializing or sending an alert notification

Configuring address masks

Address masks configured in Access control instructions (ACIs), connection handlers, connection criteria, and certificate handshake processing might trigger implicit reverse name lookups.

For more information about how address masks are configured in the server, see the following information for each server:

- ACI DNS: bind rules in Managing access control for the PingDirectory server and the PingDirectoryProxy server
- `ds-auth-allowed-address`: Restricting access through operational attributes in user entities for the PingDirectory server
- Connection Criteria: Restricting server access based on client IP address for the PingDirectory server and the PingDirectoryProxy server
- Connection Handlers: Restricting server access using the connection handlers for a configuration reference guide for all servers

dsconfig">

Configuring traffic through a load balancer using `dsconfig`

About this task

Copyright © 2025 Ping Identity Corporation

To configure the directory server to get traffic through a load balancer and to record the actual client's IP address:

Steps

1. Edit the HTTP or HTTPS connection handler object and set `use-forwarded-headers` to `true` by running `dsconfig`.

   Example:

   ```
   dsconfig set-connection-handler-prop \
       --handler-name "HTTPS Connection Handler" \
       --set use-forwarded-headers:true
   ```

2. To finalize the changes to the HTTP or HTTPS connection handler, use `dsconfig` to restart the connection handler.

   Example:

   ```
   dsconfig set-connection-handler-prop \
       --handler-name "HTTPS Connection Handler" \
       --set enabled:false

   dsconfig set-connection-handler-prop \
       --handler-name "HTTPS Connection Handler" \
       --set enabled:true
   ```

3. To provide the `X-Forwarded-*` information to your load balancer, consult your provider's guide on configuring the load balancer settings.

Managing root user accounts

The directory server provides a default root user, `cn=Directory Manager`, that is stored in the server's configuration file, such as under `cn=Root DNs,cn=config`.

About this task

The root user is the LDAP-equivalent of a UNIX superuser account and inherits its read-write privileges from the default root privilege set.

Steps

- To create or update root users, use the `dscconfig` tool.

  Example:

  ```
  bin/dsconfig create-root-dn-user --user-name "Joanne Smith" \
    --set last-name:Smith \
    --set first-name:Joanne \
    --set user-id:jsmith \
    --set 'email-address:jsmith@example.com' \
    --set mobile-telephone-number:8889997777 \
    --set home-telephone-number:5556667777 \
    --set work-telephone-number:4445556666
  ```

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Root user entries are stored in the server's configuration.

- **To limit full access to all of the servers, create separate administrator accounts with limited privileges so that you can identify the administrator responsible for a particular change.**

> **Note**
>
> Separate user accounts for each administrator make it possible to enable password policy functionality, such as password expiration, password history, and requiring secure authentication, for each administrator.

Default root privileges

The PingDirectory server contains a privilege subsystem that allows for a more fine-grained control of privilege assignments.

> **Note**
>
> Creating restricted root user accounts requires assigning privileges and necessary access controls for actions on specific data or backends. Access controls are determined by how the directory is configured and the structure of your data. See Managing access control for more information.

The following set of root privileges are available to each root user DN.

Default Root Privileges

Privilege	Description
audit-data-security	Allows the associated user to execute data security auditing tasks.
backend-backup	Allows the user to perform backend backup operations.
backend-restore	Allows the user to perform backend restore operations.
bypass-acl	Allows the user to bypass access control evaluation.
config-read	Allows the user to read the server configuration.
config-write	Allows the user to update the server configuration.
disconnect-client	Allows the user to terminate arbitrary client connections.
ldif-export	Allows the user to perform LDIF export operations.
ldif-import	Allows the user to perform LDIF import operations.
lockdown-mode	Allows the user to request a server lockdown.
manage-topology	Allows the user to modify topology setting.

Copyright © 2025 Ping Identity Corporation

Privilege	Description
metrics-read	Allows the user to read server metrics.
modify-acl	Allows the user to modify access control rules.
password-reset	Allows the user to reset user passwords but not their own. The user must also have privileges granted by access control to write the user password to the target entry.
permit-get-password-policy-state-issues	Allows the user to access password policy state issues.
privilege-change	Allows the user to change the set of privileges for a specific user, or to change the set of privileges automatically assigned to a root user.
server-restart	Allows the user to request a server restart.
server-shutdown	Allows the user to request a server shutdown.
soft-delete-read	Allows the user access to soft-deleted entries.
stream-values	Allows the user to perform a stream values extended operation that obtains all entry DNs and/or all values for one or more attributes for a specified portion of the DIT.
third-party-task	Allows the associated user to invoke tasks created by third-party developers.
unindexed-search	Allows the user to perform an unindexed search in the Oracle Berkeley DB Java Edition backend.
update-schema	Allows the user to update the server schema.
use-admin-session	Allows the associated user to use an administrative session to request that operations be processed using a dedicated pool of worker threads.

The PingDirectory server provides other privileges that are not assigned to the root user DN by default but can be added using the `ldapmodify` tool (see Modifying Individual Root User Privileges) for more information.

Other Available Privileges

Privilege	Description
bypass-pw-policy	Allows the associated user bypass password policy rules and restrictions.
bypass-read-aci	Allows the associated user to bypass access control checks performed by the server for bind, compare, and search operations. Access control evaluation may still be enforced for other types of operations.

Copyright © 2025 Ping Identity Corporation

Privilege	Description
jmx-notify	Allows the associated user to subscribe to receive JMX notifications.
jmx-read	Allows the associated user to perform JMX read operations.
jmx-write	Allows the associated user to perform JMX write operations.
permit-externally-processed-authentication	Allows the associated user accept externally processed authentication.
permit-proxied-mschapv2-details	Allows the associated user to permit MS-CHAP V2 handshake protocol.
proxied-auth	Allows the associated user to accept proxied authorization.

Configuring locations

The PingDirectoryProxy server defines locations, both for the LDAP external servers and the directory proxy instances themselves. A location defines a collection of servers that share access and latency characteristics. For example, your deployment might include two data centers, one in the east and one in the west. These data centers would be configured as two locations in the Directory Proxy Server. Each location is associated with a name and an ordered list of failover locations, which could be used if none of the servers in the preferred location are available. You can define these locations using the administrative console or the command line.

The PingDirectoryProxy server itself is also associated with a location. This location is specified in the global configuration properties of the server. If the load balancing algorithm's `use-location` property is set to true, then the load balancing component of the PingDirectoryProxy server refers to the server's location to determine the external servers it prefers to communicate with.

Modifying locations using dsconfig

Steps

1. To configure existing LDAP external server locations, use the `dsconfig` tool.

   ```
   $ bin/dsconfig
   ```

2. Enter the host name or IP address for your PingDirectoryProxy server, or press Enter to accept the default, `localhost`.

   ```
   Directory Proxy Server host name or IP address [localhost]:
   ```

3. Enter the number corresponding to how you want to connect to the PingDirectoryProxy server, or press Enter to accept the default, `LDAP`.

Copyright © 2025 Ping Identity Corporation

```
How do you want to connect?
  1) LDAP
  2) LDAP with SSL
  3) LDAP with StartTLS
```

4. Enter the port number for your PingDirectoryProxy server, or press Enter to accept the default, `389`.

```
Directory Proxy Server port number [389]:
```

5. Enter the administrator's bind distinguished name (DN) or press Enter to accept the default `cn=Directory Manager`, and then enter the password.

```
Administrator user bind DN [cn=Directory Manager]:
Password for user 'cn=Directory Manager':
```

6. In the `PingDirectoryProxy main menu`, enter the number corresponding to Global Configuration. Then enter the number to view and edit the Global Configuration.

7. Enter the number associated with the location configuration property.

```
Enter choice [b]: 2
```

8. Specify a new location for this PingDirectoryProxy server instance, in this example the East location.

   Example:

   Operations involving communications with other servers might prefer servers in the same location to ensure low-latency responses.

```
>>>> Configuring the 'location' property

...

Do you want to modify the 'location' property?

  1) Leave undefined
  2) Change it to the location: East
  3) Change it to the location: West
  4) Create a new location

  b) back
  q) quit

Enter choice [b]: 2
```

9. To finish the operation, enter `f`.

```
Enter choice [b]: f
```

Configuring locations using `dsconfig`

Steps

1. To configure the LDAP external server locations, use the `dsconfig` tool.

```
$ bin/dsconfig
```

2. Enter the host name or IP address for your PingDirectoryProxy server, or press Enter to accept the default, `localhost`.

```
Directory Proxy Server host name or IP address [localhost]:
```

3. Enter the number corresponding to how you want to connect to the PingDirectoryProxy server, or press Enter to accept the default, `LDAP`.

```
How do you want to connect?
  1) LDAP
  2) LDAP with SSL
  3) LDAP with StartTLS
```

4. Enter the port number for your PingDirectoryProxy server, or press Enter to accept the default, `389`.

```
Directory Proxy Server port number [389]:
```

5. Enter the administrator's bind distinguished name (DN) or press Enter to accept the default, `cn=Directory Manager`, and then enter the password.

```
Administrator user bind DN [cn=Directory Manager]:
Password for user 'cn=Directory Manager':
```

6. In the `PingDirectoryProxy main menu`, enter the number corresponding to location configuration. Then enter the number to create a new location.

7. Enter the name of the new location.

   Example:

   This example demonstrates configuring a location called `East`.

Copyright © 2025 Ping Identity Corporation

```
>>>>  Enter a name for the location that you want to create: east

>>>>  Configure the properties of the location

      Property                   Value(s)
      ----------------------------------
   1) description                 -
   2) preferred-failover-location  -

   ?) help
   f) finish - create the new location
   d) display the equivalent dsconfig arguments to
      create this object
   b) back
   q) quit

Enter choice [b]: f
```

8. To finish configuring the location, enter `f`.
9. Edit the configuration of an existing location, in this example a location named `East`.

   Example:

```
>>>> Location menu
What would you like to do?

  1) List existing locations
  2) Create a new location
  3) View and edit an existing location
  4) Delete an existing location

  b) back
  q) quit

Enter choice [b]: 3

>>>> Select the location from the following list:
   1) East
   2) West

   b) back
   q) quit

Enter choice [b]: 1
```

10. Define the `preferred-failover-location` property for `East`.

    This property provides alternate locations that can be used if servers in this location are not available. If more than one location is provided, the PingDirectoryProxy server tries the locations in the order listed.

    Example:

Copyright © 2025 Ping Identity Corporation

```
 >>>> Configure the properties of the Location

     Property                  Value(s)
     ----------------------------------
  1) description                 -
  2) preferred-failover-location  -

  ?) help
  f) finish - create the new location
  d) display the equivalent dsconfig arguments to create this object
  b) back
  q) quit

Enter choice [b]: 2

...

Do you want to modify the 'preferred-failover-location' property?

   1) Add one or more values

   ?) help
   q) quit

Enter choice [1]: 2

Select the locations you wish to add:

  1) East
  2) West
  3) Create a new location
  4) Add all locations

...

Enter one or more choices separated by commas[b]: 2
```

11. Verify and apply your change to the property.

    Example:

Copyright © 2025 Ping Identity Corporation

```
Do you want to modify the 'preferred-failover-location' property?

  1) Use the value: West
  2) Add one or more values
  3) Remove one or more values
  4) Leave undefined
  5) Revert changes

  ?) help
  q) quit

Enter choice [1]:

>>>> Configure the properties of the location

     Property                   Value(s)
     ----------------------------------
  1) description                -
  2) preferred-failover-location  West

  ?) help
  f) finish - apply any changes to the Location
  d) display the equivalent dsconfig command lines to either
     re-create this object or only to apply pending changes
  b) back
  q) quit

Enter choice [b]: f
```

Configuring batched transactions

Configure the PingDirectoryProxy server to use batched transactions in both simple and entry-balanced configurations.

About this task

The batched transactions feature supports two implementations: the standard LDAP transactions per RFC 5805 and the PingDirectoryProxy proprietary implementation, known as the multi-update extended operation.

Batched transactions can be used through the PingDirectoryProxy server in both simple and entry-balanced configurations, but only in cases where all operations within the transaction request can be processed within the same backend server and within the same Berkeley DB JE backend.

> **Note**
>
> Batched transactions can't be processed across multiple servers or multiple PingDirectory server backends.

You can submit multiple updates in a single request. These updates can be processed either as individual operations or as a single batch. When the PingDirectoryProxy server receives a Start Batched Transaction request, it queues all associated operations in memory until the End Batched Transaction request is received with the intention to commit, at which point the set of operations is sent as a single multi-update extended request to the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

You can include `add`, `delete`, `modify`, `modify DN`, and `password modify` extended operations to the set of operations processed during a batch transaction. The operations are processed sequentially in the order in which they were included in the extended request. If an error occurs while processing an operation in the set, then the server can be instructed to continue processing or to cancel any remaining operations. If the operations aren't canceled, you can configure the server to process all operations as a single unit.

Because of this use of multi-update, you must configure the external PingDirectory server to allow multi-update extended requests made by the PingDirectoryProxy server on behalf of the DN submitting the batched transaction.

For example, the following PingDirectory server `dsconfig` command grants anonymous access to the multi-update extended request.

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(extop="1.3.6.1.4.1.30221.2.6.17")(version 3.0; acl "Anonymous access to multi-update extended
request"; allow (read) userdn="ldap:///anyone";)'
```

> **Note**
>
> The submitter of the request still needs access rights for the individual operations within the multiple-update.

Batched transactions are managed by the Batched Transactions Extended Operation Handler. You can use it to configure the start transaction and end transaction operations used to indicate the set of `add`, `delete`, `modify`, `modify DN`, or `password modify` operations as a single atomic unit.

Steps

1. Configure batched transactions using the `dsconfig` command.

   Example:

   ```
   $ bin/dsconfig set-extended-operation-handler-prop \
     --handler-name "Batched Transactions" \
     --set enabled:true
   ```

2. Configure the external servers to allow the multi-update extended operation by granting access rights to the feature.

   See example in the previous section.

Configuring server health checks

You can use the PingDirectoryProxy server to configure different types of health checks for your deployment. The health checks define external server availability as either being available, unavailable, or degraded. The external server health is given a value from 0 to 10, which is used to determine if the server is available and how that server compares to other servers with the same state. Load-balancing algorithms can be used to check the score and prefer servers with higher scores over those with lower scores.

Copyright © 2025 Ping Identity Corporation

An individual health check can be defined for use against all external servers or assigned to individual external servers, as determined by the `use-for-all-servers` parameter within the health check configuration object. If `use-for-all-servers` is set to true, the PingDirectoryProxy server applies the health check to all external servers in all locations. If `use-for-all-servers` is set to false, then the health check is only employed against an external server if the configuration object for that external server lists the health check.

For more information about health checks and the type of health checks supported by PingDirectoryProxy, see About LDAP health checks.

About the default health checks

By default, the PingDirectoryProxy server has two health check instances enabled for use on all servers:

- Consume Admin Alerts. This health check detects administrative alerts from the PingDirectory server, as soon as they are issued, by maintaining an LDAP persistent search for changes within the `cn=alerts` branch of the PingDirectory server. When the PingDirectoryProxy server is notified by the PingDirectory server of a new alert, it immediately retrieves the base `cn=monitor` entry of the PingDirectory server. If this entry has a value for the `unavailable-alert-type` attribute, then the PingDirectoryProxy server will consider it unavailable. If this entry has a value for the `degraded-alert-type` attribute, then the PingDirectoryProxy server will consider it degraded.
- Get Root DSE. This health check detects if the root DSE entry exists on the LDAP external server. Since this entry always exists on a PingDirectory server, the absence of the entry suggests that the LDAP external server could be degraded or unavailable.

About creating a custom health check

You can create a new health check from scratch or use an existing health check as a template for the configuration of a new health check.

If you choose to create a custom health check, you can create one of the following types:

Admin Alert Health Check

This health check watches for administrative alerts generated by the LDAP external server to determine whether the server has entered a degraded or unavailable state.

Groovy Scripted LDAP Health Check

This health check allows you to create custom LDAP health checks in a dynamically-loaded Groovy script, which implements the `ScriptedLDAPHealthCheck` class defined in the Server SDK.

Replication Backlog Health Check

While the Admin Alert Health Check consumes replication backlog alerts emitted from external servers, a finer definition of external server health based on replication backlog can be defined with this health check. If a server falls too far behind in replication, then the PingDirectoryProxy server can stop sending requests to it. A server is classified as degraded or unavailable if the threshold is reached for the number of backlogged changes, the age of the oldest backlogged change, or both.

Copyright © 2025 Ping Identity Corporation

Search LDAP Health Check

This health check performs searches on an LDAP external server and gauges the health of the server depending on the response time in which the expected results were returned. For example, if an error occurs while attempting to communicate with the server, then the server is considered unavailable. You can also apply filters to the results to use values within the monitor entry as indicators of server health.

Third Party LDAP Health Check

This health check allows you to define LDAP health check implementations in third-party code using the Server SDK.

Work Queue Busyness Health Check

This health check can monitor the percentage of time that worker threads in backend servers devote to processing requests.

dsconfig">

Configuring a health check using `dsconfig`

Steps

1. To configure the LDAP external server locations, use the `dsconfig` tool.

```
$ bin/dsconfig
```

2. Enter the host name or IP address for your PingDirectoryProxy server, or press Enter to accept the default, `localhost`.

```
Directory Proxy Server host name or IP address [localhost]:
```

3. Enter the number corresponding how you want to connect to the PingDirectoryProxy server, or press Enter to accept the default, `LDAP`.

```
How do you want to connect?
  1) LDAP
  2) LDAP with SSL
  3) LDAP with StartTLS
```

4. Enter the port number for your PingDirectoryProxy server, or press Enter to accept the default, `389`.

```
Directory Proxy Server port number [389]:
```

5. Enter the administrator's bind distinguished name (DN) or press Enter to accept the default `cn=Directory Manager`. Then enter the password.

Copyright © 2025 Ping Identity Corporation

```
Administrator user bind DN [cn=Directory Manager]:
Password for user 'cn=Directory Manager':
```

6. In the `PingDirectoryProxy main menu`, enter the number corresponding to LDAP health checks.
7. Enter the number to create a new LDAP Health Check, and then press `n` to create a new health check from scratch.
8. Select the type of health check you want to create.

   Example:

   This example demonstrates the creation of a new search LDAP health check.

```
>>> Select the type of LDAP Health Check that you want to create:

      1)  Admin Alert LDAP Health Check
      2)  Custom LDAP Health Check
      3)  Groovy Scripted LDAP Health Check
      4)  Replication Backlog LDAP Health Check
      5)  Search LDAP Health Check
      6)  Third Party LDAP Health Check
      7)  Work Queue Busyness LDAP Health Check

      ?) help
      c) cancel
      q) quit

Enter choice [c]: 5
```

9. Enter a name for the new health check.

   Example:

   In this example, the health check is named `Get example.com`.

```
>>>> Enter a name for the search LDAP Health Check that you want to create: Get example.com
```

10. To enable the new health check, enter `1`.

Copyright © 2025 Ping Identity Corporation

```
>>>> Configuring the 'enabled' property

Indicates whether this LDAP health check is enabled for use in the server.

Select a value for the 'enabled' property:

   1) true
   2) false

   ?) help
   c) cancel
   q) quit

Enter choice [c]: 1
```

11. Configure the properties of the health check.

    You might need to modify the `base-dn` property as well as one or more response time thresholds for non-local external servers, accommodating WAN latency.

    Example:

    The following example is a Search LDAP Health Check for the single entry `dc=example,dc=com`, which allows non-local responses of up to 2 seconds to still be considered healthy.

Copyright © 2025 Ping Identity Corporation

```
>>>> Configure the properties of the Search LDAP Health Check

           Property                                  Value(s)
           ----------------------------------------------------------
      1)   description                               -
      2)   enabled                                   true
      3)   use-for-all-servers                       false
      4)   base-dn                                   "dc=example,dc=com"
      5)   scope                                     base-object
      6)   filter                                    (objectClass=*)

      11)  maximum-local-degraded-response-time      10 s
      12)  maximum-nonlocal-degraded-response-time   10 s
      13)  minimum-local-unavailable-response-time   5 s
      14)  minimum-nonlocal-unavailable-response-time 5 s
      15)  allow-no-entries-returned                 true
      16)  allow-multiple-entries-returned           true
      17)  available-filter                          -
      18)  degraded-filter                           -
      19)  unavailable-filter                        -

      ?) help
      f) finish - create the new Search LDAP Health Check
      d) display the equivalent dsconfig arguments to create this object
      b) back
      q) quit
```

Configuring LDAP external servers

The LDAP external server configuration element defines the connection, location, and health check information necessary for the PingDirectoryProxy server to communicate with the server properly.

PingDirectoryProxy includes a tool, `prepare-external-server`, for configuring communication between the PingDirectoryProxy server and the LDAP backend server. After you add a new LDAP external server to an existing installation, we strongly recommend that you run this tool to automatically create the user account necessary for communications. The `prepare-external-server` tool does not make configuration changes to the local PingDirectoryProxy server, only the external server is modified. When you run this tool, you must supply the user account and password that you specified for the PingDirectoryProxy server during configuration, `cn=Proxy User` by default.

Copyright © 2025 Ping Identity Corporation

Important

You should not use `cn=Directory Manager` as the account to use for communication between the PingDirectoryProxy server and the PingDirectory server. For security reasons, the account used to communicate between the PingDirectoryProxy server and the PingDirectory server should not be directly accessible by clients accessing the PingDirectoryProxy server. The account that you choose should meet the following criteria:

- For all server types, it should not exist in the PingDirectoryProxy server but only in the backend directory server instances.
- For the PingDirectory server, this user should be a root user.
- For the PingDirectory server, this user should not automatically inherit the default set of root privileges, but instead should have exactly the following set of privileges: `bypass-read-acl`, `config-read`, `lockdown-mode`, `proxied-auth`, and stream-values.
- For Sun Directory Servers, the account should be created below the `cn=Root DNs,cn=config` entry and the `nsSizeLimit`, `nsTimeLimit`, `nsLookThroughLimit`, and `nsIdleTimeout` values for the account should be set to -1. You also need to create access control rules to grant the user account appropriate permissions within the server. The **`prepare-external-server`** tool handles all of this work automatically.

About the prepare-external-server tool

Use the `prepare-external-server` tool if you have added LDAP external servers using `dsconfig`.

The `create-initial-proxy-config` tool automatically runs the `prepare-external-server` tool to configure server communications so that you do not need to invoke it separately. The `create-initial-proxy-config` tool verifies that the proxy user account exists and has the correct password and required privileges. If it detects any problems, it prompts for manager credentials to rectify them.

If you want the `prepare-external-server` tool to add the LDAP external server's certificates to the PingDirectoryProxy server's trust store, you must include the `--proxyTrustStorePath` option and either the `--proxyTrustStorePassword` or the `--proxyTrustStorePasswordFile` option.

The default location of the PingDirectoryProxy server's trust store is `config/truststore`. The pin is encoded in the `config/truststore.pin` file.

The following example prepares a PingDirectory server on the remote host `ds-east-01.example.com`, listening on port 1389 for access by the PingDirectoryProxy server using the default user account `cn=Proxy User`, as shown in the following example.

```
prepare-external-server --hostname ds-east-01.example.com \
--port 1389 --baseDN dc=example,dc=com --proxyBindPassword secret
```

When the `prepare-external-server` command is executed, it creates the `cn=Proxy User` Root distinguished name (DN) entry as well as an access control rule in the PingDirectory server to grant the proxy user the proxy access right.

Important

For non-Ping Identity servers, the `--baseDN` argument is required for the **`prepare-external-server`** tool. The base DN is used to create the global access control instruction (ACI) entries for these servers.

Copyright © 2025 Ping Identity Corporation

Configuring server communication using the prepare-external-server tool

The following example illustrates how to run the `prepare-external-server` tool to prepare a PingDirectory server.

About this task

In this example, the server is configured on the remote host `ds-east-01.example.com`, listening on port 1636.

The PingDirectory server is being accessed by a PingDirectory server that uses the default user account `cn=Proxy User,cn=Root DNs,cn=config`. Because a password to the trust store is not provided, the trust store defined in the `--proxyTrustStorePath` is referenced in a read-only manner.

Steps

- To prepare the PingDirectory server, use the `prepare-external-server` tool.

  Example:

  ```
  $ ./PingDirectoryProxy/bin/prepare-external-server \
    --baseDN dc=example,dc=com
    --proxyBindPassword password \
    --hostname ds-east-01.example.com \
    --useSSL \
    --port 1636
    --proxyTrustStorePath /full/path/to/trust/store \
    --proxyTrustStorePassword secret
  ```

- Follow the prompts to set up the external server.

Copyright © 2025 Ping Identity Corporation

```
Testing connection to ds-east-01.example.com:1636 .....

Do you wish to trust the following certificate?

Certificate Subject: CN=ds-east-01.example.com, O=Example Self-Signed Certificate
Issuer Subject:      CN=ds-east-01.example.com, O=Example Self-Signed Certificate
Validity:            Thu May 21 08:02:30 CDT 2009 to Wed May 16 08:02:30 CDT 2029

Enter 'y' to trust the certificate or 'n' to reject it.

y

The certificate was added to the local trust store

Done
Testing 'cn=Proxy User' access to ds-east-01.example.com:1636 ..... Failed to bind as
'cn=Proxy User'

Would you like to create or modify root user 'cn=Proxy User' so that it is available
for this Directory Proxy Server? (yes / no) [yes]:

Enter the DN of an account on ds-east-01.example.com:1636 with which to create or
manage the 'cn=Proxy User' account [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':

Created 'cn=Proxy User,cn=Root DNs,cn=config'

Testing 'cn=Proxy User' privileges ..... Done
```

Configuring an external server using `dsconfig`

Use the `dsconfig` tool to create and configure external servers. Then, specify the host name, connection method, port number, and bind distinguished name (DN), as described in previous procedures.

Steps

1. Run the `dsconfig` command.

   ```
   $ bin/dsconfig
   ```

2. In the `PingDirectoryProxy main menu`, enter the number corresponding to external servers.
3. Enter the number to create a new external server.
4. Select the type of server you want to create.

   Example:

   This example creates a new Ping Identity PingDirectory server.

Copyright © 2025 Ping Identity Corporation

```
>>>> Select the type of external server that you want to create:

  1) Ping Identity DS external server
  2) JDBC external server
  3) LDAP external server
  4) Sun DS external server

  ?) help
  c) cancel
  q) quit

Enter choice [c]: 1
```

5. Specify a name for the new external server.

   Example:

   In this example, the external server is named `east1`.

```
>>>> Enter a name for the Ping Identity DS external server that you want
to create: east1
```

6. Configure the host name or IP address of the target LDAP external server.

   Example:

```
Enter a value for the 'server-host-name' property:east1.example.com
```

7. Configure the location property of the new external server.

   Example:

```
Do you want to modify the 'location' property?

   1) Leave undefined
   2) Change it to the location: East
   3) Change it to the location: West
   4) Create a new location

   ?) help
   q) quit

Enter choice [1]: 2
```

8. Define the bind DN and bind password.

   Example:

Copyright © 2025 Ping Identity Corporation

```
Do you want to modify the 'bind-dn' property?

   1) Leave undefined
   2) Change the value

   ?) help
   q) quit

Enter choice [1]: 2

Enter a value for the 'bind-dn' property [continue]: cn=Proxy User,cn=Root DNs,cn=config

Enter choice [b]: 6

...

Do you want to modify the 'password' property?

   1) Leave undefined
   2) Change the value
   ?) help
   q) quit

Enter choice [1]: 2

Enter a value for the 'password' property [continue]:
Confirm the value for the 'password' property:
```

9. To finish the operation, enter `f`.

```
Enter choice [b]: f
```

Result

```
The Ping Identity DS external server was created successfully.
```

Next steps

After adding the server, run the `prepare-external-server` tool to configure communications between the PingDirectoryProxy server and the Ping Identity PingDirectory server.

For more information, see Preparing two new external servers using the prepare-external-server tool.

Configuring authentication with a SASL external certificate

By default, the PingDirectoryProxy server authenticates to the PingDirectory server using LDAP simple authentication with a bind DN and a password. You can configure the PingDirectoryProxy server to use Simple Authentication and Security Layer (SASL) EXTERNAL to authenticate to the PingDirectory server with a client certificate.

Before you begin

Copyright © 2025 Ping Identity Corporation

Install and configure the PingDirectoryProxy server instances to communicate with the backend PingDirectory server instances using either SSL or StartTLS.

Steps

1. Create a Java KeyStore (JKS) that includes a public and private key pair for a certificate that the PingDirectoryProxy server instances will use to authenticate to the PingDirectory instances.
    1. Run the following command in the instance root of one of the PingDirectoryProxy server instances.

    ```
    $ keytool -genkeypair \
      -keystore config/proxy-user-keystore \
      -storetype JKS \
      -keyalg RSA \
      -keysize 2048 \
      -alias proxy-user-cert \
      -dname "cn=Proxy User,cn=Root DNs,cn=config" \
      -validity 7300
    ```

    2. When prompted for a key store password, enter a strong password to protect the certificate.
    3. When prompted for the key password, press Enter to use the key store password to protect the private key.
2. Use a text editor to create a `config/proxy-user-keystore.pin` file containing a single line that is the key store password provided in the previous step.
3. If there are other PingDirectoryProxy server instances in the topology, copy the `proxy-user-keystore` and `proxy-user-keystore.pin` files into the `config` directory for all instances.
4. To export the public component of the proxy user certificate to a text file, run the following command.

    ```
    $ keytool -export \
      -keystore config/proxy-user-keystore \
      -alias proxy-user-cert \
      -file config/proxy-user-cert.txt
    ```

5. Copy the `proxy-user-cert.txt` file into the `config` directory of all directory server instances.
    1. Import that certificate into each server's primary trust store by running the following command from the server root.

    ```
    $ keytool -import \
      -keystore config/truststore \
      -alias proxy-user-cert \
      -file config/proxy-user-cert.txt
    ```

    2. When prompted for the keystore password, enter the password contained in the `config/truststore.pin` file.
    3. When prompted to trust the certificate, enter `yes`.

Copyright © 2025 Ping Identity Corporation

6. To update the configuration for each PingDirectoryProxy server instance to create a new key manager provider that will obtain its certificate from the `config/proxy-user-keystore` file, run the following `dsconfig` command.

```
$ dsconfig create-key-manager-provider \
  --provider-name "Proxy User Certificate" \
  --type file-based \
  --set enabled:true \
  --set key-store-file:config/proxy-user-keystore \
  --set key-store-type:JKS \
  --set key-store-pin-file:config/proxy-user-keystore.pin
```

7. To update the configuration for each LDAP external server in each PingDirectoryProxy server instance to use the newly-created key manager provider, and also to use SASL EXTERNAL authentication instead of LDAP simple authentication, run the following `dsconfig` command.

```
$ dsconfig set-external-server-prop \
  --server-name ds1.example.com:636 \
  --set authentication-method:external \
  --set "key-manager-provider:Proxy User Certificate"
```

Result:

After these changes, the PingDirectoryProxy server re-establishes connections to the LDAP external server and authenticate with SASL EXTERNAL.

8. Verify that the PingDirectoryProxy server can communicate with all backend servers by running the `bin/status` command.

Result:

All of the servers listed in the "--- LDAP External Servers ---" section are available.

9. Review the PingDirectory server access log.

The BIND RESULT log messages used to authenticate the connections from the PingDirectoryProxy server include the following:

- `authType="SASL"`
- `saslMechanism="EXTERNAL"`
- `resultCode=0`
- `authDN="cn=Proxy User,cn=Root DNs,cn=config"`

Servers and certificates

The following provides a detailed description of PingDirectory server certificate types.

The PingDirectory server uses two main types of certificates:

Copyright © 2025 Ping Identity Corporation

Listener certificates

Used to secure communication through TLS.

Inter-server certificates

Used to authenticate between server instances in a topology.

Listener certificates

When a client initiates TLS negotiation with the server, the server presents a certificate chain to the client and the certificate at the head of the chain functions as a listener certificate.

Because the client decides whether to trust the certificate chain, it is recommended that the chain be signed by an issuer whom the client is likely to trust or that the client can be easily configured to trust.

You can create self-signed certificates with long lifespans, but a certificate that a certification authority signs is likely to have a relatively short lifespan. Commercial authorities typically issue certificates that are valid for only one or two years, but some authorities use shorter validity windows.

Short certificate lifespans offer some security benefits. In particular, because most clients do not verify whether a certificate has been revoked, a shorter validity window minimizes the timeframe that a compromised certificate can be used. If the process for replacing certificates is streamlined or automated, administrative inconvenience can be kept to a minimum.

Listener certificates are stored in key stores that are referenced by key manager providers, which in turn provide the logic and configuration for accessing the key stores. If a server component, like a connection handler, requires access to a certificate that it presents to a peer during the TLS negotiation process, that component must reference the key manager provider that points to the key store containing the appropriate certificate. If the key store contains multiple certificates, and if the component referencing the key store includes a property specifying the certificate's nickname, the certificate with that alias is selected. Otherwise, the server lets the Java virtual machine (JVM) select a certificate that might not be well-defined.

The server also provides trust manager providers, which determine whether to trust the certificate chains with which it is presented. A trust manager provider can reference a specified trust store file, but other options include the JVM default trust store, which uses the Java installation's default set of trusted issuers, and the blind trust manager provider, which automatically trusts every certificate chain that is presented to it.

> **Note**
>
> Never use a blind trust manager in a production environment because it leaves the server vulnerable to impersonation and man-in-the-middle attacks. However, a blind trust manager can be convenient in test environments when troubleshooting certain types of problems.

Replacing listener certificates

Certificate authorities typically restrict the lifespans of the certificates that they sign. If you use a certification authority to issue listener certificates, you are likely replacing the certificates on a regular basis.

About this task

Copyright © 2025 Ping Identity Corporation

The `replace-certificate` tool performs the following steps:

1. Obtain a new certificate chain.
2. Make necessary updates to the key manager provider and the connection handler configurations
3. Update the server instance listener configuration with the new certificate.

The `replace-certificate` tool offers the following modes of operation:

Interactive mode

Walks you through the process of obtaining a new certificate and installing it in the server. Interactive mode also displays the non-interactive commands that are required to achieve the same result.

Non-interactive mode

Useful when scripting the process of replacing a certificate.

Steps

- To replace a listener certificate, run the `replace-listener-certificate` subcommand of the `replace-certificate` tool.

> **Note**
>
> You can replace certificates manually, but the **`replace-certificate`** tool automates the process. The **`replace-certificate`** tool provides information about multiple listener certificates during the transitional phase that occurs when you install them.
>
> The **`replace-listener-certificate`** subcommand takes arguments that provide the following information:
>
> - Arguments required to authenticate to PingDataSync, such as `--bindDN` and `--bindPasswordFile`
> - Details about the key store that contains the new certificate
> - Updates that must be made to the key and trust manager providers
> - Whether to signal the HTTP connection handler to reload its certificates after the update is complete

The following arguments are available:

Argument	Description
`--source-key-store-file {path}`	Path to the Java KeyStore (JKS) or PKCS #12 file that contains the private key entry with the new certificate chain. This argument is required.
`--source-key-store-password {password}`	Clear-text password that is needed to access the contents of the source key store.
`--source-key-store-password-file {path}`	Path to the file that contains the password necessary to access the contents of the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--source-certificate-alias {alias}`	Password that is required to access the appropriate private key in the source key store. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, the key store password is used as the private key password.
`--source-private-key-password-file {path}`	Path to the file that contains the password needed to access the appropriate private key in the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, the key store password is used as the private key password.
`--key-manager-provider {name}`	Name of the key manager provider that is updated to use the new certificate chain. The value must identify a file-based key manager provider, and the new certificate chain must be enabled. Defaults to `JKS` if a value is not specified.
`--trust-manager-provider {name}`	Name of the trust manager provider that is updated with the information required to trust the new certificate chain. The value must identify a file-based trust manager provider, and the new certificate chain must be enabled. If neither this argument nor the `--use-jvm-default-trust-manager-provider` argument is provided, the tool assumes that the name of the trust manager provider is identical to the name of the key manager provider, though these providers remain separate and distinct.
`--use-jvm-default-trust-manager-provider`	Indicates that the server must be configured to use the JVM-default trust manager provider, which trusts certificates signed by issuers in the `cacerts` trust store provided with the Java virtual machine (JVM), rather than updating an existing trust manager provider.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--target-certificate-alias {alias}`	**Alias to use for the new certificate in the key manager provider's key store, and for appropriate updates in the trust manager provider's trust store. Defaults to an alias of `server-cert` if a value is not specified.** **Note** If the key manager provider's key store, or the trust manager provider's trust store, already contains an entry with the given alias, the existing entry is renamed.
`--reload-http-connection-handler-certificates`	**Indicates that the tool is requesting that the server cause any HTTPS-based connection handlers to reload their certificates, so that the connection handlers can use the updated certificate.** **LDAP connection handlers react to the change immediately and start presenting the new certificate chain during subsequent TLS negotiations. HTTPS connection handlers continue using the former certificate until the connection handler is restarted or until the connection handler is asked specifically to reload its certificates.** **Note** This option might prevent clients with existing TLS sessions that were negotiated with the former certificate from being resumed.

- **To remove earlier certificates from the server instance listener configuration, run the `purge-retired-listener-certificates` subcommand.**

> **Note**
>
> The `purge-retired-listener-certificates` subcommand does not take arguments other than the ones that are required to authenticate to the server.
> By default, the **`replace-certificate`** tool updates the server instance listener configuration object to include the new listener certificate, and it merges the old and new certificates residing in the configuration object.

Inter-server certificates

Each server instance in a topology has an inter-server certificate that is generated during the setup process.

The inter-server certificate is not exposed to clients, so a trusted issuer does not need to sign it. Instead, the topology registry, representing a mirrored portion of the configuration with information about every PingDirectory server instance in the environment, contains the information that each instance needs to trust the inter-server certificates for all other instances.

Copyright © 2025 Ping Identity Corporation

Inter-server certificates can be used to protect certain secrets that are shared among servers within the topology, like the secrets that are used to digitally sign log files, backups, and LDIF exports. Inter-server certificates include the encryption keys that reversible password-storage schemes use.

The inter-server certificate is generated with a long lifespan. Replace it only when you suspect that its private key is compromised.

Replacing the inter-server certificate

During the installation process, the inter-server certificate is generated with a long lifespan and does not require replacement under normal circumstances. You should replace the inter-server certificate only if you suspect that its private key is compromised.

About this task

The inter-server certificate is intended for use only between server instances within the same topology. Because it is not exposed to regular clients, the inter-server certificate does not need to be trusted.

The `replace-certificate replace-inter-server-certificate` command performs the following steps:

- Acquires the new inter-server certificate from a provided Java KeyStore (JKS) or PKCS #12 key store
- Makes the necessary updates to the `config/ads-truststore` file in the server key store
- Updates the server instance configuration object to include the new inter-server certificate

> **Note**
>
> To avoid the need to replace the inter-server certificate on a regular basis,use a self-signed certificate with a long lifespan. Each server instance must possess its own, unique inter-server certificate that satisfies the following conditions:
>
> - Uses an RSA key pair
> - Has a minimum key size of 2048 bits
>
> The following types of certificates are not allowed:
>
> - Certificates with an elliptic curve key pair
> - Certificates with an RSA key that is smaller than 2048 bits

Steps

- To replace the inter-server certificate, run the `replace-inter-server-certificate` subcommand of the `replace-certificate` .

  The `replace-inter-server-certificate` subcommand takes a subset of the arguments that are used with the `replace-listener-certificate` subcommand, including the following arguments:

  - `--source-key-store-file {path}--source-key-store-password {password}`
  - `--source-key-store-password-file {path}`
  - `--source-certificate-alias {alias}`

Copyright © 2025 Ping Identity Corporation

- `--source-private-key-password {password}`
- `--source-private-key-password-file {path}`

- To delete earlier values that are no longer needed, run the `purge-retired-inter-server-certificates` subcommand.

> **Note**
>
> By default, the new inter-server certificate is merged with the existing values in the server instance configuration entry.

X.509 certificates

The server supports X.509 certificates, the most common type of certificates. RFC 5280 describes X.509v3, which provides the current version of the specification.

An X.509v3 certificate includes the following components:

X.509 encoding version

Enables the differentiation between an X.509v3 certificate and one that conforms to an earlier or later version of the specification.

Serial number of the certificate

Integer value that uniquely identifies a certificate as issued by a certification authority.

Subject DN

Distinguished name for the certificate, which often provides details about the context in which the certificate is to be used. For more information, see Certificate subject DNs.

Issuer DN

Distinguished name for the issuer certificate, which is the certificate used to sign the certificate. For a self-signed certificate, this value matches the subject DN.

Validity window

Indicates the timeframe during which the certificate is considered valid. This component includes the following elements:

- `notBefore`

  Specifies the earliest time at which the certificate is considered valid.

- `notAfter`

Specifies the latest time at which the certificate is considered valid.

Public key

Public portion of a pair of cryptographically linked keys. For more information, see Certificate key pairs.

Copyright © 2025 Ping Identity Corporation

Signature

A type of cryptographic proof that the certificate truly was sent from the issuer and has remained unaltered. A self-signed certificate is signed with its own private key. Otherwise, it is signed with the issuer's private key.

An X.509v3 certificate might also include the following optional components:

Subject unique ID

Uniquely identifies the certificate. This component has been deprecated in favor of the subject key identifier extension, so it is generally omitted from X.509v3 certificates.

Issuer unique ID

Subject unique ID of the issuer certificate, if available. This component has been deprecated in favor of the authority key identifier extension.

Set of extensions

Provides additional context for the certificate and the manner in which it is used. For more information, see Certificate extensions.

Certificate subject DNs

A certificate's subject distinguished name (DN) provides information about how the certificate should be used.

Like an LDAP DN, a certificate's subject DN consists of a comma-delimited series of attribute-value pairs. However, unlike an LDAP DN, the attribute names in a certificate subject DN are typically written in all uppercase characters.

A certificate's subject DN is also referred to as its subject. The following attributes commonly appear in a certificate subject.

Attribute name	Attribute description
`CN`	Common name **Note** For a listener certificate, the `CN` attribute typically identifies the host name that clients use to access the certificate. However, the subject alternative name extension is recommended more highly for accomplishing the same task. Most certificate subject DNs include at least the `CN` attribute.
`E`	Email address
`OU`	Name of the organizational unit, such as the relevant department
`O`	Name of the organization or company
`L`	Name of the locality, such as the appropriate city
`ST`	Full name of the state or province

Copyright © 2025 Ping Identity Corporation

Attribute name	Attribute description
`C`	ISO 3166 country code

A certificate subject includes at least one attribute-value pair, and the `CN` attribute is typically present. Other attributes can be omitted, although the `O` and `C` attributes are also common. For example, a listener certificate for a server with an address of `ldap.example.com`, which is run by the US-based company Example Corp, might have a subject of `CN=ldap.example.com,O=Example Corp,C=US`.

Certificate key pairs

Each certificate contains a key pair that consists of two keys that are linked cryptographically. If you encrypt data with one key, the data can be only decrypted with the other key.

Although a key pair can be created easily when both keys are generated simultaneously, the process of deriving one key from the other is extremely difficult, a process categorized in cryptographic terms as computationally infeasible.

When generating a key pair, one key is designated as the public key, and the other key is designated the private key. The public key can be made widely available, but the private key must be kept secret and not shared with anyone.

As long as the secrecy of the private key is maintained, the key pair can be used to perform the following functions:

- Encryption, sometimes referred to as confidentiality

  If someone wants to send you a secret message without anyone else viewing it, the message can be encrypted with your public key. Only you possess the private key, so only you can decrypt the message.

- Digital signatures

  If you encrypt data with your private key, it can be decrypted only with your public key. Because your public key can be made widely available, this encryption method does not actually protect the content. However, digital signatures prove that a message came from you because only your private key could have generated it.

  > **Note**
  >
  > When generating a digital signature, the entire message is generally not encrypted. Only a hash of the message is encrypted, typically by using a digest algorithm like SHA-256.
  > This approach protects the integrity of a message. A decrypted signature that matches the digest of the original message guarantees that the message came from you and that it has remained unaltered since you signed it.

The following public key algorithms are used primarily in certificates that facilitate TLS communication:

- RSA, which is based on the multiplication of large prime numbers
- EC, which is based on computations that involve special types of elliptical curves

Although RSA is supported more widely than EC, it is slower and requires larger keys to achieve the same level of security. To support legacy clients, you should use an RSA certificate and choose a key size of at least 2,048 bits.

If all of your clients support EC certificates, you should use an EC certificate with a key size of at least 256 bits.

Copyright © 2025 Ping Identity Corporation

Certificate extensions

Extensions provide additional context for a certificate.

Some of the more common extension types include the following:

Subject key identifier

Holds a unique identifier for the certificate, which is generally derived from the certificate's public key.

Authority key identifier

Holds the subject key identifier for the issuer certificate. This extension type helps to identify the issuer certificate, especially when presented with an incomplete certificate chain.

Subject alternative name

Holds a list of ways that clients are expected to reference a server when establishing a connection to it.

> **Note**
>
> Clients must take this information into account when deciding whether to trust a server's certificate.
> The most common types of values include DNS names, IP addresses, and URIs. DNS names must be fully qualified, but can optionally use an asterisk in the leftmost component to match any single name in that component. For example, `*.example.com` could match `www.example.com` or `ldap.example.com`, but would not match `ldap.east.example.com` or `example.com`.

Key usage

Provides information about the manner in which the certificate is expected to be used. The following key usages are allowed:

`digitalSignature`

Indicates that the certificate can be used for digitally signing data, excluding certificates and certificate revocation lists (CRL).

`nonRepudiation`

Indicates that the certificate can be used to prevent denying the authenticity of a message. `nonRepudiation` is also known as `contentCommitment`.

`keyEncipherment`

Indicates that the certificate can be used to protect encryption keys, such as symmetric keys that are derived during TLS key agreement.

`dataEncipherment`

Indicates that the certificate can be used for encrypting data directly.

Copyright © 2025 Ping Identity Corporation

`keyAgreement`

Indicates that the certificate's public key can be used for key agreement, such as deriving the symmetric key that protects TLS communication.

`keyCertSign`

Indicates that the certificate can act as a certification authority and be used for signing other certificates.

`cRLSign`

Indicates that the certificate can be used to sign CRLs.

`encipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for encrypting data during key agreement.

`decipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for decrypting data during key agreement.

Extended key usage

Acts as an alternative to the key usage extension and provides additional high-level functionality. The following extended key usages are allowed:

`serverAuth`

Indicates that the server can present the certificate to the client during TLS negotiation.

`clientAuth`

Indicates that the client can present the certificate to the server during TLS negotiation.

`codeSigning`

Indicates that the certificate can be used to sign source and compiled code.

`emailProtection`

Indicates that the certificate can be used to sign or encrypt email messages.

`timeStamping`

Indicates that the certificate can be used to assert the time that an event occurred.

`ocspSigning`

Indicates that the certificate can be used to sign an online certificate status protocol (OCSP) response.

Copyright © 2025 Ping Identity Corporation

Basic constraints

Indicates whether the certificate can act as a certification authority and, if so, the maximum number of intermediate certificates that can follow it in a certificate chain.

Certificate chains

A certificate chain is an ordered list of one or more certificates. In such a chain, each subsequent certificate is the issuer of the previous certificate.

During TLS negotiation, the server presents a certificate chain to the client, which determines whether to trust the chain and continue with the negotiation. The client can also present its own certificate chain to the server.

If a certificate is self-signed, its chain contains only that single certificate. If a certificate is signed by a self-signed certificate authority (CA) certificate, such as a root CA, the chain contains two certificates: the server certificate and the CA certificate that follows it. If a single intermediate CA (a CA certificate that is signed by a root CA) is present, the chain contains the server certificate, followed by the intermediate CA, and then the root CA.

Intermediate certificate authorities are useful for security purposes, especially in commercial authorities. If a client trusts a root CA certificate, it is likely to trust anything with that root CA certificate at the base of its chain. Consequently, the root CA certificate must be kept secure.

> **Note**
>
> If the root CA certificate is compromised, any certificate that is directly or indirectly signed by it can no longer be trusted.

With intermediate CA certificates, the root certificate can be kept offline in secure storage and used only when a new intermediate CA certificate must be signed. The intermediate CA certificates can be used to sign end-entity certificates, but must be protected to avoid compromising any of the certificates. A compromised certificate must be revoked along with all of the certificates that it signed. In such a scenario, the root CA can be used to sign a new certificate.

> **Note**
>
> The certificate chain that the server presents to the client, or that the client presents to the server, during TLS negotiation does not always need to be the complete chain. If the root CA at the end of the chain is widely trusted, the server can assume that the client already has that root CA in its default set of trusted certificates. The server can leave that root CA off the chain with the assumption that the client will retrieve it from its default trust store. While the same assumption could theoretically be true for intermediate CA certificates, only the root CA certificate is commonly omitted. When a client receives an incomplete chain, the client looks in its default trust store to determine whether the trust store contains the issuer certificate, which it can identify by using properties like the issuer distinguished name (DN) or an authority key identifier extension.

The certificate at the head of a certificate chain, which appears as the first one in the list, is often called the end-entity certificate. If this certificate appears at the head of the chain that a server presents during TLS negotiation, it is referred to as the server certificate. If the certificate appears at the head of a chain that a client presents, it is referred to as a client certificate. The certificate at the end of a complete chain must be a root CA certificate. In the case of a self-signed certificate, the chain contains only a single certificate that serves both roles.

About representing certificates, private keys, and certificate signing requests

X.509 is an encoding format that uses the ASN.1 distinguished encoding rules (DER), which exist in binary format. When writing a certificate to a file, either a raw DER format or a plain-text format called PEM can be used.

PEM encoding consists of a line that contains the text `-----BEGIN CERTIFICATE-----`, followed by a set of lines that contains the base64-encoded representation of the raw DER bytes (typically with no more than 64 characters per line), followed by a line that contains the text `-----END CERTIFICATE-----`.

The X.509 encoding contains a certificate's public key, but not its private key. The PKCS #8 specification in RFC 5958 describes the encoding for private keys. This approach uses a DER encoding with a PEM variant that instead uses the following header and footer, respectively.

```
 -----BEGIN PRIVATE KEY-----
-----END PRIVATE KEY-----
```

RFC 5958 also describes an encrypted representation of the private key, but that format is currently unsupported.

The PKCS #10 specification in RFC 2986 describes the CSR format. This format uses a DER encoding with a PEM variant that uses the following header and footer, respectively.

```
-----BEGIN CERTIFICATE REQUEST-----
-----END CERTIFICATE REQUEST-----
```

Some implementations use the following alternate, nonstandard forms.

```
-----BEGIN NEW CERTIFICATE REQUEST-----
-----END NEW CERTIFICATE REQUEST-----
```

Certificate trust

When a server presents its certificate chain to a client during TLS negotiation, the client decides whether to trust the certificate chain and concludes whether it is communicating with a legitimate server instead of an impostor.

If a client is tricked through DNS hijacking into communicating with a rogue application instead of with a legitimate server, the application can steal the client's credentials, or can fool the client into concluding that it has performed an action that it has not performed. If a rogue application acts as a broker between the client and the legitimate server, the client might be unable to detect the change, and the malicious application might be capable of stealing data or altering the communication. Consequently, you should avoid `trust all` or `blind trust` options in a production environment.

When determining whether to trust a server certificate chain, a client performs the following steps.

Copyright © 2025 Ping Identity Corporation

Processing steps

1. Verifies that it has received the complete certificate chain.

   If a server presents an incomplete chain, the client must ensure that it can complete the chain with information in an explicitly provided trust store or default trust store. If the client cannot complete the certificate chain, the chain is not trusted.

2. Verifies that each subsequent certificate in the chain is the issuer certificate for, and that its private key was used to sign, the certificate that precedes it.

   > **Note**
   >
   > If a certificate chain contains extraneous certificates, or if a subsequent certificate did not issue the certificate that precedes it, the chain is not trusted.

3. Confirms that it has a reason to trust the certificate at the root of the chain.

   > **Note**
   >
   > This step is generally performed by ensuring that the root certificate authority (CA) certificate can be found in either a default trust store or a trust store that is configured for use by the client. If the client has no prior knowledge of the root CA certificate, the chain is not trusted.

4. Verifies that the current time lies within the validity window for each certificate in the chain.

   > **Note**
   >
   > The chain is not trusted under the following conditions:
   > - When the `notBefore` value of any certificate in the chain is later than the current time.
   > - When the `notAfter` value of any certificate in the chain is earlier than the current time.

5. Verifies that the server certificate at the head of the chain is suitable for the server with which the client thinks it is communicating.

   > **Note**
   >
   > The client must verify that the address used to connect to the server matches one of the following values:
   > - The `CN` attribute of the certificate's subject.
   > - One of the values of any subject alternative name extension.

These steps represent a starting point. If necessary, the client can perform additional types of validation. For example, if a root or intermediate certification authority maintains a certificate revocation list (CRL) or supports the online certificate status protocol (OCSP), the client must verify that none of the certificates in the chain has been revoked. The client can also verify that the CA certificates include the basic constraints extension, and that the server certificate does not contain too many levels. Other checks, like those that use certificate policy extensions, can also be performed.

Keystores and truststores

A keystore is a type of database that holds certificates.

Copyright © 2025 Ping Identity Corporation

The following examples represent the most common forms of keystores:

- File that uses the Java-specific Java KeyStore (JKS) format
- File that uses the standard PKCS #12 format
- Collection of files that holds certificates and private keys, typically in PEM or DER format
- Hardware security module (HSM) that makes the certificate information available through an interface like PKCS #11

The server supports file-based keystores by using the JKS and PKCS #12 formats and by using hardware security modules that are accessible through PKCS #11. The server does not currently support a keystore format that consists of individual certificate and private key files. To import these files into a JKS or PKCS #12 keystore, use the `manage-certificates` tool.

A keystore also represents a collection of entries, each of which is identified by a name that an alias calls. Keystores can have the following entry types:

Private key entries

Contain a certificate chain and a private key. When a server accepts a TLS-based connection, it uses a private key entry to obtain the certificate chain that it presents to the client. The server can also use the private key from the same entry to process its key agreement. Similarly, a client uses a private key entry when presenting its own certificate chain to a server.

Trusted certificate entries

Contain a single certificate without a private key. As the name implies, a trusted certificate entry is intended primarily for use when determining whether to trust a certificate chain that is presented during TLS negotiation.

Secret key entries

Contain a secret key only, without an associated certificate. These types of entries are not used for TLS processing. Instead, they hold symmetric encryption keys or other types of secrets.

A password, sometimes called a PIN, protects the contents of a keystore. In some cases, like with JKS keystores, some content might be accessible without a password, and a password might be required only when trying to access private keys or secret keys. In other cases, like with PKCS #12 keystores, you might need a password for any interaction with the keystore.

Additional passwords can further protect private keys. This approach is often the same as with the keystore password, but the password can be different. This tactic is useful when a single keystore is shared for multiple purposes, for example, and when merely having access to the keystore does not guarantee access to all of the data that it contains.

> **Note**
>
> A truststore is another name for a keystore that is intended primarily for use when determining whether to trust a certificate chain that has been presented. Truststores generally contain primarily trusted certificate entries, but that case is not required.

Java runtime environments typically include a default truststore, often `jre/lib/security/cacerts` or `lib/security/cacerts`, that is pre-populated with several widely trusted certification authority certificates. When presented with a certificate that one of these authorities has signed, the default truststore can allow the certificate to be trusted without any additional configuration. When presented with a self-signed certificate, or when presented with a certificate that is signed by an issuer not in the default truststore, such as a private corporate certification authority, a separate truststore is required.

Copyright © 2025 Ping Identity Corporation

Transport Layer Security (TLS)

TLS describes a mechanism for securely communicating between two parties that might have no prior knowledge of each other.

TLS is the successor to SSL, and the two terms are often used interchangeably, even though such usage might not technically be correct.

> **Note**
>
> SSL remains the more widely recognized term. The abbreviation TLS occasionally generates confusion with the StartTLS extended operation, particularly in LDAP.

TLS provides security in the form of the following main components:

Certificate trust

Is about reassuring a connection-initiating client that it is communicating with the server to which it intended to connect. To ensure that the server shares the same degree of confidence in the identity and legitimacy of the client, it can ask the client to present its own certificate chain. For more information, see Certificate Trust.

Cipher selection

Involves choosing the cipher and the key to protect the bulk of the communication. Although a client can use a server certificate's public key to encrypt data before sending it, this approach can lead to the following issues:

- Unless the client presents its own certificate chain to the server, the server cannot encrypt the data that it sends back to the client.
- Public key encryption is considerably slower than symmetric encryption, in which the same key is used for both encryption and decryption. Public key encryption is also called asymmetric encryption because different keys are used to encrypt and decrypt data.
- If you rely entirely on the security of a private key to ensure the secrecy of a communication, and if the private key becomes compromised, data that has been encrypted with the private key must also be considered compromised.

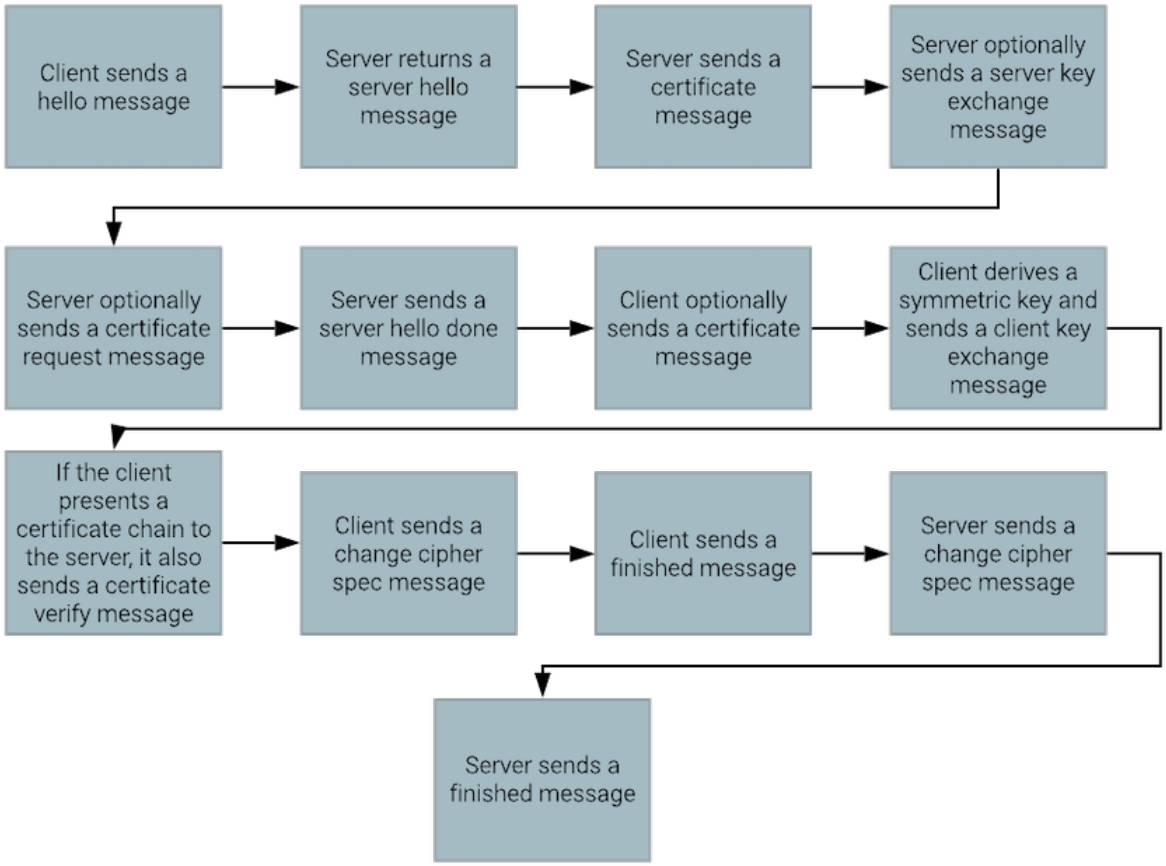
Rather than relying solely on public key encryption to protect communication between a client and server, the TLS negotiation process allows a client and server to agree on the type of encryption and the secret key to use after completing the negotiation process.

TLS handshakes

The process of negotiating the TLS is referred to as the handshake.

Copyright © 2025 Ping Identity Corporation

Although the exact process depends on the TLS version that is ultimately chosen, the following steps represent the basic components of a TLS 1.2 handshake:



TLS processing steps

1. The client sends a `hello` message that provides the server with the following information:
    - Highest supported version of the TLS protocol
    - The cipher suites that the client uses
    - Set of extensions with additional information:
        - The address that the client uses to communicate with the server
        - The signature algorithms and elliptic curves that the client supports
        - Whether the client supports secure renegotiation
2. The server returns a `server hello` message that provides the client with the following information:
    - The TLS protocol version that the server uses

Copyright © 2025 Ping Identity Corporation

- The cipher suite that the server selects

The server can also provide its own extensions to the client.

3. The server sends a `certificate` message that provides its certificate chain to the client.
4. The server can optionally send a `server key exchange` message with additional information that the client might need to securely derive the same symmetric encryption key that the server generates.
5. The server can optionally send a `certificate request` message that asks the client to present its own certificate chain to the server.
6. The server sends a `server hello done` message to inform the client that it has completed its `hello` sequence.
7. The client can optionally send a `certificate` message to the server with its own certificate chain.

> **Note**
>
> The client sends a `certificate` message only when the server initially sends a certificate request. If the client receives such a request, it can refuse to, and probably will not, send a certificate chain. The server decides whether to require a client certificate chain. In LDAP, the server commonly asks the client to present a certificate, but continues with TLS negotiation even if the client does not present one. This approach supports authentication methods like SASL EXTERNAL, in which a client uses the certificate chain that it presents during TLS negotiation as proof of its identity.

8. The client derives a symmetric key to use for the remainder of the encrypted processing, and sends a `client key exchange` message to the server. The `client key exchange` message includes the information that the server needs to generate the same key. Only the client and server know the value of the key, even if another entity can observe the communication that passes between the client and the server.
9. If the client presents a certificate chain to the server, it also sends a `certificate verify` message to prove that the private key for the certificate is included at the head of the chain.
10. The client sends a `change cipher spec` message to the server, which informs the server that the client will use the agreed-upon symmetric key to encrypt everything else that it sends to the server.
11. The client sends a `finished` message to the server to indicate that it has completed its portion of the handshake.
12. The server sends a `change cipher spec` message to the client, which informs the client that the server will use the agreed-upon symmetric key to encrypt everything else that it sends to the client.
13. The server sends a `finished` message to the client to indicate that it has completed its portion of the handshake.

TLS 1.3 uses a different handshake sequence that can require only a single round-trip to exchange the necessary information between the client and the server. TLS 1.2 requires two round-trips. To accomplish this task, TLS 1.3 tries to guess the type of key agreement that the server wants to use, and sends the relevant information to the server up front instead of waiting to hear from the server.

Because an extra round of communication between the client and server is eliminated, the server finishes its portion of the negotiation before the client. The server must assume that the client trusts its certificate chain. Because the server might log a successful negotiation only to discover late, through a TLS alert, that the client rejected the certificate, this approach might complicate certain types of troubleshooting.

Copyright © 2025 Ping Identity Corporation

Key agreement

Key agreement processing provides a critical component of TLS negotiation.

It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

RSA key exchange

The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.

Diffie-Hellman (DH) key exchange

The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, use ECHDE over DHE, and either of those options over RSA. The DH algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. The use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

LDAP StartTLS extended operation

In most scenarios, a client that uses TLS establishes a connection to a port that is dedicated to its use, like 636 (LDAPS) or 443 (HTTPS).

The client begins the TLS-negotiation process by sending a `client hello` message over the connection. In some scenarios, the client establishes a non-secure connection and later converts it to a secure one. In LDAP, this task is accomplished by using the `StartTLS` extended operation.

The `StartTLS` extended operation provides the following advantages over a dedicated LDAPS connection:

- To enable secure as well as insecure communication, only one port needs to be opened through a firewall.
- A client can use opportunistic encryption, in which the client performs the following steps:

    1. Queries the root DSE to determine whether the server supports StartTLS.
    2. Secures the connection, if possible.

  Opportunistic encryption is useful in scenarios like following referrals because LDAP URLs do not officially support LDAPS as a scheme.

Copyright © 2025 Ping Identity Corporation

To ensure that a communication is always secure, use LDAPS instead of establishing an insecure connection that you secure later with the `StartTLS` extended operation. If you enable support for unencrypted LDAP communication, as `StartTLS` requires, a client might send a password-containing bind request or other sensitive data over an unencrypted connection. A server can be configured to reject unencrypted communication, but it cannot prevent a client from sending an unencrypted request.

> **Note**
>
> Although you can use `StartTLS` to temporarily secure a connection before falling back on an unencrypted LDAP communication, the server does not support this strategy.

The manage-certificates tool

The server offers a `manage-certificates` tool that enables interaction with Java KeyStore (JKS) and PKCS #12 key stores.

Although it behaves similarly to the `keytool` utility that accompanies most Java distributions, `manage-certificates` is easier to use, provides improved usage information, and offers additional functionality.

Available subcommands

The `manage-certificates` tool uses the following subcommands to indicate which function to invoke:

Subcommand	Function
`list-certificates`	Lists the certificates in a keystore.
`import-certificate`	Imports a certificate into a trusted certificate entry or imports a certificate chain and private key into a private key entry.
`export-certificate`	Exports a certificate from a keystore.
`export-private-key`	Exports a private key from a keystore.
`generate-self-signed-certificate`	Generates a self-signed certificate.
`generate-certificate-signing-request`	Generates a certificate-signing request that can be provided to a certification authority.
`sign-certificate-signing-request`	Signs a certificate-signing request with a specified issuer certificate.
`check-certificate-usability`	Checks a specified certificate in a keystore to verify whether it is suitable for use as a listener certificate.
`trust-server-certificate`	Initiates the TLS-negotiation process with a specified server to obtain its certificate chain so that a truststore can be updated with the necessary information to trust the chain.

Copyright © 2025 Ping Identity Corporation

Subcommand	Function
`display-certificate-file`	Displays the contents of a file that contains one or more PEM-encoded or DER-encoded X.509 certificates.
`display-certificate-signing-request-file`	Displays the contents of a file that contains a PEM-encoded or DER-encoded PKCS #10 certificate-signing request (CSR).
`change-certificate-alias`	Changes the alias for an entry in a keystore.
`change-keystore-password`	Changes the password for a keystore.
`change-private-key-password`	Changes the password that protects the private key for a specified entry in a keystore.

Common arguments

Most of the `manage-certificates` subcommands require access to a Java KeyStore (JKS) or PKCS #12 keystore. In such instances, use the `--keystore` argument to specify the path to the keystore.

If the keystore already exists, the tool detects automatically whether it is a JKS or PKCS #12 keystore. If the operation creates a new keystore, you can specify the type explicitly by using the `--keystore-type` argument, followed by a value of `JKS` or `PKCS12`. If you do not specify the keystore type, a default value of `JKS` is used.

Some situations require you to provide the password that is needed to access the keystore. For a JKS keystore, you might need to provide a keystore password only for operations that involve creating a keystore or accessing a private key. However, you will likely need to provide the password for all operations that involve a PKCS #12 keystore.

To provide a keystore password, use one of the following arguments:

- `--keystore-password`, followed by the clear-text password for the keystore.
- `--keystore-password-file`, followed by the path to a file that contains the password for the keystore. The file might contain the password in the clear, or it might be encrypted with a definition from the server's encryption-settings database.
- `--prompt-for-keystore-password`. If this argument is provided, the tool prompts you interactively to provide the password.

If a private key is protected with a different password than the keystore itself, specify one of the following arguments to provide the private key password:

- `--private-key-password`, followed by the plain-text password.
- `--private-key-password-file`, followed by the path to a file that contains the clear-text or encrypted password.
- `--prompt-for-private-key-password`, which causes the tool to prompt interactively for the password.

Several operations require you to specify the keystore entry to target. In such scenarios, provide the `--alias` argument, followed by the name of the alias for that entry.

Copyright © 2025 Ping Identity Corporation

Listing the certificates in a keystore

List the certificates available in a keystore.

Steps

- To list the certificates in a keystore, use the `list-certificates` subcommand.

  This subcommand requires you to specify the path to the keystore file, and possibly the password that is needed to access the keystore. The following options are also available:

Option	Description
`--alias {alias}`	Specifies the alias of the certificate to display. If this value is not provided, all certificates are displayed. To list more than one specific certificate, specify this value multiple times.
`--display-pem-certificate`	Includes a PEM-encoded representation of each certificate as part of the output.
`--verbose`	Includes details about each certificate.

  Example:

  The following command demonstrates the basic listing of a keystore that contains a single certificate chain.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates list-certificates \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin

Alias:  server-cert (Certificate 1 of 2 in a chain)
Subject DN:  CN=ds1.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Certification Authority,O=Example Corp,C=US
Validity Start Time:  Saturday, November 9, 2019 at 11:26:09 AM CST
                      (8 minutes, 15 seconds ago)
Validity End Time:  Sunday, November 8, 2020 at 11:26:09 AM CST
(364 days, 23 hours, 51 minutes, 44 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint: 42:f8:85:97:bf:88:bc:74:4b:5b:ce:0c:54:43:9b:44:6b:
                   81:23:a3

Generating self-signed certificates

The process of creating a self-signed certificate is straightforward because a self-signed certificate claims itself as its own issuer.

Copyright © 2025 Ping Identity Corporation

Although self-signed certificates are convenient for testing environments, clients do not trust them by default. Consequently, you should not use them as listener certificates in production environments.

The `manage-certificates` tool offers a `generate-self-signed-certificate` subcommand that can create a self-signed certificate. In addition to the arguments that provide information about the keystore, certificate alias, and optional private key password, the following arguments are available.

Argument	Description
`--subject-dn {subject}`	Subject DN for the certificate to create. This value is required.
`--days-valid {number}`	Number of days that the certificate remains valid. Defaults to `365` if no value is specified.
`--validity-start-time {timestamp}`	Indicates the time at which the certificate begins its validity window. This value is assumed to reflect the local time zone, and must be expressed in the form `YYYYMMDDhhmmss`, where a value of `20190102030405` indicates January 2, 2019, at 3:04:05 AM. Defaults to the current time if no value is specified.
`--key-algorithm {name}`	Name of the algorithm to use when generating the key pair. For a listener certificate, this value is typically `RSA` or `EC`. Defaults to `RSA` if no value is specified. **Note** This argument cannot be used in conjunction with the `--replace-existing-certificate` argument.
`--key-size-bits {number}`	Length of the key, in bits, to generate. If the `--key-algorithm` argument is given, then `--key-size-bits {number}` must also be specified. Conversely, if the `--replace-existing-certificate` argument is given, then `--key-size-bits {number}` must not be specified. Typical key sizes are: • RSA key – 2048 or 4096 bits If a default RSA key is used but this argument is not provided, a default key size of 2048 bits is used. • Elliptic curve key – 256 or 384 bits

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--signature-algorithm {name}`	Name of the algorithm to use to sign the certificate. If the `--key-algorithm` argument is used to specify an algorithm other than `RSA`, then `--signature-algorithm {name}` must also be specified. If the `--replace-existing-certificate` argument is used, then `--signature-algorithm {name}` must not be specified. Typical signature algorithms include `SHA256withRSA` for certificates with RSA keys, and `SHA256withECDSA` for certificates with elliptic curve keys. If a default key algorithm is used but the `--signature-algorithm {name}` argument is not provided, a default value of `SHA256withRSA` is used.
`--replace-existing-certificate`	Uses the new certificate to replace an existing certificate in the key store (within the same alias), and reuses the key for that certificate.
`--inherit-extensions`	Indicates that, when replacing an existing certificate, the new certificate contains the same set of extensions as the existing certificate. If the `--replace-existing-certificate` argument is provided, but the `--inherit-extensions` argument is omitted, the new certificate contains only arguments that are provided explicitly.
`--subject-alternative-name-dns {name}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided DNS name. The given name must be fully qualified, although it can contain an asterisk (`*`) as a wildcard in the leftmost component. To include multiple DNS names in the subject alternative name extension, specify the `--subject-alternative-name-dns {name}` argument multiple times.
`--subject-alternative-name-ip-address {address}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided IP address. The given address must be a valid IPv4 or IPv6 address. No wildcards are allowed. To include multiple IP addresses in the subject alternative name extension, specify the `--subject-alternative-name-ip-address {address}` argument multiple times.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--subject-alternative-name-email-address {address}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided email address. To include multiple email addresses in the subject alternative name extension, specify the `--subject-alternative-name-email-address {address}` argument multiple times.
`--subject-alternative-name-uri {uri}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided URI. To include multiple URIs in the subject alternative name extension, specify the `--subject-alternative-name-uri {uri}` argument multiple times.
`--subject-alternative-name-oid {oid}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided object identifier (OID). The given value must be a valid OID. To include multiple OIDs in the subject alternative name extension, specify the `--subject-alternative-name-oid {oid}` argument multiple times.
`--basic-constraints-is-ca {value}`	Indicates that the certificate is expected to have a basic constraints extension, with a specified value of `true` or `false`, for the flag indicating whether to consider the certificate a certification authority that can be used to sign other certificates. • For root and intermediate certificate authority (CA) certificates, the `--basic-constraints-is-ca {value}` argument must be present with a value of `true`. • For end-entity certificates, the `--basic-constraints-is-ca {value}` argument can optionally be present with a value of `false`. • For a self-signed certificate, specify the `--basic-constraints-is-ca {value}` argument with a value of `false` to indicate that the certificate is not considered a CA certificate.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--basic-constraints-maximum-path-length {number}`	Indicates that the basic constraints extension is expected to include a path length constraint element with the specified value. Use this argument only if `--basic-constraints-is-ca` is provided with a value of `true`. A path length constraint value of `0` indicates that the certificate can be used to issue only end-entity certificates. A path length constraint value of `1` indicates that the certificate can be used to sign end-entity certificates or intermediate CA certificates, the latter of which can be used to sign only end-entity certificates. A value greater than `1` indicates the presence of several intermediate CA certificates between it and the end-entity certificate at the head of the chain.
`--key-usage {value}`	Indicates that the certificate is expected to have a key usage extension with the specified value. The following values are allowed: • `digital-signature` • `non-repudiation` • `key-encipherment` • `data-encipherment` • `key-agreement` • `key-cert-sign` • `crl-sign` • `encipher-only` • `decipher-only` To include multiple key usages, specify the `--key-usage {value}` argument multiple times.
`--extended-key-usage {value}`	Indicates that the certificate is expected to have an extended key usage extension with the specified value. The following values are allowed: • `server-auth` • `client-auth` • `code-signing` • `email-protection` • `time-stamping` • `ocsp-signing`

Example

For example, the following command can be used to generate a self-signed server certificate.

Copyright © 2025 Ping Identity Corporation

```
bin/manage-certificates generate-self-signed-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --keystore-type JKS \
     --alias server-cert \
     --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
     --key-algorithm EC \
     --key-length-bits 256 \
     --signature-algorithm SHA256withECDSA \
     --subject-alternative-name-dns ds.example.com \
     --subject-alternative-name-dns ds1.example.com \
     --subject-alternative-name-dns localhost \
     --subject-alternative-name-ip-address 1.2.3.4 \
     --subject-alternative-name-ip-address 127.0.0.1 \
     --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
     --key-usage digital-signature \
     --key-usage key-encipherment \
     --key-usage key-agreement \
     --extended-key-usage server-auth \
     --extended-key-usage client-auth

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=ds.example.com,O=Example Corp,C=US
Validity Start Time: Monday, January 27, 2020 at 03:40:13 PM CST
                     (0 seconds ago)
Validity End Time: Tuesday, January 26, 2021 at 03:40:13 PM CST
                   (364 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State:  The certificate is currently within the validity window.

```

Generating certificate signing requests

A certificate signing request (CSR) contains all of the information that a certification authority requires to issue a certificate.

RFC 2986 defines the request format, also known as PKCS #10, and includes the following elements:

- Certificate signing request version
- Requested subject distinguished name (DN) for the certificate
- Public key for the requested certificate
- Requested set of extensions for the certificate
- Signature that proves the requester has the private key for the given public key

Copyright © 2025 Ping Identity Corporation

To create a certificate signing request, use the `manage-certificates generate-certificate-signing-request` command, which performs the following steps:

1. Generated a public and private key pair.
2. Stores the key pair in a key store with a given alias.
3. Outputs the certificate signing request to the terminal.
4. Optionally writes the certificate signing request to a file.

Because a certificate signing request contains many of the same elements as a certificate, the command to generate one takes most of the same arguments as for generating a self-signed certificate. The following arguments are unavailable when generating a CSR:

- `--replace-existing-certificate`
- `--days-valid {number}`
- `--validity-start-time {timestamp}`

The following arguments are available when generating a certificate signing request but not when generating a self-signed certificate:

`--output-file {path}`

Path to a file to which the certificate signing request is written. If this value is not provided, the request is written only to the terminal in PEM form.

`--output-format {value}`

Format to use when writing the certificate signing request. This value can be `PEM` or `DER`, but the DER format is used only in conjunction with the `--output-file` argument. Defaults to `PEM` if the `--output-format {value}` argument is not provided.

`--use-existing-key-pair`

Indicates that the CSR uses a key pair that already exists in the key store with the given alias, rather than generating a new key pair, in which case the specified alias must not already be in use in the key store.

The following example command creates a CSR.

Copyright © 2025 Ping Identity Corporation

```
bin/manage-certificates generate-certificate-signing-request \
     --output-file ds1-cert.csr \
     --output-format PEM \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --keystore-type JKS \
     --alias server-cert \
     --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
     --key-algorithm EC \
     --key-length-bits 256 \
     --signature-algorithm SHA256withECDSA \
     --subject-alternative-name-dns ds.example.com \
     --subject-alternative-name-dns ds1.example.com \
     --subject-alternative-name-dns localhost \
     --subject-alternative-name-ip-address 1.2.3.4 \
     --subject-alternative-name-ip-address 127.0.0.1 \
     --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
     --key-usage digital-signature \
     --key-usage key-encipherment \
     --key-usage key-agreement \
     --extended-key-usage server-auth \
     --extended-key-usage client-auth

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing
request.

Successfully wrote the certificate signing request to file
'/ds/build/package/PingDirectory/ds1-cert.csr'.
```

If the contents of the resulting CSR file are made available to a certification authority to be signed, the resulting signed certificate can be imported into the key store.

To print the contents of a certificate signing request file, use the `display-certificate-signing-request-file` subcommand, which supports the following arguments:

`--certificate-signing-request-file {path}`

Path to the file that contains the certificate signing request to display.

`--verbose`

Indicates that the command is expected to display verbose information about the request, rather than a basic information set.

The following example demonstrates the basic output from the command.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates display-certificate-signing-request-file \
                                --certificate-signing-request-file ds1-cert.csr

                                PKCS #10 Certificate Signing Request Version:  v1
                                Subject DN:  CN=ds.example.com,O=Example Corp,C=US
                                Signature Algorithm:  SHA-256 with ECDSA
                                Public Key Algorithm:  EC (secP256r1)
```

The following example demonstrates the verbose output.

```
$ bin/manage-certificates display-certificate-signing-request-file \
     --certificate-signing-request-file ds1-cert.csr \
     --verbose

PKCS #10 Certificate Signing Request Version:  v1
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Signature Algorithm:  SHA-256 with ECDSA
Signature Value:
     30:45:02:20:46:31:be:9e:6d:2f:0e:e3:d0:80:5c:88:ef:da:86:07:fd:15:b7:62:

Importing signed and trusted certificates

Use the `manage-certificates import-certificate` command to import certificates into a keystore.

This command is used to accomplish the following tasks:

- Import a certificate that a certification authority has signed into the keystore in which the key pair was generated. In this scenario, the certificate is imported into a private key entry and must be imported as a certificate chain rather than an end-entity certificate.
- Import a trusted issuer certificate into a trust store. In this scenario, the certificate is imported into a trusted certificate entry as a single certificate instead of as a chain.
- Import a certificate chain, along with the private key for the end-entity certificate. This approach imports certificates that were generated through another library, like OpenSSL.

In addition to the arguments that provide information about the key store and the alias into which the certificate or certificate chain is imported, the `manage-certificates import-certificate` command accepts the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to import. The certificate can be in PEM or DER format and can be a single certificate or a certificate chain. If the certificates in the chain reside in separate files, specify the `--certificate-file {path}` argument multiple times when you import a certificate chain.

`--private-key-file {path}`

Path to the file containing the private key that corresponds to the certificate at the head of the imported chain. The private key can be in PEM or DER format.

`--no-prompt`

Indicates that the certificate is to be imported without prompting for confirmation. By default, a summary of the certificate is displayed, and you must confirm that you want to import it.

The following example command imports a signed certificate into the key store that generates the certificate signing request.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates import-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --certificate-file ds1-cert.pem \
     --certificate-file ca-cert.pem

The following certificate chain will be imported into the keystore into alias
'server-cert', preserving the existing private key associated with that alias:

Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US

                     12:7b:10:1f:26:05:b7:b9:0d:02:e0:38:3e

Do you want to import this certificate chain into the keystore? yes

Successfully imported the certificate chain.
```

If you do not provide the `--no-prompt` argument, the `manage-certificates import-certificate` tool still displays information about the certificates to import. To view additional information about a certificate before you import it, use the `display-certificate-file` subcommand, which supports the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to view.

`--verbose`

Displays verbose information about the certificate.

The output of the `display-certificate-file` subcommand has the same format and content as the `list-certificates` subcommand.

Copyright © 2025 Ping Identity Corporation

Exporting certificates

Use the `export-certificate` subcommand to export a single certificate or a certificate chain from a key store to a file in PEM or DER format.

The `export-certificate` subcommand supports the normal arguments about the key store and certificate alias, in addition to the following arguments:

`--output-file {path}`

Path to the file to which exported certificates are written. If this value is not provided, the certificates are written to standard output rather than a file.

`--output-format {format}`

Format in which exported certificates are written. The value can be `PEM` or `DER`, but the DER format can be used only if the output is written to a file. Defaults to `PEM` if no value is specified.

`--export-certificate-chain`

Indicates that a certificate chain, rather than the end-entity certificate only, is to be exported.

`--separate-file-per-certificate`

Indicates the use of separate output files for each exported certificate, rather than placing all of the certificates in a single file. If this argument is provided and multiple certificates are to be exported, then `.1` is appended to the path for the indicated output file for the first certificate in the chain, `.2` is appended for the second certificate, and so on.

The following example exports a certificate chain.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates export-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --output-file server-cert.pem \
     --output-format PEM \
     --export-certificate-chain \
     --separate-file-per-certificate

Successfully exported the following certificate to '/ds/server-cert.pem.1':
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
                     (3 hours, 26 minutes, 23 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
                           (364 days, 20 hours, 33 minutes, 36 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint: 02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb
SHA-256 Fingerprint:
1d:b5:eb:3c:f5:ff:bf:79:a2:a5:86:b8:e4:33:76:4d:d7:50:dc:a4:34:95:37:be:89:45:
86:1f:5d:79:c3:93

Successfully exported the following certificate to '/ds/server-cert.pem.2':
Subject DN:  CN=Example Root CA,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:00:07 PM CST
                     (3 hours, 35 minutes, 39 seconds ago)
Validity End Time: Saturday, November 5, 2039 at 10:00:07 PM CDT
                   (7299 days, 20 hours, 24 minutes, 20 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP384r1)
SHA-1 Fingerprint: 0e:5c:21:c9:a5:36:0a:24:eb:aa:55:b6:a5:94:0e:e0:56:03:22:e6
SHA-256 Fingerprint:
   77:cf:66:d7:3c:8a:fd:67:2d:b7:36:fd:60:1d:ca:eb:1b:03:b1:12:7b:10:1f:26:
   05:b7:b9:0d:02:e0:38:3e
```

The `export-certificate` subcommand exports only the public portion of a certificate. Its private key is not included. To export the private key, use the `export-private-key` subcommand, which supports the following arguments, in addition to the usual key store and alias arguments:

`--output-file {path}`

Path to the file to which the exported private key is written. If this value is not provided, the key is written to standard output rather than a file.

`--output-format {format}`

Format in which the exported private key is written. The value can be `PEM` or `DER`, but the DER format is used only if the output is written to a file. Defaults to `PEM` if no value is specified.

The following code provides an example of the `export-private-key` subcommand .

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates export-private-key \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --output-file server-cert-key.pem \
     --output-format PEM

Successfully exported the private key.
```

Using manage-certificates as a simple certification authority

If your server instances need to support an arbitrary or unknown set of clients, configure them with certificates from a trusted issuer, such as a commercial authority or the free Let's Encrypt service.

About this task

If you control every client that accesses the servers, you might want to create your own internal certification authority so that you have a common issuer for all servers. In such a scenario, the clients need to trust only the certificates that the issuer signs. Commercial and open-source software packages provide full-featured certification authority functionality, but you can use the `manage-certificates` tool to create a certificate authority (CA) certificate that you can use to sign certificate-signing requests.

Steps

1. Create a CA certificate.

   A CA certificate is a self-signed certificate that possesses the following extensions:

   - A key usage extension that includes at least the keyCertSign usage
   - A basic constraints extension that identifies the certificate as a CA certificate

     If you do not plan to use an intermediate CA certificate, the basic constraints extension must have a path length constraint of `0`. If you plan to use an intermediate CA certificate, the path length constraint must be `1`. Because certificates that the CA certificate signs are valid only for as long as all certificates in the chain remain valid, we recommend that you specify a long lifespan for the CA certificate.

     Example:

     The following example creates a new root CA certificate.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates generate-self-signed-certificate \
     --keystore /ca/root-ca-keystore \
     --keystore-password-file /ca/root-ca-keystore.pin \
     --keystore-type JKS \
     --alias root-ca-cert \
     --subject-dn "CN=Example Root CA,O=Example Corp,C=US" \
     --days-valid 7300 \
     --key-algorithm RSA \
     --key-size-bits 4096 \
     --signature-algorithm SHA256withRSA \
     --basic-constraints-is-ca true \
     --basic-constraints-maximum-path-length 1 \
     --key-usage key-cert-sign \
     --key-usage crl-sign

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:
Subject DN:  CN=Example Root CA,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Monday, January 27, 2020 at 03:47:29 PM CST (0 seconds ago)
Validity End Time: Sunday, January 22, 2040 at 03:47:29 PM CST
                   (7299 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
SHA-1 Fingerprint: bc:8e:5b:30:52:ec:03:63:b4:9a:aa:1a:45:a0:fc:84:49:dd:e8:64
SHA-256 Fingerprint:
   d5:47:06:cd:a2:95:42:61:1f:c7:aa:04:16:1e:c1:70:41:c4:44:48:bf:74:20:5f:1c:
   61:e2:aa:40:08:3a:ff
```

2. Export the public portion of the root CA certificate for future reference.

   When you import a signed certificate, you can import the public portion of the root CA certificate as a standalone certificate into trust stores as well as into part of a certificate chain.

3. Create a new certificate signing request to create an intermediate CA certificate,

   The certificate signing request uses essentially the same settings as the root CA. If you anticipate only a single intermediate CA, its basic constraints extension must have a path length constraint of `0`, rather than `1`, to indicate that it is used only to sign end-entity certificates and that it cannot create subordinate CA certificates by itself.

   Example:

   The following example command creates a certificate signing request.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates generate-certificate-signing-request \
     --keystore /ca/intermediate-ca-keystore \
     --keystore-password-file /ca/intermediate-ca-keystore.pin \
     --keystore-type JKS \
     --alias intermediate-ca-cert \
     --subject-dn "CN=Example Intermediate CA,O=Example Corp,C=US" \
     --key-algorithm RSA \
     --key-size-bits 4096 \
     --signature-algorithm SHA256withRSA \
     --basic-constraints-is-ca true \
     --basic-constraints-maximum-path-length 0 \
     --key-usage key-cert-sign \
     --key-usage crl-sign \
     --output-file /ca/intermediate-ca-cert.csr \
     --output-format PEM

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing
request.

Successfully wrote the certificate signing request to file
'/ca/intermediate-ca-cert.csr'.
```

4. Use the root CA certificate to sign the certificate signing request for the intermediate CA certificate with the `sign-certificate-signing-request` subcommand.

   The `sign-certificate-signing-request` subcommand takes most of the same arguments as generating a self-signed certificate. The primary differences between the argument sets are as follows:

   - The key store that contains the certificate uses the provided key store arguments to sign the request. To specify the name of the certificate to use when signing the request, use the `--signing-certificate-alias` argument.
   - To specify the path to the file that contains the certificate signing request file to generate, provide a `--request-input-file` argument.
   - To specify the path to the file to which the signed certificate is written, provide a `--certificate-output-file` argument. If this argument is omitted, the PEM representation of the certificate is written to standard output.
   - To specify the format, `PEM` or `DER`, in which the certificate is written to the output file, provide an `--output-format` argument.
   - To specify the subject to use for the signed certificate, use the `--subject-dn` argument. To use the subject DN from the certificate signing request, omit this argument.
   - To specify the name of the signature algorithm, use the `--signature-algorithm` argument.

     > **Note**
     >
     > Because the requester generated the key, you cannot specify the key algorithm or the key length.

   - To indicate that the signed certificate includes every extension that is listed in the certificate signing request, use the `--include-requested-extensions` argument. If this argument is not provided, explicitly specify the set of extensions to include.

Copyright © 2025 Ping Identity Corporation

Example:

The following example command signs the certificate signing request for an intermediate CA certificate.

```
$ bin/manage-certificates sign-certificate-signing-request \
     --keystore /ca/root-ca-keystore \
     --keystore-password-file /ca/root-ca-keystore.pin \
     --signing-certificate-alias root-ca-cert \
     --days-valid 7300 \
     --include-requested-extensions \
     --request-input-file /ca/intermediate-ca-cert.csr \
     --certificate-output-file /ca/intermediate-ca-cert.pem \
     --output-format PEM

Read the following certificate signing request:

PKCS #10 Certificate Signing Request Version:  v1
Subject DN:  CN=Example Intermediate CA,O=Example Corp,C=US
Signature Algorithm:  SHA-256 with RSA
Public Key Algorithm:  RSA (4096-bit)

Do you really want to sign this request? yes

Successfully wrote the signed certificate to file
'/ca/intermediate-ca-cert.pem'.
```

5. After you obtain the intermediate CA certificate, create secure, offline backups of the root CA certificate.
6. Remove the root CA certificate, or at least its private key, from all systems.

> **Note**
>
> Make certain that all end-entity certificates are signed with the intermediate CA certificate, and that the process is identical to the previous example. Restore the root CA certificate only if you need to sign another intermediate CA certificate.

Enabling TLS support during setup

Enable TLS support in the server.

To enable TLS support in the server, you should complete one of the following tasks during the setup procedure:

- Provide a key store that contains the certificate to use.
- Make the installer generate a self-signed certificate.

When using the `setup` tool in interactive mode, it prompts you for the information that it needs to configure secure communication, as shown in the following example.

Copyright © 2025 Ping Identity Corporation

```
Do you want to enable the Directory Server services (Available State,
Available or Degraded State, Configuration, Consent, Directory REST API,
Documentation, SCIM2, and Swagger UI) and Administrative Console over
HTTPS?  After setup, you can selectively enable or disable individual
services and applications by configuring the HTTPS Connection Handler
(yes / no) [yes]: yes

On which port should the Directory Server accept connections from HTTPS
clients? [443]: 443

On which port should the Directory Server accept connections from LDAP
clients? [389]: 389

Do you want to enable LDAPS? (yes / no) [yes]: yes
On which port should the Directory Server accept connections from LDAPS
clients? [636]: 636

Do you want to enable StartTLS? (yes / no) [yes]: yes

Certificate server options:

    1)  Generate self-signed certificate (recommended for testing purposes
        only)
    2)  Use an existing certificate located on a Java Keystore (JKS)
    3)  Use an existing certificate located on a PKCS12 keystore
    4)  Use an existing certificate on a PKCS11 token

Enter option [1]: 2

Java Keystore (JKS) path: /ca/ds1-keystore
Keystore PIN: {password}

Truststore options:

    1)  Generate a default JKS truststore
    2)  Use an existing JKS truststore
    3)  Use an existing PKCS12 truststore

Enter option [1]: 2

JKS truststore path: /ca/truststore
Truststore password (can be blank): {password}
```

When using `setup` in non-interactive mode, use the following arguments to configure TLS support.

Argument	Description
`--ldapsPort {port}`	Server enables support for LDAPS (LDAP over TLS) on the specified TCP port.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--httpsPort {port}`	Server enables support for HTTPS for SCIM, the Directory REST API, and the web-based administration console on the specified TCP port.
`--enableStartTLS`	LDAP connection handler enables support for the StartTLS extended operation.
`--generateSelfSignedCertificate`	`setup` generates a self-signed certificate that is presented to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--useJavaKeyStore {path}`	Server uses the specified Java KeyStore (JKS) key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--usePKCS12KeyStore {path}`	Server uses the specified PKCS #12 key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--usePKCS11KeyStore`	Server uses a PKCS #11 key store, like a hardware security module, to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation. The Java Virtual Machine (JVM) must already be configured to access the appropriate key store through PKCS #11.
`--keyStorePassword {password}`	Password that is needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store. The `setup` tool assumes that the private key password matches the key store password.
`--keyStorePasswordFile {path}`	Path to the file that contains the password needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store.
`--certNickname {alias}`	Alias of the private key entry in the specified key store that contains the certificate chain to present to clients during TLS negotiation. This argument is optional but recommended if the key store contains multiple certificates.
`--useJavaTrustStore {path}`	Server uses the specified JKS trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--usePKCS12TrustStore {path}`	Server uses the specified PKCS #12 trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation
`--trustStorePassword {password}`	Password that is needed to interact with the specified JKS or PKCS #11 trust store.
`--trustStorePasswordFile {path}`	Path to the file that contains the password needed to interact with the specified JKS or PKCS #11 trust store.

The following example command sets up the PingDirectory server in non-interactive mode with an existing certificate.

```
$ ./setup \
     --no-prompt \
     --acceptLicense \
     --ldapPort 389 \
     --ldapsPort 636 \
     --httpsPort 443 \
     --enableStartTLS \
     --useJavaKeyStore config/keystore \
     --keyStorePasswordFile config/keystore.pin \
     --certNickname server-cert \
     --useJavaTrustStore config/truststore \
     --trustStorePasswordFile config/truststore.pin \
     --baseDN dc=example,dc=com \
     --rootUserDN "cn=Directory Manager" \
     --rootUserPasswordFile root-pw.txt \
     --maxHeapSize 10g \
     --encryptDataWithPassphraseFromFile encryption-settings-password.txt \
     --instanceName ds1 \
     --location Austin \
     --noPropertiesFile

Enabling TLS support after setup

If the server has been set up without support for TLS, enable TLS support later by completing the following tasks.

Steps

1. Obtain a certificate chain.

Copyright © 2025 Ping Identity Corporation

For more information about obtaining a certificate chain, see Certificate chains. To prepare a Java KeyStore JKS or PKCS #12 key store with an appropriate certificate chain and private key, use the `manage-certificates` tool. We also recommend that you create a trust store that the server can use.

2. Configure the key and trust manager providers.

   For more information, see Configuring key and trust manager providers.

3. Configure connection handlers.

   For more information, see Configuring connection handlers.

Configuring key and trust manager providers

After you have a key store, configure a key manager provider to access it.

The server is preconfigured with key manager providers, `JKS` and `PKCS12`, that you can use with JKS or PKCS #12 key stores, respectively. You can update the appropriate key manager provider in most cases to reference the key store that you plan to use. The following code provides an example.

```
dsconfig set-key-manager-provider-prop \
     --provider-name JKS \
     --set enabled:true \
     --set key-store-file:config/keystore \
     --set key-store-pin-file:config/keystore.pin
```

A similar change configures a trust manager provider to reference the appropriate trust store. The following code provides an example.

```
dsconfig set-trust-manager-provider-prop \
     --provider-name JKS \
     --set enabled:true \
     --set include-jvm-default-issuers:true \
     --set trust-store-file:config/truststore \
     --set trust-store-pin-file:config/truststore.pin
```

> **Note**
>
> If all clients and servers use certificates that are signed by issuers and are included in the JVM's default trust store, you can use the `JVM-Default` trust manager provider to accomplish this task.

Configuring connection handlers

After you configure the key and trust manager providers, update the connection handlers to use the key and trust manager providers.

Steps

- For the LDAP connection handler, use the following command to enable StartTLS with a configuration change. By default, the LDAP connection handler accepts non-secure connections.

  Example:

Copyright © 2025 Ping Identity Corporation

```
dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --set allow-start-tls:true \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert \
  --set ssl-client-auth-policy:optional
```

- If you did not configure secure communication during setup, the LDAPS connection handler is disabled. To configure LDAPS support in this scenario, enable the connection handler and configure most of the same settings. You must set `allow-start-tls` to `false` and `use-ssl` to `true`. See the following code for an example configuration.

  Example:

  ```
  dsconfig set-connection-handler-prop \
    --handler-name "LDAPS Connection Handler" \
    --set enabled:true \
    --set key-manager-provider:JKS \
    --set trust-manager-provider:JKS \
    --set ssl-cert-nickname:server-cert \
    --set ssl-client-auth-policy:optional
  ```

  Example:

  The following example uses a similar configuration change to enable the HTTPS connection handler.

  ```
  dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set enabled:true \
    --set listen-port:443 \
    --set key-manager-provider:JKS \
    --set trust-manager-provider:JKS \
    --set ssl-cert-nickname:server-cert
  ```

Updating the topology registry

After the server connection handlers are updated to enable TLS, update the topology registry to provide information about the new configuration.

The topology registry holds information about server instances that are part of the environment, and it helps to facilitate inter-server communication, such as replication, mirroring portions of the configuration, and the PingDirectory server's automatic backend server-discovery functionality.

The following table details the two types of entries that require updating.

Copyright © 2025 Ping Identity Corporation

Configuration types and their update descriptions

Configuration Type	Update description

Server instance listener configuration	• Provides information that is needed to trust the TLS certificates that instances in the topology present.
	• The server instance listener configuration must include the server certificate, which is defined as the certificate at the head of the chain. This version must be the multi-line, PEM-formatted representation of the certificate. You can use `dsconfig` to import the certificate from a file, as shown in the following example.
	`bin/dsconfig set-server-instance-listener-prop \`
	`--instance-name ds1 \`
	`--listener-name ldap-listener-mirrored-config \`
	`--set server-ldap-port:636 \`
	`--set connection-security:ssl \`
	`--set 'listener-certificate>/ca/ds1-cert.pem'`
	Note
	The less-than operator `>` in the final line indicates that the value is read from a file rather than provided directly. In addition, you might not need to enclose the property name and path within single straight quotes to prevent the shell from interpreting the less-than symbol as an attempt to redirect input.

Server instance configuration	• Provides information about options for communicating with those instances.
	• Update the server instance configuration object to reflect the new methods that are available for communication with the instance. For example, the `preferred-security` property identifies the mechanism by which other instances in the topology attempt to communicate with the instance.
	The following example code sets the LDAPS and HTTPS ports, indicates that StartTLS support is enabled, and instructs other instances to use SSL (LDAPS) when communicating with the instance.
	`dsconfig set-server-instance-prop \`
	`--instance-name ds1 \`
	`--set ldaps-port:636 \`
	`--set https-port:443 \`
	`--set preferred-security:ssl \`
	`--set start-tls-enabled:true`

Troubleshooting TLS-related issues

Use this section for troubleshooting problems that might arise during TLS configuration, including communication and security issues that affect clients as well as the PingDirectory server.

- Log messages

Copyright © 2025 Ping Identity Corporation

- manage-certificates check-certificate-usability
- ldapsearch
- Using low-level TLS debugging

Log messages

The following describes how to use the server's log messages to troubleshoot TLS-related issues.

To troubleshoot TLS-related issues, start by checking the server's access log. If the client can establish a TCP connection to the server, which must occur before TLS negotiation can start, the access log shows a `CONNECT` message with the following information:

- Source and destination address and port for the connection
- Protocol
- Selected client connection policy

The `CONNECT` message does not appear

If the `CONNECT` does not appear, the client might be unable to communicate with the server. The culprit can be a network problem, a firewall that is blocking attempts to communicate, or the client is trying to use an incorrect address or port.

The `CONNECT` message does appear

If the `CONNECT` message appears in the access log, it typically includes a `conn` element that specifies the connection ID. To view additional log messages for the client connection, use the `search-logs` tool. For example, if the connection ID is `12345`, the following command displays the complete set of associated log messages.

```
$ bin/search-logs --logFile logs/access conn=12345
```

If you are using LDAPS

If you are attempting to use LDAPS, one of the following log messages appears next:

- `SECURITY-NEGOTIATION` message – Indicates that the client and server successfully completed the negotiation process and that the issue likely occurred after the TLS session was established. This message also includes details about the negotiation, including the TLS protocol and the selected cipher suite.

Copyright © 2025 Ping Identity Corporation

- `DISCONNECT` message – The issue might involve a failure in the TLS-negotiation process. In such scenarios, the message usually includes a `reason` element that provides additional information about the reason for the disconnect.

  If the failure occurred during TLS negotiation, the usefulness of the `DISCONNECT` message depends in part on whether the failure occurred on the client or the server. For example, if the server decided to abort the negotiation, the message ideally contains the specific reason. If the problem occurred on the client, the log message likely contains only the general category for the failure.

  > **Note**
  >
  > The TLS protocol does not provide a mechanism for conveying detailed error messages. Instead, it offers only a basic alert mechanism with a fixed set of alert types. For example, if a client does not trust the certificate chain that the server presents to it, the server might receive a generic alert like `certificate_unknown`, even if the client knows the precise reason for rejecting the chain. In such instances, you might need to determine whether the client can provide additional details about the issue.

If the access log does not provide useful information

If the access log does not provide useful information, check the server error log. Although the error log does not normally include information about issues that relate to client communication, it provides helpful information in certain circumstances, like when an internal error within the server interferes with communication attempts.

manage-certificates check-certificate-usability

The `manage-certificates` tool offers a `check-certificate-usability` subcommand to examine a specified entry in a key store and to identify potential issues that might interfere with secure communication.

The `check-certificate-usability` tool completes the following tasks:

- Ensures that a specified entry in the key store includes a private key and a complete certificate chain
- Checks whether the certificate at the root of the chain is found in the Java virtual machine's (JVM's) default set of trusted certificates
- Ensures that the current time lies is within the validity window for all certificates in the chain
- Validates the signatures for all certificates in the chain
- Warns if the end-entity certificate is self-signed
- Warns if the end-entity certificate does not contain an extended key usage extension with the `serverAuth` usage
- Warns if the issuer certificates do not have a key usage extension with the `keyCertSign` usage
- Warns if the issuer certificates do not have a basic constraints extension indicating that it can operate as a certification authority

  If the chain violates a path length constraint, the `check-certificate-usability` tool reports an error.
- Ensures that the signature algorithm uses a strong message digest algorithm, like SHA-256

Copyright © 2025 Ping Identity Corporation

The `check-certificate-usability` tool reports an error for weak digest algorithms like MD5 or SHA-1, and reports a warning for unrecognized digest algorithms.

- Ensures that none of the certificates that use an RSA key pair have a key size less than 2048 bits

The following example demonstrates the usage for the `manage-certificates check-certificate-usability` command and its output when no problems are identified.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates check-certificate-usability \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert

Successfully retrieved the certificate chain for alias 'server-cert':

ldapsearch

The `ldapsearch` command-line utility is a powerful tool for issuing searches against an LDAP directory server. It also provides a convenient method for troubleshooting a variety of issues, including problems that are relevant to TLS communication.

The following table details arguments that are the most useful for TLS-related communication.

TLS-related communication arguments and their descriptions

Argument	Description
`--hostname {address}`	Address of the server to which the connection is established
`--port {port}`	TCP port of the server to which the connection is established. The standard port for non-secure LDAP, or LDAP to be secured with StartTLS, is `389`, and the standard port for secure LDAPS is `636`. Many deployments use alternate ports, especially non-privileged ports above `1024`.
`--useSSL`	The tool establishes an initially insecure LDAP connection, which is secured later with the StartTLS extended operation.
`--trustStorePath {path}`	Path to the trust store that is used when determining whether to trust the certificate chain that the server presents during TLS negotiation. If neither this argument nor the `--trustAll` argument is provided, the tool prompts you interactively whether to trust server certificates that are not signed by an issuer in the Java virtual machine's (JVM's) default trust store.
`--trustStoreFormat {format}`	Format for the trust store, which is typically `JKS` or `PKCS12`.
`--trustStorePassword {password}`	Password that is required to access the contents of the trust store.
`--trustStorePasswordFile {path}`	Path to the file that contains the password that is required to access the contents of the trust store.
`--trustAll`	The tool blindly trusts all TLS certificate chains that are presented to it. Although this argument can prove useful for troubleshooting purposes, it is not recommended for general use.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--keyStorePath {path}`	**Path to the key store to use if a client certificate chain is presented to the server.** **Note** Use this argument only when one of the following conditions is satisfied: • The server is configured to require clients to present a certificate. • You intend to use the certificate to authenticate through SASL EXTERNAL.
`--keyStoreFormat {format}`	**Format for the key store, which is typically `JKS` or `PKCS12`.**
`--keyStorePassword {password}`	**Password to access the key store.**
`--keyStorePasswordFile {path}`	**Path to the file that contains the password necessary to access the key store.**
`--certNickname {alias}`	**Alias of the private key entry in the key store. Use when obtaining the certificate chain to present to the server.**
`--useSASLExternal`	**The client authenticates with the EXTERNAL SASL mechanism, which typically identifies the client using the certificate chain that is presented during TLS negotiation.**
`--enableSSLDebugging`	**The tool activates the low-level TLS-debugging feature that the JVM provides.**

The following command provides an example of the simplest method for testing TLS communication with the PingDirectory server.

Example

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
The server presented the following certificate chain:

     Subject: CN=ds1.example.com,O=Example Corp,C=US
     Valid From: Tuesday, November 12, 2019 at 08:28:08 PM CST
     Valid Until: Wednesday, November 11, 2020 at 08:28:08 PM CST
     SHA-1 Fingerprint:

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

Trust stores and trust-related arguments

If no trust-related arguments are provided, the tool uses the JVM's default trust store to verify whether to trust the certificate chain, based on the information that it contains. If a trusted authority has signed the server certificate, the negotiation process continues without further interaction.

If the chain cannot be trusted, based on the information in the JVM-default trust store, `ldapsearch` prompts you interactively about whether to trust the certificate. If you accept the chain, the client and server complete the negotiation process, and the client sends the search request to the server. If the search succeeds, the server can communicate over TLS.

Copyright © 2025 Ping Identity Corporation

To test with a trust store instead of being prompted interactively, use the `--trustStorePath` argument that points to the appropriate trust store. If you are using a Java Keystore (JKS) trust store, you might not need to provide the trust store password. If you are using a PKCS #12 trust store, you need to provide the trust store password. The following code provides an example.

Example

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore.p12 \
     --trustStorePasswordFile config/truststore.pin \
     --trustStoreFormat PKCS12 \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

Client certificate chains and key stores

To present a client certificate chain to the server, either because the server's connection handler is configured with an `ssl-client-auth-policy` value of `required` or because you plan to use the certificate to authenticate by way of the SASL EXTERNAL mechanism, provide at least the key store and its corresponding password. You can also specify the alias of the certificate chain to present, which is recommended if your client key store contains multiple certificates. The following code provides an example.

Example

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore.p12 \
     --trustStorePasswordFile config/truststore.pin \
     --trustStoreFormat PKCS12 \
     --keyStorePath client-keystore \
     --keyStorePasswordFile client-keystore.pin \
     --certNickname client-cert \
     --useSASLExternal \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

If you need to further troubleshoot a TLS-related issue

If you encounter a TLS-related issue that you cannot resolve by examining the `ldapsearch` output or the server logs, use the `--enableSSLDebugging` option to enable the JVM's support for low-level debugging of TLS processing. For more information, see Using low-level TLS debugging.

Using low-level TLS debugging

Use tools other than the command-line tools that are provided with the PingDirectory server for performing low-level TLS debugging.

Before you begin

> **Note**
>
> If you need to use low-level debugging options, enable the Java Virtual Machine (JVM)'s support for TLS debugging. Many of the command-line tools that are provided with the PingDirectory server, such as **`ldapsearch`**, offer an `--enableSSLDebugging` argument that simplifies this process.

Steps

1. In the `config/java.properties` file, add the following line to the set of properties for the appropriate tool.

   ```
   -Djavax.net.debug=all
   ```

Copyright © 2025 Ping Identity Corporation

2. For the changes to take effect, run the `bin/dsjavaproperties` command.

Next steps

The next time the tool is run, an output is generated detailing the TLS-related processing that the JVM is performing. You and the Ping Identity support team can use the output to identify the issue.

Enabling low-level debugging

About this task

> **Note**
>
> Because this approach requires multiple server restarts, it is not a popular option. You might be able to obtain more information without a restart by using the debugging support that is built into the server. For more information and to enable this level of support, see Using the debug log publisher.

To enable low-level debugging:

Steps

1. In the `config/java.properties` file, add `-Djavax.net.debug=all` to the `start-server.java-args` property.
2. Run `bin/dsjavaproperties`.
3. Restart the server.

Using the debug log publisher

To obtain more information for troubleshooting without a restart, use the server's built-in debugging support.

About this task

To use the debug log publisher:

Steps

1. To enable the debug log publisher and set the debug target, run the following configuration changes:
    1. Run `dsconfig` with the `create-debug-target` option.

       Example:

       ```
       dsconfig create-debug-target \
            --publisher-name "File-Based Debug Logger" \
            --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
            --set debug-level:verbose
       ```

    2. Run `dsconfig` with the `set-log-publisher-prop` option.

       Example:

Copyright © 2025 Ping Identity Corporation

```
dsconfig set-log-publisher-prop \
     --publisher-name "File-Based Debug Logger" \
     --set enabled:true
```

Result:

The `logs/debug` file captures a substantial amount of information about the TLS-related processing that the server is performing. Although this file doesn't provide as much detail as the Java virtual machine's (JVM) built-in debugging information, it might help to pinpoint the cause of the problem and to identify potential solutions.

2. To disable the debug log publisher and remove the debug target, run the following configuration changes:

    1. Run `dsconfig` with the `set-log-publisher-prop` option.

        Example:

        ```
        dsconfig set-log-publisher-prop \
             --publisher-name "File-Based Debug Logger" \
             --set enabled:false
        ```

    2. Run `dsconfig` with the `delete-debug-target` option.

        Example:

        ```
        dsconfig delete-debug-target \
             --publisher-name "File-Based Debug Logger" \
             --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider
        ```

        Tip

        To troubleshoot TLS communication with a non-Java client that does not offer its own TLS debugging mechanism, and if the server-side debugging support is insufficient, use a network protocol analyzer to capture the communication between the client and the server and to examine its content. The free, open-source Wireshark utility is a graphical tool that runs on a variety of platforms and provides support for understanding TLS communication. Even if you can't decipher the encrypted content, you can view at least some of the handshake messages.

        Note

        More of the handshake is encrypted in TLS 1.3 than in earlier versions of the protocol. Although this change improves security and privacy, it might interfere with troubleshooting attempts.

Configuring load balancing

You can distribute the load on your PingDirectoryProxy server using one of the load-balancing algorithms provided with the PingDirectoryProxy server. By default, the PingDirectoryProxy server prefers local servers over non-local servers, unless you set the `use-location` property of the load-balancing algorithm to false. Within a given location, the PingDirectoryProxy server prefers available servers over degraded servers. This means that if at all possible, the PingDirectoryProxy server sends requests to servers that are local and available before considering selecting any server that is non-local or degraded.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If the `use-location` property is set to true, then the load is balanced only among available external servers in the same location. If no external servers are available in the same location, the PingDirectoryProxy server will attempt to use available servers in the first preferred failover location, and so on. The failover based on no external servers with AVAILABLE health state can be customized to allow the PingDirectoryProxy server to prefer local DEGRADED health servers to servers in a failover location. See the online PingDirectoryProxy Configuration Reference Guide for more information on the `prefer-degraded-servers-over-failover` property.

The PingDirectoryProxy server provides the following load-balancing algorithms:

- Failover load balancing. This algorithm forwards requests to servers in a given order, optionally taking the location into account. If the preferred server is not available, then it will fail over to the alternate server in a predefined order. This balancing method can be useful if certain operations, such as LDAP writes, need to be forwarded to a primary external server, with secondary external servers defined for failover if necessary.

  This algorithm also offers load spreading to multiple failover servers. If the failover load-balancing algorithm is configured with one or more load-spreading base DNs, then requests that target entries below a load-spreading base DN can be balanced across any of the servers with the same health check state and location. Requests targeting a specific portion of the data will consistently be routed to the same server, but requests targeting a different portion of the data might be sent to a different server.

- Fewest operations load balancing. This algorithm forwards requests to the backend server with the fewest operations currently in progress and tends to exhibit the best performance.

- Health weighted load balancing. This algorithm assigns weights to servers based on their health scores and, optionally, their locations. For example, servers with a higher health check score will receive a higher proportion of the requests than servers with lower health check scores.

- Single server load balancing. This algorithm forwards all operations to a single external server that you specify.

- Weighted load balancing. This algorithm uses statically defined weights for sets of servers to divide load among external servers. External servers are grouped into weighted sets, the values of which, when added to all of the weighted sets for the load balancing algorithm, represent a percentage of the load the external servers should receive.

- Criteria based load balancing. This algorithm allows you to balance your load across a server topology depending on the types of operations received or the client issuing the request.

  For example, ds1 and ds2 are assigned to a weighted set named Set-80 and assigned the weight 80. The external servers ds3 and ds4 are assigned to the weighted set Set-20 and assigned the weight 20. When both sets, Set-80 and Set-20, are assigned to the load balancing algorithm, 80 percent of the load will be forwarded to ds1 and ds2, while the remaining 20 percent will be forwarded to ds3 and ds4.

Configure failover load-balancing for load spreading

If the failover load-balancing algorithm is configured with one or more load-spreading base distinguished names (DNs), then requests that target entries below a load-spreading base DN can be balanced across any of the servers with the same health check state and location.

Requests targeting a specific portion of the data are consistently routed to the same server, but requests targeting a different portion of the data might be sent to a different server.

Copyright © 2025 Ping Identity Corporation

Load spreading is useful for deployments:

- Where the directory information tree (DIT) contains a large number of branches below a common parent
- Where most operations (including search operations, as indicated by the search base DN) only target entries at least one level below that common parent.

For example, load spreading can be useful for a multi-tenant deployment in which all of the entries for a given tenant are within their own branch, and all of the tenant branches reside below a common parent.

Load spreading is configured with the `load-spreading-base-dn` property. The value or values of this property are the base DN or DNs below which the tenant entries reside.

In a deployment with a DIT as in the following example, the `load-spreading-base-dn` value would be set to `ou=customers,dc=example,dc=com`.

```
dc=example,dc=com
ou=customers,dc=example,dc=com
ou=Customer 1,ou=customers,dc=example,dc=com
ou=Customer 2,ou=customers,dc=example,dc=com
ou=Customer 3,ou=customers,dc=example,dc=com
...
```

If the `load-spreading-base-dn` property is not configured, the failover load-balancing algorithm uses the default behavior. If the property is configured with one or more values, but a client requests an operation that targets an entry that is not below any of the configured base DNs, then that operation is handled using the default behavior.

When the `load-spreading-base-dn` property is configured with one or more values, the load-balancing algorithm continues to generate the same list of lists, but the order of the servers within each list is determined using the following algorithm:

1. If the list is empty or contains only a single item, then leave it unchanged and skip the remaining steps.
2. Identify the Relative Distinguished Name (RDN) component from the target entry DN that is exactly one level below one of the `load-spreading-base-dn` values. If the targeted entry is not below any of the configured `load-spreading-base-dn` values, the order of servers in each of those lists is based only on the order in which they appear in the load-balancing algorithm's `backend-server` property. The remaining steps are skipped.
3. Compute a SHA-1 digest from the normalized string representation of the identified RDN component. SHA-1 is notably faster than more secure digest algorithms, and it does a good job at distributing bits across the entire range of the 160 bits that it generates.
4. Create a non-negative integer from the last 31 bits of the computed SHA-1 digest.
5. Compute a modulus using the integer value as the dividend and the number of servers in the current list as the divisor. This yields an integer value that is between 0 and `(list.size() - 1)`, inclusive.

   > **Note**
   >
   > `(list.size() - 1)` is the number of servers minus 1.

6. If the modulus computed is equal to 0, no further action is necessary. If not, move a number of servers equal to the computed modulus from the beginning of the list to the end of the list. The order of the elements that are moved should be preserved.

Copyright © 2025 Ping Identity Corporation

For example, consider a `load-spreading-base-dn` value of `"ou=customers,dc=example,dc=com"`, a list that contains three servers (ds1, ds2, and ds3, in that order), and a modify request that targets the entry with DN `"uid=jdoe,ou=People,ou=Acme,ou=customers,dc=example,dc=com"`. The RDN component immediately below the `load-spreading-base-dn` is `"ou=Acme"`. The normalized string representation of that RDN component is `"ou=acme"`, and the hexadecimal representation of the SHA-1 digest of that is `"f0c69713535daf8816038f1bceab70380c92b83e"`. The last 31 bits of that SHA-1 digest are `0c92b83e` hex, which is 210942014. With 210942014 modulo 3 is 2, which means that the first two servers are moved from the beginning of the list to the end of the list, resulting in an order of ds3, ds1, ds2.

While this algorithm spreads the load across multiple backend servers, it does not mean that there will be an even distribution of the load across all of those servers. The load-balancing algorithm still prioritizes based on location and health check state, so the load is generally spread only across the available servers in the same location as the PingDirectoryProxy server. Assuming that the entries that are immediate children of a `load-spreading-base-dn` are the tops of the branches that define tenants, some tenants are targeted more heavily than others because they have more entries or because their entries are accessed more frequently. The modulo operation might not result in an even distribution across those servers.

dsconfig">

Configuring load balancing using `dsconfig`

Create and configure a load-balancing algorithm with `dsconfig.`

About this task

To create and configure a load-balance algorithm:

Steps

1. Run the `dsconfig` tool.

   When prompted, specify the host name, connection method, port number, and bind distinguished name (DN).

   Example:

   ```
   $ bin/dsconfig
   ```

2. In the PingDirectoryProxy main menu, enter the selection for `load-balancing algorithms`.
3. To create the Load Balancing Algorithm, in the `Load Balancing Algorithm menu`, select an option.

   Choose from:

   - To use an existing load-balancing algorithm as a template, enter `t`.
   - To create a new load-balancing algorithm from scratch, enter `n`.

     Example:

     In this example, a new Load Balancing Algorithm is created from scratch.

Copyright © 2025 Ping Identity Corporation

```
>>>>Choose how to create the new Load Balancing Algorithm:

n) new Load Balancing Algorithm created from scratch
t) use an existing Load Balancing Algorithm as a template
b) back
q) quit

Enter a choice [n]: n
```

4. In `Select the type of Load Balancing Algorithm menu`, select the type of load-balancing algorithm that you want to create.

   Depending on type of algorithm you select, you're guided through a series of configuration properties, such as providing a name and selecting an LDAP external server.

   Example:

   ```
   >>>> Select the type of Load Balancing Algorithm that you want to
   create:

       1)  Failover Load Balancing Algorithm
       2)  Fewest Operations Load Balancing Algorithm
       3)  Health Weighted Load Balancing Algorithm
       4)  Single Server Load Balancing Algorithm
       5)  Weighted Load Balancing Algorithm

       ?)  help
       c)  cancel
       q)  quit

   Enter choice [c]: 3
   ```

5. Review the configuration properties for your new load-balancing algorithm and enter `f`.

Configuring criteria-based load-balancing algorithms

You can configure alternate load-balancing algorithms that determine how they function according to request or connection criteria.

These algorithms allow you to balance your load across a server topology depending on the types of operations received or the client issuing the request. They are called criteria-based load-balancing algorithms and are configured using at least one connection criteria or request criteria.

For example, you can configure criteria-based load-balancing algorithms to accomplish the following:

- Route write operations to a single server from a set of replicated servers to prevent replication conflicts while load balancing all other operations across the full set of servers.

Copyright © 2025 Ping Identity Corporation

- Route all operations from a specific client to a single server in a set of replicated servers, eliminating errors that arise from replication latency and load balancing operations from other clients across the full set of servers. This configuration is useful for certain provisioning applications that need to write and then immediately read the same data.

When a request is received, the proxying request processor first iterates through all of the criteria-based load-balancing algorithms in the order in which they are listed to determine whether the request matches the associated criteria. If there is a match, then the criteria-based load-balancing algorithm is selected. If there is not a match, then the default load-balancing algorithm is used.

Preferring failover LBA for write operations

You can configure the PingDirectoryProxy server to use criteria-based load-balancing algorithms to balance providing a consistent view of directory server data for applications that require it with taking advantage of all servers in a topology for handling read-only operations, such as `search` and `bind`. The flexible configuration model supports a wide range of criteria for choosing which load-balancing algorithm to use for each operation.

In most PingDirectoryProxy server deployments, you should use a failover load-balancing algorithm for at least `add`, `delete`, and `modifyDN` operations

Each Proxying Request Processor configured in the PingDirectoryProxy server uses a load-balancing algorithm to choose which PingDirectoryProxy server to use for a particular operation.

The load-balancing algorithm takes several factors into account when choosing a server:

- The availability of the directory servers
- The location of the directory servers

  By default, load-balancing algorithms prefer directory servers in the same location as the PingDirectoryProxy server.
- If the PingDirectoryProxy server is degraded for any reason, such as having a local database (DB) index being rebuilt
- The result of configured health checks

  For instance, a server with a small replication backlog can be preferred over one with a larger backlog.
- Recent operation routing history

How these factors are used depends on the specific load-balancing algorithm. The two most commonly used load-balancing algorithms are:

- The failover load-balancing algorithm
- The fewest operations load-balancing algorithm

These two algorithms are similar when determining which directory servers are the possible candidates for a specific operation. The algorithms use the same criteria to determine server availability and health, and by default they prefer directory servers in the same location as the PingDirectoryProxy server. However, they differ in the criteria they use to choose between available servers. The following sections describe the algorithms in more detail.

Copyright © 2025 Ping Identity Corporation

Choosing between available servers

The failover load-balancing algorithm sends all operations to a single server until it is unavailable, and then sends all operations to the next preferred server, and so forth. This algorithm provides the most consistent view of the topology to clients because all clients, at least those in the same location as the PingDirectoryProxy server,, see the same, up-to-date view of the data, but it leaves unused capacity in the failover instances because most topologies include multiple directory server replicas within each data center.

The fewest operations load-balancing algorithm efficiently distributes traffic among multiple servers by choosing to send each operation to the server that has the fewest number of outstanding operations, which is the server from the PingDirectoryProxy server's point of view that is the least busy.

> **Note**
>
> The fewest operations load-balancing algorithm routes traffic to the least loaded server, which, in a lightly-loaded environment, can result in an imbalance because the first server in the list of configured servers is more likely to receive a request.

This algorithm naturally routes to servers that are more responsive as well as limits the impact of servers that have become unreachable. However, this implies that consecutive operations that depend on each other can be routed to different directory servers, which can cause issues for some types of clients:

- If two entries are added in quick succession where the first entry is the parent of the second in the LDAP hierarchy, the addition of the child entry could fail if that operation is routed to a different directory server instance than the first `add` operation, and this happens within the replication latency.
- Some clients add or modify an entry and then immediately read the entry back from the server, expecting to see the updates reflected in the entry.

In these situations, you should configure the PingDirectoryProxy server to route dependent requests to the same server.

The server affinity feature

The server affinity feature achieves this in some environments but not in all because the affinity is tracked independently by each PingDirectoryProxy server instance, and some clients send requests to multiple proxies. It is common for a client to not connect to the PingDirectoryProxy servers directly but instead to connect through a network load balancer, which in turn opens connections to the PingDirectoryProxy servers. Each individual client connection is established to a single PingDirectoryProxy server so that operations on that connection are routed to the same PingDirectoryProxy server, and server affinity configured within the PingDirectoryProxy server ensures those operations are routed to the same directory servers.

However, many clients establish a pool of connections that are reused across operations, and within this pool, connections are established through the load balancer to different PingDirectoryProxy servers. Dependent operations sent on different connections could then be routed to different PingDirectoryProxy servers, and then on to different PingDirectoryProxy servers.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> For more information about the server affinity feature, see Configuring Server Affinity.

A failover load-balancing algorithm addresses this issue by routing all requests to a single server, but that leaves unused search capacity on the other instances. A criteria-based load-balancing algorithm enables the proxy to route certain types of requests (or requests from certain clients) using a different load-balancing algorithm than the default. For instance, all write operations (`add` , `delete` , `modify` , and `modifyDN`) could be routed using a failover load-balancing algorithm while all other operations (`bind` , `search` , and `compare`) use a fewest operations load-balancing algorithm.

If there are clients that are particularly sensitive to reading entries immediately after modifying them, additional connection criteria can be specified to all operations from those clients using the failover load-balancing algorithm.

> **Note**
>
> Routing all write requests to a single server in a location instead of evenly across servers does not limit the overall throughput of the system because all servers ultimately have to process all write operations either from the client directly or through replication.

Replication conflicts

Another benefit of using the failover load-balancing algorithm for write operations is reducing replication conflicts. The PingDirectory server follows the traditional LDAP replication model of eventual consistency. This provides high availability for handling write traffic even in the presence of network partitions, but it can lead to replication conflicts. Replication conflicts involving modify operations can be automatically resolved, leaving the servers in a consistent state where each attribute on each entry reflects the most recent update to that attribute. However, conflicts involving `add` , `delete` , and `modifyDN` operations cannot always be resolved automatically and might require manual involvement from an administrator. By routing all write operations (or at least `add` , `delete` , and `modifyDN` operations) to a single server, replication conflicts can be avoided.

> **Note**
>
> When using a failover load-balancing algorithm, consider the following:
>
> - When using the failover load-balancing algorithm in a configuration with multiple locations, the load-balancing algorithm fails over between local instances before failing over to servers in a remote location. The list of servers in the `backend-server` configuration property of the load-balancing algorithm should be ordered such that preferred local servers should appear before failover local servers, but the relative order of servers in different locations is unimportant as the `preferred-failover-location` of the PingDirectoryProxy server's configuration is used to decide which remote location to fail over to. It is also advisable that the order of local servers match the `gateway-priority` configuration settings of the replication server configuration object on the directory server instances. This can reduce the WAN replication delay because the PingDirectoryProxy server will then prefer to send writes to the directory server with the WAN Gateway role, avoiding an extra hop to the remote locations.
> - For PingDirectoryProxy server configurations that include multiple Proxying Request Processors, including Entry-Balancing environments, each Proxying Request Processor should be updated to include its own criteria-based load-balancing algorithm.

Copyright © 2025 Ping Identity Corporation

Routing operations to a single server

About this task

The following example shows how to extend a PingDirectoryProxy server's configuration to use a criteria-based load-balancing algorithm to route all write requests to a single server using a failover load-balancing algorithm. This example can be extended to support alternate criteria and more complex topologies using multiple locations or entry balancing.

> **Note**
>
> This example uses a basic deployment of a PingDirectoryProxy server fronting three directory servers: `ds1.example.com`, `ds2.example.com`, and `ds3.example.com`.

Steps

1. To create a location, run `dsconfig` with the `create-location` option.

   Example:

   ```
   dsconfig create-location --location-name Austin
   ```

2. To update the failover location for your server, run `dsconfig` with the `set-location-prop` option.

   Example:

   ```
   dsconfig set-location-prop --location-name Austin
   ```

3. To set the location as a global configuration property, run `dsconfig` with the `set-global-configuration-prop` option.

   Example:

   ```
   dsconfig set-global-configuration-prop --set location:Austin
   ```

4. To set up the health checks for each external server, run `dsconfig` with the `create-ldap-health-check` option.

   Example:

   ```
   dsconfig create-ldap-health-check \
   --check-name ds1.example.com:389_dc_example_dc_com-search-health-check \
   --type search --set enabled:true --set base-dn:dc=example,dc=com

   dsconfig create-ldap-health-check \
   --check-name ds2.example.com:389_dc_example_dc_com-search-health-check \
   --type search --set enabled:true --set base-dn:dc=example,dc=com

   dsconfig create-ldap-health-check \
   --check-name ds3.example.com:389_dc_example_dc_com-search-health-check \
   --type search --set enabled:true --set base-dn:dc=example,dc=com
   ```

5. To create the external servers, run `dsconfig` with the `create-external-server` option.

Copyright © 2025 Ping Identity Corporation

Example:

```
dsconfig create-external-server --server-name ds1.example.com:389 \
--type Ping Identity-ds \
--set server-host-name:ds1.example.com --set server-port:389 \
--set location:Austin --set "bind-dn:cn=Proxy User,cn=Root DNs,cn=config" \
--set password:AADoPkhx22qpiBQJ7T0X4wH7 \
--set health-check:ds1.example.com:389_dc_example_dc_com-search-health-check

dsconfig create-external-server --server-name ds2.example.com:389 \
--type Ping Identity-ds \
--set server-host-name:ds2.example.com --set server-port:389 \
--set location:Austin --set "bind-dn:cn=Proxy User,cn=Root DNs,cn=config" \
--set password:AAAoVqVYsEavey80T0QfR60I \
--set health-check:ds2.example.com:389_dc_example_dc_com-search-health-check

dsconfig create-external-server --server-name ds3.example.com:389 \
--type Ping Identity-ds \
--set server-host-name:ds3.example.com --set server-port:389 \
--set location:Austin --set "bind-dn:cn=Proxy User,cn=Root DNs,cn=config" \
--set password:AADOkveb0TtYR9xpkVrNgMtF \
--set health-check:ds3.example.com:389_dc_example_dc_com-search-health-check
```

6. To create a load-balancing algorithm, run `dsconfig` with the `create-load-balancing-algorithm` option.

   Example:

   This example creates a load-balancing algorithm for `dc=example,dc=com`.

   ```
   dsconfig create-load-balancing-algorithm \
   --algorithm-name dc_example_dc_com-fewest-operations \
   --type fewest-operations --set  enabled:true \
   --set backend-server:ds1.example.com:389 \
   --set backend-server:ds2.example.com:389 \
   --set backend-server:ds3.example.com:389
   ```

7. To create a request processor, run `dsconfig` with the `create-request-processor` option.

   Example:

   This example creates a request processor for `dc=example,dc=com`.

   ```
   dsconfig create-request-processor \
   --processor-name dc_example_dc_com-req-processor \
   --type proxying \
   --set load-balancing-algorithm:dc_example_dc_com-fewest-operations
   ```

8. To create a subtree view, run `dsconfig` with the `create-subtree-view` option.

   Example:

   This example creates a subtree view for `dc=example,dc=com`.

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-subtree-view \
--view-name dc_example_dc_com-view \
--set base-dn:dc=example,dc=com \
--set request-processor:dc_example_dc_com-req-processor
```

9. To update the client connection policy, run `dsconfig` with the `set-client-connection-policy-prop` option.

   Example:

   This example updates the client connection policy for `dc=example,dc=com`.

   ```
   dsconfig set-client-connection-policy-prop \
   --policy-name default \
   --add subtree-view:dc_example_dc_com-view
   ```

10. To create a new request criteria object to match all write operations, run `dsconfig` with the `create-request-criteria` option.

    Example:

    ```
    dsconfig create-request-criteria \
    --criteria-name any-write \
    --type simple --set "description:All Write Operations" \
    --set operation-type:add --set operation-type:delete \
    --set operation-type:modify --set operation-type:modify-dn
    ```

11. To create a new failover load-balancing algorithm listing the servers that should be included, run `dsconfig` with the `create-load-balancing-algorithm` option.

    Example:

    In this example, the order that the servers are listed in is the failover order between servers.

    ```
    dsconfig create-load-balancing-algorithm \
    --algorithm-name dc_example_dc_com-failover \
    --type failover --set enabled:true \
    --set backend-server:ds1.example.com:389 \
    --set backend-server:ds2.example.com:389 \
    --set backend-server:ds3.example.com:389
    ```

12. To tie the request criteria and the failover load-balancing algorithm together into a criteria-based load-balancing algorithm, run `dsconfig` with the `create-criteria-based-load-balancing-algorithm` option.

    Example:

    ```
    dsconfig create-criteria-based-load-balancing-algorithm \
    --algorithm-name dc_example_dc_com-write-traffic-lba \
    --set "description:Failover LBA For All Write Traffic" \
    --set request-criteria:any-write \
    --set load-balancing-algorithm:dc_example_dc_com-failover
    ```

Copyright © 2025 Ping Identity Corporation

13. To update the proxying request processor to use the criteria-based load-balancing algorithm, run `dsconfig` with the `set-request-processor-prop` option.

    Example:

    ```
    dsconfig set-request-processor-prop \
    --processor-name dc_example_dc_com-req-processor \
    --set criteria-based-load-balancing-algorithm:dc_example_dc_com-write-traffic-lba
    ```

Result

The PingDirectoryProxy server routes all write operations to `ds1.example.com` as long as it's available and then to `ds2.example.com` if it's not. The PingDirectoryProxy server routes other types of operations, such as searches and binds, to all three servers using the fewest operations load-balancing algorithm.

Routing operations from a single client to a specific set of servers

About this task

To create a type of server affinity where all operations from a single client are routed to a specific set of servers, follow a similar process as in the previous task, but configure connection criteria instead of request criteria. These connection criteria identify clients that could be impacted by replication latency. These clients use the failover load-balancing algorithm rather than the default fewest operations load-balancing algorithm.

For example, an administrative tool includes a `delete user` function. If the application immediately re-queries the directory for an updated list of users, the just-deleted entry must not be included.

To configure a criteria-based load balancing algorithm:

Steps

1. Create the new failover load-balancing algorithm using `dsconfig` with the `create-load-balancing-algorithm` option.

   > **Note**
   >
   > The failover load-balancing algorithm should list the same set of servers as the existing fewest operation load-balancing algorithm.

   Example:

   ```
   dsconfig create-load-balancing-algorithm \
     --algorithm-name client_one_routing_algorithm \
     --type failover --set enabled:true \
     --set backend-server:east1.example.com:389 \
     --set backend-server:east2.example.com:389
   ```

2. To route operations from a single client to a single server in a set of replicated servers, create connection criteria using `dsconfig` with the `create-connection-criteria` option.

   Example:

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-connection-criteria \
  --criteria-name "Client One"  --type simple \
  --set included-user-base-dn:cn=Client One,ou=Apps,dc=example,dc=com
```

3. Configure a criteria-based load balancing algorithm and assign it to the proxying request processor, using `dsconfig` with the `create-criteria-based-load-balancing-algorithm` option.

   Use the load balancing algorithm and connection criteria created in steps 1-2.

   Example:

   ```
   dsconfig create-criteria-based-load-balancing-algorithm \
     --algorithm-name dc_example_dc_com-client-operations \
     --set load-balancing-algorithm:dc_example_dc_com-failover \
     --set "request-criteria:Client One Requests"
   ```

4. Assign the new criteria-based load balancing algorithm to the proxying request processor using `dsconfig` with the `set-request-processor-prop` option.

   Example:

   ```
   dsconfig set-request-processor-prop \
     --processor-name dc_example_dc_com-req-processor \
     --add criteria-based-load-balancing-agorithm:dc_example_dc_com-client-operations
   ```

Understanding failover and recovery

After a previously degraded or unavailable server has recovered, it should be eligible to start receiving traffic within the time configured for the `health-check-frequency` property that is 30 seconds by default. However, failover and recovery also depend on the load-balancing algorithm in use.

The load-balancing algorithm provides an ordered list of servers to check, with the number of servers in the list based on the maximum number of retry attempts. The server checks to see if affinity should be used and, if so, whether an affinity is set for that load-balancing algorithm.

> **Note**
>
> If there is an affinity to a particular server and that server is classified as available, that server is always the first in the list.

Next, the PingDirectoryProxy server creates a two-dimensional matrix of servers based on:

- The health check state, with available preferred over degraded and unavailable not considered at all
- Location, with backend servers in the same location as the PingDirectoryProxy server most preferred, then servers in the first failover location, then the second, and so forth

Copyright © 2025 Ping Identity Corporation

Within each of these sets, and ideally at least one server in the local data center is classified as available, the load-balancing algorithm selects the servers in the order of most preferred to least preferred based on whatever logic the load-balancing algorithm uses. The load-balancing algorithm keeps selecting servers until enough of them have been selected to satisfy the maximum number of possible retries.

The load-balancing algorithm includes a configuration option that allows you to decide whether to prefer location over availability or availability over location, such as specifying if a local degraded server is more or less preferred than a remote available server.

By default, the algorithm prefers available servers over degraded ones, even if it has to go to another data center to access them. You can change the load-balancing algorithm to try to stay in the same data center if at least one server is not unavailable.

The PingDirectoryProxy server does both proactive and reactive health checking.

Proactive health checking

The PingDirectoryProxy server periodically (by default, every 30 seconds) runs a full set of tests against each backend server. The result of these tests are used to determine the overall health check state (available, degraded, or unavailable) and score (an integer value from 10 to 0).

Reactive health checking

The PingDirectoryProxy server kicks off a lesser set of health checks against a server if an operation forwarded to that server did not complete successfully.

Proactive health checking can be used to promote and demote the health of a server. Reactive health checking can only be used to demote the health of a server. As a result, if a server is determined to be unavailable, then it will remain that way until a subsequent proactive health check determines that it has recovered. If a server is determined to be degraded, it might not become available until the next proactive health check, but it could be downgraded to unavailable by a reactive check if other failures are encountered against that server.

Both proactive and reactive health check assignments take effect immediately and are considered for all subsequent requests routed to the load-balancing algorithm. If a server is considered degraded, then it's immediately considered less desirable than available servers in the same data center, and possibly less desirable than available servers in more remote data centers. If a server is considered unavailable, then it's not eligible to be selected until it is reclassified as available or degraded.

Configuring HTTP connection handlers

HTTP connection handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. HTTP connection handlers can be used to host web applications on the server.

Each HTTP connection handler should be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this does not prevent the entire directory server from starting. The server's `start-server` tool outputs any errors to the error log. This allows the server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with an HTTP connection handler include the following:

Copyright © 2025 Ping Identity Corporation

listen-address

Specifies the address on which the connection handler listens for requests from clients. If not specified, then requests are accepted on all addresses bound to the system.

listen-port

Specifies the port on which the connection handler listens for requests from clients. Required.

use-ssl

Indicates whether the connection handler uses SSL/TLS to secure communications with clients, such as whether it uses HTTPS rather than HTTP. If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.

http-servlet-extension

Specifies the set of servlet extensions that are enabled for use with the connection handler. You can have multiple HTTP connection handlers listening on different address/port combinations with identical or different sets of servlet extensions. You must configure at least one servlet extension.

http-operation-log-publisher

Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers are used.

key-manager-provider

Specifies the key manager provider that is used to obtain the certificate presented to clients if SSL is enabled.

trust-manager-provider

Specifies the trust manager provider that is used to determine whether to accept any client certificates presented to the server.

num-request-handlers

Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads are automatically selected based on the number of CPUs available to the Java virtual machine (JVM).

web-application-extension

Specifies the web applications hosted by the server.

Configuring an HTTP connection handler

About this task

An HTTP connection handler has two dependent configuration objects:

- One or more HTTP servlet extensions

Copyright © 2025 Ping Identity Corporation

- An optional HTTP log publisher.

You must configure the HTTP servlet extension and log publisher before configuring the HTTP connection handler. The log publisher is optional but in most cases, you should configure one or more logs to troubleshoot any issues with your HTTP connection.

Steps

1. To configure your HTTP servlet extensions, run `dsconfig` with the `create-http-servlet-extension` option.

   Example:

   This example uses the `ExampleHTTPServletExtension` in the Server SDK.

   ```
   $ bin/dsconfig create-http-servlet-extension \
     --extension-name "Hello World Servlet" \
     --type third-party \
     --set "extension-class:com.unboundid.directory.sdk.examples.ExampleHTTPServletExtension" \
     --set "extension-argument:path=/" \
     --set "extension-argument:name=example-servlet"
   ```

2. To configure an HTTP log publisher, run `dsconfig` with the `create-log-publisher` option.

   Example:

   This example configures one log publisher for common access and one for detailed access. Both log publishers use the default configuration settings for log rotation and retention.

   ```
   $ bin/dsconfig create-log-publisher \
     --publisher-name "HTTP Common Access Logger" \
     --type common-log-file-http-operation \
     --set enabled:true \
     --set log-file:logs/http-common-access \
     --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
     --set "rotation-policy:Size Limit Rotation Policy" \
     --set "retention-policy:File Count Retention Policy" \
     --set "retention-policy:Free Disk Space Retention Policy"

   $ bin/dsconfig create-log-publisher \
     --publisher-name "HTTP Detailed Access Logger" \
     --type detailed-http-operation \
     --set enabled:true \
     --set log-file:logs/http-detailed-access \
     --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
     --set "rotation-policy:Size Limit Rotation Policy" \
     --set "retention-policy:File Count Retention Policy" \
     --set "retention-policy:Free Disk Space Retention Policy"
   ```

3. To configure the HTTP connection handler, run `dsconfig` with the `create-connection-handler` option to specify the HTTP servlet extension and log publishers.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Some configuration properties can be updated while the HTTP connection handler is enabled while others, such as `listen-port`, require that the HTTP connection handler be disabled and then re-enabled for the change to take effect.

Example:

```
$ bin/dsconfig create-connection-handler \
  --handler-name "Hello World HTTP Connection Handler" \
  --type http \
  --set enabled:true \
  --set listen-port:8443 \
  --set use-ssl:true \
  --set "http-servlet-extension:Hello World Servlet" \
  --set "http-operation-log-publisher:HTTP Common Access Logger" \
  --set "http-operation-log-publisher:HTTP Detailed Access Logger" \
  --set "key-manager-provider:JKS" \
  --set "trust-manager-provider:JKS"
```

4. To monitor the connection handler, use the `ldapsearch` tool.

> **Note**
>
> By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE`.

Example:

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

HTTP correlation IDs

Correlation IDs make it easier to track log messages across a software system request that passes through multiple subsystems.

Scattered and intermingled log messages create challenges for tracing the request flow on distributed systems. A correlation ID can be assigned to a request and added to all associated operations as the request is processed. A correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP or HTTPS Connection Handler.

When an HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID might also be passed to the LDAP subsystem.

The correlation ID appears with associated requests in LDAP logs in the `correlationID` key for the following REST APIs:

- SCIM 1
- Delegated admin

Copyright © 2025 Ping Identity Corporation

- Consent
- Directory

The correlation ID is used as the default client request ID value in intermediate client request controls used by the following REST APIs:

- SCIM 2
- Consent
- Directory

Values related to the intermediate client request control appear in the LDAP logs in the `via` key and are forwarded to downstream LDAP servers when received by PingDirectoryProxy server. The correlation ID header is also added to requests forwarded by the PingDirectory gateway.

For Server SDK extensions that have access to the current `HttpServletRequest`, the current correlation ID can be retrieved as a string through the `HttpServletRequest` `com.pingidentity.pingdata.correlation_id` attribute, as shown.

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

Configuring HTTP correlation ID support

About this task

Correlation ID support is enabled by default for each HTTP Connection Handler.

Steps

- To enable or disable correlation ID support for the HTTPS Connection Handler, use the `set-connection-handler-prop` option with `dsconfig`.

  Example:

  This example shows how to enable correlation ID support.

  ```
  $ dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set use-correlation-id-header:true
  ```

  Example:

  This example shows how to disable correlation ID support.

  ```
  $ dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set use-correlation-id-header:false
  ```

- To customize the response header name for the correlation ID, use the `set-connection-handler-prop` option with `dsconfig`.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The server generates a correlation ID for every HTTP request and sends it in the response through the **`Correlation-Id`** response header.

Example:

This example changes the **`correlation-id-response-header`** property value to `X-Request-Id`.

```
$ dsconfig set-connection-handler-prop \
   --handler-name "HTTPS Connection Handler" \
   --set correlation-id-response-header:X-Request-Id
```

- To designate the names of one or more HTTP request headers that contain an existing correlation ID value, use the `set-connection-handler-prop` option with **`dsconfig`**.

> **Note**
>
> This enables the server to integrate with a larger system consisting of every servers using correlation IDs. By default, the server generates a new, unique correlation ID for each HTTP request and ignores any correlation ID that might be set on the request.

Example:

```
$ dsconfig set-connection-handler-prop --handler-name "HTTPS Connection Handler" \
  --set correlation-id-request-header:X-Request-Id \
  --set correlation-id-request-header:X-Correlation-Id \
  --set correlation-id-request-header:Correlation-Id \
  --set correlation-id-request-header:X-Amzn-Trace-Id
```

HTTP correlation ID example

In this example, a request to the directory REST API is made and the correlation ID enables finding HTTP-specific log messages that also have LDAP-specific log messages. The response to the API call includes a `Correlation-Id` header with the value `ee919049-6710-4594-9c66-28b4ada4b127`.

Copyright © 2025 Ping Identity Corporation

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
 Accept: /
 Accept-Encoding: gzip, deflate

Configuring the PingDirectoryProxy server to use an HTTP proxy server

Some organizations configure their network so that internal systems cannot directly access the Internet, but instead must use an HTTP proxy server to access external services.

Copyright © 2025 Ping Identity Corporation

The PingDirectoryProxy server now supports using an HTTP proxy server in conjunction with the following components:

- The Amazon Key Management Service cipher stream provider
- The Amazon Secrets Manager cipher stream provider
- The Amazon Secrets Manager passphrase provider
- The Amazon Secrets Manager password storage scheme
- The Azure Key Vault cipher stream provider
- The Azure Key Vault passphrase provider
- The Azure Key Vault password storage scheme
- The PingOne pass-through authentication plugin
- The Pwned Passwords password validator
- The Twilio alert handler
- The Twilio OTP delivery mechanism
- The UNBOUNDID-YUBIKEY-OTP SASL mechanism handler

Setting up the server to use an HTTP proxy server involves two steps, which are described in the following sections.

1. Creating an HTTP proxy external server in the configuration.
2. Configuring the appropriate component(s) to use the HTTP proxy server.

Creating an HTTP proxy external server

An HTTP proxy external server configuration object provides information about a proxy server that should be used. At present, we only support HTTP proxy servers (which can handle both unencrypted HTTP and encrypted HTTPS connections), with or without authentication.

HTTP proxy external server definitions support the following configuration properties:

`server-host-name`

The resolvable name or IP address of the HTTP proxy server to use. This is required.

`server-port`

The port on which the HTTP proxy server is listening for connections. This is required.

`basic-authentication-username`

The username to use if the proxy server requires authentication. This should be omitted if the proxy server does not require authentication.

`basic-authentication-passphrase-provider`

The passphrase provider to use to obtain the password to use if the proxy server requires authentication. This should be omitted if the proxy server does not require authentication.

Copyright © 2025 Ping Identity Corporation

For example, you can use a configuration change like the following to create an HTTP proxy external server that does not require authentication:

```
dsconfig create-external-server \
     --server-name "Example HTTP Proxy Server" \
     --type http-proxy \
     --set server-host-name:proxy.example.com \
     --set server-port:3128
```

Configuring server components to use the HTTP proxy external server

Merely defining an HTTP proxy external server in the configuration does not cause the server to use that proxy server for anything. Instead, you must indicate which components should use that proxy server.

This is necessary because it may only be necessary to use an HTTP proxy server for certain components (for example, it might be necessary when accessing external web services, but not for services on the internal private network).

All of the components that support the use of an HTTP proxy server offer an `http-proxy-external-server` configuration property whose value should be the name of the appropriate HTTP proxy external server definition in the configuration. For example, to update the Pwned Passwords password validator to use the HTTP proxy server defined in the "Example HTTP Proxy Server" configuration object, use a configuration change like the following:

```
dsconfig set-password-validator-prop \
     --validator-name "Pwned Passwords" \
     --set "http-proxy-external-server:Example HTTP Proxy Server"
```

Configuring proxy transformations

The PingDirectoryProxy server provides proxy transformations to alter the contents of client requests as they are sent from the client to the LDAP external server. Proxy transformations can also be used to alter the responses sent back from the server to the client, including altering or omitting search result entries. The PingDirectoryProxy server provides the following types of data transformations:

- Attribute mapping. The attribute mapping transformation rewrites client requests so that references to one attribute type can be replaced with an alternate attribute type. The PingDirectoryProxy server can perform extensive replacements, including attribute names used in DNs and attribute names encoded in the values of a number of different controls and extended operations. For example, a client requests a `userid` attribute, which is replaced with `uid` before being forwarded on to the backend server. This mapping applies in reverse for the response returned to the client.
- Default value. The default value transformation instructs the PingDirectoryProxy server to include a static attribute value in search results being sent back to the client, in ADD requests being forwarded to an external server, or both. For example, a value of "marketing" for `businessCategory` could be returned for all search results under the base DN `ou=marketing,dc=example,dc=com`.
- DN mapping. The DN mapping transformation rewrites client requests so that references to entries below a specified DN will be mapped to appear below another DN. For example, references to entries below `o=example.com` could be rewritten so that they are below `dc=example,dc=com` instead. The mapping applies in reverse for the response returned to the client.

Copyright © 2025 Ping Identity Corporation

- Groovy scripted. The Groovy scripted custom transformation is written in Groovy and does not need to be compiled, though they use the Server SDK. These scripts make it possible to alter requests and responses in ways not available using the transformations provided with the PingDirectoryProxy server.
- Suppress attribute. The suppress attribute proxy transformation allows you to exclude a specified attribute from search result entries. It also provides the ability to reject add, compare, modify, modify DN, or search requests if they attempt to reference the target attribute.
- Suppress entry. The suppress entry proxy transformation allows you to exclude any entries that match a specified filter from a set of search results. Search requests are transformed so that the original filter will be ANDed with a NOT filter containing the exclude filter. For example, if the suppression filter is `"(objectClass=secretEntry)"`, then a search request with a filter of `"(uid=john.doe)"` will be transformed so that it has a filter of `"(&(uid=john.doe)(!(objectClass=secretEntry)))"`.
- Simple to external bind. The simple to external bind proxy transformation can be used to intercept a simple bind request and instead process the bind as a SASL EXTERNAL bind. If the SASL EXTERNAL bind fails, then the original simple bind request might or might not be processed, depending on how you configure the server.
- Third-party scripted. The third-party scripted custom transformation is created using the Server SDK, making it possible to alter requests and responses in ways not available using the transformations provided with the PingDirectoryProxy server.

dsconfig">

Configuring proxy transformations using `dsconfig`

Create and configure a proxy transformation.

About this task

To create and configure a proxy transformation:

Steps

1. Run the `dsconfig` tool.

   Example:

   ```
   $ bin/dsconfig
   ```

2. When prompted, enter the connection parameters to the server.

   Connection parameters can include:

   - Host name
   - Connection method
   - Port
   - Bind distinguished name (DN)
   - Bind DN password

Copyright © 2025 Ping Identity Corporation

3. In the PingDirectoryProxy server main menu, enter the selection for `Proxy transformations`.
4. In the `Proxy Transformation menu`, enter the selection for `Create a new proxy transformation`.
5. Select the type of proxy transformation you want to create. Enter a name for the new transformation.

   Example:

   This example creates an attribute mapping transformation.

   ```
    >>>> Enter a name for the Attribute Mapping Proxy Transformation that you
   want to create: userid-to-uid
   ```

6. To choose if the proxy transformation is enabled by default or not, select `true` or `false`.

   Example:

   ```
   Select a value for the 'enabled' property:

     1) true
     2) false

     ?) help
     c) cancel
     q) quit

   Enter choice [c]: 1
   ```

7. Enter the name of the client attribute that you want to remap to a target attribute.

   > **Note**
   >
   > This attribute must not be equal to the target attribute.

   Example:

   ```
   Enter a value for the 'source-attribute' property: userid
   ```

8. Enter the name of the target attribute to which the client attribute should be mapped.

   Example:

   ```
   Enter a value for the 'target-attribute' property: uid
   ```

   Result:

   The properties of your new proxy transformation are displayed.

9. (Optional) To make any modifications, enter the selection for the desired property.
10. To finish the creation of the proxy transformation, enter `f`.

    Example:

Copyright © 2025 Ping Identity Corporation

```
Enter choice [b]: f
```

Next steps

The transformation must be assigned to a request processor. For information on creating and configuring request processors, see Configuring request processors.

Configuring request processors

A request processor is responsible for handling client requests by passing the request through a load-balancing algorithm or one or more subordinate request processors. The request processor is also the PingDirectoryProxy server component that performs proxy transformations. You can create one of the following types of request processors:

- Proxying request processor. This request processor is responsible for passing allowed operations through a load balancing algorithm. Proxy transformations can be applied to requests and responses that are processed. Multiple servers can be configured to provide high availability and load balancing, and various transformations can be applied to the requests and responses that are processed.
- Entry-balancing request processor. This request processor is used to distribute entries under a common parent entry among multiple backend sets. A backend set is a collection of replicated directory servers that contain identical portions of the data. This request processor uses multiple, subordinate proxying request processors to process operations and maintains in-memory indexes to speed the processing of specific search and modify operations.
- Failover request processor. This request processor performs ordered failover between subordinate proxying processors, sometimes with different behavior for different types of operations.

dsconfig">

Configuring request processors using `dsconfig`

About this task

To create and configure a request processor:

Steps

1. Run the `dsconfig` tool.

   Example:

   ```
   $ bin/dsconfig
   ```

2. When prompted, enter the connection parameters to the server.

   Connection parameters can include:

   - Host name
   - Connection method
   - Port

Copyright © 2025 Ping Identity Corporation

- Bind distinguished name (DN)
- Bind DN password

3. In the PingDirectoryProxy server's main menu, enter the selection for `Request Processor configuration`.
4. Enter the selection for `Create a new request processor`.
5. Select an existing request processor to use as a template for creating a new one or enter `n` to create one from scratch.
6. Select an existing load balancing algorithm or create a new one.

   Result:

   The following example shows the configuration of a new proxying request processor after the selection of the load balancing algorithm.

```
Property                    Value(s)
-----------------------------------------------------------
1)  description             -
2)  enabled                 true
3)  allowed-operation       abandon, add, bind, compare, delete,
                            extended, modify, modify-dn, search
4)  load-balancing-algorithm dc_example_dc_com-fewest-operations
5)  transformation          -
6)  referral-behavior       pass-through
7)  supported-control       account-usable, assertion,
                            authorization-identity,
                            get-authorization-entry,
                            get-effective-rights, get-server-id,
                            ignore-no-user-modification,
                            intermediate-client, manage-dsa-it,
                            matched-values, no-op, password-policy,
                            permissive-modify, post-read, pre-read,
                            proxied-authorization-v1,
                            proxied-authorization-v2,
                            real-attributes-only, retain-identity,
                            subentries, subtree-delete,
                            virtual-attributes-only
8)  supported-control-oid   -

?)  help
f)  finish - create the new Proxying Request Processor
d)  display the equivalent dsconfig arguments to create this object
b)  back
q)  quit
```

7. Review the configuration properties of the new request processor. To finish, enter `f`.

> **Note**
>
> To use the request processor, you must associate it with a subtree view.

Passing LDAP controls with the proxying request processor

About this task

If your deployment does not use entry balancing and requires the use of LDAP controls not defined in the request processor's supported-control property, configure the PingDirectoryProxy to forward these controls correctly.

Steps

- Configure the `supported-control-oid` property to define the request OID of the LDAP control.

  Result:

  The PingDirectoryProxy server updates the root DSA-specific entry (DSE) `supportedControl` attribute with the values entered for the `supported-control-oid` property.

Configuring server affinity

About this task

The PingDirectoryProxy server supports the ability to forward a sequence of requests to the same external server if specific conditions are met. This feature, called server affinity, is applied by the load balancing algorithms. The following server affinity methods are available in the PingDirectoryProxy server:

- Client Connection. Requests from the same PingDirectoryProxy server client connection are consistently routed to the same external server.
- Client IP. PingDirectoryProxy server client requests coming from the same client IP address are routed to the same external server.
- Bind DN. Requests from all client connections authenticated as the same bind DN are routed to the same external server.

For each algorithm, you can specify the set of operations for which an affinity will be established, as well as the set of operations for which affinity will be used. Affinity assignments have a time-out value so that they are in effect for some period of time after the last operation that might cause the affinity to be set or updated.

In this example, we create a bind DN server affinity provider for any client requesting write operations to have subsequent requests, whether read or write, forwarded to the same external server. The affinity period will last for 30 seconds after the last write request.

Steps

1. Use the `dsconfig` tool to configure server affinity. Specify the host name, connection method, port number, and bind DN as described in previous procedures.

   Example:

   ```
   $ bin/dsconfig
   ```

2. In the PingDirectoryProxy server main menu, enter the number associated with server affinity provider configuration
3. On the Server Affinity menu, enter the number corresponding to creating a new server affinity provider.

Copyright © 2025 Ping Identity Corporation

4. Enter a name for your new server affinity provider.

   Example:

   ```
   >>>> Enter a name for the Bind DN Server Affinity Provider
   that you want to create: Affinity for Writing Applications
   ```

5. Indicate whether you want the server affinity provider to be enabled for use by the Directory Proxy Server. In this example, enter `1` to enable to the server affinity provider.

6. Next, configure the properties of the server affinity provider. For example, you can customize the types of operations for which affinity can be set and the types of operations for which affinity can be used, as well as the length of time for which the affinity should persist. This example illustrates the properties of the bind DN server affinity provider.

   Example:

   ```
   >>>> >>>> Configure the properties of the Bind DN Server Affinity Provider

           Property                 Value(s)
           -----------------------------------------------------------
       1)  description              -
       2)  enable                   true
       3)  affinity-duration        30 s
       4)  set-affinity-operation   add, delete, modify, modify-dn
       5)  use-affinity-operation   add, bind, compare, delete, modify,
                                    modify-dn, search

       ?)  help
       f)  finish - create the new Bind DN Server Affinity Provider
       d)  display the equivalent dsconfig arguments to create this object
       b)  back
       q)  quit

   Enter choice [b]:
   ```

7. Review the properties of the server affinity provider. If you are satisfied, enter `f` to finish. Once defined, the affinity provider can now be assigned to a load balancing algorithm.

Configuring subtree views

About this task

You provide clients access to a specific portion of the DIT creating a subtree view and assigning it to a client connection policy. You can configure subtree views from the command line or using the administrative console.

When you create a subtree view, you provide the following information to configure its properties:

- Subtree view name
- Base DN managed by the subtree view
- Request processor used by the subtree view to route requests. If one does not exist already, you will create a new one.

Copyright © 2025 Ping Identity Corporation

Steps

1. Use `dsconfig` to configure a subtree view.
2. In the PingDirectoryProxy server's main menu, enter the number associated with subtree view configuration.
3. In the Subtree View menu, enter the number corresponding to creating a new subtree view.
4. Enter a name for the subtree view.
5. Enter the base DN of the subtree managed by this subtree view.

   Example:

   ```
   Enter a value for the 'base-dn' property:dc=example,dc=com
   ```

6. Select a request processor for this subtree view to route requests or make the appropriate selection to create a new one.

   Example:

   ```
   Select a Request Processor for the 'request-processor' property:

   1) dc_example_dc_com-req-processor
   2) Create a new Request Processor

   ?) help
   c) cancel
   q) quit

   Enter choice [c]: 1
   ```

7. Review the properties of the subtree view. If you are satisfied, enter `f` to finish.

   Example:

   ```
   >>>> Configure the properties of the Subtree View
    >>>> via creating 'example.com' Subtree View

          Property           Value(s)
          -------------------------------------------------
      1)  description        -
      2)  base-dn            "dc=example,dc=com"
      3)  request-processor  dc_example_dc_com-req-processor

      ?)  help
      f)  finish - create the new Subtree View
      d)  display the equivalent dsconfig arguments to create
          this object
      b)  back
      q)  quit
   ```

   Result:

   Once configured, you can assign one or more subtree views to any client connection policies.

Copyright © 2025 Ping Identity Corporation

Client connection policy configuration

Client connection policies help distinguish what portions of the DIT the client can access.

They enforce restrictions on what clients can do in the server. A client connection policy specifies criteria for membership based on information about the client connection, including client address, protocol, communication security, and authentication state and identity. The client connection policy, however, does not control membership based on the type of request being made.

Every client connection is associated with exactly one client connection policy at any given time, which is assigned to the client when the connection is established. The choice of which client connection policy to use is reevaluated when the client attempts a bind to change its authentication state or uses the StartTLS extended operation to convert an insecure connection to a secure one. Any changes you make to the client connection policy do not apply to existing connections. The changes only apply to new connections.

Client connections are always unauthenticated when they are first established. If you plan to configure a policy based on authentication, you must define at least one client connection policy with criteria that match unauthenticated connections.

When a client has been assigned to a policy, you can determine what operations they can perform. For example, your policy might allow only SASL bind operations. Client connection policies are associated with one or more subtree views, which determine the portions of the DIT a particular client can access. For example, you might configure a policy that prevents users connecting over the extranet from accessing configuration information. The client connection policy is evaluated in addition to access control, so even a root user connecting over the extranet would not have access to the configuration information.

About the client connection policy

Client connection policies are based on two factors.

Connection criteria

The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can be used in other instances when the server needs to perform matching based on connection-level properties, such as filtered logging. A single connection can match multiple connection criteria definitions.

Evaluation order index

If multiple client connection policies are defined in the server, then each of them must have a unique value for the `evaluation-order-index` property. The client connection policies are evaluated in order of ascending evaluation order index. If a client connection does not match the criteria for any defined client connection policy, then that connection will be terminated.

If the connection policy matches a connection, then the connection is assigned to that policy and no further evaluation occurs. If, after evaluating all of the defined client connection policies, no match is found, the connection is terminated.

Copyright © 2025 Ping Identity Corporation

When a client connection policy is assigned

A client connection policy can be associated with a client connection at the following times.

- When the connection is initially established. This association occurs exactly once for each client connection.
- After completing processing for a StartTLS operation. This association occurs once at most for a client connection because StartTLS cannot be used more than once on a particular connection. You can not stop using StartTLS while keeping the connection active.
- After completing processing for a bind operation. This association occurs zero or more times for a client connection because the bind request can be processed many times on a given connection.

StartTLS and bind requests are subject to whatever constraints are defined for the client connection policy that is associated with the client connection at the time that the request is received. When they have completed, then subsequent operations are subject to the constraints of the new client connection policy assigned to that client connection. This policy might not be the same client connection policy that was associated with the connection before the operation was processed. That is, any policy changes do not apply to existing connections and only apply when the client reconnects.

All other types of operations are subject to whatever constraints are defined for the client connection policy used by the client connection at the time that the request is received. The client connection policy assigned to a connection never changes as a result of processing any operation other than a bind or StartTLS. The server does not re-evaluate the client connection policy for the connection in the course of processing an operation. For example, the client connection policy is never re-evaluated for a search operation.

Restricting the type of search filter used by clients

You can restrict the types of search filters that a given client might be allowed to use to prevent the use of potentially expensive filters, like range or substring searches.

You can use the `allowed-filter-type` property to provide a list of filter types that can be included in the search requests from clients associated with the client connection policy. This setting is only used if search is included in the set of allowed operation types. This restriction only applies to searches with a scope other than `baseObject`, such as searches with a scope of `singleLevel`, `wholeSubtree`, or `subordinateSubtree`.

You can use the `minimum-substring-length` property to specify the minimum number of non-wildcard characters in a substring filter. Any attempt to use a substring search with an element containing fewer than this number of bytes is rejected. For example, you can configure the server to reject filters like `"(cn=a*)"` and `"(cn=ab*)"`, but to allow `"(cn=abcde*)"`. This property setting is only used if search is included in the set of allowed operation types and at least one of `sub-initial`, `sub-any`, or `sub-final` is included in the set of allowed filter types.

There are two primary benefits to enforcing a minimum substring length:

- Allowing short substrings can require the server to perform more expensive processing. The search requires more server effort to assemble a candidate entry list for short substrings because the server has to examine more index keys.
- Allowing short substrings makes it easier for a client to put together a series of requests to retrieve all the data from the server, a process known as "trawling". If a malicious user wants to obtain all the data from the server, then it is easier to issue 26 requests like the following:

  `"(cn=a*)", "(cn=b*)", "(cn=c*)" … "(cn=z*)"`

Copyright © 2025 Ping Identity Corporation

Than if the user is required to do something like the following:

```
"(cn=aaaaa*)", "(cn=aaaab*)", "(cn=aaaac*)" … "(cn=zzzzz*)"
```

Defining Request Criteria

The client connection policy provides several properties that allow you to define the kinds of requests that it can issue.

`required-operation-request-criteria`

This property causes the server to reject any requests that do not match the referenced request criteria.

`prohibited-operation-request-criteria`

This property causes the server to reject any request that matches the referenced request criteria.

Setting Resource Limits

A client connection policy can specify resource limits, helping to ensure that no single client monopolizes server resources.

The resource limits are applied in addition to any global configuration resource limits. A client connection policy can't grant additional resources beyond what is set in the global configuration. If a client connection exceeds either a globally-defined limit or a policy limit, it is terminated.

> **Note**
>
> The PingDirectoryProxy server's global configuration can enforce limits on the number of concurrent connections that can be established in the following ways:
>
> - Limit the total number of concurrent connections to the server.
> - Limit the total number of concurrent connections from the same IP address.
> - Limit the total number of concurrent connections authenticated as the same bind distinguished name (DN).

Defining the operation rate

Configure the maximum operation rate for individual client connections and collectively for all connections associated with a client connection policy.

If the operation rate limit is exceeded, the server can either reject the operation or terminate the connection. You can define multiple rate limit values, making it possible to fine tune limits for both a long term average operation rate and short term operation bursts. For example, you can define a limit of one thousand operations per second and one million operations per day, which works out to an average of fewer than twelve operations per second, but with bursts of up to one thousand operations per second.

Specify rate limit strings as a maximum count, followed by a slash and a duration. The count portion must contain an integer and can be followed by the following multipliers:

- k (to indicate that the integer should be interpreted as thousands)
- m (to indicate that the integer should be interpreted as millions)

Copyright © 2025 Ping Identity Corporation

- g (to indicate that the integer should be interpreted as billions)

The duration portion must contain a time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w) and can be preceded by an integer to specify a quantity for that unit.

For example, the following are valid rate limit strings:

- 1/s (no more than one operation over a one-second interval)
- 10K/5h (no more than ten thousand operations over a five-hour interval)
- 5m/2d (no more than five million operations over a two-day interval)

You can provide time units in many different formats. For example, a unit of seconds can be signified using s, sec, sect, second, and seconds.

Client connection policy deployment example

In this example scenario, we assume the following:

1. Two external LDAP clients are allowed to bind to the server.
2. Client 1 should be allowed to open only one connection to the server.
3. Client 2 should be allowed to open up to five connections to the server.

For more information on this client connection policy deployment example, see the following topics:

- Define the connection policies
- How the policy is evaluated
- Configuring a client connection policy using the console
- Configuring a client connection policy using dsconfig
- Restricting server access based on client IP address

Define the connection policies

Set a per-client connection policy limit on the number of connections that can be associated with a particular client connection policy

Define at least two client connection policies, one for each of the two clients. Each policy must have different connection criteria for selecting the policy with which a given client connection should be associated.

Because the criteria is based on authentication, you must create a third client connection policy that applies to unauthenticated clients because client connections are always unauthenticated as soon as they are established and before they have sent a bind request. Clients are not required to send a bind request as their first operation.

Define the following three client connection policies:

- Client 1 Connection Policy, which only allows client 1, with an evaluation order index of 1
- Client 2 Connection Policy, which only allows client 2, with an evaluation order index of 2

Copyright © 2025 Ping Identity Corporation

- Unauthenticated Connection Policy, which allows unauthenticated clients, with an evaluation order index of 3

Define simple connection criteria for the Client 1 Connection Policy and the Client 2 Connection Policy with the following properties:

- The `user-auth-type` must not include none so that it only applies to authenticated client connections.
- The `included-user-base-dn` should match the bind DN for the target user. This distinguished name (DN) can be full DN for the target user, or it can be the base DN for a branch that contains a number of users that you want treated in the same way.

> **Tip**
>
> To create more generic criteria that match more than one user, you could list the DNs of each of the users explicitly in the `included-user-base-dn` property. If there is a group that contains all of the pertinent users, then you could instead use the `[all|any|not-all|not-any]-included-user-group-dn` property to apply to all members of that group. If the entries for all of the users match a particular filter, then you could use the `[all|any|not-all|not-any]-included-user-filter` property to match them.

How the policy is evaluated

Whenever a connection is established, the server associates the connection with exactly one client connection policy.

The server does this by iterating over all of the defined client connection policies in ascending order of the evaluation order index. Policies with a lower evaluation order index value are examined before those with a higher evaluation order index value. The first policy that the server finds whose criteria match the client connection is associated with that connection. If no client connection policy is found with criteria matching the connection, then the connection is terminated.

So, in this example, when a new connection is established, the server first checks the connection criteria associated with the Client 1 Connection Policy because it has the lowest evaluation order index value. If it finds that the criteria do not match the new connection, the server then checks the connection criteria associated with the Client 2 Connection Policy because it has the second lowest evaluation order index. If these criteria do not match, the server finally checks the connection criteria associated with the Unauthenticated Connection Policy because it has the third lowest evaluation order index. It finds a match, so the client connection is associated with the Unauthenticated Connection Policy.

After the client performs a bind operation to authenticate to the server, then the client connection policies are re-evaluated. If Client 2 performs the bind, then the Client 1 Connection Policy does not match, but the Client 2 Connection Policy does, so the connection is re-associated with that client connection policy. Whenever a connection is associated with a client connection policy, the server checks to see if the maximum number of client connections have already been associated with that policy. If so, then the newly-associated connection is terminated.

For example, Client 1 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. Client 1 then sends a bind request. The determination of whether the bind operation is allowed is made based on the constraints defined in the Unauthenticated Connection Policy because it is the client connection policy already assigned to the client connection. When the bind has completed, the server re-evaluates the client connection policy against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to the Client 1 Connection Policy.

Copyright © 2025 Ping Identity Corporation

Next, Client 2 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. When Client 2 sends a bind request, the operation is allowed based on the constraints defined in the Unauthenticated Connection Policy. When the bind is complete, the client connection is evaluated against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria do not match, so the Client 2 connection is evaluated against the connection criteria associated with Client 2 Connection Policy because it has the next lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to Client 2 Connection Policy.

Client 1 sends a search request. The Client 1 Connection Policy is used to determine whether the search operation should be allowed because this is the client connection policy assigned to the client connection for Client 1. The connection is not re-evaluated before or after processing the search operation.

dsconfig">

Configuring a client connection policy using `dsconfig`

Creates and configure a new client connection policy using `dsconfig`.

About this task

To create and configure a client connection policy:

Steps

1. Run the `dsconfig` tool.

   Example:

   ```
   $ bin/dsconfig
   ```

2. Enter the connection parameters to the server.

   Connection parameters can include:

   - Host name
   - Connection method
   - Port
   - bind distinguished name (DN)
   - Bind DN password

3. In the PingDirectoryProxy main menu, enter the selection for `Client connection policy configuration`. To create a new client connection policy, enter `2`.

   Example:

Copyright © 2025 Ping Identity Corporation

```
>>>> Client connection policy menu

What would you like to do?

  1) List existing client connection policies
  2) Create a new client connection policy
  3) View and edit an existing client connection policy
  4) Delete an existing client connection policy

  b) back
  q) quit

Enter choice [b]: 2
```

4. To create a new client connection policy from scratch, enter `n`.

   Example:

```
>>>> Select an existing Client Connection Policy to use as a
template for the new Client Connection Policy configuration or
'n' to create one from scratch:

  1) default

  n) new Client Connection Policy created from scratch
  c) cancel
  q) quit
```

5. Enter a name for the new client connection policy.

   Example:

```
Enter the 'policy-id' for the Client Connection Policy that you
want to create: new_policy
```

6. To set up the policy to be enabled by default or not, select `true` or `false`.

   Example:

```
Select a value for the 'enabled' property:

  1) true
  2) false

  ?) help
  c) cancel
  q) quit

Enter choice [c]: 1
```

7. Enter a value for the `evaluation-order-index` property.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Client connection policies with a lower index are evaluated before those with a higher index.

Example:

```
Enter a value for the 'evaluation-order-index' property: 2
```

Result:

The properties of your new client connection policy are displayed.

8. (Optional) To make any further modifications, enter the number corresponding to the property.
9. To finish the creation of the client connection policy, enter `f`.

> **Note**
>
> Any changes that you make to the client connection policy don't apply to existing connections. They only apply to new connections.

Configuring globally unique attributes

PingDirectoryProxy supports a globally unique attributes feature that ensures uniqueness for values defined for a set of attributes within a subtree view.

You can configure the attributes when the server checks for attribute conflicts, either prior to any `add`, `modify`, or `modifyDN` change request (pre-commit) or after the successful completion of a change request (post-commit).

About the Globally Unique Attribute plugin

The PingDirectoryProxy server supports a globally unique attribute plugin that prevents any value within a defined set of attributes to appear more than once in any entry for one or more subtree views.

Administrators can also configure whether conflict validation should be checked before an `add`, `modify`, or `modifyDN` request to one or more backend servers or after the change has successfully completed.

For example, if the `pre-commit-validation` property is enabled, the Globally Unique Attribute Plugin performs one or more searches to determine whether any entries conflict with the change, such as `add`, `modify`, or `modifyDN`. If a conflict is detected, the change request is rejected. If the `post-commit-validation` property is enabled, the server performs one or more searches after the change has been processed to determine if a conflict was created in multiple servers at the same time. If a conflict is detected in this manner, an administrative alert is generated to notify administrators of the problem so that they can take any manual corrective action.

The Globally Unique Attribute plugin attempts to detect and prevent unique attribute conflicts for changes processed through this PingDirectoryProxy server, but it cannot detect conflicts introduced by changes applied by clients communicating directly with backend servers.

You should enable the plugin for all backend servers with the same configuration so that conflicts can be detected within individual backend server instances. However, the Unique Attribute plugin alone might not be sufficient for cases in which the content is split across multiple sets of servers, such as in an entry-balanced environment or in proxy configurations with different branches on different servers.

Copyright © 2025 Ping Identity Corporation

The LDAP SDK uniqueness request control can be used for enforcing uniqueness on a per-request basis. See the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control. See the ASN.1 specification to implement support for it in other APIs.

> **Note**
>
> Consider the following points about pre-commit validation versus post-commit validation:
>
> - Pre-commit validation is the only mechanism that can try to prevent conflicts. It increases the processing time for **`add`**, **`modify`**, or **`modifyDN`** operations because the necessary searches to look for conflicts happen before the update request is forwarded to any backend servers.
> - Post-commit validation only sends administrative alerts about conflicts that already exist in the data. It can't prevent conflicts, but can allow you to deal with them in a timely manner. It also operates during the post-response phase, so it does not affect the processing time for the associated write operation.

In most cases, pre-commit validation should be sufficient to prevent conflicts. However, you should periodically run the **`identify-unique-attribute-conflicts`** tool to find any conflicts that might have arisen.

> **Note**
>
> If you want to mitigate any risks due to conflicts being generated by concurrent operations in different servers, then using both **`pre-commit-validation`** and **`post-commit-validation`** properties provides the best combination of preventing most conflicts in advance, and detecting and alerting about conflicts that arise from concurrent writes.

Configuring the Globally Unique Attribute plugin

About this task

The following example shows how to configure the Globally Unique Attribute plugin. The example defines an attribute set consisting of the `telephoneNumber` and `mobile` attributes within the `test-view` subtree view.

The `multiple-attribute-behavior` property determines the scope of how attributes might differ among entries and is the same property for the directory server plugin. The property is set to `unique-across-all-attributes-including-in-same-entry`, which indicates that the `telephone` and `mobile` attributes must be unique throughout the subtree view, even within an entry.

The `pre-commit-validation` property ensures that the Globally Unique Attribute Plugin performs one or more searches to determine whether any entries conflict with the change, such as **`add`**, **`modify`**, or **`modifyDN`**. If a conflict is detected, the change request is rejected.

> **Note**
>
> You should index all configured attributes for equality in all backend servers.

Steps

- To create the Globally Unique Attribute plugin, run **`dsconfig`** with the `create-plugin` option.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-plugin \
  --plugin-name "Globally-Unique telephone and mobile" \
  --type globally-unique-attribute \
  --set enabled:true \
  --set type:telephoneNumber \
  --set type:mobile \
  --set subtree-view:test-view \
  --set multiple-attribute-behavior:unique-across-all-attributes-including-in-same-entry \
  --set pre-commit-validation:all-available-backend-servers
```

Configuring the Global Referential Integrity plugin

PingDirectoryProxy supports a global referential integrity plugin mechanism that maintains distinguished name (DN) references from a specified set of attributes to entries that exist in the server, such as between the members values of a static group and the corresponding user entries.

The plugin intercepts `delete` and `modifyDN` operations and updates any references to the target entry. For a `delete` operation, any references to the target entry are removed. For `modifyDN` operations, any references to the target entry are updated to reflect the new DN of the entry.

The plugin is similar to the Directory Server Referential Integrity plugin but does not have an asynchronous mode. When enabled on the PingDirectoryProxy server, the client response is delayed until the referential integrity processing is complete.

For PingDirectoryProxy server deployments not using entry balancing and using directory server external servers, use the Referential Integrity plugin on the directory server.

> **Note**
>
> An equality index must be defined on all attributes referenced within the Global Referential Integrity plugin across all external servers.

Sample Global Referential Integrity plugin

Steps

- To configure the Global Referential Integrity plugin, run `dsconfig` with the `create-plugin` option.

  > **Note**
  >
  > Any attributes for which referential integrity should be maintained should have values that are DNs and should be indexed for equality in all backend servers.

  Example:

  In this example, the plugin ensures that the `member`, `uniqueMember`, and `manager` attributes maintain their DN references in the defined subtree views.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-plugin \
  --plugin-name "Global Referential Integrity" \
  --type global-referential-integrity \
  --set "enabled:true" \
  --set "attribute-type:member" \
  --set "attribute-type:uniqueMember" \
  --set "attribute-type:manager" \
  --set "subtree-view:employee-view" \
  --set "subtree-view:groups-view"
```

Configuring an Active Directory Server back-end

To configure an Active Directory (AD) server backend, run a `dsconfig` script.

The following settings are required for an Active Directory server:

- `verify-credentials-method:bind-on-existing-connections` and `authorization-method:rebind`

> **Note**
>
> Active Directory does not support `proxy-as`. Existing connections must be reused.

- `set max-connection-age:5m` and `health-check-pooled-connections:true`

> **Note**
>
> Active Directory drops idle connections after 15 minutes. The proxy must refresh the connection pool in a shorter interval.

Example

The following example `dsconfig` script configures two Active Directory servers, AD-SRV1 and AD-SRV2.

Copyright © 2025 Ping Identity Corporation

```
dsconfig set-ldap-health-check-prop --check-name "Consume Admin Alerts" \
  --reset use-for-all-servers

dsconfig set-trust-manager-provider-prop \
  --provider-name "Blind Trust" \
  --set enabled:true

dsconfig create-external-server --server-name AD-SRV1 --type active-directory \
  --set server-host-name:example.server \
  --set server-port:636 \
  --set bind-dn:cn=ProxyUser,dc=dom-ad2,dc=local \
  --set password:password --set connection-security:ssl \
  --set key-manager-provider:Null --set trust-manager-provider:"Blind Trust" \
  --set authorization-method:rebind \
  --set verify-credentials-method:bind-on-existing-connections \
  --set max-connection-age:5m \
  --set health-check-pooled-connections:true

dsconfig create-external-server --server-name AD-SRV2 --type active-directory \
  --set server-host-name:example.server \
  --set server-port:636 \
  --set bind-dn:cn=ProxyUser,dc=dom-ad2,dc=local \
  --set password:password \
  --set connection-security:ssl \
  --set key-manager-provider:Null \
  --set trust-manager-provider:"Blind Trust" \
  --set authorization-method:rebind \
  --set verify-credentials-method:bind-on-existing-connections \
  --set max-connection-age:5m \
  --set health-check-pooled-connections:true

dsconfig create-load-balancing-algorithm --algorithm-name AD-LBA \
  --type fewest-operations \
  --set enabled:true \
  --set backend-server:AD-SRV1 \
  --set backend-server:AD-SRV2 \
  --set use-location:false

dsconfig create-request-processor --processor-name AD-Proxy --type proxying \
  --set load-balancing-algorithm:AD-LBA

dsconfig create-subtree-view --view-name AD-View \
  --set base-dn:dc=dom-ad2,dc=local \
  --set request-processor:AD-Proxy

dsconfig set-client-connection-policy-prop --policy-name default \
  --set subtree-view:AD-View
```

Managing access control

The PingDirectoryProxy server provides a fine-grained access control model to ensure that users can access the information they need, but are prevented from accessing information that they shouldn't be allowed to see.

Copyright © 2025 Ping Identity Corporation

The access control model also includes a privilege subsystem that provides even greater flexibility and protection in many key areas.

This section presents the access control model and how it applies to the PingDirectoryProxy server, and includes the following topics:

- Overview of access control
- Access token validators
- Working with targets
- Examples of common access control rules
- Validating ACIs before migrating data
- Migrating ACIs from Oracle to the PingDirectory server
- Working with privileges
- Working with proxied authorization
- Working with parameterized ACIs
- $attr.attrName macro

Overview of access control

The access control model uses access control instructions (ACIs) to determine what a user or a group of users can do with a set of entries, down to the attribute level.

The ACIs are stored in the `aci` operational attribute. The operational attribute can appear on any entry and affects the entry or any subentries within that branch of the directory information tree (DIT).

Access control instructions specify four items:

Resources

Resources are the targeted items or objects that specifies the set of entries and operations to which the access control instruction applies. For example, you can specify access to certain attributes, such as the `cn` or `userPassword` password.

Name

Name is the descriptive label for each ACI. Typically, you have multiple ACIs for a given branch of your DIT. The access control name helps describe its purpose. For example, you can configure an ACI labeled "ACI to grant full access to administrators."

Clients

Clients are the users or entities to which you grant or deny access. You can specify individual users or groups of users using an LDAP URL. For example, you can specify a group of administrators using the LDAP URL: `groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com."`

Copyright © 2025 Ping Identity Corporation

Rights

Rights are permissions granted to users or client applications. You can grant or deny access to certain branches or operations. For example, you can grant `read` or `write` permission to a `telephoneNumber` attribute.

Key access control features

The directory server provides important access control features that provide added security for its entries.

Improved validation and security

The server provides an access control model with strong validation to help ensure that invalid access control instructions (ACIs) are not allowed into the server.

The server ensures that all access control rules (ACRs) added over LDAP are valid and can be fully parsed. The server rejects any operation that attempts to store one or more invalid ACIs. It also validates ACIs contained in data imported from an LDIF file. The server rejects any entry containing a malformed `aci` value.

As an additional level of security, the server examines and validates all ACIs stored in the data whenever a backend is brought online. If the server finds any malformed ACIs in the backend, it generates an administrative alert to notify administrators of the problem and places itself in lockdown mode. While in lockdown mode, the server only allows requests from users who have the `lockdown-mode` privilege. This action allows administrators to correct the malformed ACI while ensuring that no sensitive data is inadvertently exposed because of an ACI not being enforced. When the problem has been corrected, the administrator can use the `leave-lockdown-mode` tool or restart the server to allow it to resume normal operation.

Global ACIs

Global ACIs are a set of ACIs that apply to entries anywhere in the server or scoped to only apply to a specific set of entries.

Global ACIs work in conjunction with ACRs stored in user data and provide a convenient way to define ACIs that span disparate portions of the directory information tree (DIT).

In the Server, global ACIs are defined within the server configuration, in the `global-aci` property of the configuration object for the access control handler. To view and manage global ACIs, use configuration tools like `dsconfig` and the administrative console.

The global ACIs available by default in the Server include:

- Allow anyone, including unauthenticated users, to access key attributes of the root DSA-specific entry (DSE), including:
  - `namingContexts`
  - `subschemaSubentry`
  - `supportedAuthPasswordSchemes`
  - `supportedControl`
  - `supportedExtension`
  - `supportedFeatures`

Copyright © 2025 Ping Identity Corporation

- `supportedLDAPVersion`
- `supportedSASLMechanisms`
- `vendorName`
- `vendorVersion`

• Allow anyone, including unauthenticated users, to access key attributes of the subschema subentry, including:

- `attributeTypes`
- `dITContentRules`
- `dITStructureRules`
- `ldapSyntaxes`
- `matchingRules`
- `matchingRuleUse`
- `nameForms`
- `objectClasses`

• Allow anyone, including unauthenticated users, to include the following controls in requests made to the server:

- Authorization identity request
- Manage DSA IT
- Password policy
- Real attributes only
- Virtual attributes only

• Allow anyone, including unauthenticated users, to request the following extended operations:

- Get symmetric key
- Password modify request
- Password policy state
- StartTLS
- Who Am I?

Access controls for public or private backends

Depending on their intended purpose, the PingDirectory server classifies backends as either public or private.

A backend is private if one of the following applies:

• Its content is generated by the server itself, such as the root DSE, monitor, and backup backends.

• It is used in the operation of the server, such as the configuration, schema, task, and trust store backends.

Copyright © 2025 Ping Identity Corporation

- Its content is maintained by the server, such as the LDAP changelog backend.

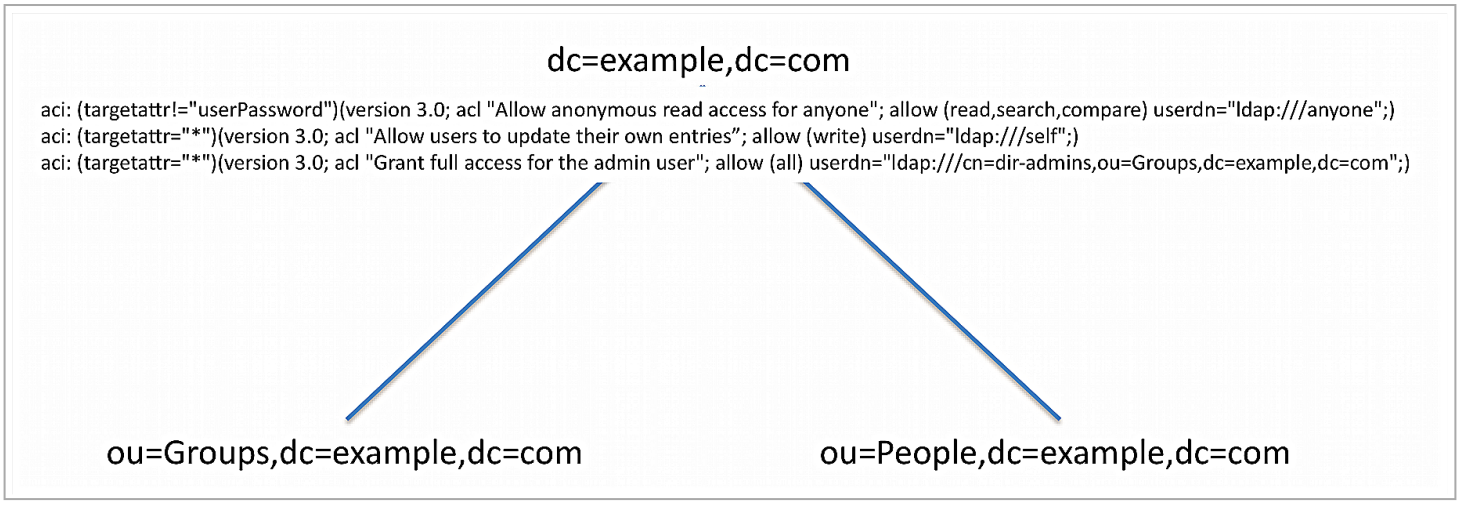
A public backend is intended to hold user-defined content, such as user accounts, groups, application data, and device data.

The server access control model also supports the distinction between public backends and private backends. Many private backends do not allow writes of any kind from clients, and some of the private backends that do allow writes only allow changes to a specific set of attributes. As a result, you should define any ACI intended to permit or restrict access to information in private backends as global ACIs, rather than attempting to add those instructions to the data for that private backend.

General format of the access control rules

Access control instructions (ACIs) are represented as strings that are applied to one or more entries within the directory information tree (DIT).

Typically, an ACI is placed on a subtree, such as `dc=example,dc=com`, and applies to that base entry and all entries below it in the tree. The directory server iterates through the DIT to compile the access control rules into an internally-used list of denied and allowed targets and their permissible operations. When a client application, such as `ldapsearch`, enters a request, the server checks that the user who binds with the server has the necessary access rights to the requested search targets. ACIs are cumulatively applied so that a user who has an ACI at an entry can also have other access rights available if ACIs are defined higher in the DIT and are applicable to the user. In most environments, ACIs are defined at the root of a main branch or a subtree, and not on individual entries unless absolutely required.



ACI

An access control rule has the following basic syntax.

```
aci:(targets) (version 3.0; acl "name";permissionsbind rules;)
```

Copyright © 2025 Ping Identity Corporation

Access Control Components

Access Control Component	Description
targets	Specifies the set of entries and attributes to which an access control rule applies. Use the following syntax: `(target keyword = || != expression)`
name	Specifies the name of the ACI
permissions	Specifies the type of operations to which an access control rule might apply. Use the following syntax: `allow||deny (permission)`
bind rules	Specifies the criteria that indicate whether an access control rule should apply to a given requester. Use the following syntax: `bind rule keyword = ||!= expression;` **Note** The bind rule syntax requires that it be terminated with a `;`.

Summary of access control keywords

This section provides an overview of the supported keywords in the server access control implementation.

Targets

A target expression specifies the set of entries and attributes to which an access control rule applies.

A target expression has three components:

Keyword

The keyword specifies the type of target element.

Expression

The expression specifies the items that are targeted by the access control rule.

Operator

The operator is either equal, `=`, or not-equal, `!=`.

Note

You cannot use the `!=` operator with the `targattrfilters` and `targetscope` keywords.

For specific examples of each target keyword, see Working with targets.

```
(keyword[=\|\|!=]expression)
```

Copyright © 2025 Ping Identity Corporation

You can use the following keywords in the target portion of ACIs:

Summary of Access Control Target Keywords

Target Keyword	Description	Wildcards
`extop`	Specifies the OIDs for any extended operations to which the access control rule should apply.	No

`requestcriteria`	Determines whether an access control rule applies to an operation based on whether that operation matches a given request criteria definition.
	If present in an access control rule, the operator must be either "=" or "!=". The value must be enclosed in quotation marks and it must be the name or full DN of the configuration object that defines the desired request criteria.
	For example, let's say that you want to allow members of the `cn=Sales Administrators,ou=Groups,dc=example,dc=com` group to be able to read from and write to the entries for the users that are members of the `cn=Sales Employees,ou=Groups,dc=example,dc=com` group. To do this, you must first create a request criteria object that will match entries for users in the `cn=Sales Employees,ou=Groups,dc=example,dc=com` group. You can do this with the following configuration change:
	`dsconfig create-request-criteria \ --criteria-name "Requests Targeting Sales Employees" \ --type simple \ --set "any-included-target-entry-group-dn:cn=Sales Employees,ou=Groups,dc=example,dc=com"`
	With that request criteria defined, you can use a modification like the following to create the corresponding access control rule:
	`dn: dc=example,dc=com changetype: modify add: aci aci: (targetattr="*")(requestcriteria="Requests Targeting Sales Employees")(version 3.0; acl "Allow sales administrators to manage sales employees"; allow (read,search,compare,write) groupdn="ldap:///cn=Sales Administrators,ou=Groups,dc=example,dc=com";)`	

`target`	Specifies the set of entries, identified using LDAP URLs, to which the access control rule applies.	Yes
`targattrfilters`	Identifies specific attribute values based on filters that can be added to or removed from entries to which the access control rule applies.	Yes
`targetattr`	Specifies the set of attributes to which the access control rule should apply.	Yes

Copyright © 2025 Ping Identity Corporation

Target Keyword	Description	Wildcards
`targetcontrol`	Specifies the OIDs for any request controls to which the access control rule should apply.	No
`targetfilter`	Specifies one or more search filters that can be used to indicate the set of entries to which the access control should apply.	Yes
`targetscope`	Specifies the scope of entries, relative to the defined target entries or the entry containing the ACI if there is no target, to which the access control rule should apply.	No

Permissions

Permissions indicate the types of operations to which an access control rule could apply.

You can specify if the user or group of users are allowed or not allowed to carry out a specific operation. For example, you can grant read access to targeted entries using the `allow (read)` permission. You can also deny access to the target entries and attributes using the `deny (read)` permission. You can list multiple permissions as required in the ACI.

```
allow(permission1...,permission2,...permissionN)
```

```
deny(permission1...,permission2,...permissionN)
```

You can use the following keywords in the permissions portion of ACIs.

Keyword	Description
`add`	Indicates that the access control applies to `add` operations.
`compare`	Indicates that the access control applies to `compare` operations and to search operations with a base-level scope that targets a single entry.
`delete`	Indicates that the access control applies to `delete` operations.
`export`	Indicates that the access control applies only to `modify DN` operations in which an entry is moved below a different parent by specifying a new superior distinguished name (DN) in the `modify DN` request. The requestor must have the `export` permission for operations against the entry's original DN. The requestor must have the `import` permission for operations against the entry's new superior DN. For `modify DN` operations that alter the relative distinguished name (RDN) of an entry but keeps it below the same parent, such as renaming the entry, only the `write` permission is required. This is true regardless of whether the entry being renamed is a leaf entry or has subordinate entries.
`import`	See the description for the `export` permission.

Copyright © 2025 Ping Identity Corporation

Keyword	Description
`proxy`	Indicates that the access control rule applies to operations that attempt to use an alternate authorization identity, such as operations that include a proxied authorization request control, an intermediate client request control with an alternate authorization identity, or a client that has authenticated with a Simple Authentication and Security Layer (SASL) mechanism that allows an alternate authorization identify to be specified.
`read`	Indicates that the access control rule applies to search result entries returned by the server.
`search`	Indicates that the access control rule applies to `search` operations with a non-base scope.
`selfwrite`	Indicates that the access control rule applies to operations in which a user attempts to add or remove their own DN to the values for an attribute, such as users adding or removing themselves from groups.
`write`	Indicates that the access control rule applies to `modify` and `modify DN` operations.
`all`	An aggregate permission that includes all other permissions except `import`, `export`, and `proxy`. This is equivalent to providing a permission of `add`, `compare`, `delete`, `read`, `search`, `selfwrite`, and `write`.

Bind rules

The bind rules indicate whether an access control rule should apply to a given requester.

The syntax for the target keyword has three components:

Keyword

The keyword specifies the type of target element.

Expression

The expression specifies the items that are targeted by the access control rule.

Operator

The operator is either equal, `=`, or not-equal, `!=`.

You must use the semicolon delimiter symbol, `;`, after the end of the final bind rule.

```
keyword[=||!=]expression;
```

For added access control precision, you can combine multiple bind rules using the Boolean operations `AND`, `OR`, and `NOT`. The standard Boolean rules for evaluation apply:

- Innermost to outer parentheses first
- Left to right expressions

Copyright © 2025 Ping Identity Corporation

- `NOT` before `AND` or `OR`

For example, an access control instruction (ACI) with the following bind rule targets all users who are not `uid=admin,dc=example,dc=com` and use simple authentication.

```
(userdn!="ldap:///uid=admin,dc=example,dc=com" and authmethod="simple");
```

The following bind rule targets users that are `uid=admin,dc=example,dc=com` and authenticate using Simple Authentication and Security Layer (SASL) EXTERNAL or access the server from a loopback interface.

```
(userdn="ldap:///uid=admin,dc=example,dc=com and (authmethod="SSL" or ip="127.0.0.1"));
```

You can use the following keywords in the bind rule portion of ACIs.

Bind Rule Keyword	Description

`authmethod`	Indicates that the requester's authentication method is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.
	Use the syntax `authmethod = method` where *method* is one of the following representations:
	• `none`
	• `simple` indicates that the client is authenticated to the server using a bind DN and password.
	• `ssl` indicates that the client is authenticated with an SSL/TLS certificate (for example, via SASL EXTERNAL), and not just over a secure connection to the server.
	• `sasl \{sasl_mechanism}` indicates that the client is authenticated to the server using a specified SASL mechanism.
	The following example allows users who authenticate with an SSL/TLS certificate (for example, using SASL EXTERNAL) to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write) (userdn="ldap:///self" and authmethod="ssl");)`

Copyright © 2025 Ping Identity Corporation

Bind Rule Keyword	Description

`connectioncriteria`	Allows or denies an operation based on whether the client connection matches a given connection criteria definition.
	If present in an access control rule, the operator must be either "`=`" or "`!=`". The value must be enclosed in quotation marks, and it must be the name or full DN of the configuration object that defines the desired connection criteria.
	For example, you can use a modification like the following to allow any client matching the "Root Users and Topology Administrators" connection criteria to have full read and write access to entries below `dc=example,dc=com`:
	`dn: dc=example,dc=com`
	`changetype: modify`
	`add: aci`
	`aci: (targetattr="*")(version 3.0; acl "Full read and write access for administrators"; allow (read,search,compare,write) connectioncriteria="Root Users and Topology Administrators";)`

`dayofweek`	Indicates that the day of the week is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.
	You can separate multiple day of week values by commas. Use the following syntax.
	`dayofweek = day1, day2, ...`
	day is one of the following:
	• `sun`
	• `mon`
	• `tues`
	• `wed`
	• `thu`
	• `fri`
	• `sat`
	The following example allows users who authenticate on weekdays with an SSL/TLS certificate, such as SASL EXTERNAL, to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write) (dayofweek!="sun,sat" and userdn="ldap:///self"`
	`and authmethod="ssl");)`

Copyright © 2025 Ping Identity Corporation

Bind Rule Keyword	Description

`dns`	Indicates that the requester's DNS-resolvable host name is taken into account when determining whether the access control rule should apply to an operation. You can use wildcards in this expression.
	You can separate multiple DNS patterns by commas. Use the following syntax.
	`dns = dns-host-name`
	The following example allows users on host name `server.example.com` to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write) (dns="server.example.com" and userdn="ldap:///self");)`

`groupdn`	Indicates that the requester's group membership is taken into account when determining whether the access control rule should apply to any operation. You cannot use wildcards in this expression.
	`groupdn [ = || != ] "ldap:///groupdn [ || ldap:///groupdn ] ..."`
	The following example allows users in the managers group to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write)`
	`(groupdn="ldap:///cn=managers,ou=groups,dc=example,dc=com");)`

`ip`	Indicates that the requester's IP address is taken into account when determining whether the access control rule should apply to an operation. You can use wildcards in this expression.
	You can separate multiple IP address patterns by commas. Use the following syntax.
	`ip [ = || != ] <ipAddressList>`
	ipAddressList is one of the following:
	• A specific IPv4 address: 127.0.0.1
	• An IPv4 address with wildcards to specify a subnetwork: 127.0.0.*
	• An IPv4 address or subnetwork with subnetwork mask: 123.4.5.0+255.255.255.0
	• An IPv4 address range using CIDR notation: 123.4.5.0/24
	• An IPv6 address as defined by RFC 2373.
	The following example allows users on 10.130.10.2 and localhost to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write) (ip="10.130.10.2,127.0.0.1" and userdn="ldap:///self");)`

Copyright © 2025 Ping Identity Corporation

Bind Rule Keyword	Description

`oauthscope`	Indicates that the scopes associated with any OAuth 2.0 access token presented by a SCIMv2 client is taken into account when determining whether the access control rule applies to an operation.
	Use the following syntax.
	`oauthscope [ = || != ] "<scopeIdentifier>"`
	scopeIdentifier is one of the following:
	• The name of a single scope to match. The name will be treated as case-sensitive.
	• A substring assertion that contains one or more asterisks as wildcards.
	• A single asterisk by itself, which will match any scope.
	The following example grants all rights to any client that presented an OAuth 2.0 token that is associated with the `scim_admin` scope.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Full rights for users with the scim_admin OAuth 2.0 scope";`
	`allow (all) oauthscope="scim_admin";)`

`secure`	Allows or denies an operation based on whether the client is communicating with the server over a secure connection; for example, using LDAPS or StartTLS over LDAP.
	If present in an access control rule, the operator must be either "`=`" or "`!=`", and the value must be either `"true"` or `"false"` including the quotation marks. With this in mind, the `secure` bind rule takes the following forms:
	• `secure="true"` indicates that the ACI will apply only if the connection was received over a secure connection.
	• `secure="false"` indicates that the ACI will only apply if the connection was received over a non-secure connection.
	• `secure!="true"` indicates that the ACI will apply only if the connection was received over a non-secure connection.
	• `secure!="false"` indicates that the ACI will apply only if the connection was received over a secure connection.
	For example, you can use a modification like the following to allow users below `dc=example,dc=com` to update their own passwords over a secure connection:
	`dn: dc=example,dc=com`
	`changetype: modify`
	`add: aci`
	`aci: (targetattr="userPassword")(version 3.0; acl "Allow users to update`
	`their own passwords over a secure connection"; allow (write)`
	`userdn="ldap:///self" and secure="true";)`

Copyright © 2025 Ping Identity Corporation

Bind Rule Keyword	Description

`timeofday`	Indicates that the time of day is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.
	Use the following syntax.
	`timeofday [ = || != || >= || > || <= || < ]  <time>`
	time is one of the following:
	• 4-digit 24-hour time format (0000 to 2359, where the first two digits represent the hour of the day and the last two represent the minute of the hour)
	• You cannot use wildcards in this expression
	The following example allows users to update their own entries if the request is received before 12 noon.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users who authenticate before noon`
	`to update their own entries";`
	`allow (write) (timeofday<1200 and userdn="ldap:///self"`
	`and authmethod="simple");)`

Copyright © 2025 Ping Identity Corporation

`userattr`

Indicates that the requester's relation to the value of the specified attribute is taken into account when determining whether the access control rule should apply to an operation.
Use the following syntax.

```
userattr =  <attrName># [  <bindType>  ||  <attrValue> ]
```

Where:

- *attrName* = name of the attribute for matching
- *bindType*= `USERDN`, `GROUPDN`, `LDAPURL`
- *attrValue* = an attribute value. The *attrVALUE* of the attribute must match on both the bind entry and the target of the ACI.

A *bindType* value of `USERDN` indicates that the target attribute should have a value which matches the DN of the authenticated user. A *bindType* value of `GROUPDN` indicates that the target attribute should have a value which matches the DN of a group in which the authenticated user is a member. A *bindType* value of `LDAPURL` indicates that the target attribute should have a value that is an LDAP URL whose criteria matches the entry for the authenticated user.
Any value other than `USERDN`, `GROUPDN`, or `LDAPURL` is expected to be present in the target attribute of the authenticated user's entry.
The following example allows a manager to change employee's entries. If the bind DN is specified in the manager attribute of the targeted entry, the bind rule is evaluated to `TRUE`.

```
aci: (targetattr="*")
(version 3.0; acl "Allow a manager to change employee entries";
allow (write) userattr="manager#USERDN";)
```

The following example allows any member of a group to change employee's entries. If the bind DN is a member of the group specified in the `allowEditors` attribute of the targeted entry, the bind rule is evaluated to `TRUE`.

```
aci: (targetattr="*")
(version 3.0; acl "Allow allowEditors to change employee entries";
allow (write) userattr="allowEditors#GROUPDN";)
```

The following example allows a user's manager to edit that user's entry and any entries below the user's entry up to two levels deep. You can specify up to five levels (`0`, `1`, `2`, `3`, `4`) below the targeted entry, with zero `0` indicating the targeted entry.

```
aci: (targetattr="*")
(version 3.0; acl "Allow managers to change employees entries two levels below";
allow (write) userattr="parent[0,1,2].manager#USERDN";)
```

The following example allows any member of the engineering department to update any other member of the engineering department at or below the specified ACI.

```
aci: (targetattr="*")
(version 3.0; acl "Allow any member of Eng Dept to update any other member of the
enginering department at or below the ACI";
allow (write) userattr="department#ENGINEERING";)
```

The following example allows an entry to be updated by any user whose entry matches the criteria defined in the LDAP URL contained in the `allowedEditorCriteria` attribute of the target entry.

Copyright © 2025 Ping Identity Corporation

Bind Rule Keyword	Description

	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow a user that matches the filter to change entries";`
	`allow (write) userattr="allowedEditorCriteria#LDAPURL";)`

`userdn`	Indicates that the user's DN is taken into account when determining whether the access control rule should apply to an operation.
	Use the following syntax..
	`userdn [ = || != ] "ldap:///<value>  [ || "ldap:///<value>  ..."]`
	Where *value* is one of the following representations:
	• The DN of the target user
	• A value of `anyone` to match any client, including unauthenticated clients.
	• A value of `all` to match any authenticated client.
	• A value of `parent` to match the client authenticated as the user defined in the immediate parent of the target entry.
	• A value of `self` to match the client authenticated as the user defined in the target entry.
	If the value provided is a DN, then that DN can include wildcard characters to define patterns. A single asterisk will match any content within the associated DN component, and two consecutive asterisks can be used to match zero or more DN components.
	The following example allows users to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write) userdn="ldap:///self";)`

Access token validators

Access token validators verify the tokens that HTTP client applications submit when they request access to protected resources and associate each token with an identity stored in the directory server.

To authenticate to PingDirectory server's HTTP services, clients use OAuth 2 bearer token authentication to present an access token in the HTTP Authorization request header.

To process the incoming access tokens, PingDirectory server uses access token validators, which determine whether to accept an access token and translate it into a set of properties, called claims, which PingDirectory server's HTTP services use to make access control decisions.

Most access tokens identify a user as its subject using the `sub` claim. Access token validators can retrieve the token subject's attributes from the directory using an identity mapper, which correlates the access token subject to an Lightweight Directory Access Protocol (LDAP) entry.

Copyright © 2025 Ping Identity Corporation

Access token validators are used by the following services:

- Directory REST API
- SCIM 2
- Delegated Admin
- Consent API

You can configure the PingDirectory server to accept access tokens provided by LDAP clients using the OAUTHBEARER Simple Authentication and Security Layer (SASL) authentication method.

Access token validator processing

You can configure any number of access token validators for the server.

Each access token validator has an evaluation order index, which is an integer that determines the processing priority when multiple access token validators are configured. Lower values are processed before higher values.

> **Note**
>
> Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by PingDirectory server.

Processing steps

1. If an incoming HTTP request contains an access token, the token is sent to the access token validator with the lowest evaluation order index.
2. The access token validator validates the access token. Validation logic varies by access token validator type, but the validator generally verifies the following information:
    - A trusted source issued the token.
    - The token is not expired.
3. If the access token contains a subject, the access token validator uses its identity mapper to find a matching Lightweight Directory Access Protocol (LDAP) entry.
4. If the access token validator is unable to validate the access token, it passes the token to the access token validator with the next lowest evaluation order index, and the previous two steps are repeated.
5. HTTP request processing continues, and the policy request is sent to the HTTP service, such as the Directory REST API, for further evaluation.
6. Using either the access token claims parsed by the access token validator or the LDAP entry found by the identity mapper, the HTTP service determines whether the request should be accepted and which access control rules should be applied. This access control behavior varies by each HTTP service.

Copyright © 2025 Ping Identity Corporation

Access token validator types

The server works with a variety of access token validators.

Configuring a sample PingFederate access token validator

To verify the access tokens that a PingFederate authorization server issues, the PingFederate access token validator uses HTTP to submit the tokens to PingFederate server's token introspection endpoint.

Before you begin

Before using a PingFederate access token validator, create a client that represents the access token validator in the PingFederate configuration. This client must use the Access Token Validation grant type.

About this task

This step allows the authorization server to determine whether a token is valid.

> **Note**
>
> Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by the directory server.

Because this step requires an outgoing HTTP request to the authorization server, the PingFederate access token validator might perform slower than other access token validator types. The validation result is guaranteed to be current, which is an important consideration if the authorization server permits the revocation of access tokens.

Steps

1. In PingFederate, create a client with the following properties:
    - Client ID: Ping Identity
    - Client authentication: Client Secret
    - Allowed grant types: Access Token Validation
2. Take note of the client secret and use the directory server's `dsconfig` command to create an access token validator, as shown.

Copyright © 2025 Ping Identity Corporation

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
        --mapper-name "User ID Identity Mapper" \
        --type exact-match \
        --set enabled:true \
        --set match-attribute:uid \
        --set match-base-dn:ou=people,dc=example,dc=com
# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031
# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "PingFederate Access Token Validator" \
  --type ping-federate \
  --set enabled:true \
  --set "authorization-server:PingFederate External Server" \
  --set client-id:PingDirectory \
  --set "client-secret:<client secret>"
  --set evaluation-order-index:2000
  --set "identity-mapper:User ID Identity Mapper"
```

3. Replace *<client secret>* with the client secret value generated by the PingFederate client.

JWT access token validator

The JWT access token validator verifies access tokens that are encoded in JSON Web Token (JWT) format, which can be signed in JSON web signature (JWS) format or signed and encrypted in JSON web encryption (JWE) format.

The JWT access token validator inspects the JWT token without presenting it to an authorization server for validation. Because the JWT access token validator does not make a token introspection request for every access token that it processes, it performs faster than the PingFederate access token validator. The access token is self-validated, so the JWT access token validator cannot determine whether the token has been revoked.

Supported JWS/JWE features

For signed tokens, the JWT access token validator supports the following JWT web algorithm (JWA) types:

- RS256
- RS384
- RS512
- ES256
- ES384

Copyright © 2025 Ping Identity Corporation

- ES512

For encrypted tokens, the JWT access token validator supports the following key-encryption algorithms:

- RSA-OAEP
- ECDH-ES
- ECDH-ES+A128KW
- ECDH-ES+A192KW
- ECDH-ES+A256KW

For encrypted tokens, the JWT access token validator supports the following content-encryption algorithms:

- A128CBC-HS256
- A192CBC-HS384
- A256CBC-HS512

The JWT access token validator configuration defines three allow lists for the JWS/JWE signing and encryption algorithms that it accepts. Customize these allow lists to reflect only the signing and encryption algorithms used by your access token issuer and no others. This minimizes the access token validator's security threat surface.

Configure these allow lists using the following configuration properties:

`allowed-signing-algorithm`

Specifies the signing algorithms that the access token validator accepts.

`allowed-key-encryption-algorithm`

Specifies the key-encryption algorithms that the access token validator accepts.

`allowed-content-encryption-algorithm`

Specifies the content-encryption algorithms that the access token validator accepts.

Handling signed tokens

The token issuer must cryptographically sign all access tokens that the JSON web token (JWT) access token validator handles. The JWT access token validator validates a token's signature using a public signing key provided by the issuer.

Steps

- Configure the JWT access token validator with the issuer's public signing key:

  Choose from:

  - Store the public key as a trusted certificate in the server's local configuration using the `trusted-certificate` property.

Copyright © 2025 Ping Identity Corporation

- Provide the issuer's JSON Web Key Set (JWKS) endpoint using the `jwks-endpoint-path` property.

> **Note**
>
> The JWT access token validator then retrieves the issuer's public keys when it initializes. This method ensures that the JWT access token validator uses updated copies of the issuer's public keys.

Example: Use a locally configured trusted certificate

The following example configures a JWT access token validator to use a locally stored public signing certificate to validate access token signatures. The signing certificate is assumed to have been obtained out-of-band and must be a PEM-encoded X.509v3 certificate.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
        --mapper-name "User ID Identity Mapper" \
        --type exact-match \
        --set enabled:true \
        --set match-attribute:uid \
        --set match-base-dn:ou=people,dc=example,dc=com

# Add the public signing certificate to the server configuration
dsconfig create-trusted-certificate \
        --certificate-name "JWT Signing Certificate" \
        --set "certificate</path/to/signing-certificate.pem"

# Create the Access Token Validator
dsconfig create-access-token-validator \
        --validator-name "JWT Access Token Validator" \
        --type jwt \
        --set enabled:true \
        --set evaluation-order-index:1000 \
        --set allowed-signing-algorithm:RS256 \
        --set "trusted-certificate:JWT Signing Certificate"
        --set "identity-mapper:User ID Identity Mapper"
```

Example: Use the issuer's JWKS endpoint

The following example configures a JWT access token validator to retrieve public keys from a PingFederate authorization server's JWKS endpoint.

Copyright © 2025 Ping Identity Corporation

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
        --mapper-name "User ID Identity Mapper" \
        --type exact-match \
        --set enabled:true \
        --set match-attribute:uid \
        --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
        --server-name "PingFederate External Server" \
        --type http \
        --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
        --validator-name "JWT Access Token Validator" \
        --type jwt \
        --set enabled:true \
        --set evaluation-order-index:1000 \
        --set allowed-signing-algorithm:RS256 \
        --set "authorization-server:PingFederate External Server" \
        --set jwks-endpoint-path:/ext/oauth/jwks
        --set "identity-mapper:User ID Identity Mapper"
```

Handling encrypted tokens

Configure the JSON web token (JWT) access token validator to accept encrypted access tokens. You must configure the access token validator with a private and public key pair and provide the public key to the token issuer.

Steps

1. Create an encryption key pair.
2. Create the JWT access token validator.
3. Export the public encryption key from the PingDirectory server and provide it to your token issuer.

   Choose from:

   - To copy the public key to a file, run `dsconfig`.
   - Copy the value of the key pair's `certificate-chain` property in the administrative console.

     > **Note**
     >
     > Without this public encryption key, the issuer cannot encrypt tokens that can be decrypted by the JWT access token validator.

Example

Copyright © 2025 Ping Identity Corporation

The following example configures a JWT access token validator to handle access tokens signed and encrypted using elliptic curve algorithms.

For RSA signing and encryption algorithms, the configuration is similar, but you choose different values for the `allowed-signing-algorithm` and `allowed-encryption-algorithm` properties.

1. Create an encryption key pair.

```
# Create an encryption key pair
        dsconfig create-key-pair \
        --pair-name "JWT Elliptic Curve Encryption Key Pair" \
        --set key-algorithm:EC_256
```

2. Create the JWT access token validator.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
        --mapper-name "User ID Identity Mapper" \
        --type exact-match \
        --set enabled:true \
        --set match-attribute:uid \
        --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
        --server-name "PingFederate External Server" \
        --type http \
        --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
        --validator-name "JWT Access Token Validator" \
        --type jwt \
        --set enabled:true \
        --set evaluation-order-index:1000 \
        --set allowed-signing-algorithm:ES256 \
        --set "authorization-server:PingFederate External Server" \
        --set jwks-endpoint-path:/ext/oauth/jwks \
        --set "encryption-key-pair:JWT Elliptic Curve Encryption Key Pair" \
        --set allowed-key-encryption-algorithm:ECDH_ES
        --set "identity-mapper:User ID Identity Mapper"
```

3. Export the public encryption key from the PingDirectory server and provide it to your token issuer.

   The following command copies the key to a file.

```
dsconfig get-key-pair-prop \
        --pair-name "JWT Elliptic Curve Encryption Key Pair" \
        --property certificate-chain \
        --no-prompt \
        --script-friendly > jwt-public-encryption-key.pem
```

Copyright © 2025 Ping Identity Corporation

Mock access token validator

A mock access token validator is a special access token validator type for development or testing purposes.

A mock access token validator accepts arbitrary tokens without validating whether a trusted source issued them. This allows you to make bearer token-authenticated requests without first setting up an authorization server.

Mock access tokens are formatted as plain-text JSON objects using standard JSON web token (JWT) claims.

Always provide the boolean `active` claim when creating a mock token. If this value is `true`, the token is accepted. If this value is `false`, the token is rejected.

If the `sub` claim is provided, a token owner lookup populates the `TokenOwner` policy request attribute as with the other access token validator types.

The following example cURL command shows a mock access token in an HTTP request.

```
curl -k -X GET https://localhost:1443/directory/v1/Me -H 'Authorization: Bearer {"active": true, "sub":"user.1",
"scope":"email profile", "client_id":"client1"}'
```

> **Important**
>
> Never use mock access token validators in a production environment because they do not verify whether a trusted source issued an access token.

ExampleSample configuration

The configuration for a mock access token validator resembles the configuration for a JWT access token validator. However, the JSON web signature (JWS) signatures require no configuration because mock tokens are not authenticated.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --validator-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "Mock Access Token Validator" \
  --type mock --set enabled:true \
  --set evaluation-order-index:9999 \
  --set "identity-mapper:User ID Identity Mapper"
```

Third-party access token validator

To create custom access token validators, use the Server SDK.

Copyright © 2025 Ping Identity Corporation

Working with targets

The following section presents a detailed look and examples of the target access control instruction (ACI) keywords:

- `target`
- `targetattr`
- `targetfilter`
- `targattrfilters`
- `targetscope`
- `targetcontrol`
- `extop`

target

The `target` keyword indicates that the ACI should apply to one or more entries at or below the specified distinguished name (DN).

The target DN must be equal or subordinate to the DN of the entry in which the ACI is placed. For example, if you place the ACI at the root of `ou=People,dc=example,dc=com`, you can target the DN, `uid=user.1,ou=People,dc=example,dc=com`, within your ACI rule. The DN must meet the string representation specification of distinguished names, outlined in RFC 4514, and requires that special characters be properly escaped.

The `target` clause has the following format, where *DN* is the distinguished name of the entry or branch:

```
(target = ldap:///<DN>)
```

For example, to target a specific entry, use a clause like the following.

```
(target = ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

> **Note**
>
> In most cases, you should avoid specifying a target DN. Instead, define the ACI in that entry and omit the `target` element altogether.
> For example, although you can have `(target="ldap:///uid=john.doe,ou=People,dc=example,dc=com)` in any of the `dc=example,dc=com` or `ou=People` entries, you should define it in the `uid=john.doe` entry and not explicitly include the `target` element.

The expression allows for the not equal operator (`!=`) to indicate that all entries within the scope of the given branch that do not match the expression be targeted for the ACI. The following expression targets all entries within the subtree that do not match `uid=john.doe`.

```
(target != ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

Copyright © 2025 Ping Identity Corporation

The `target` keyword also supports the use of asterisk (`*`) characters as wildcards to match elements within the distinguished name.

- The following target expression matches all entries that contain and begin with `john.d`.

```
(target = ldap:///uid=john.d*,ou=People,dc=example,dc=com)
```

  Entries such as `john.doe,ou=People,dc=example,dc=com` and `john.davies,ou=People,dc=example,dc=com` would match the target expression.

- The following target expression matches all entries whose DN begins with `john.d` and matches the `ou` attribute.

```
(target = ldap:///uid=john.d*,ou=*,dc=example,dc=com)
```

  Entries such as `john.doe,ou=People,dc=example,dc=com` and `john.davies,ou=asia-branch,dc=example,dc=com` would match the target expression.

Another example of a complete ACI targets the entries in the `ou=People,dc=example,dc=com` branch and the entries below it and grants the users the privilege to modify all of their user attributes within their own entries.

```
aci:(target="ldap:///ou=People,dc=example,dc=com")
(targetattr="*")
(version 3.0; acl "Allow all the ou=People branch to modify their own entries";
allow (write) userdn="ldap:///self";)
```

targetattr

The `targetattr` keyword targets the attributes for which the access control instruction should apply.

There are four general forms that it can take in the Server:

`(targetattr="*")`

Indicates that the access control rule applies to all user attributes. Operational attributes are not automatically included in this set.

`(targetattr="+")`

Indicates that the access control rule applies to all operational attributes. User attributes are not automatically included in this set.

`(targetattr="<attr1>\|\|<attr2>\|\|<attr3>\|\|…\|\|<attrN>")`

Indicates that the access control rule applies only to the named set of attributes.

`(targetattr!="attr1\|\|attr2\|\|attr3\|\|…\|\|attrN")`

Indicates that the access control rule applies to all user attributes except the named set of attributes. It does not apply to any operational attributes.

Copyright © 2025 Ping Identity Corporation

The targeted attributes can be classified as user attributes and operational attributes. User attributes define the actual data for that entry while operational attributes provide additional metadata about the entry that can be used for informational purposes, such as when the entry was created, last modified and by whom. Metadata can also include attributes specifying which password policy applies to the user, or overrided default constraints like size limit, time limit, or look-through limit for that user.

The Server distinguishes between these two types of attributes in its access control implementation. The PingDirectory server does not automatically grant any access at all to operational attributes. For example, the following clause applies only to user attributes and not to operational attributes.

```
(targetattr="*")
```

You can also target multiple attributes in the entry. The following clause targets the common name (`cn`), surname (`sn`) and state (`st`) attribute.

```
(targetattr="cn||sn||st")
```

You can use the `+` symbol to indicate that the rule should apply to all operational attributes.

```
(targetattr="+")
```

To include all user and all operational attributes, use both symbols.

```
(targetattr="*||+")
```

If you need to target a specific operational attribute rather than all operational attributes, include it in the values of the `targetattr` clause.

```
(targetattr="ds-rlim-size-limit")
```

If you want to target all user attributes and a specific operational attribute, use them in the `targetattr` clause.

```
(targetattr="*||ds-rlim-size-limit")
```

The following sample ACIs are placed on the `dc=example,dc=com` tree. The first ACI allows any user anonymous read access to all entries except the `userPassword` attribute. The second ACI allows users to update their own contact information. The third ACI allows the `uid=admin` user full access privileges to all user attributes in the `dc=example,dc=com` subtree.

Copyright © 2025 Ping Identity Corporation

```
aci: (targetattr!="userPassword")(version 3.0; acl "Allow anonymous
   read access for anyone"; allow (read,search,compare) userdn="ldap:///anyone";)
aci: (targetattr="telephonenumber||street||homePhone||l||st")
  (version 3.0; acl "Allow users to update their own contact info";
   allow (write) userdn="ldap:///self";)
aci: (targetattr="*")(version 3.0; acl "Grant full access for the admin user";
  allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

When assigning access to user and operational attributes, it is easy to inadvertently create an access control instruction that grants far more capabilities to a user than originally intended. The following example shows the implications of the PingDirectory server not distinguishing between these attributes.

```
aci: (targetattr!="uid||employeeNumber")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)
```

This instruction is intended to allow a user to update any attribute in his or her own entry with the exception of `uid` and `employeeNumber`. This ACI is a common rule and seems harmless, but has serious consequences for a PingDirectory server that does not distinguish between user attributes and operational attributes. It allows users to update operational attributes in their own entries, and could be used for a number of malicious purposes, including:

- A user could alter password policy state attributes to become exempt from password policy restrictions.
- A user could alter resource limit attributes and bypass size limit, time limit, and look-through-limit constraints.
- A user could add access control rules to his or her own entry, which could allow them to make their entry completely invisible to all other users, including administrators granted full rights by access control rules, but excluding users with the `bypass-acl` privilege allows them to edit any other attributes in their own entry, including those excluded by rules like `uid` and `employeeNumber` in the previous example, or add, modify, or delete any entries below his or her own entry.

Because the Server does not automatically include operational attributes in the target attribute list, these types of ACIs do not present a security risk for it. Users cannot add ACIs to any entries unless they have the `modify-acl` privilege.

Another danger in using the `(targetattr!="x")` pattern is that two ACIs within the same scope could have two different `targetattr` policies that cancel each other out. For example, if one ACI has `(targetattr!="cn\|\|sn")` and a second ACI has `(targetattr!="userPassword")`, then the net effect is `(targetattr="*")`, because the first ACI inherently allows `userPassword` and the second allows `cn` and `sn`.

targetfilter

The `targetfilter` keyword targets all attributes that match results returned from a filter.

The `targetfilter` clause has the following syntax.

```
(targetfilter =  <ldap_filter>)
```

For example, the following clause targets all entries that contain the `ou=engineering` attribute.

Copyright © 2025 Ping Identity Corporation

```
(targetfilter = "(ou=engineering)")
```

You can only specify a single filter, but that filter can contain multiple elements combined with the `OR` operator. The following clause targets all entries that contain `ou=engineering`, `ou=accounting`, and `ou=marketing`.

```
(targetfilter = "(|(ou=engineering)(ou=accounting)(ou=marketing)")
```

The following example allows the user, `uid=eng-mgr`, to modify the `departmentNumber`, `cn`, and `sn` attributes for all entries that match the filter `ou=engineering`.

```
aci:(targetfilter="(ou=engineering)")
  (targetattr="departmentNumber||cn||sn")
  (version 3.0; acl "example"; allow (write)
   userdn="ldap:///uid=eng-mgr,dc=example,dc=com";)
```

targattrfilters

The `targattrfilters` keyword targets specific attribute values that match a filtered search criteria.

This keyword allows you to set up an ACI that grants or denies permissions on an attribute value if that value meets the filter criteria. The `targattrfilters` keyword applies to individual values of an attribute, not to the whole attribute. The keyword also allows the use of wildcards in the filters.

The keyword clause has the following format.

```
(target = "add=attr1:Filter1 && attr2:Filter2... && attrn:FilterN,
del=attr1:Filter1 && attr2:Filter2 ... && attrN:FilterN" )
```

Where:

`add`

Represents the operation of adding an attribute value to the entry.

`del`

Represents the operation of removing an attribute value from the entry.

`<attr1>, <attr2>... <attrN>`

Represents the targeted attributes.

`<filter1>, <filter2>... <filterN>`

Represents filters that identify matching attribute values.

The following conditions determine when the attribute must satisfy the filter:

- When adding or deleting an entry containing an attribute targeted a `targattrfilters` element, each value of that attribute must satisfy the corresponding filter.

Copyright © 2025 Ping Identity Corporation

- When modifying an entry, if the operation adds one or more values for an attribute targeted by a `targattrfilters` element, each value must satisfy the corresponding filter. If the operation deletes one or more values for a targeted attribute, each value must satisfy the corresponding filter.
- When replacing the set of values for an attribute targeted by a `targattrfilters` element, each value removed must satisfy the delete filters and each value added must satisfy the add filters.

The following example allows any user who is part of the `cn=directory server admins` group to add the `soft-delete-read` privilege.

```
aci:(targattrfilter="add=ds-privilege-name:(ds-privilege-name=soft-delete-read)")
  (version 3.0; acl "Allow members of the the directory server admins group to grant the
   soft-delete-read privilege"; allow (write)
   groupdn="ldap:///cn=PingDirectory Server admins,ou=group,dc=example,dc=com";)
```

targetscope

Use the `targetscope` keyword to restrict the scope of an access control rule (ACR).

ACIs use a subtree scope by default, meaning they are applied to the target entry and all entries below it, either as defined by the target clause of the ACI or the entry in which the ACI is defined if it does not include a target. However, you can add the `targetscope` element into an ACR to restrict the set of entries to which it applies.

The following `targetscope` keyword values are allowed:

base

Indicates that the ACR applies only to the target entry and not to any of its subordinates.

onelevel

Indicates that the ACR applies only to entries that are immediate children of the target entry and not to the target entry itself nor to any subordinates of the immediate children of the target entry.

subtree

Indicates that the ACR applies to the target entry and all of its subordinates. This is the default behavior if no `targetscope` is specified.

subordinate

Indicates that the ACR applies to all entries below the target entry but not the target entry itself.

The following ACI targets all users to view the operational attributes present in the root DSA-specific entry (DSE):

- `supportedControl`
- `supportedExtension`
- `supportedFeatures`
- `supportedSASLMechanisms`
- `vendorName`

Copyright © 2025 Ping Identity Corporation

- `vendorVersion`

In the following example, `targetscope` is set to `base` to limit users to view only those attributes in the root DSE.

```
aci: (target="ldap:///")(targetscope="base")
    (targetattr="supportedControl||supportedExtension||
     supportedFeatures||supportedSASLMechanisms||vendorName||vendorVersion")
    (version 3.0; acl "Allow users to view Root DSE Operational Attributes";
     allow (read,search,compare) userdn="ldap:///anyone")
```

targetcontrol

Use the `targetcontrol` keyword to indicate whether a given request control can be used by users targeted in the ACI.

You can provide multiple OIDs by separating them with two pipe characters, optionally surrounded by spaces. When specifying control OIDs, wildcards are not allowed.

The following ACI example shows the controls required to allow an administrator to use and manage the soft delete feature. The soft delete request control allows the user to soft-delete an entry, so that it could be undeleted at a later time. The hard delete request control allows the user to permanently remove an entry or soft-deleted entry. The undelete request control allows the user to undelete a currently soft-deleted entry. The soft-deleted entry access request control allows the user to search for any soft-deleted entries in the server.

```
aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.22||
   1.3.6.1.4.1.30221.2.5.23||1.3.6.1.4.1.30221.2.5.24")
  (version 3.0; acl "Allow admins to use the Soft Delete Request Control,
   Hard Delete Request Control,Undelete Request Control, and
   Soft-deleted entry access request control";
   allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

extOp

Use the `extop` keyword to indicate whether a given extended request operation can be used.

You can provide multiple OIDs by separating them with two pipe characters, optionally surrounded by spaces. When specifying extended request OIDs, wildcards are not allowed.

The following ACI example allows the `uid=user-mgr` to use the password modify request, `OID=1.3.6.1.4.1.4203.1.11.1`, and the StartTLS, `OID=1.3.6.1.4.1.1466.20037`, which are extended request OIDs.

```
aci:(extop="1.3.6.1.4.1.4203.1.11.1 || 1.3.6.1.4.1.1466.20037")
  (version 3.0; acl "Allows the mgr to use the Password Modify Request and StartTLS;
   allow(read) userdn="ldap:///uid=user-mgr,ou=people,dc=example,dc=com";)
```

Examples of common access control rules

This section demonstrates access controls that are commonly used in your environment.

To modify access control definitions in the server, a user must have the `modify-acl` privilege.

Copyright © 2025 Ping Identity Corporation

Administrator access

The following access control instructions (ACIs) grant members of the `cn=admins,ou=groups,dc=example,dc=com` group the following permissions:

- Add, modify, and delete entries
- Reset passwords
- Read operational attributes, such as `isMemberOf` and password policy state

```
aci: (targetattr="+")(version 3.0; acl "Administrators can read, search or compare operational attributes";
allow (read,search,compare) groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com";)
aci: (targetattr="*")(version 3.0; acl "Administrators can add, modify and delete entries";
allow (all) groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com";)
```

Anonymous and authenticated access

The following ACIs allow anonymous read, search, and compare on select attributes of `inetOrgPerson` entries while authenticated users can access several more. An authenticated user inherits the privileges of the anonymous ACI and can also change `userPassword`.

```
aci: (targetattr="objectclass || uid || cn || mail || sn || givenName")
(targetfilter="(objectClass=inetorgperson)")
(version 3.0; acl "Anyone can access names and email addresses of entries representing people";
allow (read,search,compare) userdn="ldap:///anyone";)
aci: (targetattr="departmentNumber || manager || isMemberOf")(targetfilter="(objectClass=inetorgperson)")
(version 3.0; acl "Authenticated users can access these fields for entries representing people";
allow (read,search,compare) userdn="ldap:///all";)
aci: (targetattr="userPassword")(version 3.0; acl "Authenticated users can change password";
allow (write) userdn="ldap:///all";)
```

To prevent anonymous access to the directory server, set the global configuration property `reject-unauthenticated-requests` to `true`.

Delegated access to a manager

The following ACI allows an employee's manager to edit the value of the employee's `telephoneNumber` attribute. This ACI uses the `userattr` keyword with a bind type of `USERDN`, which indicates that the target entry's manager attribute must have a value equal to the distinguished name (DN) of the authenticated user.

```
aci: (targetattr="telephoneNumber")
(version 3.0; acl "A manager can update telephone numbers of her direct reports";
allow (read,search,compare,write) userattr="manager#USERDN";)
```

Proxy authorization

The following ACI allows the application `cn=OnBehalf,ou=applications,dc=example,dc=com` to use the proxied authorization V2 control to request that operations be performed using an alternate authorization identity.

Copyright © 2025 Ping Identity Corporation

```
aci: (version 3.0;acl "Application OnBehalf can proxy as another entry";
allow (proxy) userdn="ldap:///cn=OnBehalf,ou=applications,dc=example,dc=com";)
```

> **Note**
>
> The application user must have the `proxied-auth` privilege.

Validating ACIs before migrating data

Identify any access control instruction (ACI) syntax problems before migrating data.

Many directory servers allow for a less restrictive application of their access control instructions so that they accept invalid ACIs. For example, if an Oracle directory server encounters an access control rule that it can't parse, it ignores the rule without providing a warning, and the server might not offer the intended access protection. The Server rejects any ACIs that it can't interpret, which ensures that data access is limited as intended. However, this can cause problems when migrating data with existing access control rules to a The Server.

To validate an ACI, the Server provides a `validate-acis` tool in the `bin` directory on UNIX or Linux systems or in the `bat` directory on Windows systems.

The `validate-acis` tool identifies any ACI syntax problems before you migrate data. The tool can examine access control rules contained in either an LDIF file or an LDAP directory and write its result in LDIF with comments providing information about any problems that were identified.

Each entry in the output contains a single ACI. If an entry in the input contains multiple ACIs, then it can be present multiple times in the output, each time with a different ACI value. The entries contained in the output contains only ACI values. All other attributes are ignored.

Validating ACIs from a file

Use the `validate-acis` tool to process data contained in an LDIF file.

About this task

> **Note**
>
> The **`validate-acis`** tool ignores all attributes except `aci` and ignores all entries that do not contain the `aci` attribute. You can use any existing LDIF file that contains access control rules.

Steps

1. Run the `validate-acis` tool and specify the input file and output file.

   Choose from:

   - UNIX or Linux: `bin/validate-acis`
   - Windows: `bat\validate-acis`

   If the output file already exists, the existing file contents are re-written. If no output file is specified, the results are written to standard output.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/validate-acis --ldifFile test-acis.ldif --outputFile validated-acis.ldif
```

Result:

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

2. Open the output file and review the results.

Example:

For example, the `validated-acis.ldif` file generated in the previous step reads as follows.

```
# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr!="userPassword")
  (version 3.0; acl "Allow anonymous read access for anyone";
    allow (read,search,compare) userdn="ldap:///anyone";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

Example:

If the input file has any malformed access control instructions (ACIs), then the generated output file will show what was incorrectly entered. For example, if `userPassword` in the `test-acis.ldif` file does not have quotation marks around it, the output file reports an error. The following command uses the `--onlyReportErrors` option to write any error messages to the output file only if a malformed ACI syntax is encountered.

```
$ bin/validate-acis --ldifFIle test-acis.ldif --outputFile validated-acis.ldif \
  --onlyReportErrors
```

Result:

Copyright © 2025 Ping Identity Corporation

```
# Processing complete
# Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 1
# Other processing errors encountered: 0
```

The output file shows the following message.

```
# The following access control rule is malformed or contains an unsupported
# syntax: The provided string '(targetattr!=userPassword)(version 3.0; acl
# "Allow anonymous read access for anyone"; allow (read,search,compare)
# userdn="ldap:///anyone";)' could not be parsed as a valid Access Control
# Instruction (ACI) because it failed general ACI syntax evaluation
dn: dc=example,dc=com
aci: (targetattr!=userPassword)
  (version 3.0; acl "Allow anonymous read access for anyone";
    allow (read,search,compare) userdn="ldap:///anyone";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

Validating ACIs in another directory server

Use the `validate-acis` tool to examine access control instructions (ACIs) in data that exists in another directory server that you are planning to migrate to the current server.

About this task

The tool helps to determine whether the PingDirectory server accepts those ACIs.

Steps

- Run the `validate-acis` tool.

  Choose from:

  - UNIX or Linux: `bin/validate-acis`
  - Windows: `bat\validate-acis`

  Provide arguments that specify:

  - The address and port of the target PingDirectory server

Copyright © 2025 Ping Identity Corporation

- Credentials to use to bind
- The base DN of the subtree containing the ACIs to validate

Example:

```
$ bin/validate-acis
```

Result:

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

Migrating ACIs from Oracle to the PingDirectory server

This section describes the most important differences in access control evaluation between Oracle and the server.

Support for macro ACIs

Oracle supports macro access control instructions (ACIs), making it possible to define a single ACI that you can use to apply the same access restrictions to multiple branches in the same basic structure.

Macro ACIs are infrequently used and can cause severe performance degradation, so the server does not support them. However, you can achieve the same result by creating the same ACIs in each branch.

Support for the roleDN bind rule

Oracle roles are a proprietary, non-standard grouping mechanism that provide little value over standard grouping mechanisms.

The server does not support Oracle Directory Server Enterprise Edition (DSEE) roles and does not support the use of the `roleDN` ACI bind rule. However, you can achieve the same behavior by converting the DSEE roles to standard groups and using the `groupDN` ACI bind rule.

Targeting operational attributes

The Oracle access control model doesn't differentiate between user attributes and operational attributes.

In the Oracle access control model, using `targetattr="*"` automatically targets both user and operational attributes. Using an exclusion list like `targetattr!="userPassword"` automatically targets all operational attributes in addition to all user attributes except `userPassword`. This presents several significant security holes here users are unintentionally given access to operational attributes. In some cases, it could allow users to exempt themselves from password policy restrictions.

The server treats operational attributes differently from user attributes and never automatically includes operational attributes. For example, `targetattr="*"` targets all user attributes but no operational attributes, and `targetattr!="userPassword"` targets all user attributes except `userPassword` but no operational attributes.

Copyright © 2025 Ping Identity Corporation

You can target specific operational attributes by including the names in the list, such as `targetattr="creatorsName\|\|modifiersName"`. You can target all operational attributes by using the `""`` character. For example, [.codeph]``targetattr=""` targets all operational attributes but no user attributes, and `targetattr="*\|\|+"` targets all user and operational attributes.

Example

The following example searches for all immediate children of `ou=People,dc=example,dc=com`. The attributes returned are restricted to `sn`, `givenName`, and all operational attributes.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
     --baseDN ou=People,dc=example,dc=com --searchScope one '(objectclass=*)' \
     sn givenName "+"
```

Example

You can use compound filters to search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree. The following example limits the returned entry amount to 200, and the server will spend no more than 5 seconds processing the request.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
     --baseDN ou=People,dc=example,dc=com --searchScope sub --sizeLimit 200 \
     --timeLimit 5 "(&(sn<=Doe)(employeeNumber<=1000))" ds-entry-unique-id \
     entryUUID
```

Returning all user and operational attributes in a schema search

Specify `"*"` in a search attribute list to represent all user attributes. Specifying `"+"` retrieves all operational attributes.

About this task

The following standards are used in PingDirectory as part of the LDAP specification.

Standard	Overview
RFC 3673	Describes the use of `"+"` to represent all operational attributes
RFC 4511	Describes the use of `"*"` to represent all user attributes

Steps

- To search the `cn=schema` entry and return all user and operational attributes, run `ldapsearch`.

  Example:

  ```
  bin/ldapsearch --baseDN cn=schema --searchScope base "(objectclass=*)" "*" "+"
  ```

Copyright © 2025 Ping Identity Corporation

Exclude attributes

The accepts syntax, in addition to the RFC 3673, RFC 4511, and RFC 4529 standards, that allows you to exclude attributes from search results.

About this task

To exclude an attribute from the search results in PingDirectory:

Steps

- Prefix the attribute name with either `"^"` or `"!"`

  Example:

  The following example returns organizational units (OUs) that are part of the object class `group` in Colorado with the exception of OUs in Denver.

  ```
  (&(objectClass=group)(&(ou:dn:=Colorado)(!(ou:dn:=Denver))))
  ```

  Example:

  The following example returns all users that aren't `device`.

  ```
  (&(objectClass=user)(!(objectClass=device)))
  ```

  > **Note**
  >
  > To exclude all attributes associated with an object class, prefix the object class name with either `"^@"` or `"!@"`.

Returning all user and operational attributes in a schema search

Specify `"*"` in a search attribute list to represent all user attributes. Specifying `"+"` retrieves all operational attributes.

About this task

The following standards are used in PingDirectory as part of the LDAP specification.

Standard	Overview
RFC 3673	Describes the use of `"+"` to represent all operational attributes
RFC 4511	Describes the use of `"*"` to represent all user attributes

Steps

- To search the `cn=schema` entry and return all user and operational attributes, run `ldapsearch`.

  Example:

Copyright © 2025 Ping Identity Corporation

```
bin/ldapsearch --baseDN cn=schema --searchScope base "(objectclass=*)" "*" "+"
```

Exclude attributes

The accepts syntax, in addition to the RFC 3673, RFC 4511, and RFC 4529 standards, that allows you to exclude attributes from search results.

About this task

To exclude an attribute from the search results in PingDirectory:

Steps

- Prefix the attribute name with either `"^"` or `"!"`

  Example:

  The following example returns organizational units (OUs) that are part of the object class `group` in Colorado with the exception of OUs in Denver.

  ```
  (&(objectClass=group)(&(ou:dn:=Colorado)(!(ou:dn:=Denver))))
  ```

  Example:

  The following example returns all users that aren't `device`.

  ```
  (&(objectClass=user)(!(objectClass=device)))
  ```

  > **Note**
  >
  > To exclude all attributes associated with an object class, prefix the object class name with either `"^@"` or `"!@"`.

Specification of global ACIs

Both Oracle Directory Server Enterprise Edition (DSEE) and the server support global ACIs, which you can use to define ACIs that apply throughout the server.

In servers with multiple naming contexts, this feature allows you to define a rule once as a global ACI rather than maintaining an identical rule in each naming context.

In DSEE, global ACIs are created by modifying the root DSA-specific entry (DSE) to add values of the `aci` attribute. In the server, you manage global ACIs with `dsconfig` referenced in the `global-aci` property of the access control handler.

Defining ACIs for non-user content

In Oracle Directory Server Enterprise Edition (DSEE), you can write to the following backends to define ACIs:

- Configuration
- Monitor

Copyright © 2025 Ping Identity Corporation

- Changelog
- Tasks

In the server, you should define access control for private backends as global ACIs, such as the following backends:

- Configuration
- Monitor
- Schema
- Changelog
- Tasks
- Encryption settings
- Backups
- Alerts

Limiting access to controls and extended operations

Oracle Directory Server Enterprise Edition (DSEE) provides limited support for restricting access to controls and extended operations.

To the extent that you can control access to controls and extended operations with access control instructions (ACIs), DSEE defines entries with a distinguished name (DN), such as `oid={oid},cn=features,cn=config`, where `{oid}` is the OID of the associated control or extended operation. For example, the following DSEE entry defines ACIs for the persistent search control.

```
oid=2.16.840.1.113730.3.4.3,cn=features,cn=config
```

In the server, you can use the `targetcontrol` keyword to define ACIs that grant or deny access to controls. You can use the `extop` keyword to define ACIs that grant or deny access to extended operation requests.

Tolerance for malformed ACI values

If the server is running with less than the intended set of access control instructions (ACIs), it might prevent access to data that should be allowed or grant access to data that should be restricted. In Oracle Directory Server Enterprise Edition (DSEE), if the server encounters a malformed access control rule (ACR), it ignores the rule. This can cause the server to run with less than the intended set of ACIs. To guard against this, the server is more strict about the ACRs that it accepts.

When performing an LDIF import, the server rejects any entry containing a malformed or unsupported ACR. The server also rejects any `add` or `modify` request that attempts to create an invalid ACI.

In the unlikely event that a malformed ACI is accepted into the data, the server immediately places itself in lockdown mode. In lockdown mode, the server terminates connections and rejects requests from users without the `lockdown-mode` privilege. Lockdown mode allows an administrator to correct the problem without risking exposure to user data.

> **Note**
>
> To review any rejected ACIs, run the **`import-ldif`** tool with the `--rejectFile` option.

Copyright © 2025 Ping Identity Corporation

About the privilege subsystem

In Oracle Directory Server Enterprise Edition (DSEE), only the root user is exempt from access control evaluation.

While administrators can create access control instructions (ACIs) that give normal users full access to any content, they can also create ACIs that would make a portion of the data inaccessible to those users. Additionally, some tasks can only be accomplished by the root user and the capabilities assigned to the root user can't be restricted.

The server uses a privilege subsystem to control the capabilities available to various users. Non-root users can be granted limited access to certain administrative capabilities, and restrictions can be enforced on root users. Additionally, certain risky actions require that the requester have certain privileges in addition to the sufficient access control rights to process the operation.

These risky actions include:

- Interacting with the server configuration
- Changing another user's password
- Impersonating another user
- Shutting down and restarting the server

Identifying unsupported ACIs

To determine whether access control instructions (ACIs) are suitable for use, the server provides a `validate-acis` tool that you can use to examine content in an LDIF file or data in another directory server, such as an Oracle Directory Server Enterprise Edition (DSEE) instance.

When migrating data from a DSEE deployment into a server instance, use the `validate-acis` tool to determine whether ACIs contained in the data are acceptable. If any problems exist, update the data to redefine the ACIs so they are suitable for use in the server.

For more information, see Validating ACIs before migrating data.

Targeting operational attributes

The Oracle access control model doesn't differentiate between user attributes and operational attributes.

In the Oracle access control model, using `targetattr="*"` automatically targets both user and operational attributes. Using an exclusion list like `targetattr!="userPassword"` automatically targets all operational attributes in addition to all user attributes except `userPassword`. This presents several significant security holes here users are unintentionally given access to operational attributes. In some cases, it could allow users to exempt themselves from password policy restrictions.

The server treats operational attributes differently from user attributes and never automatically includes operational attributes. For example, `targetattr="*"` targets all user attributes but no operational attributes, and `targetattr!="userPassword"` targets all user attributes except `userPassword` but no operational attributes.

You can target specific operational attributes by including the names in the list, such as `targetattr="creatorsName\|\|modifiersName"`. You can target all operational attributes by using the `""`` character. For example, [.codeph]``targetattr=""` targets all operational attributes but no user attributes, and `targetattr="*\|\|+"` targets all user and operational attributes.

Copyright © 2025 Ping Identity Corporation

Example

The following example searches for all immediate children of `ou=People,dc=example,dc=com`. The attributes returned are restricted to `sn`, `givenName`, and all operational attributes.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
     --baseDN ou=People,dc=example,dc=com --searchScope one '(objectclass=*)' \
     sn givenName "+"
```

Example

You can use compound filters to search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree. The following example limits the returned entry amount to 200, and the server will spend no more than 5 seconds processing the request.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
     --baseDN ou=People,dc=example,dc=com --searchScope sub --sizeLimit 200 \
     --timeLimit 5 "(&(sn<=Doe)(employeeNumber<=1000))" ds-entry-unique-id \
     entryUUID
```

Returning all user and operational attributes in a schema search

Specify `"*"` in a search attribute list to represent all user attributes. Specifying `"+"` retrieves all operational attributes.

About this task

The following standards are used in PingDirectory as part of the LDAP specification.

Standard	Overview
RFC 3673	Describes the use of `"+"` to represent all operational attributes
RFC 4511	Describes the use of `"*"` to represent all user attributes

Steps

- To search the `cn=schema` entry and return all user and operational attributes, run `ldapsearch`.

  Example:

  ```
  bin/ldapsearch --baseDN cn=schema --searchScope base "(objectclass=*)" "*" "+"
  ```

Exclude attributes

The accepts syntax, in addition to the RFC 3673, RFC 4511, and RFC 4529 standards, that allows you to exclude attributes from search results.

About this task

To exclude an attribute from the search results in PingDirectory:

Copyright © 2025 Ping Identity Corporation

Steps

- Prefix the attribute name with either `"^"` or `"!"`

  Example:

  The following example returns organizational units (OUs) that are part of the object class `group` in Colorado with the exception of OUs in Denver.

  ```
  (&(objectClass=group)(&(ou:dn:=Colorado)(!(ou:dn:=Denver))))
  ```

  Example:

  The following example returns all users that aren't `device`.

  ```
  (&(objectClass=user)(!(objectClass=device)))
  ```

  > **Note**
  >
  > To exclude all attributes associated with an object class, prefix the object class name with either `"^@"` or `"!@"`.

Working with privileges

In addition to the access control implementation, the server includes a privilege subsystem that you can use to control what users are allowed to do.

The privilege subsystem works in conjunction with the access control subsystem to only allow privileged operations that are permitted by the access control configuration. The user must also have all of the necessary privileges.

You can use privileges to grant normal users the ability to perform certain tasks that, in most other directories, would only be allowed for the root user. The capabilities given to root users in the server are all granted through privileges, so you can create a normal user account with the ability to perform the same actions as root users.

Administrators can also remove privileges from root users so that they are unable to perform certain types of operations. To restrict root users to only the tasks that they must perform, define multiple root users in the server with different sets of privileges.

Available privileges

The following privileges are defined in the server.

Summary of Privileges

Privilege	Description
`audit-data-security`	This privilege is required to initiate a data security audit on the server, which is invoked by the `audit-data-security` tool.

Copyright © 2025 Ping Identity Corporation

Privilege	Description
`backend-backup`	This privilege is required to initiate an online backup through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
`backend-restore`	This privilege is required to initiate an online restore through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
`bypass-acl`	This privilege allows a user to bypass access control evaluation. For a user with this privilege, any access control determination made by the server immediately returns that the operation is allowed. **Note** This does not bypass privilege evaluation, so the user must have the appropriate set of additional privileges to be able to perform any privileged operation. For example, a user with the `bypass-acl` privilege but without the `config-read` privilege is not allowed to access the server configuration.
`bypass-pw-policy`	This privilege allows a user entry to bypass password policy evaluation. This privilege is intended for cases where external synchronization might require passwords that violate the password validation rules. The privilege is also evaluated for bind operations, meaning password restrictions are also bypassed when binding as a user who has this privilege.
`bypass-read-acl`	This privilege allows the associated user to bypass access control checks performed by the server for bind, search, and compare operations. Access control evaluation can still be enforced for other types of operations.
`config-read`	This privilege is required for a user to access the server configuration. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to see.
`config-write`	This privilege is required for a user to alter the server configuration. The user must also have the `config-read` privilege. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to alter.
`disconnect-client`	This privilege is required for a user to request that an existing client connection be terminated. The connection is terminated through the disconnect client task. The server's access control configuration must also allow the user to add the corresponding entry to the tasks backend.
`jmx-notify`	This privilege is required for a user to subscribe to Java Management Extensions (JMX) notifications generated by the server. The user is also required to have the `jmx-read` privilege.
`jmx-read`	This privilege is required for a user to access any information provided by the server through the JMX.

Copyright © 2025 Ping Identity Corporation

Privilege	Description
`jmx-write`	This privilege is required for a user to update any information exposed by the server through the JMX. The user is also required to have the `jmx-read` privilege. **Note** Currently, all of the information exposed by the server over JMX is read-only.
`ldif-export`	This privilege is required to initiate an online LDIF export through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, you can set up a global access control instruction (ACI) that allows access to members of an Administrators group.
`ldif-import`	This privilege is required to initiate an online LDIF import through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, configure the global ACI as described in the previous description of the `ldif-export` privilege.
`lockdown-mode`	This privilege allows the associated user to request that the server enter or leave lockdown mode, or to perform operations while the server is in lockdown mode.
`modify-acl`	This privilege is required for a user to add, modify, or remove access control rules defined in the server. The server's access control configuration must also allow the user to make the corresponding change to the `aci` operational attribute.
`password-reset`	This privilege is required for one user to be allowed to change another user's password. This privilege is not required for a user to be allowed to change his or her own password. The user must also have the access control instruction privilege to write the `userPassword` attribute to the target entry.
`privilege-change`	This privilege is required for a user to change the set of privileges assigned to a user, including the set of privileges, which are automatically granted to root users. The server's access control configuration must also allow the user to make the corresponding change to the `ds-privilege-name` operational attribute.
`proxied-auth`	This privilege is required for a user to request that an operation be performed with an alternate authorization identity. This privilege bears some security risk, because it allows users to inherit the level of access of any user, including root users and administrators. Consider restricting proxy users as described in the section Restricting proxy users.
`server-restart`	This privilege is required to initiate a server restart through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
`server-shutdown`	This privilege is required to initiate a server shutdown through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
`soft-delete-read`	This privilege is required for a user to access a soft-deleted-entry.

Copyright © 2025 Ping Identity Corporation

Privilege	Description
`stream-values`	This privilege is required for a user to perform a stream values extended operation, which obtains all entry distinguished names (DNs) and all values for one or more attributes for a specified portion of the directory information tree (DIT).
`unindexed-search`	This privilege is required for a user to be able to perform a search operation in which a reasonable set of candidate entries cannot be determined using the defined index and instead, a significant portion of the database needs to be traversed to identify matching entries. The server's access control configuration must also allow the user to request the search.
`update-schema`	This privilege is required for a user to modify the server schema. The server's access control configuration must allow the user to update the operational attributes that contain the schema elements.

Privileges automatically granted to root users

The special abilities that root users have are granted through privileges.

You can assign privileges to root users in two ways:

- By default, root users can be granted a specified set of privileges.

  > **Note**
  >
  > You can create root users which are not automatically granted these privileges by including the `ds-cfg-inherit-default-root-privileges` attribute with a value of `FALSE` in the entries for those root users.

- You can grant additional privileges to individual root users and remove some automatically-granted privileges from individual root users.

The `default-root-privilege-name` property of the root distinguished name (DN) configuration object controls the set of privileges that are automatically granted to root users. By default, these privileges include:

- `audit-data-security`
- `backend-backup`
- `backend-restore`
- `bypass-acl`
- `config-read`
- `config-write`
- `disconnect-client`
- `ldif-export`
- `lockdown-mode`
- `manage-topology`

Copyright © 2025 Ping Identity Corporation

- `metrics-read`
- `modify-acl`
- `password-reset`
- `permit-get-password-policy-state-issues`
- `privilege-change`
- `server-restart`
- `server-shutdown`
- `soft-delete-read`
- `stream-values`
- `unindexed-search`
- `update-schema`

The privileges not granted to root users by default include:

- `bypass-pw-policy`
- `bypass-read-acl`
- `jmx-read`
- `jmx-write`
- `jmx-notify`
- `permit-externally-processed-authentication`
- `permit-proxied-mschapv2-details`
- `proxied-auth`

You can change the set of default root privileges to add or remove values as necessary. This requires the `config-read`, `config-write`, and `privilege-change` privileges, and either the `bypass-acl` privilege or sufficient permission granted by the access control configuration to change the server's configuration.

Assigning additional privileges for administrators

Steps

- **To allow access to the Tasks backend, set up a global access control instruction (ACI) using `dsconfig` that allows access to members of an Administrators group.**

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ dsconfig set-access-control-handler-prop \
  --add 'global-aci:(target="ldap:///cn=tasks")(targetattr="*||+")
        (version 3.0; acl "Access to the tasks backend for administrators";
         allow (all) groupdn="ldap:///
         cn=admins,ou=groups,dc=example,dc=com";)'
```

Assigning privileges to normal users and individual root users

You can grant privileges to normal users on an individual basis.

Add the `ds-privilege-name` operational attribute to the user's entry with the names of the desired privileges. For example, the following change grants the `proxied-auth` privilege to the `uid=proxy,dc=example,dc=com` account.

```
dn: uid=proxy,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: proxied-auth
```

The user making this change must have the `privilege-change` privilege, and the server's access control configuration must also allow the requester to write to the `ds-privilege-name` attribute in the target user's entry.

You can use the same method to grant root users privileges that aren't included in the set of default root privileges. You can also remove default root privileges from root users by prefixing the name of the privilege to remove with a minus sign. For example, the following change grants a root user the `jmx-read` privilege in addition to the set of default root privileges and removes the `server-restart` and `server-shutdown` privileges.

```
dn: cn=Sync Root User,cn=Root DNs,cn=config
changetype: modify
add: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: -server-restart
ds-privilege-name: -server-shutdown
```

> **Note**
>
> Because root user entries exist in the configuration, this update requires the `config-read` and `config-write` privileges in addition to the `privilege-change` privilege.

Disabling privileges

Although the privilege subsystem in the server is a powerful feature, it might break some applications if they expect to perform an operation requiring a privilege that they do not have.

In the majority of these cases, you can assign the necessary privilege manually to the account used by that application. However, if this workaround isn't sufficient, or if you need to remove a particular privilege, such as allowing anyone to access information through Java Management Extensions (JMX) without requiring the `jmx-read` privilege, then you can disable privileges on an individual basis.

The `disabled-privilege` property in the global configuration object controls the set of disabled privileges. By default, no privileges are disabled. If a privilege is disabled, then the server behaves as if all users have that privilege.

Deploying a standard PingDirectoryProxy server

You can deploy a PingDirectoryProxy server in a variety of ways depending on the needs of your enterprise.

This section describes and illustrates a standard deployment scenario and includes the following topics:

- Introduction
- Automatic server discovery
- Creating a standard multi-location deployment
- Expanding the deployment
- Merging two data sets using proxy transformations

Introduction

Derived from the words development and operations, the term DevOps refers to the practices that a company follows to ensure the production of high-quality products while also minimizing the amount of time between the commitment of a system change and the implementation of that change in a production environment.

Most companies practice one of the following service models:

Pets

With the pets service model, servers are built and managed manually and are treated as unique and indispensable. Examples include mainframes, database systems, and load balancers.

Cattle

With the cattle service model, arrays of multiple replaceable servers are built with automated tools. During a failure event, an array automatically restarts failed services and replicates data. Examples include web server arrays, search clusters, and multi-primary datastores.

Historically, servers have been treated like pets. The failure of one or multiple servers was often viewed as an emergency, and extensive resources were usually required to repair the damage. In the new DevOps paradigm, servers are recognized as dispensable and treated like cattle. When a server fails, the infrastructure replaces it immediately, configuring the replacement server identically to the failed one. Because no human intervention is required to fix them, the servers are considered self-healing.

To help treat your servers more like cattle than pets, PingDirectoryProxy server supports server profiles and features like topology-management tools. For example, the `manage-profile setup` represents a single command that performs all the steps from the pet service model on a `server-profile` directory, a well-defined directory structure with all the necessary server configuration bits. Similarly, the `manage-profile replace-profile` command performs similar steps with a single command invocation after a server is updated to a new version.

The scripts in the `server-profile` directory are declarative of the environment. What you define in the `server-profile` directory is what you get on the servers. No one needs to identify a server's current configuration and compute the differences that must be applied to attain the appropriate end state.

Copyright © 2025 Ping Identity Corporation

Before server profiles, this problem was difficult to address, especially where no history was available. In such scenarios, an administrator might have needed to obtain the current configuration from the servers, to manually compute the difference between the current and desired configuration, and to apply the configuration changes, hoping that nobody had changed the configuration during the process.

Server profiles eliminate this procedural approach to applying configuration changes, and they simplify the steps associated with determining what's deployed in an environment. For more information on server profiles, see Server profiles.

Another principle that relates closely to DevOps is infrastructure as code (IaC), the concept of managing your operations in the same manner as your application and other code for general release with proper versioning, continuous integration, quality control, and release cycles. Customers who deploy PingDirectoryProxy servers as pets today can take advantage of current DevOps and IaC principles to turn them into cattle.

Automatic server discovery

Version 8.3 supports the use of information in the topology registry to automatically discover the backend PingDirectory server instances to which requests might be forwarded.

This is an alternative to explicitly configuring the PingDirectoryProxy server with the backend servers that should be used. This option is only available if all of the backend servers are PingDirectory server instances and only if the following are true:

- The PingDirectoryProxy server must be a member of the same topology as the PingDirectory server instances to which requests will be forwarded.
- The PingDirectoryProxy server must be configured with an LDAP external server template that provides the settings to use when communicating with dynamically discovered backend PingDirectory server instances.
- The PingDirectoryProxy server's load-balancing algorithms must be configured to use the desired LDAP external server template.
- The topology registry entries for each PingDirectory server instance must be updated to indicate which of the PingDirectoryProxy server's load-balancing algorithms can forward requests to the server.

> **Note**
>
> When using automatic server discovery, you don't need to run the `prepare-external-server` command. Servers do not need a service account and associated ACIs before discovery since the inter-server bind process is used to initiate communication. The server is identified using information contained in the topology registry and is given appropriate privileges during the inter-server bind process.

Joining a PingDirectoryProxy server to an existing PingDirectory server topology

PingDirectory server 8.0.0.0 supports the addition of PingDirectoryProxy server instances to the same topology as the PingDirectory server instances.

You can do this when the PingDirectoryProxy server instance is initially configured using either the setup utility (in either interactive or non-interactive mode) or the `manage-profile setup` command. You can do this later using the `manage-topology add-server` command.

Copyright © 2025 Ping Identity Corporation

Joining a topology with interactive setup

If you run `setup` without any arguments, it starts in interactive mode and prompts you for all of the necessary information. After you accept the license, the next prompt asks if you want to add the server to an existing Directory server topology.

If you have at least one PingDirectoryProxy server instance that is already in the desired topology, you can enter `yes` at this prompt and it walks you through the process of creating a new instance that is a copy of the existing instance (with all of the same configuration). You are then asked for the information needed to connect and authenticate to the existing PingDirectoryProxy server instance, as shown in the following example.

Copyright © 2025 Ping Identity Corporation

```
Do you accept the terms of this license agreement?  Enter 'yes' to accept,
'no' to reject, or press ENTER to display the next page of the agreement []: yes

Would you like to add this server to an existing Directory Proxy Server
topology? (yes / no) [no]: yes

Enter the host name of the peer Directory Proxy Server from which you would
like to copy configuration settings. [proxy2.example.com]: proxy1.example.com

Enter the LDAP port of the peer Directory Proxy Server [389]: 636

How would you like to connect to the peer Directory Proxy Server?

    1)  None
    2)  SSL
    3)  StartTLS

Enter option [1]: 2

Enter the manager account DN for the peer Directory Proxy Server [cn=Directory
Manager]: cn=Directory Manager

Enter the password for cn=Directory Manager:
The server presented the following certificate chain:

     Subject: CN=proxy1.example.com,O=Example Corp,C=US
     Valid From: Saturday, November 2, 2019 at 10:34:09 PM CDT
     Valid Until: Sunday, November 1, 2020 at 09:34:09 PM CST
     SHA-1 Fingerprint: 54:7f:6c:c1:99:73:c4:19:66:6e:da:4b:ee:a9:d5:62:24:2e:ba:41
     256-bit SHA-2 Fingerprint: 54:ce:59:c5:25:85:95:17:17:69:e0:5c:57:9e:ed:27:3d:af:9c:bd:

65:f1:1f:4e:26:f0:89:a3

Do you wish to trust this certificate?  Enter 'y' or 'n': y

Initializing ..... Done
Reading Peer Configuration ..... Done
Connecting to 'proxy1' ..... Done
```

However, cloning an existing installation isn't possible when setting up the first PingDirectoryProxy server instance.

In this case, if you enter `no` at the prompt to join an existing PingDirectoryProxy server topology, setup asks if you want to join a PingDirectory server topology instead. If you enter `yes`, the process is basically the same as joining an existing directory server topology, and you are prompted for the information needed to connect and authenticate to a PingDirectory server instance in the topology. The primary difference is that you have to define the PingDirectoryProxy server configuration yourself, as shown in the following example.

Copyright © 2025 Ping Identity Corporation

```
Do you accept the terms of this license agreement?  Enter 'yes' to accept,
'no' to reject, or press ENTER to display the next page of the agreement []: yes

Would you like to add this server to an existing Directory Proxy Server
topology? (yes / no) [no]: no

Would you like to add this server to an existing PingDirectory server topology
to enable automatic backend server discovery? (yes / no) [no]: yes

Enter the host name of a PingDirectory server instance in the topology to
join. [proxy1.example.com]: ds1.example.com

```

Joining a topology with non-interactive setup

About this task

Interactive mode is a convenient method to get the server up and running when you're just getting started, but the installation process for production deployments is generally scripted. For this process, non-interactive mode is a better choice and setup offers several useful arguments.

Copyright © 2025 Ping Identity Corporation

To join a topology with non-interactive setup:

Steps

- Run `setup`:

  Choose from:

  - Use the following arguments to join an existing PingDirectory server topology:

    `--existingDSTopologyHostName {address}`

    The address of a PingDirectory server instance in the topology to be joined.

    `--existingDSTopologyPort {port}`

    The port for communication with the PingDirectory server to retrieve information about the topology.

    `--existingDSTopologyUseSSL`

    Indicates that the communication with the PingDirectory server to retrieve information about the topology should be encrypted with SSL.

    `--existingDSTopologyUseStartTLS`

    Indicates that the communication with the PingDirectory server to retrieve information about the topology should be encrypted with the StartTLS extended operation.

    `--existingDSTopologyUseNoSecurity`

    Indicates that the communication with the PingDirectory server to retrieve information about the topology should be not be encrypted.

    `--existingDSTopologyUseJavaTruststore {path}`

    The path to a JKS trust store that has the information needed to trust the certificate presented by the PingDirectory server when using SSL or StartTLS.

    `--existingDSTopologyUsePkcs12Truststore {path}`

    The path to a PKCS #12 trust store that has the information needed to trust the certificate presented by the PingDirectory server when using SSL or StartTLS.

    `--existingDSTopologyTrustStorePassword {password}`

    The password needed to access the contents of the JKS or PKCS #12 trust store. A password is typically required when using a PKCS #12 trust store but is optional when using a JKS trust store.

    `--existingDSTopologyTrustStorePasswordFile {path}`

    The path to a file containing the password needed to access the contents of the JKS or PKCS #12 trust store.

Copyright © 2025 Ping Identity Corporation

`--existingDSTopologyBindDN {path}`

The DN of the account to use to authenticate to the PingDirectory server. This account must have full read and write access to the configuration and to manage the topology.

`--existingDSTopologyBindPassword {password}`

The password for the account to use to authenticate to the PingDirectory server.

`--existingDSTopologyBindPasswordFile {path}`

The path to a file containing the password to use to authenticate to the PingDirectory server.

For example, you can use a command similar to the following to set up a PingDirectoryProxy server instance in the same topology as a PingDirectory server instance.

```
$ ./setup --acceptLicense \
     --licenseKeyFile PingDirectory.lic
     --maxHeapSize 2g \
     --localHostName proxy1.example.com \
     --skipHostnameCheck \
     --instanceName proxy1 \
     --location Austin \
     --rootUserDN "cn=Directory Manager" \
     --rootUserPasswordFile directory-manager-password.txt \
     --ldapPort 389 \
     --ldapsPort 636 \
     --httpsPort 443 \
     --enableStartTLS \
     --useJavaKeyStore config/keystore \
     --keyStorePasswordFile config/keystore.pin \
     --certNickname server-cert \
     --useJavaTrustStore config/truststore \
     --trustStorePasswordFile config/truststore.pin \
     --encryptDataWithPassphraseFromFile encryption-passphrase.txt \
     --existingDSTopologyHostName ds1.example.com \
     --existingDSTopologyPort 636 \
     --existingDSTopologyBindDN "cn=Directory Manager" \
     --existingDSTopologyBindPasswordFile directory-manager-password.txt \
     --existingDSTopologyUseSSL \
     --existingDSTopologyUseJavaTrustStore config/truststore \
     --no-prompt
```

- Use the following arguments to clone the configuration of an existing PingDirectoryProxy server instance, including joining the same topology as the existing instance:

`--peerHostName {address}`

The address of a PingDirectoryProxy server instance whose configuration should be cloned and whose topology should be joined.

`--peerPort {port}`

The port communication with the PingDirectoryProxy server to retrieve the configuration and topology information.

Copyright © 2025 Ping Identity Corporation

`--peerUseSSL`

Indicates that communication with the PingDirectoryProxy server to retrieve configuration and topology information should be encrypted with SSL.

`--peerUseStartTLS`

Indicates that communication with the PingDirectoryProxy server to retrieve configuration and topology information should be encrypted with the StartTLS extended operation.

`--peerUseNoSecurity`

Indicates that communication with the PingDirectoryProxy server to retrieve configuration and topology information should not be encrypted.

> **Note**
>
> When using SSL or StartTLS to encrypt the communication, you also need to use one of the `--useJavaTruststore` or `--usePkcs12Truststore` arguments to specify the path to a trust store with the information needed to trust the certificate that is presented by the PingDirectoryProxy server.

The following is an example of a sample command to set up a new PingDirectoryProxy server as a clone of an existing PingDirectoryProxy server instance.

```
$ ./setup --acceptLicense \
     --licenseKeyFile PingDirectory.lic
     --maxHeapSize 2g \
     --localHostName proxy2.example.com \
     --skipHostnameCheck \
     --instanceName proxy2 \
     --location Austin \
     --rootUserDN "cn=Directory Manager" \
     --rootUserPasswordFile directory-manager-password.txt \
     --ldapPort 389 \
     --ldapsPort 636 \
     --httpsPort 443 \
     --enableStartTLS \
     --useJavaKeyStore config/keystore \
     --keyStorePasswordFile config/keystore.pin \
     --certNickname server-cert \
     --useJavaTrustStore config/truststore \
     --trustStorePasswordFile config/truststore.pin \
     --encryptDataWithPassphraseFromFile encryption-passphrase.txt \
     --peerHostName proxy1.example.com \
     --peerPort 636 \
     --peerUseSSL \
     --no-prompt
```

Joining a topology with manage-profile setup

About this task

Copyright © 2025 Ping Identity Corporation

You can use the `manage-profile` tool to set up an instance of the server from information contained in a server profile. This tool invokes `setup` and performs other tasks, such as applying configuration changes, installing schema and extensions, and adding files to the server root.

Steps

1. Place an appropriate set of arguments in the `setup-arguments.txt` file in the root directory of the profile, along with all of the other arguments that should be used when invoking `setup`.

   Because `manage-profile setup` uses the setup tool in non-interactive mode, you should use the arguments listed in the previous section, including:

   - `--existingDSTopologyHostName {address}`
   - `--existingDSTopologyPort {port}`
   - `--existingDSTopologyUseSSL`
   - `--existingDSTopologyUseStartTLS`
   - `--existingDSTopologyUseNoSecurity`
   - `--existingDSTopologyUseJavaTruststore {path}`
   - `--existingDSTopologyUsePkcs12Truststore {path}`
   - `--existingDSTopologyTrustStorePassword {password}`
   - `--existingDSTopologyTrustStorePasswordFile {path}`
   - `--existingDSTopologyBindDN {path}`
   - `--existingDSTopologyBindPassword {password}`
   - `--existingDSTopologyBindPasswordFile {path}`

   > **Note**
   >
   > Unlike the `setup` utility, `manage-profile setup` does not support cloning an existing PingDirectoryProxy server instance, so the `--peerHostName`, `--peerPort`, and other related arguments cannot be included in the `setup-arguments.txt` file.

2. Run `manage-profile setup`.
3. If you have already set up an instance of the server, run `manage-profile generate-profile` to generate a profile from the information contained in that instance.

   If the server was added to the topology during the setup process, the generated profile includes an appropriate set of arguments for joining the same topology.

Joining a topology with manage-topology add-server

Steps

- Use the `manage-topology add-server` command to add a PingDirectoryProxy server instance to a topology after it has been installed.

Copyright © 2025 Ping Identity Corporation

You can only do this if the PingDirectoryProxy server instance is not already part of any other topology, since it is not possible to join two topologies together. This tool supports all of the normal arguments for connecting and authenticating to the local server instance, including the following:

- `--hostname` *{address}*
- `--port` *{port}*
- `--useSSL`
- `--useStartTLS`
- `--trustStorePath` *{path}*
- `--trustStorePassword` *{password}*
- `--trustStorePasswordFile` *{path}*
- `--bindDN` *{dn}*
- `--bindPassword` *{password}*
- `--bindPasswordFile` *{path}*

The `manage-topology add-server` command also allows the following arguments to provide information about a server in the topology to be joined:

`--remoteServerHostname {address}`

The address of a server in the topology to be joined.

`--remoteServerPort {port}`

The port for communication with the remote server.

`--remoteServerConnectionSecurity` *{noSecurity|useSSL|useStartTLS}*

The type of security to use when communicating with the remote server. This value must be one of the following:

- `useSSL`, to indicate that the communication should be encrypted with SSL
- `useStartTLS`, to indicate that the communication should be encrypted with the StartTLS extended operation
- `noSecurity`, to indicate that the communication should not be encrypted

`--remoteServerBindDN {dn}`

The DN of the account to use to authenticate to the remote server.

`--remoteServerBindPassword {password}`

The password for the account to use to authenticate to the remote server.

Copyright © 2025 Ping Identity Corporation

`--remoteServerBindPasswordFile {path}`

The path to a file containing the password for the account to use to authenticate to the remote server.

Example:

Use a command similar to the following to add a PingDirectoryProxy server to an existing PingDirectory server topology.

```
$ bin/manage-topology add-server \
     --hostname proxy1.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore \
     --bindDN "cn=Directory Manager" \
     --bindPasswordFile directory-manager-password.txt \
     --remoteServerHostname ds1.example.com \
     --remoteServerPort 636 \
     --remoteServerConnectionSecurity useSSL \
     --remoteServerBindDN "cn=Directory Manager" \
     --remoteServerBindPasswordFile directory-manager-password.txt
```

Creating an LDAP external server template

An LDAP external server template is a configuration object that can be used to provide a load-balancing algorithm with many of the settings that it should use when communicating with a backend server that has been discovered from the topology registry.

An LDAP external server template configuration object has most of the same properties as an LDAP external server configuration object but omits those related to information that it obtains from the topology registry. The omitted properties include:

- `server-host-name`
- `server-port`
- `location`
- `connection-security`

Additionally, the `health-check-state` property is not available for LDAP external server templates because it primarily applies to individual servers rather than all of the servers associated with a load-balancing algorithm.

Because the only LDAP servers which can be in the topology registry are PingDirectory servers, most of the remaining properties in LDAP external server templates have the same default values as the corresponding properties in the PingDirectory server external server type. However, there are exceptions, including the following:

- The `authentication-method` property has a default value of `inter-server` in LDAP external server templates while it has a default value of `simple` in PingDirectory server external servers. The `inter-server` authentication type indicates that the PingDirectoryProxy server should authenticate to the PingDirectory server with a proprietary authentication method that uses inter-server certificates stored in the topology registry.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> This option is only supported if all of the PingDirectory server instances are 8.0.0.0 or later.

- The `key-manager-provider` property has a default value of `Null` in LDAP external server templates, while it has no default value in PingDirectory server external servers. When using the inter-server authentication type, the topology registry is used to obtain the inter-server certificates, so no additional key manager provider is required.
- The `trust-manager-provider` property has a default value of `JVM-Default` in LDAP external server templates while it has no default value in PingDirectory server external servers. When using the inter-server authentication type, the topology registry is used to obtain information about the listener certificates that the servers are expected to present.

In many cases the PingDirectoryProxy server's default settings for an LDAP external server template are acceptable for most properties. However, you might want to add custom health checks that are invoked against servers created from the template. The PingDirectoryProxy server automatically checks to see whether the server reports any degraded or unavailable alert types, and also verifies that the backend server's root DSA-specific entry (DSE) is accessible in a timely manner, but you might want to add additional health checks including the following:

- A search health check that verifies that the base entry from the associated subtree view can be retrieved in a timely manner.
- A replication backlog health check that verifies that replication is working and that none of the servers is too far out of sync.

The following example demonstrates the process for creating these health checks and then creating an LDAP external server template that uses them.

```
# Create a health check to verify that the dc=example,dc=com entry can be
# retrieved in a timely manner.
dsconfig create-ldap-health-check \
     --check-name dc_example_dc_com-retrieve-base-entry \
     --type search \
     --set enabled:true \
     --set base-dn:dc=example,dc=com \
     --set allow-no-entries-returned:false \
     --set allow-multiple-entries-returned:false

# Create a health check to verify that replication is working without a
# significant backlog.
dsconfig create-ldap-health-check \
     --check-name dc_example_dc_com-replication-backlog \
     --type replication-backlog \
     --set enabled:true \
     --set base-dn:dc=example,dc=com

# Create an LDAP external server template with the above
dsconfig create-ldap-external-server-template \
     --template-name dc_example_dc_com \
     --set health-check:dc_example_dc_com-retrieve-base-entry \
     --set health-check:dc_example_dc_com-replication-backlog
```

Copyright © 2025 Ping Identity Corporation

Defining the load-balancing algorithm configuration

In versions earlier than 8.0.0.0, each load-balancing algorithm had to be explicitly configured with a set of backend servers. This is still supported and might be the preferred configuration in some cases.

For example, explicitly configured algorithms are required if any backend server is not a PingDirectory server or if it is a PingDirectory server version earlier than 8.0.0.0. It might also be preferable if you want to have more direct control over the configuration that the PingDirectoryProxy server uses for each backend server.

Beginning with 8.0.0.0, it is possible to configure the fewest operations and failover load-balancing algorithms so that they can automatically discover the appropriate set of backend servers from information in the topology registry. To do this, the load-balancing algorithm should be configured with a value for the `ldap-external-server-template` property rather than with one or more values for the `backend-server` property.

For example, the following configuration change can be used to create a fewest operations load-balancing algorithm that uses an LDAP external server template named `dc_example_dc_com`.

```
dsconfig create-load-balancing-algorithm \
     --algorithm-name fewest-operations-load-balancer \
     --type fewest-operations \
     --set enabled:true \
     --set ldap-external-server-template:dc_example_dc_com
```

You can use a similar change to create an instance of a failover load-balancing algorithm that automatically discovers its backend servers, as in the following example.

```
dsconfig create-load-balancing-algorithm \
     --algorithm-name failover-load-balancer \
     --type failover \
     --set enabled:true \
     --set ldap-external-server-template:dc_example_dc_com
```

Note

With the failover load-balancing algorithm, the backend servers are ordered lexicographically by instance name. This ensures that all PingDirectoryProxy server instances have a consistent ordering, but it is not as easy to control the ordering when automatically discovering backend servers as when they are explicitly configured. This is acceptable in many cases because the primary use of failover load-balancing is often to avoid replication and unique attribute conflicts for write operations, and potentially to avoid read-after-write issues. However, if you want to direct all traffic to a specific instance as long as it is available, then it might be better to explicitly configure the set of backend servers rather than use automatic discovery.

Copyright © 2025 Ping Identity Corporation

Although you can use just the fewest operations load-balancing algorithm or the failover load-balancing algorithm, you should use both of these together with failover load-balancing for writes and fewest operations for reads. When combined with the PingDirectory server's default use of assured replication (for all add, delete, and modify DN operations, as well as for modify operations that target passwords or password-related attributes) this provides an excellent balance that minimizes the chance for replication and unique attribute conflicts, minimizes the chance for read-after-write issues that result from propagation delay, and maximizes performance and minimizes response time for read operations. You can do this by using criteria-based load balancing, which involves the following:

- Creating a failover load-balancing algorithm instance for write operations
- Creating a fewest operations load-balancing algorithm instance for read operations
- Creating a criteria-based load-balancing algorithm instance that uses failover load-balancing for write operations
- Configuring the proxying request processor to use the above criteria-based load balancing algorithm for writes and the fewest operations load-balancing algorithm for everything else

The following is an example of this configuration.

Copyright © 2025 Ping Identity Corporation

```
# Create a health check to verify that the dc=example,dc=com entry can be
# retrieved in a timely manner.
dsconfig create-ldap-health-check \
     --check-name dc_example_dc_com-retrieve-base-entry \
     --type search \
     --set enabled:true \
     --set base-dn:dc=example,dc=com \
     --set allow-no-entries-returned:false \
     --set allow-multiple-entries-returned:false

# Create a health check to verify that replication is working without a
# significant backlog.
dsconfig create-ldap-health-check \
     --check-name dc_example_dc_com-replication-backlog \
     --type replication-backlog \
     --set enabled:true \
     --set base-dn:dc=example,dc=com

# Create an LDAP external server template with the above
dsconfig create-ldap-external-server-template \
     --template-name dc_example_dc_com \
     --set health-check:dc_example_dc_com-retrieve-base-entry \
     --set health-check:dc_example_dc_com-replication-backlog

# Create a fewest operations failover load-balancing algorithm instance that
# uses the default LDAP external server template for backend servers that it
# discovers from the topology registry.
dsconfig create-load-balancing-algorithm \
     --algorithm-name dc_example_dc_com-fewest-operations \
     --type fewest-operations \
     --set enabled:true \
     --set ldap-external-server-template:dc_example_dc_com

# Create a failover load-balancing algorithm instance that also uses the
# default LDAP external server template for backend servers that it
# discovers from the topology registry.
dsconfig create-load-balancing-algorithm \
     --algorithm-name dc_example_dc_com-failover \
     --type failover \
     --set enabled:true \
     --set ldap-external-server-template:dc_example_dc_com

# Create a criteria-based load-balancing algorithm instance that will use
# failover load-balancing for writes.
dsconfig create-criteria-based-load-balancing-algorithm \
     --algorithm-name failover-for-writes \
     --set load-balancing-algorithm:dc_example_dc_com-failover \
     --set "request-criteria:Write Requests"

# Create a proxying request processor instance that uses criteria-based load
# balancing to ensure that writes use a failover strategy, and the remaining
# read operations use a default fewest operations strategy.
dsconfig create-request-processor \
     --processor-name dc_example_dc_com \
```

Copyright © 2025 Ping Identity Corporation

```
     --type proxying \
     --set load-balancing-algorithm:dc_example_dc_com-fewest-operations \
     --set criteria-based-load-balancing-algorithm:failover-for-writes

# Create a subtree view to ensure that operations below "dc=example,dc=com"
# will use the above proxying request processor.
dsconfig create-subtree-view \
     --view-name dc_example_dc_com \
     --set "base-dn:dc=example,dc=com" \
     --set request-processor:dc_example_dc_com

# Update the default client connection policy to include the above subtree
# view.
dsconfig set-client-connection-policy-prop \
     --policy-name default \
     --add subtree-view:dc_example_dc_com
```

Associating PingDirectory server instances with the appropriate load-balancing algorithms

When the PingDirectory server is configured with an LDAP external server template, either the fewest operations algorithm or the failover load-balancing algorithm uses the topology registry to determine which PingDirectory server instances should be accessible through the server.

To accomplish this, the load-balancing algorithm searches for `directory-server-instance` objects with a `load-balancing-algorithm-name` property that matches the name of the load-balancing algorithm. For example, in the following sample configuration, the load-balancing algorithms are named `dc_example_dc_com-fewest-operations` and `dc_example_dc_com-failover`, so if you want a PingDirectory server instance to be accessible through those load-balancing algorithms, add those values to the `load-balancing-algorithm-name` property in the topology registry's entry for that instance. You can do this with a configuration change similar to the following.

```
dsconfig set-server-instance-prop \
     --instance-name ds1.example.com:636 \
     --add load-balancing-algorithm-name:dc_example_dc_com-fewest-operations \
     --add load-balancing-algorithm-name:dc_example_dc_com-failover
```

The PingDirectoryProxy Server automatically detects and reacts to applicable changes in the topology registry. This includes the following:

Adding a new PingDirectory server instance to the topology

If this instance has any `load-balancing-algorithm-name` values that match the names of any load-balancing algorithms that are configured for automatic backend server discovery, the new instance is immediately eligible to process client requests as soon as the instanced satisfies all of the configured health checks.

Removing an existing PingDirectory server instance

If this instance was associated with any load-balancing algorithms, then it is no longer eligible to receive requests through these load-balancing algorithms.

Copyright © 2025 Ping Identity Corporation

Modifying an existing PingDirectory server instance to add one or more values to the `load-balancing-algorithm-name` *property*

If any of the new values matches the name of any of the configured load-balancing algorithms, the instance is immediately eligible to process client requests.

Modifying an existing PingDirectory server instance to remove one or more values from the `load-balancing-algorithm-name` *property*

If any of the removed values matches the name of any of the configured load-balancing algorithms, then the instance is no longer eligible to receive requests through these load-balancing algorithms.

Automatic backend server discovery with entry balancing

Entry balancing allows directory data to be split across multiple mutually exclusive sets of backend servers.

This can provide better scalability by allowing a data set to be fully cached even if it is too large to fit in the memory of any single system. It can also provide better write performance by spreading entries into multiple independent replication sets.

Entry balancing breaks the data into backend sets. Each backend set has its own proxying request processor, which has its own load-balancing configuration which might optionally include criteria-based load balancing. Each of these load-balancing algorithms can be configured to use automatic backend set discovery in exactly the same way as in a non-entry-balanced configuration. The backend sets must be explicitly configured, but the servers within each set can be automatically determined from the information in the topology registry.

Creating a standard multi-location deployment

In this example deployment, the PingDirectoryProxy server will be deployed in the data centers of two geographic locations, east and west. All LDAP external servers in this deployment are PingDirectory servers.

The directory servers in the eastern city are assigned to the location named east, and the directory servers in the western city are assigned to the location named west.

> **Note**
>
> Password policies should be kept synchronized across all PingDirectory server and PingDirectoryProxy server instances. See the PingDirectory Server Administration Guide for details about configuring password policies.

This example refers to four PingDirectory server instances in two locations with replication of the `dc=example,dc=com` base distinguished name (DN) enabled:

- `ds-east-01.example.com`
- `ds-east-02.example.com`
- `ds-west-01.example.com`
- `ds-west-01.example.com`

Copyright © 2025 Ping Identity Corporation

You will configure four PingDirectoryProxy server instances:

- `proxy-east-01.example.com`
- `proxy-east-02.example.com`
- `proxy-west-01.example.com`
- `proxy-west-02.example.com`

Overview of the deployment steps

This deployment scenario involves the following procedure.

- Install the first PingDirectoryProxy server in the east location using the `setup` or `setup.bat` file included in the `.zip` installation file.
- Use the `create-initial-proxy-config` tool to provide a proxy user bind DN and password, define locations for each of our data centers, and configure the LDAP external servers in these data centers.
- Test that external server communications after initial setup is complete and test a simulated external server failure.
- Install the second proxy server in the east location using the `setup` or `setup.bat` file included in the zip installation file and copy the configuration of the first PingDirectoryProxy server using the configuration cloning feature.
- Install two PingDirectoryProxy server instances in the west location, which includes using the `setup` file and manually setting the location to west using the `dsconfig` command and then copying the configuration of the PingDirectoryProxy server using the configuration cloning feature.

After you have configured and tested the proxy server, tour the configuration of each of the proxy server components. You can modify these properties later as needed using the `dsconfig` tool.

Installing the first PingDirectoryProxy server

Install the first PingDirectoryProxy server from the `.zip` installation file.

About this task

To begin with, we have the PingDirectoryProxy installation `.zip` file. In this example, we plan to use SSL security, so we also have a key store certificate database and a `.pin` file that contains the private key password for the key store. The key store files are only necessary when using SSL or StartTLS.

In this deployment scenario, the key store database is assumed to be a Java KeyStore (JKS), which can be created by the keytool program.

The PingDirectoryProxy directory contains the following.

```
root@proxy-east-01: ls
ExampleKeystore.jks   ExampleTruststore.jks ExampleKeystore.pin
PingDirectoryProxy-8.0.0.0-with-je.zip
```

Copyright © 2025 Ping Identity Corporation

The `ExampleKeystore.jks` key store file contains the private key entry for the `proxy-east-01.example.com` server certificate with the alias `server-cert`. The server certificate, certificate authority (CA), and intermediate signing certificates are all contained in the `ExampleTruststore.jks` file. The password for `ExampleKeystore.jks` is defined in clear text in the corresponding `.pin` file, though the name of the file need not match as it does in this example. The private key password in this example is the same as the password defined for the `ExampleKeystore.jks` key store.

Steps

1. Extract the compressed archive file into the PingDirectoryProxy directory and change to this directory.

   Example:

   ```
   root@proxy-east-01: unzip -q PingDirectoryProxy-<version>-with-je.zip
   root@proxy-east-01: cd PingDirectoryProxy
   ```

2. Copy the key store and `.pin` files into the `config` directory.

   Example:

   ```
   root@proxy-east01: cp ../Keystore config/
   root@proxy-east01: cp ../Truststore config/
   ```

3. Install the first proxy server by running the `setup` tool on `proxy-east-01.example.com`.

   Example:

   ```
   root@proxy-east01: ./setup --no-prompt --acceptLicense \
   --ldapPort 389 --rootUserPassword pass \
   --maxHeapSize 1g --enableStartTLS --ldapsPort 636 \
   --useJavaKeystore config/ExampleKeystore.jks \
   --keyStorePasswordFile config/ExampleKeystore.pin \
   --certNickname server-cert \
   --useJavaTrustStore config/ExampleTruststore.jks
   ```

   Result:

   New key store password files are created in `config/keystore.pin`. The original file, `config/ExampleKeystore.pin`, is no longer needed. If you are not using SSL or StartTLS, then the SSL arguments are not necessary.

   ```
   root@proxy-east01: ./setup --no-prompt --acceptLicense \
   --ldapPort 389 --rootUserPassword pass --maxHeapSize 1g
   ```

Next steps

After installing the PingDirectoryProxy server, you can configure it using the `create-initial-proxy-config` tool as presented in Configuring the first PingDirectory server.

Configuring the first PingDirectoryProxy server

After the PingDirectoryProxy server has been installed, it can be automatically configured using the `create-initial-proxy-config` tool.

Copyright © 2025 Ping Identity Corporation

About this task

The tool `create-initial-proxy-config` can only be used once for this initial configuration, after which you must use `dsconfig` to make any changes to your proxy server configuration.

Configuring the PingDirectoryProxy server with the `create-initial-proxy-config` tool involves the following steps:

- Providing PingDirectoryProxy server base distinguished name (DN) and password.
- Defining locations for each of our data centers, east and west.
- Configuring the LDAP external server in the east location.
- Configuring the LDAP external servers in the west location.
- Applying the changes to the PingDirectoryProxy server.

Steps

1. After completing setup, run the `create-initial-proxy-config` tool.

   Example:

   ```
   root@proxy-east01: bin/create-initial-proxy-config
   ```

2. Provide the bind DN and password that the PingDirectoryProxy server will use to authenticate to the backend PingDirectory server instances.

   The `create-initial-proxy-config` tool requires that the same bind DN and password be used to authenticate to all of the backend servers. All PingDirectoryProxy server instances have identical proxy user accounts and passwords. If necessary, the proxy user account password can be defined differently for each external server using `dsconfig` after the `create-initial-proxy-config` tool has been executed.

3. Specify the type of external server communication security that will be used to communicate with the PingDirectory server instances.

   For this example, enter the option for `None`.

4. Specify the base DNs of the PingDirectory server instances that the PingDirectoryProxy server will access.

   For this example, use `dc=example,dc=com`.

5. Enter any other base DNs of the PingDirectory server instances that will be accessed through the proxy server.

   Because you are only using one proxy base DN, press Enter to finish.

Defining locations

Define the first location, east, to accommodate the servers in the deployment located on the East Coast of the United States.

About this task

Continuing from the same `create-initial-proxy-config` session:

Copyright © 2025 Ping Identity Corporation

Steps

1. Enter a location name for the PingDirectoryProxy server. Press Enter.

   In this example, enter `east`.

2. Define a location named `west` for the servers in our deployment located on the West Coast. Press Enter.

3. Select the location that contains the PingDirectoryProxy server itself.

   The PingDirectoryProxy server is located in the east.

Configuring the external servers in the east and west locations

After the locations have been defined, identify the directory servers.

Start by defining one of the servers in the east location.

Configuring the external servers in the east location

Steps

1. Define one of the servers in the east location by entering the host name and port of the server.

   Example:

   For this example, enter `ds-east-01.example.com:389`.

   ```
   >>>> External Servers

   External Servers identify directory server instances including
   host, port, and authentication information.

   Enter the host and port (host:port) of the first directory server
   in 'east'

       b)  back
       q)  quit

   Enter a host:port or choose a menu item [localhost:389]: ds-east-01.example.com:389
   ```

2. Enter the option to prepare the server and all subsequent servers.

   Preparing the servers involves testing the connections to these servers and sets up the `cn=Proxy User` account on the PingDirectoryProxy server.

3. Enter the DN of the account with which to manage the `cn=Proxy User,cn=Root DNs,cn=config` account.

   For this example, use the default, `cn=Directory Manager`.

4. Repeat the previous steps to prepare the other server in the east location, `ds-east-02.example.com`.

5. Press Enter to complete preparing the servers.

Copyright © 2025 Ping Identity Corporation

Configuring the external servers in the west location

About this task

The same process used for the east location is used to define the LDAP external servers for the west location.

Steps

1. Define the first external server, `ds-west-01.example.com`.
2. Define the second server in the west location, `ds-west-02.example.com`.
3. Press Enter.

Apply the configuration to the PingDirectoryProxy server

Review the configuration summary.

About this task

After confirming that the changes are correct, press Enter to write the configuration.

Steps

1. Review the configuration and then apply the changes to the PingDirectoryProxy server. Press Enter to write the configuration to the server.

   During the configuration process, the **`create-initial-proxy-config`** tool writes the configuration settings to a **`dsconfig`** batch file, which are applied to the PingDirectoryProxy server. The batch file can be reused to configure other servers. On the final step, the **`create-initial-proxy-config`** tool presents a configuration summary.

2. On the final confirmation prompt, press Enter to apply the changes to the proxy server, and then enter the LDAP connection parameters to the server.

   After the changes have been applied, the **`create-initial-proxy-config`** tool cannot be used to configure this proxy server again.

Configuring additional PingDirectoryProxy server instances

Install and configure additional PingDirectoryProxy server using the **`setup`** tool.

About this task

Install and configure the second PingDirectoryProxy server by running the **`setup`** tool on `proxy-east-02.example.com`.

Steps

1. Copy the key store and `.pin` files into the `config` directory for the `proxy-east-02.example.com` server.

   Example:

   ```
   root@proxy-east-02: cp ../Keystore config/
   root@proxy-east-02: cp ../Truststore config/
   ```

Copyright © 2025 Ping Identity Corporation

2. Install the second PingDirectoryProxy server by running the `setup` tool on `proxy-east-02.example.com`.

   Example:

   ```
   root@proxy-east-02: ./setup --no-prompt \
   --listenAddress proxy-east-02.example.com \
   --ldapPort 389 --enableStartTLS --ldapsPort 636 \
   --useJavaKeystore config/ExampleKeystore.jks \
   --keyStorePasswordFile config/ExampleKeystore.pin \
   --certNickName server-cert \
   --useJavaTrustStore config/ExampleTruststore.jks \
   --rootUserPassword pass --acceptLicense \
   --maxHeapSize 1g --localHostName proxy-east-02.example.com \
   --peerHostName proxy-east-01.example.com \
   --peerPort 389 --location east
   ```

3. Configure the third PingDirectoryProxy server, `proxy-west-01.example.com` in the same way as shown in steps 1 - 2.

   Example:

   ```
   root@proxy-west-01: cp ../Keystore config/
   root@proxy-west-01: cp ../Truststore config/
   ```

4. Run the `setup` tool on `proxy-west-01.example.com`.

   Example:

   ```
   root@proxy-west-01: ./setup --no-prompt \
   --listenAddress proxy-west-01.example.com \
   --ldapPort 389 --enableStartTLS --ldapsPort 636 \
   --useJavaKeystore config/ExampleKeystore.jks \
   --keyStorePasswordFile config/ExampleKeystore.pin \
   --certNickName server-cert \
   --useJavaTrustStore config/ExampleTruststore.jks \
   --rootUserPassword pass --acceptLicense \
   --maxHeapSize 1g --localHostName proxy-west-01.example.com \
   --peerHostName proxy-east-01.example.com \
   --peerPort 389 --location west
   ```

5. Repeat steps 1 - 4 to install the last PingDirectoryProxy server.

Result

All proxies have the same Admin Data backend and have the `all-servers` group defined as their configuration-server-group in the PingDirectoryProxy Server Global Configuration object. When making a change to a PingDirectoryProxy server using the `dsconfig` command-line tool or the administrative console, you have the choice to apply the changes locally only or to all proxies in the `all-servers` group.

Testing external server communications after initial setup

After setting up the basic deployment scenario, the communication between the proxies and the LDAP external servers can be tested using a feature in the proxy server in combination with an LDAP search.

Copyright © 2025 Ping Identity Corporation

About this task

After initial setup, the PingDirectoryProxy server exposes a special search base distinguished name (DN) for testing external server connectivity, called the `backend server pass-through` subtree view. While disabled by default, you can enable this feature using `dsconfig` in the `Client Connection Policy menu`.

Steps

1. Run `dsconfig` to set the `include-backend-server-passthrough-subtree-views` property to `TRUE`.

   Example:

   ```
   root@proxy-east-01: dsconfig set-client-connection-policy-prop \
   --policy-name default \
   --set include-backend-server-passthrough-subtree-views:true
   ```

   Result:

   When set to `TRUE`, an LDAP search against the PingDirectoryProxy server with the base DN `dc=example,dc=com,ds-backend-server=ds-east-02.example.com:389` instructs the PingDirectoryProxy server to perform the search against the `ds-east-02.example.com:389` external server with the base DN set to `dc=example,dc=com`. The value of `ds-backend-server` should be the name of the configuration object representing the external server. Depending on your naming scheme, this name might not be a `host:port` combination.

2. Run `ldapsearch` to fetch the `dc=example,dc=com` entry from the `ds-east-01.example.com` server.

   Perform this search on each external server to determine if external server communication has been configured correctly on the Directory Proxy Server.

   Example:

   ```
   root@proxy-east-01: bin/ldapsearch \
   --bindDN "cn=Directory Manager" \
   --bindPassword password \
   --baseDN "dc=example,dc=com,ds-backend-server=ds-east-01.example.com:389" \
   --searchScope base --useStartTLS "(objectclass=*)"
   ```

3. Use this special subtree view to track the operations performed on each external server to help determine load balancing requirements.

   This LDAP search can be run with the base DN values for the `ds-east-01` and `ds-east-02` servers to track the distribution of search and bind requests over time. These statistics are reset to zero when the server restarts.

   Example:

   The following example searches an external server's monitor entry to display operation statistics.

Copyright © 2025 Ping Identity Corporation

```
root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=directory manager" \
--bindPassword password \
--baseDN "cn=monitor,ds-backend-server=ds-east-02.example.com:389" \
--searchScope sub --useStartTLS "(cn=ldap*statistics)"

Testing a simulated external server failure

After you have tested connectivity, run a simulated failure of a load-balanced external server to verify that the PingDirectoryProxy server redirects LDAP requests appropriately.

About this task

Copyright © 2025 Ping Identity Corporation

In this procedure, stop the `ds-east-01.example.com:389` server instance and test searches through `proxy-east-01.example.com`.

Steps

1. Perform several searches against the PingDirectoryProxy server. Verify activity in each of the servers in the east location, `ds-east-01` and `ds-east-02`, by looking at the access logs.

   Because you used the default load balancing algorithm of fewest operations, it's likely that all of the searches go to only one of the proxies.

   Example:

   The following simple search can be repeated as needed.

   ```
   root@proxy-east-01: bin/ldapsearch \
   --bindDN "cn=Directory Manager" \
   --bindPassword password --baseDN "dc=example,dc=com" \
   --searchScope base --useStartTLS "(objectclass=*)"
   ```

2. Stop the directory server instance on `ds-east-01.example.com` using the `stop-server` command and immediately retry the searches in step 1.

   > **Note**
   >
   > There should be no errors or noticeable delay in processing the search.

   Example:

   ```
   root@ds-east-01: bin/stop-server

   root@proxy-east-01: bin/ldapsearch \
   --bindDN "cn=Directory Manager" \
   --bindPassword password --baseDN "dc=example,dc=com" \
   --searchScope base --useStartTLS "(objectclass=*)"
   ```

3. Restart the PingDirectoryProxy server instance on `ds-east-01.example.com`.

4. Check the access log to confirm that the PingDirectoryProxy server started to include the `ds-east-01` server in load-balancing within 30 seconds.

   The default time is 30 seconds, but you can change this default.

Expanding the deployment

In the following example deployment, the PingDirectory server is deployed in a third, centrally-located data center.

The directory servers in the central city is assigned to a new location named central. The proxies use StartTLS to communicate with the directory servers in the central region.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Other than the ability to add to the PingDirectoryProxy server's trust store, the **`prepare-external-server`** tool does not alter the PingDirectoryProxy server configuration in any way.

The PingDirectoryProxy server itself, installed on `proxy-east-01.example.com`, remains in the east location. This example reconfigures load balancing between the six directory servers in these locations:

- `ds-east-01.example.com`
- `ds-east-02.example.com`
- `ds-west-01.example.com`
- `ds-west-02.example.com`
- `ds-central-01.example.com`
- `ds-central-02.example.com`

Overview of deployment steps

This deployment scenario takes the following steps:

1. Prepare the new external servers using the **`prepare-external-server`** tool.
2. Use the **`dsconfig`** tool to configure the new LDAP external servers in the central data center and reconfigure the load-balancing algorithm to take these servers into account.
3. Test external server communications after the servers have been configured and test a simulated external server failure.

Preparing two new external servers using the prepare-external-server tool

Prepare the external directory servers, `ds-central-01` and `ds-central-02`, by creating the proxy user account and the supporting access rules.

About this task

Connect to the `ds-central-01` PingDirectory server using StartTLS. Because you are using StartTLS, you must capture the `ds-central-01` server's certificate and put it in the trust store on your PingDirectoryProxy server instance.

The **`prepare-external-server`** tool is located in the `bin` or `bat` directory of the server root directory, PingDirectoryProxy. In this example, run the tool on the `ds-east-01` instance of the PingDirectoryProxy server.

Steps

1. Run the **`prepare-external-server`** tool to prepare the two new servers.

   Example:

Copyright © 2025 Ping Identity Corporation

On the first attempted bind to the server, the tool reports a `failed to bind` message because it can't bind to the `cn=Proxy User` entry because it hasn't been created yet. The tool sets up the `cn=Proxy User` entry so that the PingDirectoryProxy server can access it and tests the communication settings to the server.

```
root@proxy-east-01: ./prepare-external-server \
--hostname ds-central-01.example.com --port 389 \
--baseDN dc=example,dc=com \
--proxyBindPassword password  \
--useStartTLS \
--proxyTrustStorePath ../config/ExampleTruststore.jks

Failed to bind as 'cn=Proxy User'

Would you like to create or modify root user 'cn=Proxy User' so that it is
available for this Directory Proxy Server? (yes / no)[yes]:

Enter the DN of an account on ds-central-01:389 with which to create or manage the 'cn=Proxy User'
account [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':

Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User' privileges ....Done
```

2. Repeat the process on the other new server in the central location, `ds-central-02`.

> **Note**
>
> For entry-balancing deployments, the global base distinguished name (DN) is required when using **`prepare-external-server`**.

Adding the new PingDirectory servers to the PingDirectoryProxy server

After preparing the external PingDirectory servers to communicate with the PingDirectoryProxy server, add the two servers in the central location to the proxy server instance.

About this task

Because you ran the `prepare-external-server` tool, the two servers have the `cn=Proxy User` entry configured.

Steps

- Run the `dsconfig` tool.

  Example:

Copyright © 2025 Ping Identity Corporation

```
root@proxy-east-01:./dsconfig

>>>> Specify LDAP connection parameters

Directory Proxy Server host name or IP address [localhost]:

How do you want to connect to the Directory Proxy Server at
localhost?

    1)  LDAP
    2)  LDAP with SSL
    3)  LDAP with StartTLS

Enter choice [1]: 1

Directory Proxy Server at localhost port number [389]:
Administrator user bind DN [cn=Directory Manager]:
Password for user 'cn=Directory Manager':
```

Adding new locations

Add a new central location to which the new PingDirectory servers will be added.

About this task

The following steps show how to add the new servers to a new location using `dsconfig` interactive.

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.

   Example:

   ```
   $ bin/dsconfig
   ```

2. In the main menu, enter the number corresponding to Location.
3. In the `Location menu`, enter the number corresponding to creating a new location.
4. Enter the option to create a new location from scratch.
5. Configure the `preferred-failover-location` property of the new location so that this location fails over first to the east location and then to the west location if all of the servers in the central location become unavailable.
6. Add the east and west locations as values of the property, specifying them in the order that they will be used for failover.
7. Confirm that these are the correct values and finish configuring the location.

Copyright © 2025 Ping Identity Corporation

Editing the existing locations

Edit the existing east and west locations to include the new central location in their failover logic.

About this task

The new failover logic is be based on geographic distance so that the east location will first fail over to the central and then the west location.

The following example procedure uses `dsconfig` interactive mode to edit the east location.

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. In the PingDirectoryProxy server console configuration menu, enter the number corresponding to Location.
3. In the `Location menu`, enter the number corresponding to viewing and editing an existing location. Then, enter the number corresponding to the Location to be changed.
4. Remove the west location from the `preferred-failover-location` property.

   You will add the west location later.
5. Add a new value to the `preferred-failover-location` property.
6. Select the values of the new failover locations for the east.
7. Confirm the new configuration information and save the changes.
8. Repeat steps 2-7 to reconfigure the failover logic for the west location to include the new central location.
9. List the locations to confirm that the new location was added correctly.

Adding new health checks for the central servers

Add new health checks for the two new servers.

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. Select the number corresponding to creating a new health check.
3. Enter the option to use an existing health check as a template.
4. Enter the number corresponding to the `ds-east-01` health check to use it as a template for the new health check.
5. Name the new health check using the same naming strategy established for the other servers in the deployment.

   Example:

   As this health check is for the `ds-central-01` server, the name takes the following format.

Copyright © 2025 Ping Identity Corporation

```
>>>> Enter a name for the Search LDAP Health Check that you want to create:
ds-central-01.example.com:389_dc_example_dc_com-search-health-check
```

6. Review the configuration properties and then enter `f` to finish configuring the new health check and save changes.
7. Repeat steps 2-6 to create another new health check for the `ds-central-02` server.

Adding new external servers

Add new external servers using `dsconfig`.

About this task

Add new external servers by selecting `External Server` from the main menu.

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. In the `External Server menu`, enter the number corresponding to `Create a new External Server`.
3. Base the configuration of the new external server on the existing configuration of the `ds-east-01` server. Enter `t` to use an existing external server as a template.
4. Enter the number to base the configuration of the new server on the configuration of the `ds-east-01` server.
5. Enter a name for the new `ds-central-01` server that complies with the naming strategy.

   Example:

   ```
   >>>> Enter a name for the Ping Identity DS External Server that you
   want to create: ds-central-01.example.com:389
   ```

6. Enter the value of the `server-host-name` property.
7. Review and modify the configuration properties of the external server.
8. In the `External Server menu`, change the `server-host-name` property to reflect the name of the `ds-central-01` server.
9. In the `External Server menu`, change the `location` property to reflect the central location.
10. Change the `health-check` property to reflect the new health check created for the `ds-central-01` server in the previous section.
11. On the `'health-check' Property` menu, enter the number to remove one or more values.
12. Add the health-check created in the previous section.
13. Select the health check associated with the `ds-central-01` server.
14. Press Enter to use the value associated with `ds-central-01` health check.
15. Review the configuration of the new external server and enter `f` to create the server.

Copyright © 2025 Ping Identity Corporation

16. Repeat steps 1-15 to add the new `ds-central-02` external server.

Modifying the load-balancing algorithm

Modify the existing load-balancing algorithm to include the newly created servers.

About this task

To modify the existing load-balancing algorithm to include the newly created servers, select `Load-Balancing Algorithm` from the main menu.

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. Select the option for Load-Balancing Algorithm.
3. On the `Load-Balancing Algorithm menu`, enter the number corresponding to view and edit an existing Load-Balancing Algorithm.
4. Add the `ds-central-01` and `ds-central-02` servers to the `backend-server` configuration property.
5. On the `backend-server property menu`, enter the number corresponding to adding one or more values.
6. Select the external servers to add.

   For this example, select `ds-central-01.example.com` and `ds-central-02.example.com`.
7. Review the changes made to the load-balancing algorithm's configuration properties, and enter `f` to save changes.

   Result:

   The change is saved and applied to the PingDirectoryProxy server. The load-balancing algorithm is referenced in the `load-balancing-algorithm` property of the request processor used by this PingDirectoryProxy server.
8. To view this property, go to the main menu and select the `Request Processor` option.
9. In the `Request Processor menu`, enter the number corresponding to view and edit an existing request processor.
10. Select the request process used by the PingDirectoryProxy server, and review the configuration properties.

    Result:

    This request processor is used by the subtree view serviced by the PingDirectoryProxy server, which is in turn referenced by the client connection policy.

> **Note**
>
> The changes made in this procedure are already in effect. The PingDirectoryProxy server does not have to be restarted.

Copyright © 2025 Ping Identity Corporation

Testing external server communications after initial setup

After setting up the basic deployment scenario, the communication between the proxies and the LDAP external servers can be tested using a feature in the proxy server in combination with an LDAP search.

About this task

After initial setup, the PingDirectoryProxy server exposes a special search base distinguished name (DN) for testing external server connectivity, called the `backend server pass-through` subtree view. While disabled by default, you can enable this feature using `dsconfig` in the `Client Connection Policy menu`.

Steps

1. Run `dsconfig` to set the `include-backend-server-passthrough-subtree-views` property to `TRUE`.

   Example:

   ```
   root@proxy-east-01: dsconfig set-client-connection-policy-prop \
   --policy-name default \
   --set include-backend-server-passthrough-subtree-views:true
   ```

   Result:

   When set to `TRUE`, an LDAP search against the PingDirectoryProxy server with the base DN `dc=example,dc=com,ds-backend-server=ds-east-02.example.com:389` instructs the PingDirectoryProxy server to perform the search against the `ds-east-02.example.com:389` external server with the base DN set to `dc=example,dc=com`. The value of `ds-backend-server` should be the name of the configuration object representing the external server. Depending on your naming scheme, this name might not be a `host:port` combination.

2. Run `ldapsearch` to fetch the `dc=example,dc=com` entry from the `ds-east-01.example.com` server.

   Perform this search on each external server to determine if external server communication has been configured correctly on the Directory Proxy Server.

   Example:

   ```
   root@proxy-east-01: bin/ldapsearch \
   --bindDN "cn=Directory Manager" \
   --bindPassword password \
   --baseDN "dc=example,dc=com,ds-backend-server=ds-east-01.example.com:389" \
   --searchScope base --useStartTLS "(objectclass=*)"
   ```

3. Use this special subtree view to track the operations performed on each external server to help determine load balancing requirements.

   This LDAP search can be run with the base DN values for the `ds-east-01` and `ds-east-02` servers to track the distribution of search and bind requests over time. These statistics are reset to zero when the server restarts.

   Example:

   The following example searches an external server's monitor entry to display operation statistics.

Copyright © 2025 Ping Identity Corporation

```
root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=directory manager" \
--bindPassword password \
--baseDN "cn=monitor,ds-backend-server=ds-east-02.example.com:389" \
--searchScope sub --useStartTLS "(cn=ldap*statistics)"

Testing a simulated external server failure

After you have tested connectivity, run a simulated failure of a load-balanced external server to verify that the PingDirectoryProxy server redirects LDAP requests appropriately.

About this task

Copyright © 2025 Ping Identity Corporation

To run a simulated external server failure:

Steps

1. Stop the `ds-east-01.example.com:389` and `ds-east-02.example.com:389` server instances and test searches through `proxy-east-01.example.com`.
2. Perform several searches against the PingDirectoryProxy server and verify activity in each of the servers in the east location, `ds-east-01` and `ds-east-02`, by looking at the access logs.

   Example:

   The following simple search can be repeated as needed.

   ```
   root@proxy-east-01: bin/ldapsearch --bindDN "cn=Directory Manager" \
   --bindPassword password --baseDN "dc=example,dc=com" \
   --searchScope base --useStartTLS "(objectclass=*)"
   ```

3. Stop the directory server instance on `ds-east-01.example.com` and `ds-east-02.example.com` using the `stop-server` command and immediately retry the searches in step 2.

   There should be no errors or noticeable delay in processing the search.

   Example:

   ```
   root@proxy-east-01: bin/stop-server

   root@proxy-east-01: bin/ldapsearch \
   --bindDN "cn=Directory Manager" --bindPassword password \
   --baseDN "dc=example,dc=com" --searchScope base --useStartTLS \
   "(objectclass=*)"
   ```

4. Check the access log to confirm that requests made to these servers are routed to the central servers because these servers are the first failover location in the failover list for the `ds-east-01` and `ds-east-02` servers.
5. Restart the directory server instance on `ds-east-01.example.com` and `ds-east-02.example.com`.
6. Check their access logs to ensure that traffic is redirected back from the failover servers.

Merging two data sets using proxy transformations

In the following example, the Example.com company acquires Sample Corporation.

During the merger, Example.com migrates data from Sample Corporation's `o=sample` rooted directory, converting Sample Corporation's `sampleAccount` auxiliary object class usage to Example.com's `exampleAccount` object class for entries rooted under `dc=example,dc=com`.

Knowing that it can take considerable time for Sample Corporation's directory clients to become aware of the new directory information tree (DIT) and schema, proxy data transformations are created to give the Sample Corporation's clients as consistent a view of the data as possible during the migratory period. These transformations allow the clients to search and modify entries under `o=sample` using the Sample Corporation schema.

Copyright © 2025 Ping Identity Corporation

Overview of the attribute and DN mapping

To achieve the merger of the two data sets, create proxy transformations that map the Sample Corporation's source attributes to Example.com target attributes.

The Example.com schema already defines an attribute to contain the relative distinguished name (RDN) of user entries, called `uid`. However, Example.com chooses to create two new attributes within its `exampleAccount` object class to accommodate two attributes in the Sample Corporation schema for representing the region and the distinguished name (DN) of linked accounts.

During the merger, Example.com decides to re-parent the Sample Corporation's customer entries, which are defined under two different subtrees, `ou=east,o=sample` and `ou=west,o=sample`, placing them under Example.com's `ou=people,dc=example,dc=com` subtree. Associated proxy transformations are described in the DN Mappings table below. In this process, Example.com collapses the Sample Corporation tree, moving entries from the east and west region under a single DN, `dc=example,dc=com`. The DN proxy transformations assume that all the Sample Corporation users have been co-located under this single Example.com subtree.

Sample Attribute	Example.com Attribute	Description
`sampleID`	`uid`	RDN of user entries
`sampleRegion`	`exSampleRegion`	String value representing the region
`sampleLinkedAccounts`	`exSampleLinkedAccounts`	DN value

Legacy Sample LDAP applications searching for entries in either the Sample Corporation base DN `ou=east,o=sample` or `ou=west,o=sample` will be successfully serviced, though there will be one or more differences in the user entries seen by the Sample Corporation legacy applications.

Because the Example.com directory server has no knowledge of the Sample Corporation user's former `ou=east` or `ou=west` association, search results for client searching under `o=sample` will return a DN that might differ from the original search base. For instance, a search for `sampleID=abc123` under `ou=west,o=sample` might return the user entry for abc123 with the DN of `sampleID=abc123,ou=east,o=sample`.

The following table illustrates the mapping DNs.

Sample DN	Example.com DN
`ou=east,o=sample`	`dc=example,dc=com`
`ou=west,o=sample`	`dc=example,dc=com`
`o=sample`	`dc=example,dc=com`

About mapping multiple source DNs to the same target DN

Some complications exist when defining multiple distinguished names (DN) mappings that are used for the same request processor and the same source or target DN or that have source or target DNs that are hierarchically related.

Copyright © 2025 Ping Identity Corporation

The client request might not include enough information to disambiguate and determine the proper rule to follow.

Several solutions exist to avoid problems of disambiguation. If the client does not need to be able to see all mappings at the same time, then a new client connection policy can be created to use connection criteria that select the set of mappings applied to the client based on information such as the IP address or bind DN. Each client connection policy would have separated subtree views with separate proxying request processors that reference the appropriate transformation for that client.

Alternatively, if it is unnecessary to search under the `o=sample` base DN, then you can create separate subtree views in the same client connection policy. For example, you would create one subtree view for `ou=east,o=sample` and one for `ou=west,o=sample`. Each subtree view is then associated with its own proxying request processor, one for `ou=east` requests and one for `ou=west` requests.

Example of a migrated sample customer entry

The following is an example of a Sample Corporation customer entry that has been migrated to the Example.com database.

The user entry is defined in the Example.com directory server's database as follows.

> **Note**
>
> This view is how the entry appears to search requests under the `dc=example,dc=com` base distinguished name (DN).

```
dn: uid=scase,ou=People,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: exampleAccount
objectClass: top
description: A customer account migrated from Sample merger
uid: scase
exAccountNumber: 234098
exSampleRegion: east
exSampleLinkedAccounts: uid=jcase,ou=people,dc=example,dc=com
userPassword: password
givenName: Sterling
cn: Sterling Case
sn: Case
telephoneNumber: +1 804 094 3356
street: 00468 Second Street
l: Arlington
mail: sterlingcase@maildomain.com st: VA
```

The following example shows what the PingDirectoryProxy server returns to LDAP clients who have requested the entry when searching under the `o=sample` base DN.

> **Note**
>
> The DN returned includes `ou=east` even though this branch doesn't exist in the Example.com directory information tree (DIT). It also returns the attribute names as they are defined in the Sample Corporation schema.

Copyright © 2025 Ping Identity Corporation

```
dn:  sampleID=scase,ou=east,o=sample
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: exampleAccount
objectClass: top
description: A customer account migrated from Sample merger
uid: scase
exAccountNumber: 234098
exSampleRegion: east
exSampleLinkedAccounts: sampleID=jcase,ou=people,dc=example,dc=com
userPassword: password
givenName: Sterling
cn: Sterling Case
sn: Case
telephoneNumber: +1 804 094 3356
street: 00468 Second Street
l: Arlington
mail: sterlingcase@maildomain.com st: VA
```

Overview of deployment steps

This deployment scenario takes the following steps:

- Install any necessary schema on the PingDirectoryProxy server.
- Create three attribute mapping proxy transformations and three distinguished name (DN) mapping proxy transformations.
- Create a new proxying request processor using the existing `dc_example_dc_com` request processor as a template.
- Assign the six proxy transformations to the new proxying request processor.
- Create a new subtree view for `o=sample` that references the new proxying request processor.
- Add the new subtree view to the existing client connection policy.
- Test the configuration by performing some searches on the Sample Corporation directory information tree (DIT).

About the schema

The PingDirectoryProxy server inherits user-defined schema from all external servers by comparing `cn=schema` on these servers at PingDirectoryProxy server startup and at five minute intervals.

In the following example, the Example.com company acquires Sample Corporation. The Example.com schema does not need to be added manually to the PingDirectoryProxy server's `config/schema` directory. We assume that the schema for Sample Corporation's entries has been defined on the external servers with the example.com directory information tree (DIT), requiring no direct schema management on the PingDirectoryProxy server. The following schema definitions are assumed to exist on the external directory server.

Copyright © 2025 Ping Identity Corporation

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( 1.3.6.1.4.1.32473.2.1.1
  NAME 'exAccountNumber'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  SINGLE-VALUE )
attributeTypes: ( 1.3.6.1.4.1.32473.1.1.3
  NAME 'sampleLinkedAccounts'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.12 )
attributeTypes: ( 1.3.6.1.4.1.32473.1.1.2
  NAME 'sampleRegion'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15

```

The schema file defines some example.com schema, such as `exAccountNumber` and `exSampleRegion`, and some Sample Corporation schema, such as `sampleRegion` and `sampleID`.

Creating proxy transformations

In this deployment scenario, you create three attribute mapping proxy transformations and three distinguished name (DN) mapping proxy transformations.

About this task

To create attribute and distinguished name (DN) mapping proxy transformations, you can use the `dsconfig` tool, which is located in the `bin` or `bat` directory of the server root directory, PingDirectoryProxy.

Copyright © 2025 Ping Identity Corporation

Steps

1. In the main server root directory, PingDirectoryProxy, run the `start-server` command.
2. Run `dsconfig` in interactive mode and enter the LDAP connection parameters.
3. Inn the `Configuration main menu`, enter the number corresponding to your desired `Proxy Transformation`.

Creating the Attribute Mapping Proxy Transformations

Create the attribute mapping proxy transformations using `dsconfig` interactive.

For this example, assume you are continuing from the previous `dsconfig` session in Creating proxy transformations. In Creating the DN mapping proxy transformations, this transformation maps `ou=east,o=sample` in the `Sample Corporation` schema `dc=example,dc=com` in the `Example.com` schema.

Creating the DN mapping proxy transformations

Create the distinguished name (DN) mapping proxy transformations.

Steps

1. In the `Proxy Transformation` menu, enter the number corresponding to `Create a new Proxy Transformation`.
2. Enter the option to create a new `Proxy Transformation`.
3. Enter the option for `DN Mapping Proxy Transformation`.
4. Enter a name for the `DN Mapping Proxy Transformation`.

   This transformation maps `ou=east,o=sample` in the `Sample Corporation` schema `dc=example,dc=com` in the `Example.com` schema.
5. To enable the transformation by default, select `True`.
6. Specify the source DN as it appears in client requests.

   Example:

```
>>>> Configuring the 'source-dn' property

     Specifies the source DN that may appear in client
     requests which should be remapped to the target DN.
     Note that the source DN must not be equal to the target DN.

     Syntax: DN

Enter a value for the 'source-dn' property:
ou=east,o=sample
```

7. Specify the target DN, where requests for the source DN should be routed.

   Example:

Copyright © 2025 Ping Identity Corporation

```
>>>> Configuring the 'target-dn' property

    Specifies the DN to which the source DN should be mapped.
    Note that the target DN must not be equal to the source
    DN.

    Syntax: DN

Enter a value for the 'target-dn' property: dc=example,dc=com
```

8. To create the new DN mapping proxy transformation, enter `f`.
9. Repeat the previous steps to create a new DN mapping proxy transformation that maps `ou=west,o=sample` in the `Sample Corporation` schema to `dc=example,dc=com` in the `Example.com` schema, and name it `sample_west-to-example`.
10. Create a DN mapping proxy transformation for the base DN of the `Sample Corporation` database.

Creating a request processor to manage the proxy transformations

Create a new proxying request processor that includes your new attribute and distinguished name (DN) mapping proxy transformations.

About this task

Use the existing `dc_example_dc_com` request processor as a template.

Steps

1. In the `Configuration` main menu, enter the number corresponding to `Request Processor`.
2. On the `Request Processor` menu, enter the number corresponding to `Create a new Request Processor`.
3. Select the option to use the current request processor as a template.
4. Enter a name for the new proxying request processor, such as `o_sample-req-processor`.
5. Review the properties and enter the number corresponding to the `Transformation` property.

> **Note**
>
> The load-balancing algorithm is the same as for the previous request processor, but you must change the transformation property.

6. Enter the number corresponding to the proxy transformations that were previously created.
7. Select the attribute mapping proxy transformations, then select the DN mapping proxy transformations.

> **Note**
>
> The order of the selection is important because you have related DNs. Begin with the DNs that are lower in the tree, and finish with the base DN transformation.

Example:

Copyright © 2025 Ping Identity Corporation

```
Select the Proxy Transformations you wish to add:

    1)  sample-to-example       5)  sampleLinkedAccounts-to-
                                    exSampleLinkedAccounts
    2)  sample_east-to-example  6)  sampleRegion-to-
                                    exSampleRegion
    3)  sample_west-to-example  7)  Create a new Proxy
                                    Transformation
    4)  sampleID-to-uid         8)  Add all Proxy Transformations

    ?)  help
    b)  back
    q)  quit

Enter one or more choices separated by commas [b]: 4,5,6,2,3,1
```

8. Confirm that the proxy transformations are listed in the correct order and press Enter to accept and use the values.
9. To save your changes, enter `f`.

Creating subtree views

About this task

To configure subtree views for the PingDirectoryProxy server:

Steps

1. In the `Configuration` main menu, enter the number corresponding to `Subtree View`.
2. In the `Subtree View` menu, enter the number corresponding to `Create a new Subtree View`.
3. Enter the option to create the new subtree view from an existing subtree.
4. Select the `dc_example_dc_com-view` subtree view.
5. Enter a descriptive name for the subtree view configuration.
6. Configure the base distinguished name (DN) property of the `Sample Corporation` data set.
7. Enter the request processor created in Creating a request processor to manage the proxy transformations.
8. To save the changes, press `f`.

   Example:

Copyright © 2025 Ping Identity Corporation

```
>>>> Configure the properties of the Subtree View

        Property           Value(s)
        -----------------------------------------------
    1)  description        -
    2)  base-dn            "o=sample"
    3)  request-processor  o_sample-req-processor

    ?)  help
    f)  finish - create the new Subtree View
    d)  display the equivalent dsconfig arguments to create this
        object
    b)  back
    q) quit
```

Editing the client connection policy

Edit the client connection policy.

About this task

To add the new `o=sample` subtree view:

Steps

1. In the `Configuration` main menu, enter the number corresponding to `Client Connection Policy`.
2. In the `Client Connection` menu, enter the number corresponding to `Create a new Client Connection`.
3. In the configuration properties, select the `subtree-view` property and enter the number corresponding to "Add one or more values" to add the new subtree view created for the previous example.
4. Select the subtree view that you created in Creating subtree views.

   Example:

   ```
   Select the Subtree Views you wish to add:

       1)  o_sample-view
       2)  Create a new Subtree View
   ```

5. Review the subtree views now referenced by the property and press Enter to use these values.
6. Review the configuration properties of the client connection policy and enter `f` to save changes.

Testing proxy transformations

You can test the proxy transformation service by imitating example client requests to search and modify users.

About this task

Copyright © 2025 Ping Identity Corporation

After setting up the deployment scenario, the PingDirectoryProxy server will respond to requests to the `dc=example,dc=com` and `o=sample` base distinguished names (DNs).

Steps

1. To view a Sample Corporation entry, run `ldapsearch`.

   Example:

   The following example fetches the user with `sampleID=scase` under the `ou=east,o=sample` base DN.

   ```
   root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
   --bindPassword password --baseDN "ou=east,o=sample" "(sampleID=scase)"
   ```

   Result:

   ```
   dn: sampleID=scase,ou=People,ou=east,o=sample
   objectClass: person
   objectClass: organizationalPerson
   objectClass: inetOrgPerson
   objectClass: exampleAccount
   objectClass: top
   description: A customer account migrated from Sample merger
   sampleID: scase
   userPassword: {SSHA}A5O4RrQHWXc2Ii3btD4exGdP0TVW9VL3CR3ZXA==
   exAccountNumber: 234098
   givenName: Sterling
   cn: Sterling Case
   sn: Case
   telephoneNumber: +1 804 094 3356
   street: 00468 Second Street
   mail: sterlingcase@maildomain.com
   l: Arlington
   st: VA
   sampleRegion: east
   sampleLinkedAccounts: sampleID=jcase,ou=People,ou=east,o=sample
   ```

2. Modify the `sampleRegion` value by changing it to `west`.

   Example:

   To modify the value, create an `ldapmodify` input file, called `scase-mod.ldif`, with the following contents.

   ```
   dn: sampleID=scase,ou=People,ou=east,o=sample
   changetype: modify
   replace: sampleRegion
   sampleRegion: west
   ```

3. Use the file as an argument in the `ldapmodify` command.

   Example:

Copyright © 2025 Ping Identity Corporation

```
root@proxy-east-01: bin/ldapmodify --bindDN "cn=Directory Manager" \
--bindPassword password --filename scase-mod.ldif
```

Result:

```
Processing MODIFY request for sampleID=scase,ou=People, ou=east,o=sample
MODIFY operation successful for DN sampleID=scase,ou=People, ou=east,o=sample
```

4. Search for the `scase` `sampleRegion` value under `o=sample`

   Example:

   ```
   root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
   --bindPassword password --baseDN "o=sample"  "(sampleID=scase)" \
   sampleRegion
   ```

   Result:

   ```
   dn: sampleID=scase,ou=People,ou=east,o=sample
   sampleRegion: west
   ```

5. To search for `scase`, use `uid` instead of `sampleID`, under the `dc=example,dc=com` base DN.

   Example:

   You can see the Example.com schema version of the entry in the following sample.

   ```
   root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
   --bindPassword password --baseDN "dc=example,dc=com"  "(uid=scase)"
   ```

   Result:

   ```
   dn: uid=scase,ou=People,dc=example,dc=com
   objectClass: person
   objectClass: exampleAccount
   objectClass: inetOrgPerson
   objectClass: organizationalPerson
   objectClass: top
   description: A customer account migrated from Sample merger
   uid: scase
   userPassword: {SSHA}A5O4RrQHWXc2Ii3btD4exGdP0TVW9VL3CR3ZXA==
   exAccountNumber: 234098
   givenName: Sterling
   cn: Sterling Case
   sn: Case
   telephoneNumber: +1 804 094 3356
   street: 00468 Second Street
   mail: sterlingcase@maildomain.com
   l: Arlington
   st: VA
   exSampleRegion: west
   exSampleLinkedAccounts: uid=jcase,ou=People,dc=example,dc=com
   ```

Copyright © 2025 Ping Identity Corporation

Deploying an entry-balancing PingDirectoryProxy server

Depending upon the needs of your enterprise, you can deploy a PingDirectoryProxy server in a variety of ways.

This section describes and illustrates an entry-balancing deployment scenario that involves:

- Deploying an entry-balancing proxy configuration
- Rebalancing your entries
- Managing the global indexes in entry-balancing configurations
- Working with alternate authorization identities

Deploying an entry-balancing proxy configuration

Entry-balancing is a PingDirectoryProxy server configuration that allows the entries within a portion of the directory information tree (DIT) to reside on multiple external servers.

This configuration is useful when the DIT contains many millions of entries, which can be difficult to bring completely into memory for optimal performance. Entry-balancing allows entries under a balancing point base distinguished name (DN) to be divided among any number of separate directory servers, making the PingDirectoryProxy server responsible for intelligently routing requests based on the division.

In this example scenario, the entries in the DIT outside of the balancing point are replicated across all external servers known to the PingDirectoryProxy server. You must properly configure replication on the external directory servers before proceeding through this example. The directory servers are expected to contain two replication domains: the global domain, `dc=example,dc=com`, and the balancing point, `ou=people,dc=example,dc=com`.

In this deployment scenario, an `austin-proxy1` instance of the PingDirectoryProxy server communicates with four external directory servers. The PingDirectoryProxy server is configured to use entry balancing for the `ou=people,dc=example,dc=com` base DN with two sets of user entries split beneath it. The first set of user entries is defined in the replicated pair of external servers, `austin-set1.example.com` and `newyork-set1.example.com`.

The second set of entries is defined in `austin-set2.example.com` and `newyork-set2.example.com`. The entries in the `dc=example,dc=com` DIT outside of the balancing point base DN are replicated among the four external servers.

The following `dsreplication status` output from the PingDirectory external servers describes the replication configuration that exists before creating the PingDirectoryProxy server configuration.

Copyright © 2025 Ping Identity Corporation

```
--- Replication Status for dc=example,dc=com: Enabled ---

Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
--------:---------:--------:--------------------------:-------------
austin-set1.example.com:389  : 10003   : 0   : N/A  : 722087263
austin-set2.example.com:389  : 10003   : 0   : N/A  : 722087263
newyork-set1.example.com:389 : 10003   : 0   : N/A  : 722087263
newyork-set2.example.com:389 : 10003   : 0   : N/A  : 722087263

--- Replication Status for ou=people,dc=example,dc=com (Set: dataset1): Enabled ---

Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
--------:---------:---------:--------------------------:-----------------
austin-set1.example.com:389  : 100001  : 0  : N/A               : 178892712
newyork-set1.example.com:389 : 100001  : 0  : N/A               : 178892712

--- Replication Status for ou=people,dc=example,dc=com (Set: dataset2): Enabled ---

Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
---------:---------:---------:--------------------------:-----------------
austin-set2.example.com:389  : 100001  : 0       : N/A        : 1057593890
newyork-set2.example.com:389 : 100001  : 0       : N/A        : 1057593890
```

Determining how to balance your data

If a single PingDirectory server instance can hold all of your data, then you should store your data on a single server and replicate for high availability to simplify your deployment.

If a single server can't hold all of your data, then you can spread it across multiple servers in these ways:

- If the data is already broken up by hierarchy and all of the clients understand how to access it that way, the number of top-level branches is small and a single PingDirectory server instance can hold all of the information within one or more branches. Configure the PingDirectoryProxy server with multiple base distinguished names (DNs) and use simple load-balancing rather than entry balancing to simplify your deployment.
- If simply breaking up the data using the existing hierarchy is not an option, for example if a large number of top-level branches must be configured, then consider using entry balancing. The contents of any single branch still must fit on a given server, because only entries that are immediate subordinates of the entry-balancing base DN might be spread across multiple servers. Any entries that are further subordinates must be placed in the same directory server instance as their parent.
- If one or more branches are so large that any single PingDirectory server instance can't hold all of the data, you need to use entry balancing within that branch to divide the entries among two or more sets of PingDirectory servers. You might also need to change the way that the data is arranged in the server so that it uses as flat a directory information tree (DIT) as possible, which is easier to use in an entry-balancing deployment.

In an entry-balancing deployment, there can be data that is common to all external directory servers outside the balancing point. This data is referred to as the global domain. The PingDirectoryProxy server entry-balancing configuration will contain at least two subtree views and associated request processors, one for the global domain and one for the entry-balancing domain. In our examples, the global domain is `dc=example,dc=com`, and the entry-balancing domain is `ou=people,dc=example,dc=com`.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The entry-balancing base DN, `ou=people,dc=example,dc=com`, is also the balancing point.

Entry balancing and ACIs

In an entry-balancing deployment, access control instructions (ACIs) are still configured in the backend PingDirectory server data.

When defining access controls in an entry-balancing deployment, you must ensure that the data used by the access control rule is available for evaluation on all data sets.

If you use groups for access control and a group contains users from different data sets, then that group must exist on each data set. For a single ACI to apply to entries in all data sets, it must be specified above the entry-balancing point. For example, if an ACI allows access to modify users that are part of group 1, then two things must exist on both data sets:

- Group 1 must exist in the `ou=groups` branch of both data sets.
- The ACI referencing group 1 must exist in the `ou=people` branch or above. The `ou=people` branch entry itself is part of the common data.

The PingDirectoryProxy server ensures that any changes to entries within the scope of the entry-balancing request processor, but outside the balancing point, are applied to all backend server sets. Any ACI stored at the entry-balancing point is kept in sync if changes are made through the PingDirectoryProxy server.

Overview of deployment steps

This deployment scenario takes the following steps.

- Install the PingDirectoryProxy server on `austin-proxy1`.
- Use the `create-initial-proxy-config` tool to provide our initial setup for entry balancing.

  The initial setup includes defining multiple subtree views and global indexes in support of entry balancing.
- Change the placement algorithm of the `austin-proxy-01` server to use an entry-count placement algorithm.

  This algorithm is used to select the backend set to which to forward an add request. It looks at the number of entries in the backend sets and forwards the add request to the backend with either the fewest or the most entries, depending on the configuration. You can also configure the placement algorithm to make the decision based on the on-disk database size rather than the number of entries.

Installing the PingDirectoryProxy server

About this task

The four external servers, `austin-set1.example.com`, `newyork-set1.example.com`, `austin-set2.example.com`, and `newyork-set2.example.com`, are running.

Copyright © 2025 Ping Identity Corporation

Steps

- Run the `setup` program in non-interactive mode.

  Example:

```
root@austin-proxy1: ./setup --acceptLicense \
--listenAddress austin-proxy1.example.com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --entryBalancing \
--maxHeapSize 2g --no-prompt
```

Configuring the entry-balancing PingDirectoryProxy server

After the PingDirectoryProxy server has been installed, it can be automatically configured using the `create-initial-proxy-config` tool.

About this task

This tool can only be used once for this initial configuration after which you will have to use `dsconfig` to make any changes to the PingDirectoryProxy server configuration.

Steps

1. Run the `create-initial-proxy-config` tool.

   Example:

```
root@austin-proxy1: ./bin/create-initial-proxy-config
```

2. If the topology meets the requirements, press Enter to continue.

   Example:

```
Some assumptions are made about the topology to keep
this tool simple:

1) all servers will be accessible via a single user account
2) all servers support the same communication security type
3) all servers are PingDirectoryProxy Servers

If your topology does not have these characteristics you can
use this tool to define a basic configuration and then use the
'dsconfig' tool or the Administrative Console to fine tune the configuration.

Would you like to continue? (yes / no) [yes]:
```

3. Provide the external server access credentials.

   All of the proxies have identical proxy user accounts and passwords.

   Example:

Copyright © 2025 Ping Identity Corporation

```
Enter the DN of the proxy user account [cn=Proxy User,cn=Root DNs,cn=config]:

Enter the password for 'cn=Proxy User,cn=Root DNs,cn=config':
Confirm the password for 'cn=Proxy User,cn=Root DNs,cn=config':
```

4. Specify the type of security that the PingDirectoryProxy server will use to communicate with PingDirectory servers.
5. Enter a base distinguished name (DN) of the PingDirectory server instances that will be accessed by the PingDirectoryProxy server.
6. Define the balancing point as a separate base DN, which is entry balanced.

   Example:

```
Enter another base DN of the directory server instances that
will be accessed through the Directory Proxy Server:

    1)Remove dc=example,dc=com

    b)back

    q)quit

Enter a DN or choose a menu item [Press ENTER when finished
entering base DNs]: ou=people,dc=example,dc=com

Are entries within 'ou=people,dc=example,dc=com' split across
multiple servers so that each server stores only a subset of
the entries (i.e. is this base DN 'entry balanced')? (yes / no)
[no]: yes
```

7. Because the data in `ou=people,dc=example,dc=com` will be split across two backend sets, enter `2` to specify that the data will be balanced across two sets of servers.

   Example:

```
Across how many sets of servers is the data balanced?

    c) cancel creating ou=people,dc=example,dc=com
    q) quit

Enter a number greater than one or choose a menu item: 2
```

8. Because the balancing point is the same as the base DN, `ou=people,dc=example,dc=com`, use it as the entry balancing base.

   Example:

Copyright © 2025 Ping Identity Corporation

```
>>>> Entry Balancing Base

The entry balancing base DN specifies the entry below which the
data is balanced. Entries not below this entry must be duplicated
in all the server sets. If all the entries in the base DN are
distributed the entry balancing base DN is the same as the base DN.

    c) cancel creating ou=people,dc=example,dc=com
    b) back
    q) quit

Enter the entry balancing base DN or choose a menu item
[ou=people,dc=example,dc=com]: ou=people,dc=example,dc=com
```

9. To improve the performance for equality search filters referencing the `uid` attribute, create a `uid` global index. Enter `yes` to add a new attribute to the global index.
10. Specify the `uid` attribute.

    Example:

    ```
    Enter attributes that you would like to add to the global index:

        c)cancel creating ou=people,dc=example,dc=com
        b)back
        q)quit

    Enter an attribute name or choose a menu item [Press ENTER when
    finished entering index attributes]: uid
    ```

11. To optimize PingDirectoryProxy server performance from the moment it starts accepting connections, enter the number corresponding to `Yes, and all subsequent attributes`.
12. Press Enter to finish specifying index attributes.
13. Press Enter to enable relative distinguished name (RDN) index priming.

    Example:

    ```
    Would you like to enable RDN index priming for
    'ou=people,dc=example,dc=com'? (yes / no) [yes]:
    ```

14. Press Enter to finish specifying base DNs.

    Example:

Copyright © 2025 Ping Identity Corporation

```
Enter another base DN of the directory server instances that
will be accessed through the Directory Proxy Server:

    1) Remove dc=example,dc=com
    2) Remove ou=people,dc=example,dc=com (distributed)

    b)  back
    q)  quit

Enter a DN or choose a menu item [Press ENTER when finished
entering base DNs]:
```

15. The external servers are spread among two locations, New York and Austin. Define austin as the location of this PingDirectoryProxy server instance.

    Example:

```
A good rule of thumb when naming locations is to use the
name of your data centers or the cities containing them.

    b)  back
    q)  quit

Enter a location name or choose a menu item: austin

    1)  Remove austin

    b)  back
    q)  quit
```

16. Define the newyork location.

    Example:

```
Enter another location name or choose a menu item [Press ENTER
when finished entering locations]: newyork

    1)  Remove austin
    2)  Remove newyork

    b)  back
    q)  quit

Enter another location name or choose a menu item [Press ENTER
when finished entering locations]:
```

17. Select the austin location for this PingDirectoryProxy server instance.

    Example:

Copyright © 2025 Ping Identity Corporation

```
Choose the location for this Directory Proxy Server

    1) austin
    2) newyork

    b) back
    q) quit

Enter choice [1]:
```

18. Specify the LDAP external server instances associated with this location.

    Example:

```
Enter the host and port (host:port) of the first directory server
in 'austin'

     b)  back
     q)  quit

Enter a host:port or choose a menu item [localhost:389]:
austin-set1.example.com:389
```

19. Specify that the `austin-set1` server can handle requests from the global domain and from set 1 restricted domain.

    Example:

```
Assign server austin-set1.example.com:389 to handle requests for
one or more of the defined sets of data:

    1) dc=example,dc=com
    2) ou=people,dc=example,dc=com; Server Set 1
    3) ou=people,dc=example,dc=com; Server Set 2

Enter one or more choices separated by commas: 1,2
```

20. Enter the number corresponding to `Yes, and all subsequent servers` to prepare the server for access by the Directory Proxy Server.

    Example:

```
Would you like to prepare austin-set1.example.com:389 for access
by the Directory Proxy Server?

       1)Yes
       2)No
       3)Yes, and all subsequent servers
       4)No, and all subsequent servers

Enter choice [3]:
```

21. Select the entry-balanced data set that the `austin-set1` server replicates with other servers.

Copyright © 2025 Ping Identity Corporation

Example:

```
You may choose a single entry-balanced data set with which
austin-set1.example.com:389 will replicate data with other servers

    1) ou=people,dc=example,dc=com; Server Set 1
    2) None, data will not be replicated

Enter choice: 1

Testing connection to austin-set1.example.com:389 ..... Done
Testing 'cn=Proxy User,cn=Root DNs,cn=config' access ....Denied
```

22. Modify the root user for use by the PingDirectoryProxy server, specifying the directory manager password for the initial creation of the proxy user.

    Example:

```
Would you like to create or modify root user 'cn=Proxy User,
cn=Root DNs,cn=config' so that it is available for this
Directory Proxy Server? (yes / no) [yes]:

Enter the DN of an account on austin-set1.example.com:389
with which to create or manage the 'cn=Proxy User,cn=Root DNs,
cn=config' account and configuration [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':
Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User,cn=Root DNs,cn=config'privileges...Done
Setting replication set name .....
```

23. Because the replication set name has already been configured, you do not need to use the name created automatically by the PingDirectoryProxy server.

    Example:

```
This server is currently configured for replication set 'dataset1'.
Would you like to reconfigure this server for replication set
'set-1'? (yes / no) [no]:

Setting replication set name ..... Done
Verifying backend 'dc=example,dc=com' ..... Done
Verifying backend 'ou=people,dc=example,dc=com' ..... Done
Testing 'cn=Proxy User' privileges ..... Done
Verifying backend 'dc=example,dc=com' ..... Done
```

24. Define the other Austin and New York servers using the same procedure in steps 17-24.

    Example:

Copyright © 2025 Ping Identity Corporation

```
Enter another server in 'austin'

    1) Remove austin-set1.example.com:389
    b) back
    q) quit

Enter a host:port or choose a menu item [Press ENTER when
finished entering servers]: austin-set2.example.com:389

Assign server austin-set2.example.com:389 to handle requests
for one or more of the defined sets of data

    1) dc=example,dc=com
    2) ou=people,dc=example,dc=com; Server Set 1
    3) ou=people,dc=example,dc=com; Server Set 2

Enter one or more choices separated by commas: 1,3

You may choose a single entry-balanced data set with which
austin-set2.example.com:389 will replicate data with other
servers

    1) ou=people,dc=example,dc=com; Server Set 2
    2) None, data will not be replicated

Enter choice: 1

Testing connection to austin-set2.example.com:389 ....Done
Testing 'cn=Proxy User,cn=Root DNs,cn=config' access ... Denied

Would you like to create or modify root user 'cn=Proxy User,
cn=Root DNs,cn=config' so that it is available for this

```

Configuring the placement algorithm using a batch file

Configure the placement algorithm using a batch file.

About this task

You want to place new entries added through the proxy using LDAP `ADD` operations into the least used dataset. Do this using an entry-count placement algorithm. To change the placement algorithm from round-robin to entry-count, first create and enable an entry-count placement algorithm configuration object, and then disable the existing round-robin placement algorithm. The batch file, `dsconfig.post-setup`, contains the `dsconfig` commands required to create the entry-count placement algorithm and disable the old round-robin algorithm.

The batch file contains comments to explain each `dsconfig` command.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> In this example, line wrapping is used for clarity. The **`dsconfig`** command requires that the full command be provided on a single line.

The batch file itself looks like the following.

```
root@austin-proxy1:more ../dsconfig.post-setup

# This dsconfig operation creates the entry-count placement
# algorithm with the default behavior of adding entries to the
# smallest backend dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name entry-count --type entry-counter --set enabled:true

# Note that once the entry-count placement algorithm is created
# and enabled, we can disable the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then disable the
# original round-robin algorithm created during the setup
# procedure.

dsconfig set-placement-algorithm-prop
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin --set enabled:false

# At this point, LDAP ADD operations will be forwarded to an external
# server representing the dataset with the least number of entries.
```

Steps

- Run the `dsconfig` command using the batch file.

  Example:

  ```
  root@austin-proxy1: bin/dsconfig --no-prompt \
  --bindDN "cn=directory manager" --bindPassword password \
  --port 389  --batch-file ../dsconfig.post-setup
  ```

  Result:

  After the batch file has executed, a new entry-count placement algorithm, called `entry-count`, has been created and the old round-robin placement algorithm, `round-robin`, has been disabled.

Copyright © 2025 Ping Identity Corporation

```
Batch file '../dsconfig.post-setup' contains 2 commands

Executing: create-placement-algorithm --no-prompt
--bindDN "cn=directory manager" --bindPassword pass
--port 1389
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name entry-count --type entry-counter --set enabled:true

Executing: delete-placement-algorithm --no-prompt
--bindDN "cn=directory manager" --bindPassword pass
--port 1389
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin --set enabled:false
```

Rebalancing your entries

If your deployment distributes entries using an entry counter placement algorithm or third party algorithm, you might need to redistribute your entries.

If you have an environment that distributes entries across three backends using an entry counter placement algorithm, this algorithm distributes entries to the backend that has the most space. If the backends all reach their maximum capacity and you decide to add a new backend to the deployment, you must move the entries from the full backends and distribute them evenly across all the backends, including the new backend.

You might also want to deliberately rebalance your entries to meet the needs of your organization, such as by direct entry balancing based on attributes on the entries themselves. You can write a custom algorithm that looks at the value of an attribute that is being modified on the entry. Based on the attribute, you can then put this entry somewhere specific. You might use this feature if you want to have certain entries closer geographically to the client application using them. The geographical information could be included in the entry. Rebalancing would be used to move these entries to the server in the correct geographical location.

You can redistribute entry-balanced entries in two ways:

Using dynamic rebalancing

With dynamic rebalancing, as existing entries get modified, they get moved. You configure dynamic rebalancing in the entry counter placement algorithm.

Using the `move-subtree` *tool*

This tool can be used to move either small subtrees through a transactional method or to move large subtrees, potentially taking them offline for a short period.

This section describes each of these methods of entry rebalancing in more detail.

About dynamic rebalancing

During dynamic rebalancing, entries get moved as they are modified. You configure dynamic rebalancing in the entry counter placement algorithm or a third-party placement algorithm that supports rebalancing.

Copyright © 2025 Ping Identity Corporation

This algorithm keeps a count of the number of entries or the size of the backend set. Configure dynamic rebalancing using the following parameters:

`rebalancing-enabled`

Determines whether entry rebalancing is enabled. When rebalancing is enabled, the placement algorithm is consulted after `modify` and `add` operations to determine whether the target entry should be moved to a different backend set. `rebalancing-scope`

Indicates which modified entries are candidates for rebalancing. A value of `top-level` indicates that only entries immediately below the entry-balancing base can be rebalanced. A value of any indicates that entries at any level below the entry-balancing base might be rebalanced. `rebalancing-minimum-percentage`

Specifies the minimum threshold for entries to be migrated from one backend set to a preferred backend set with a smaller size. Entries are not migrated unless the percentage difference between the value of the current backend set and the value of the preferred backend set exceeds this threshold. This parameter prevents unnecessarily migrating entries back and forth between backend sets of similar sizes. `rebalancing-subtree-size-limit`

Specifies the maximum size of a subtree that can be rebalanced. `poll-interval`

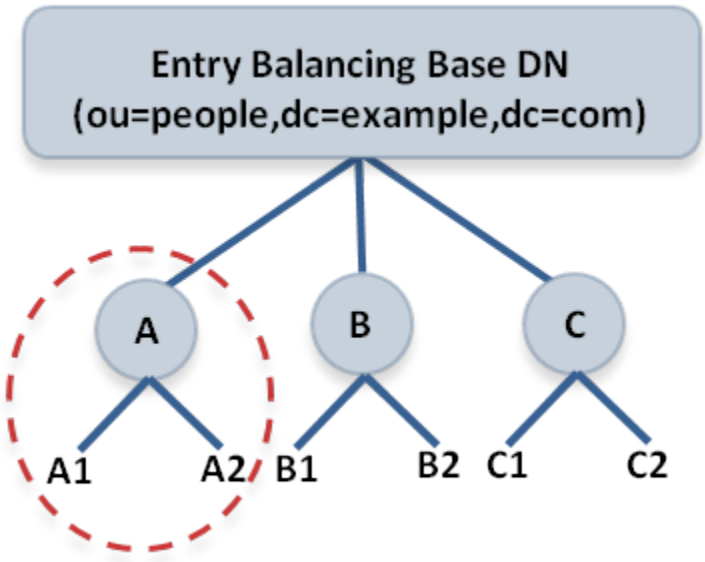
Specifies how long to wait between polling the size of the backends to determine how to rebalance and works in conjunction with the `rebalancing-minimum-percentage` property. `placement-criteria`

Determines which approach to use to select a destination backend for rebalancing. Possible values are:

- `entry-count`
- `backend-size`
- `custom`

The following figure illustrates an entry-balancing base DN and three subtrees, A, B, and C. If the rebalancing scope is set to `any`, any child entries under the base DN can be rebalanced. For example, if a change is made to entry A1, the entire subtree A might be rebalanced, depending upon how you have configured rebalancing. If the rebalancing scope is set to `top-level`, rebalancing is only triggered when entries at the top level, such as A, are modified. Changes made to subentries, such as A1 or A2, do not trigger rebalancing. Rebalancing is also triggered upon the addition of entries such as `A1`, `A2`, provided the scope is `any`.

Copyright © 2025 Ping Identity Corporation



If you are writing your own third-party algorithm, you program dynamic rebalancing using the `SelectRebalancingBackendSet` method on the placement algorithm. For more information, see the Server SDK documentation.

Configuring dynamic rebalancing

Configure dynamic rebalancing on an existing entry balancing configuration.

Steps

1. If the current placement algorithm does not support rebalancing, create an entry counter placement algorithm.

   Example:

   You can either do this using `dsconfig` in interactive mode or using the `dsconfig` command line as in this example.

   ```
   $ dsconfig create-placement-algorithm \
     --processor-name dc_example_dc_com-eb-req-processor \
     --algorithm-name rebalancing --type entry-counter \
     --set enabled:true --set rebalancing-enabled:true
   ```

2. Remove any placement algorithm previously configured on this entry-balancing request processor.

3. Throttle how many entries are being moved by the proxy so that the backend servers do not have too heavy a load by setting the `rebalancing-queue-maximum-size` property of the request processor created in the previous step.

   Example:

   By default, the value is 1000. If the load is too high, reduce this value

Copyright © 2025 Ping Identity Corporation

```
$ dsconfig set-request-processor-prop \
  --processor-name dc_example_dc_com-eb-req-processor \
  --set rebalancing-queue-maximum-size:50
```

4. Verify that the access logs are configured to display the subtrees being moved by dynamic rebalancing.

   The access logs provide a good way to monitor progress. If the write load on the backend servers is high and you see lots of rebalancing activity in the access log, lower the queue size to lower the rebalancing activity.

   Example:

   This example configures the access log to display entry rebalancing processing information.

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set log-entry-rebalancing-requests:true
```

About the move-subtree tool

The `move-subtree` tool allows you to specify subtrees for rebalancing.

You specify the source server, the target server, and one or more base distinguished names (DNs) identifying the subtrees you want to move. You can move small subtrees using the transactional method or move large subtrees, which does not use this method.

Instead, the large subtree is not fully accessible during the move, so clients might get an `insufficient access rights` error if they try to access the subtree. As entries are moved, clients can read but not write to them. When the transfer is complete, the entries are fully available to client requests.

This tool accepts a file containing a list of the base DNs of the subtrees you want to move.

> **Note**
>
> The **`move-subtree`** tool requires users to have access to the extended operations and controls needed to run the tool. Make sure to apply the following ACIs to your data.
>
> ```
> aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.5 ||
>       1.3.6.1.4.1.30221.2.5.24 || 1.3.6.1.4.1.30221.2.5.13")
>      (version 3.0; acl "Allow admin to submit move-subtree controls";
>       allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
> aci: (extop="1.3.6.1.4.1.30221.2.6.19")
>      (version 3.0; acl "Allow admin to request move-subtree extended
>       operation"; allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
> ```

About the subtree-accessibility tool

The `subtree-accessibility` tool helps you determine if a subtree has restricted access and helps you fix any problems.

Copyright © 2025 Ping Identity Corporation

If, during rebalancing, the PingDirectory server issues an alert that a subtree has been unavailable for too long, then you can use this tool to evaluate the problem.

For example, if the `move-subtree` tool is interrupted by a host machine going down unexpectedly, the subtree can't be successfully moved. You can use the `subtree-accessibility` tool to evaluate and correct any problems with the subtrees and then re-run the `move-subtree` tool.

Managing the global indexes in entry-balancing configurations

In an entry-balancing configuration, the PingDirectoryProxy server maintains the default relative distinguished name (RDN) index as well as one or more in-memory global attribute indexes.

The global indexes allow the PingDirectoryProxy server to select the correct backend server set for incoming operations, which avoids broadcasting operations to all backend sets.

The indexes can be preloaded from peer proxies or the backend directory servers when the server starts up and are updated by certain operations that come through the PingDirectoryProxy server. For example, when a new entry is added, the distinguished name (DN) of the new entry is added to the DN index of the PingDirectoryProxy server performing the operation. The indexes are also fault-tolerant and can adapt to changes made in the backend servers without going through the PingDirectoryProxy server. For example, operations are processed directly through the backend server.

This section describes:

- When to create a global attribute index
- How to reload the global index
- How to monitor the global index growth
- How to prime the global index from a peer at startup

Creating a global attribute index

Create a global attribute index for PingDirectoryProxy server to use as a optional index.

About this task

The relative distinguished name (RDN) index is referenced whenever a `modify`, `delete`, or base search is requested. The RDN index is needed when the LDAP request contains the complete distinguished name (DN) of the targeted entry. If the entry-balancing request processor is not configured to prime the RDZ index at startup, then the index is populated over time as LDAP requests are processed.

A global attribute index is an optional index and is referenced when the PingDirectoryProxy server is handling a search request with an equality filter involving an attribute, such as the `telephoneNumber` attribute with the `telephoneNumber=+11234567890` filter.

Because the PingDirectoryProxy server doesn't know what the data within the subtree view looks like or how it is searched, it can't create or recommend default global attribute index definitions. The creation of a global attribute index is based on the range of equality-filtered search requests processed by the PingDirectoryProxy server. The PingDirectory server must also have an equality or ordering index type for the associated attribute Local database (DB) Index.

Copyright © 2025 Ping Identity Corporation

The common candidates for global attribute indexing are the uniquely-valued equality-indexed attributes on the external servers, such as `uid`, `mail` and `telephoneNumber`. These attributes don't require unique values for use as global attribute indexes by the entry-balancing request processor.

Steps

- Create a global attribute index using the `dsconfig` tool with the `create-global-attribute-index` option.

  Example:

  In this example, a PingDirectoryProxy server deployment expects to process frequent searches of the form `(&(mail=user@example.com)(objectclass=person))`. The `mail` attribute is indexed for equality searches on each of the external servers behind the PingDirectoryProxy server. Because the filter is constructed with an equality match and `&` clause, you can use a global attribute index on the `mail` attribute to avoid forwarding the search request to each entry balanced dataset.

  ```
  $ bin/dsconfig create-global-attribute-index \
    --processor-name ou_people_dc_example_dc_com-eb-req-processor \
    --index-name mail --set prime-index:true \
  ```

Result

The index begins populating as search requests are made to the PingDirectoryProxy server that involve the mail attribute.

> **Tip**
>
> You can use the `reload-index` tool to fully populate the index for optimal performance as described in Reloading the global indexes.

Reloading the global indexes

The `reload-index` tool allows you to manually reload the PingDirectoryProxy server global indexes.

Use the `reload-index` tool to reload all configured indexes in the global index, including the relative distinguished name (RDN) index and all attribute indexes or to reload only the indexes you specify.

You might need to reload the index when:

- The PingDirectoryProxy server fails to successfully load its global indexes on startup.
- Changes are made to the set of indexed attributes.
- Significant changes are made to the content in backend servers.
- The integrity of the index is in question.

The `reload-index` tool schedules an operation to run within the PingDirectoryProxy server's process. You must supply the LDAP connection information so that the tool can communicate with the server through its task interface. You can schedule tasks to run immediately or at a later time. After the tasks are scheduled, manage them using the `manage-tasks` tool.

Copyright © 2025 Ping Identity Corporation

Reloading all of the indexes

About this task

Reload all the indexes within the scope of the base distinguished name (DN) `dc=example,dc=com`. The task is performed as `cn=Directory Manager` on port 389 of the localhost server.

> **Note**
>
> The existing index contents are erased before reloading.

Steps

- To reload all of the indexes within the scope of the `dc=example,dc=com` base DN, run the **`reload-index`** tool.

  Example:

  ```
  $ bin/reload-index --task --bindPassword password --baseDN "dc=example,dc=com"
  ```

Reloading the RDN and UID index

About this task

To reload the RDN and unique identifier (UID) index in the background so that the existing contents of these indexes can continue to be used:

Steps

- Run the **`reload-index`** tool with the `--index rdn` and `--index uid` options.

  Example:

  ```
  $ bin/reload-index --task --bindPassword password \
    --baseDN "dc=example,dc=com" --index rdn --index uid --background
  ```

Priming the backend server using the --fromDS option

About this task

You can force the PingDirectoryProxy server to prime from the backend directory server using the `--fromDS` option, which overrides the configuration of the `prime-index-source` property.

> **Tip**
>
> You can do this on a one-off basis if the global index appears to be growing too large.

To prime the backend server:

Steps

- Run the **`reload-index`** tool with the `--fromDS` option.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/reload-index --bindPassword password --baseDN "dc=example,dc=com" --fromDS
```

Monitoring the size of the global indexes

Monitor the size of the global indexes over LDAP and reload the indexes to prevent a build up of stale entries in the global indexes.

About this task

The proxies don't communicate changes to the indexes with one another, which can result in stale entries building up over time in the global indexes. In this situation, the PingDirectoryProxy server continues to operate normally because the global indexes are used only as a hint for where to find entries.

The rate of this growth is typically slow because in most environments the key attributes change infrequently. In addition, the global indexes are compact. However, if the global indexes start to fill up the allocated memory, you might need to flush and reload them.

If the global indexes become full, the PingDirectoryProxy server continues to operate normally, but it needs to start evicting entries from the indexes. Evicting the entries leads to more broadcast searches and reduces the overall performance of the PingDirectoryProxy server.

Steps

- To monitor the size of the global indexes over LDAP, use the `ldapsearch` with the `global-index-current-memory-percent` option.

  Example:

  ```
  $ bin/ldapsearch -b "cn=monitor" -D "uid=admin,dc=example,dc=com" -w password \
    "(objectClass=ds-entry-balancing-request-processor-monitor-entry)" \
    global-index-current-memory-percent
  ```

- To reload the indexes so they no longer hold stale information, run the `reload-index` command with the `--fromDS` option.

  This option ensures that data is loaded from backend directory servers.

  > **Tip**
  >
  > You should reload the indexes during off-peak hours because it might impact the performance while the reload is in progress.

Sizing the global indexes

Use the PingDirectoryProxy server `global-index-size` tool to help you estimate the memory size of your global indexes.

About this task

Copyright © 2025 Ping Identity Corporation

You can estimate the size of more than one index in a single invocation by providing multiple sets of options.

The `global-index-size` tool creates its estimate using the following information:

Number of keys in the index

For example, for the built-in relative distinguished name (RDN) index, the number of keys is the total number of entries in the PingDirectory server that are immediately below the balancing point. Entries more than one level below the balancing point and entries that are not subordinate to the balancing point aren't contained in the RDN index. For attribute indexes, the number of keys is the number of unique values for that attribute in the entry-balanced portion of the data.

Average size of each key, in bytes

For attributes indexes, the key is the attribute value. For the built-in RDN index, the key is the RDN directly below the balancing base distinguished name (DN). For example, for the DN `uid=user.0,dc=example,dc=com` under the balancing base DN of `dc=example,dc=com`, the key size is 10 bytes (the number of bytes in the RDN `uid=user.0`).

Estimated number of keys

This value corresponds to the maximum number of keys you expect in your PingDirectory server. The number of keys is provided in the index-size configuration property of the `global-attribute-index` object when you configure an attribute index. For the built-in RDN index, the configured number of keys is provided in the `rdn-index-size` property. If you do not provide a value, the tool assumes that the configured number of keys is the same as the actual number of keys.

Steps

- To estimate the size of two separate indexes, run the `global-index-size` tool.

  Example:

  In this example, the two indexes both have 10,000,000 keys but with differing average key sizes. The configured number of keys is assumed to be equal to the actual number of keys.

```
$ bin/global-index-size --numKeys 10000000 \
  --averageKeySize 11 --numKeys 10000000 \
  --averageKeySize 15

Num Keys : Cfg. Num Keys : Avg. Key Size : Est. Memory Size
---------:---------------:---------------:-----------------
10000000 : 10000000      : 11            : 159 mb
10000000 : 10000000      : 15            : 197 mb
```

Priming the global indexes on startup

The PingDirectoryProxy server can prime the global indexes at startup from the backend directory server or from a peer proxy server, preferably one that resides on the same LAN or subnet.

Copyright © 2025 Ping Identity Corporation

When priming occurs locally, you can avoid WAN bandwidth consumption and reduce the processing load on the directory servers in the topology. You can specify the data sources for the index priming and the order in which priming occurs from these sources. Use the `prime-index-source` property to specify the sources of data, either `ds`, `file` or some combination of the two.

The order you specify is the order in which priming is attempted from these sources. Priming is most efficient if the source server is on the same local network as the PingDirectoryProxy server.

For example, if you specify `prime-index-source:file,ds`, priming is performed from the `global-index` data file created from the previous run of the directory servers. If the entire global index has been primed previously from a startup or reloaded-index directory server's source, the contents of the global index are written to disk periodically with the `file,ds` configuration.

Configuring all indexes at startup

Steps

- To prime all indexes at startup, run the `dsconfig` tool.

  Example:

  The following example configures the entry-balancing request processor so that it primes the global index from the persisted file, if present, or from an external directory server's source, if necessary.

```
$ bin/dsconfig set-request-processor-prop \
  --processor-name dc_example_dc_com-eb-req-processor \
  --set prime-all-indexes:true --set prime-index-source:file \
  --set prime-index-source:ds
```

Configuring the global indexes manually

About this task

If you don't want to configure priming during setup, you can configure the index priming manually.

To do this, create an external server, create a global attribute index, and change the entry-balancing request processor to load indexes from the external server.

Steps

1. To create an external server of the PingDirectoryProxy type to represent a peer of the PingDirectoryProxy server, use the `dsconfig` tool with the `create-external-server` subcommand.

   Example:

```
$ bin/dsconfig create-external-server \
  --server-name intra-proxy-host.example.com:3389 \
  --type PingDirectoryProxy-server \
  --set server-host-name:intra-proxy-host \
  --set server-port:338 \
  --set "bind-dn:cn=Directory Manager" \
  --set "password:secret123"
```

Copyright © 2025 Ping Identity Corporation

2. Create a global attribute index on the `uid` attribute.

   Example:

   ```
   $ bin/dsconfig create-global-attribute-index \
     --processor-name dc_example+dc+com-eb-req-processor \
     --index-name uid \
   ```

3. To load the indexes at startup from the peer PingDirectoryProxy server, change the entry-balancing request processor using `dsconfig set-request-processor-prop`.

Persisting the global index from a file

About this task

The PingDirectoryProxy server supports periodically persisting the global index to a file and priming the global index from the persisted file when the server is restarted.

You can configure an Entry Balancing Request Processor to periodically persist the global index to disk so that when the Entry Balancing Request Processor is reinitialized on startup it can prime the values from disk instead of putting load on the remote servers. Reading the index from disk eliminates the load on backend PingDirectory server instances if many PingDirectoryProxy server instances are starting at the same time.

You can configure an entry-balancing request processor to persist the global index to disk by including `file` as one of the prime index sources with the `prime-index-source` property. The `persist-global-index-frequency` property controls the frequency at which the file is written.

The global index must be primed before it is persisted. It can be primed initially using a peer PingDirectoryProxy server or from a backend PingDirectory server.

When new global attribute indexes are added on a running PingDirectoryProxy, the global index can be primed with those attribute indexes by running the `rebuild-index` tool. The `rebuild-index` tool uses a remote server for priming the global index, even if `file` is configured as a source.

On subsequent restarts of the PingDirectoryProxy server, the global index is primed from the persisted file instead of going over the network to a remote server, which allows it to be primed much faster than if it is using a remote priming source. During server startup, the global index priming works by using each configured `prime-index-source` property in the specified order until it is fully primed to take advantage of what is available locally before contacting one or more remote servers.

Steps

- To prime all indexes at startup from a file, run the `dsconfig` tool.

  Example:

  ```
  dsconfig -n set-request-processor-prop \
    --processor-name entry-balancing \
    --set prime-index-source:file \
    --set prime-index-source:ds \
    --set persist-global-index-frequency:10s \
    --set persist-global-index-directory:/servers/proxy-1/index-files \
    --set prime-all-indexes:true
  ```

Copyright © 2025 Ping Identity Corporation

Priming or reloading the global indexes from Sun Directory servers

When priming or reloading a global index based on a Sun Directory Server environment, the Sun servers might become overwhelmed and unresponsive because of their method of streaming data.

About this task

To reduce the impact of priming and reloading on these servers, use the `prime-search-entry-per-second` property and the `--searchEntryPerSecond` property of the `reload-index` command. These properties control the rate at which the PingDirectoryProxy server accepts search result entries from the backend directory servers.

The `index-priming-idle-listener-timeout` property specifies the amount of time an extended operation response listener can be idle while the global index priming is in progress. For example, if the global index is priming and a backend server stops returning results but doesn't disconnect, this timeout can be used to force a retry of the operation.

> **Tip**
>
> To find the optimum rate, start low and specify a few thousand search entries per second. Then increase as necessary.

To reduce the impact on server performance:

Steps

- To reduce the impact of priming on servers, use the `prime-search-entry-per-second` property.
- To reduce the impact of reloading these indexes, use the `--searchEntryPerSecond` property of the **`reload-index`** command.
- To specify the amount of time an extended operation response listener can be idle while the global index priming is in progress, use the `index-priming-idle-listener-timeout`.

Working with alternate authorization identities

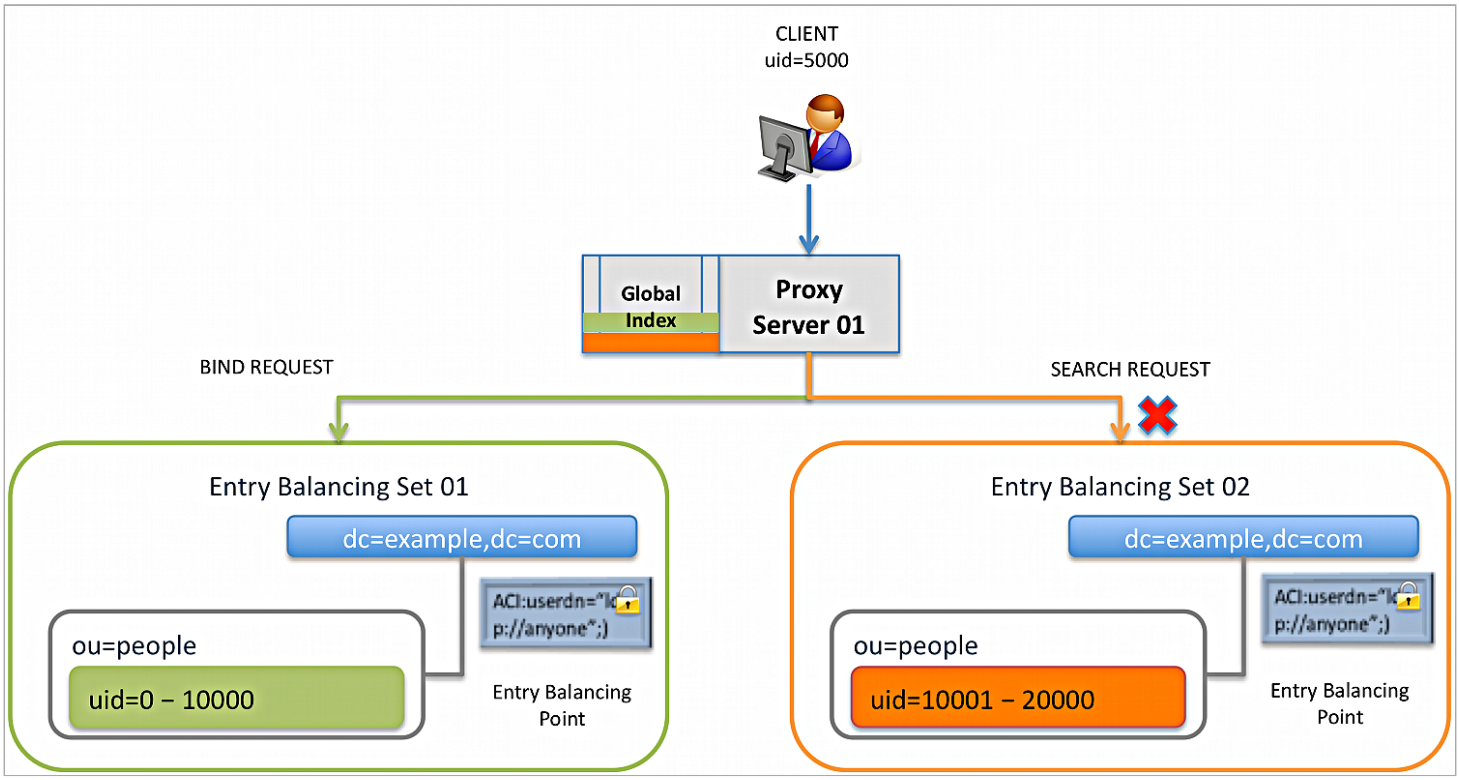
The following sections cover the procedures to configure the alternate authorization identities for the PingDirectoryProxy server.

Access control rules in an entry-balanced deployment are configured in the PingDirectory backend servers and require access to the entry contents of the user issuing the request.

This can introduce a potential issue when clients to the PingDirectoryProxy server authenticate as users whose entries are among the entry-balanced sets. If the server processing a request doesn't contain the issuing user's entry, the access control can't be evaluated. One solution to this problem is to make use of an alternate authorization identity for the user, which references an entry that exists in all PingDirectory server's in all backend sets and has an equivalent set of access control rights as the authenticated user.

For the following example, assume a deployment has two entry-balancing sets: set-01 and set-02. Set-01 has entries in the `uid=0-10000` range, while set-02 has entries for `uid=10001-20000`.

Copyright © 2025 Ping Identity Corporation



Entry-Balancing Issue with Clients Not Present in the Underlying Data Set

Processing steps

1. The client with `uid=5000` binds to the PingDirectoryProxy server, which sends a `BIND` request to entry-balancing set-01.
2. The client sends a `SEARCH` request with filter `(uid=15000)`.
3. The PingDirectoryProxy server determines that `uid=15000` lives on entry-balancing set-02.
4. The PingDirectoryProxy server determines that the entry for the authenticated user with `uid=5000` doesn't exist in set-02 and that the access control handler has to reject the `SEARCH` request issued by an unknown user.
5. The PingDirectoryProxy server observes that the PingDirectory server processing a request doesn't contain the entry of the user issuing the request and decides to use an alternate authorization identity.

About alternate authorization identities

Alternate authorization identities allow for the proper evaluation of access control rules for users whose entries aren't present within an entry-balanced dataset.

Whenever the PingDirectoryProxy server forwards a request to the backend set containing the user's entry, it forwards the request with an authorization identity that reflects the user's actual identity because the user is known to servers in that set. However, when forwarding a request to a backend set that doesn't contain the user's entry, the PingDirectoryProxy server uses an alternate authorization identity that reflects the generic user with the same set of rights as the actual user issuing the request.

Alternate authorization identities allow for the proper evaluation of access control rules for users whose entries are not present within an entry-balanced dataset.

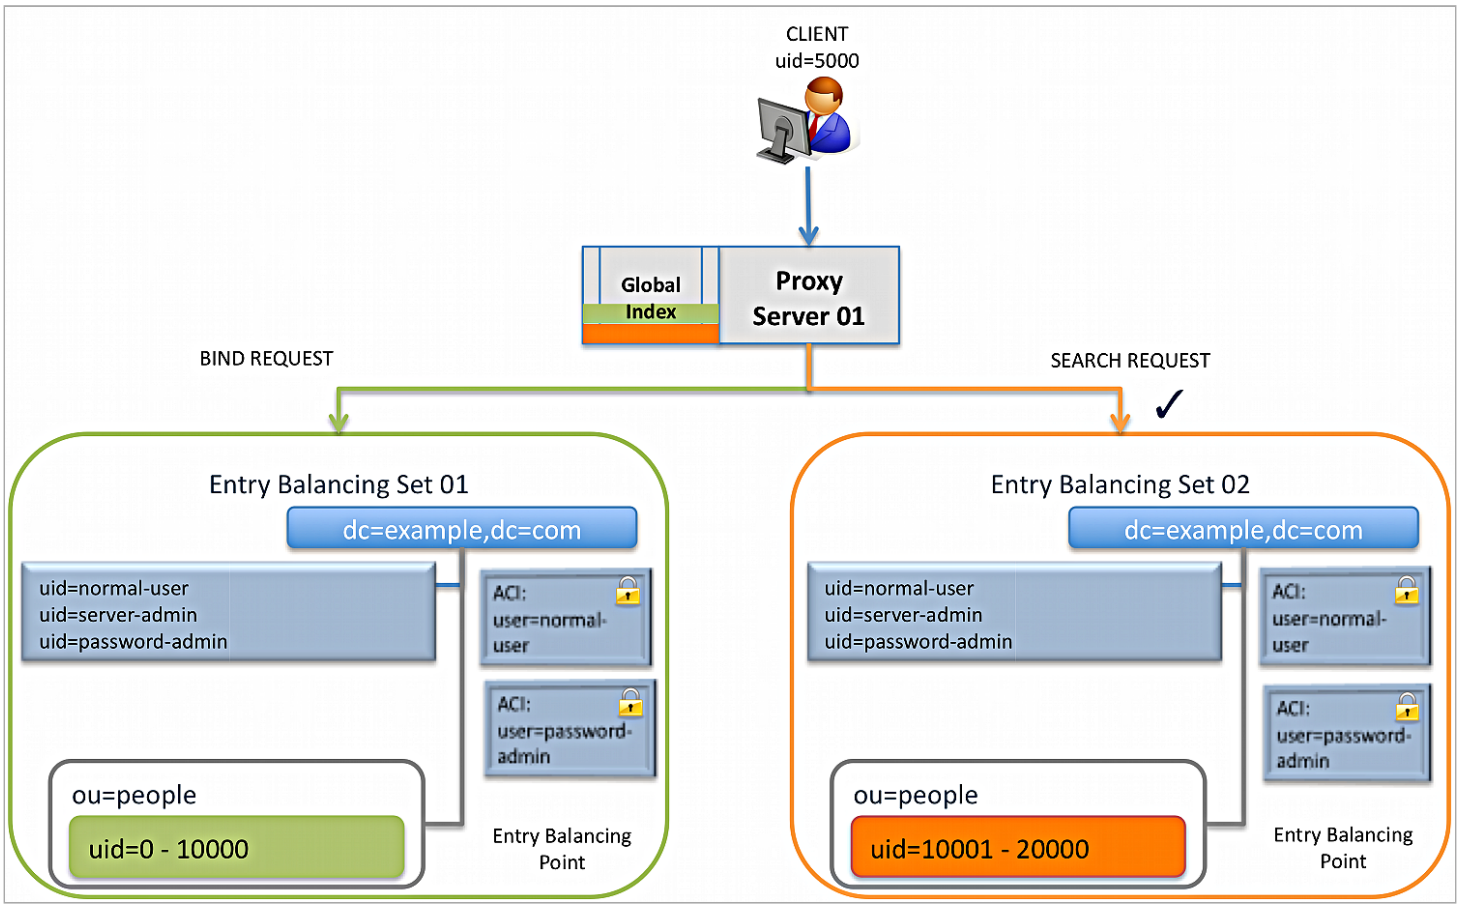
Copyright © 2025 Ping Identity Corporation

There are only a few different generic classes of users from an access control perspective. These can be placed in a portion of the directory information tree (DIT) that isn't below the entry-balancing base distinguished name (DN) and is replicated to all servers in the topology.

Whenever a user authenticates to the PingDirectoryProxy server, the server can keep track of which backend set holds that user's entry and determine whether an alternate authorization identity is required. The server can determine which of these generic accounts best describes the rights that the user should have.

For the following example, assume that you have three classes of users: full administrators, password administrators, and normal users. Assume that you create the following entries in the topology and assign them the appropriate access rights:

- `uid=normal user,dc=example,dc=com`
- `uid=server-admin,dc=example,dc=com`
- `uid=password-admin,dc=example,dc=com`



Alternate Authorization Identity Solves Access Control Issues in Entry-Balancing Deployments

Processing steps

1. The client with `uid=5000` binds to the PingDirectoryProxy server, which sends a `BIND` request to entry-balancing set-01.
2. The client sends a `SEARCH` request for `uid=15000`.
3. The PingDirectoryProxy server determines that `uid=15000` lives on entry-balancing set-02.

Copyright © 2025 Ping Identity Corporation

4. The PingDirectoryProxy server then determines that the client `uid=5000` doesn't have an entry on entry-balancing set-02.
5. The PingDirectoryProxy server uses an alternate authorization identity that reflects the generic user, `uid=normal user`, which has the same set of rights as the client `uid=5000` issuing the request.
6. The access control is accepted and the `SEARCH` request returns a response for `uid=5000`.
7. When an alternate authorization identity is invoked, `authzID='dn:uid=normal user,dc=example,dc=com` records in the server log, which indicates the use of the alternate authorization identity.

   For example, if the `user.15000` is in a different backend set from `user.5000`, the log shows the following response.

```
% bin/ldapsearch -D "uid=user.5000,ou=people,dc=example,dc=com" -w pasword \
  -b uid=user15000,ou=people,dc=example,dc=com "(objectclass=)"

[18/Aug/2013:11:54:35 -0500] SEARCH REQUEST conn=153 op=1 msgID=2
via="app='Directory-Proxy address='127.0.0.1'
authzID='dn:uid=normal user,dc=example,dcom' sessionID='conn=2'
requestID='op=1'" base="uid=user.150000,ou=people,dc=example,dc=com"scope=2
filter="(objectclass=)" attrs="ALL"

[18/Aug/2013:11:54:35 -0500] SEARCH REQUEST conn=153 op=1 msgID=2 resultCode=0 etime=2.038
entriesReturned=1 authzDN="uid=normal-user,dc=example,dc=com"
```

Configuring alternate authorization identities

Alternate authorization identities are specified by the `authz-attribute` property of the entry-balancing request processor configuration object.

About this task

By default, the `authz-attribute` property has the default value of `ds-authz-map-to-dn`, which is an attribute reserved for this purpose.

If a user entry has a value for `ds-authz-map-to-dn`, whether it's explicitly contained in the entry or only present with a virtual attribute, that value is used to specify the alternate authorization identity for the user. Otherwise, the default authorization identity, as indicated with the `authz-dn` configuration property, is used to determine the alternate authorization identity.

Steps

1. Set the `authz-dn` property of the entry-balancing request processor configuration using the `dsconfig` tool.

   > **Note**
   >
   > If any user among the balanced entries doesn't have an alternate authorization identity defined, the PingDirectoryProxy server uses the value of the `authz-dn` property of the entry-balancing request processor configuration.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-request-processor-prop \
  --processor-name dc_example_dc_com-eb-req-processor \
  --set "authz-dn:uid=normal user,dc=example,dc=com"
```

2. Create an auxiliary object class containing `ds-authz-map-to-dn` as an allowed attribute.
3. Add the auxiliary object class value to all user entries of interest.
4. Add the following attribute value to a `server-admin` user.

   Example:

   ```
   ds-authz-map-to-dn: uid=server-admin,dc=example,dc=com
   ```

Managing entry-balancing replication

Replication in the PingDirectoryProxy server synchronizes directory data between all servers in the topology.

However, In a deployment using the entry-balancing feature, directory data under the entry-balancing point is split into multiple data sets. Each data set is replicated to ensure high availability between a subset of the servers in the topology.

Other directory data, such as the schema or data above the entry-balancing point, is replicated between all servers in the topology.

This section about replication in an entry-balancing environment contains the following:

- Overview of replication in an entry-balancing environment
- Replication prerequisites in an entry-balancing deployment
- About the --restricted argument of the dsreplication command-line Tool
- Checking the status of replication in an entry-balancing deployment
- Example of configuring entry-balancing replication

Overview of replication in an entry-balancing environment

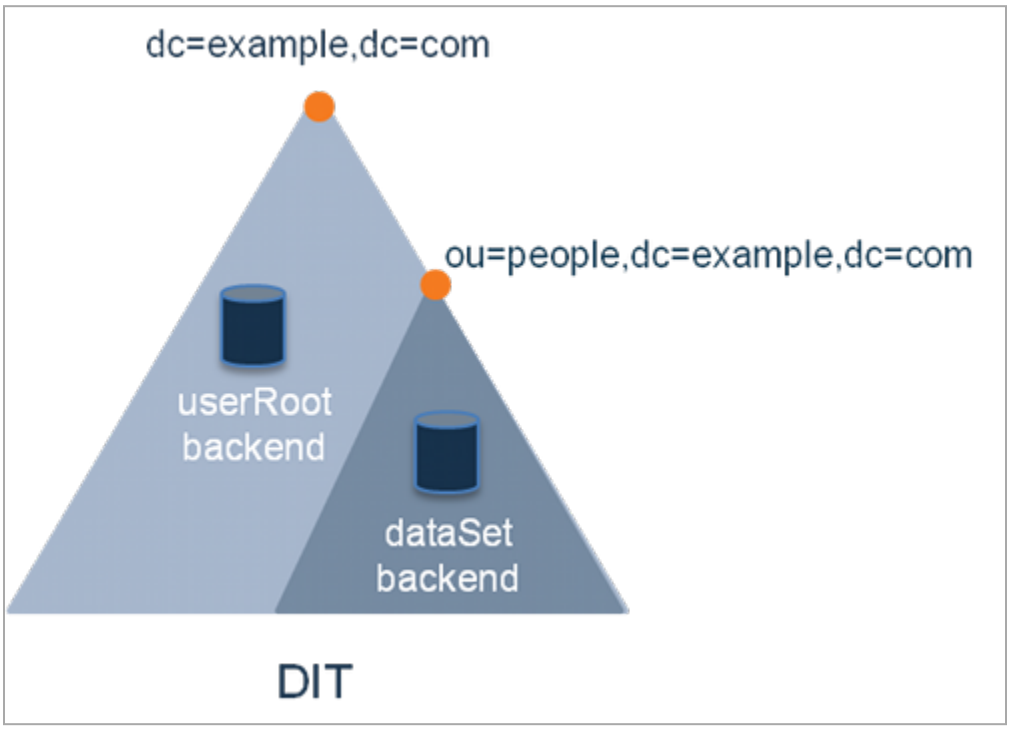
In an entry-balanced deployment some data is replicated everywhere, such as the schema, the server registry, and other shared data, and some data is replicated only on certain servers.

A replication domain contains all of the servers in a replicated topology and shares a schema. The replication domain is associated with the base distinguished name (DN) and must be a base DN of a backend.

By default, replication propagates updates to all replication servers in the topology. However, updates to data under the entry-balancing point must be replicated only among server instances in the same data set. Replication requires that in these deployments the PingDirectory server is configured with a `replication-set-name` global configuration property and two backends. One backend has a base DN that is replicated globally, such as `dc=example,dc=com`, and the second backend has a base DN associated with the entry-balancing point, such as `ou=people,dc=example,dc=com`.

Copyright © 2025 Ping Identity Corporation

The following illustration demonstrates the global and restricted backends in a directory information tree (DIT).



If a data set name is not defined when you set up the PingDirectoryProxy server, one is provided by default. The proper configuration of an entry-balancing environment requires coordination between the PingDirectory server and the PingDirectoryProxy server. After you enable replication, you can designate the replication domain as the domain participating in entry balancing.

For more details about replication, managing the replication topology, and working with multiple backends, see the PingDirectory Server Administration Guide.

Replication prerequisites in an entry-balancing deployment

Before you can enable replication in an entry-balancing deployment, you must have the following set up in your server topology:

Multiple local DB backends

When you set up the PingDirectory server instances, you need two backends:

- A global backend for globally replicated data, such as `userRoot`
- A backend for the balancing point base distinguished name (DN), such as `dataSet`

Both backends must be enabled for replication and initialized separately.

Replication set name

Every PingDirectory server in your replicated topology must have a replication set name. This replication set name coordinates the PingDirectoryProxy server and the PingDirectory server.

The restricted domain is only replicated within instances using the same replication set name.

Copyright © 2025 Ping Identity Corporation

Multiple PingDirectoryProxy server subtree views

The entry-balanced proxy configuration relies on multiple subtree views, one for the globally replicated base DN and one for the entry-balancing point base DN. The globally replicated base DN has a proxying request processor associated with it. The restricted base DN has an entry-balancing request processor associated with it.

> **Tip**
>
> Configure the subtree views after running your setup using the `create-initial-proxy-config` tool.

Homogeneous domains

All servers in a replication topology must have the same domains.

> **Note**
>
> Because the PingDirectory server replication topology assumes that all domains are on all servers, it is not suitable for environments with an inconsistent presence of domains across the server topology.

About the --restricted argument of the dsreplication command-line Tool

The `dsreplication` tool with the `--restricted` argument specifies a base distinguished name (DN) when multiple domains are enabled in an entry balanced environment.

When enabling replication for a server that takes part in an entry-balanced environment, the multiple domains involved are enabled at the same time. There is a global domain and a restricted domain. The restricted domain represents the entry-balancing point. Each base DN is defined in a separate local database (DB) backend. Use the `dsreplication` command-line interface (CLI) tool with the `--restricted` argument to specify which base DN is considered an entry-balancing point.

Using the --restricted argument of the dsreplication command-line tool

About this task

To enable replication between two servers with entry balancing:

Steps

- Choose one of the following ways to run the `dsreplication` command:

  Choose from:

  - Run `dsreplication` in non-interactive mode.

    See the following example.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsreplication enable --host1 host1.example.com \
  --port1 1389 --bindDN1 "cn=Directory Manager" \
  --bindPassword1 secret --replicationPort1 8989 \
  --host2 host2.example.com --port2 2389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 secret \
  --replicationPort2 8989 --baseDN dc=example,dc=com \
  --baseDN ou=people,dc=example,dc=com \
  --restricted ou=people,dc=example,dc=com
```

- Run `dsreplication` using the interactive command line.

  1. Enter `dsreplication` and the LDAP connection parameters.
  2. Specify that an entry balancing is being used.
  3. Specify the base distinguished name (DN) of the entry-balancing point.

  See the following example.

```
You must choose at least one base DN to be replicated.

Replicate base DN dc=example,dc=com? (yes / no) [yes]: yes

Replicate base DN ou=people,dc=example,dc=com? (yes / no) [yes]: yes

Do you plan to configure entry balancing using the Directory Proxy Server? (yes / no) [no]:
yes

Is dc=example,dc=com an entry-balancing point? (yes / no) [no]: no

Is ou=people,dc=example,dc=com an entry-balancing point? (yes / no) [no]: yes
```

Checking the status of replication in an entry-balancing deployment

You can use the `dsreplication` status tool to check the status of an entry-balancing deployment.

About this task

In this example, the `ou=people,dc=example,dc=com` subtree is entry-balanced.

The data is split into two sets, `set1` and `set2`. The servers `host1` and `host2` are in replication set `set1` and servers `host3` and `host4` are in replication set `set2`.

Steps

- To get a status of replication in the entry-balancing deployment, run the `dsreplication` command.

  Example:

> **Note**
>
> By default, all of the sets are displayed. To view only a specific replication set, use the `--setName` option.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsreplication status --hostname host1.example.com \
  --port 1389 --adminUID admin --adminPassword secret
```

Result:

```
          --- Replication Status for dc=example,dc=com: Enabled ---

Server    : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security

----------:--------:------------------:--------------------------:------:--------

austin1.example.com:1389 : 1000    : 0            : N/A              : 8989 : Enabled
austin2.example.com:2389 : 1000    : 0            : N/A              : 8989 : Enabled
newyork1.example.com:3389: 1000    : 0            : N/A              : 8989 : Enabled
newyork2.example.com:4389: 1000    : 0            : N/A              : 8989 : Enabled

 -- Replication Status for ou=people,dc= example,dc=com (Set: set1): Enabled --

Server    : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security

----------:--------:------------------:--------------------------:------:--------

austin1.example.com:1389 : 1000000 : 0            : N/A            : 8989 : Enabled
austin2.example.com:2389 : 1000000 : 0            : N/A            : 8989 : Enabled

---Replication Status for ou=people,dc= example,dc=com (Set: set2): Enabled ---

Server    : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security

----------:--------:------------------:--------------------------:------:--------

newyork1.example.com:3389 : 1000000 : 0            : N/A            : 8989 : Enabled
newyork2.example.com:4389 : 1000000 : 0            : N/A            : 8989 : Enabled
```

Example of configuring entry-balancing replication

This section covers how to set up a four-server replication topology that uses entry balancing to distribute entries across the servers and provides a start-to-finish example to walk you through this process.

Assumptions

The example assumes the following conditions:

- None of the servers have participated in any previous replication topology. This is supported for one or multiple entry balancing domains.
- This example uses the LDAP (389) and replication (8989) ports. It configures the following hosts:
  - austin1.example.com
  - newyork1.example.com
  - austin2.example.com

Copyright © 2025 Ping Identity Corporation

- newyork2.example.com

- The global domain is `dc=example,dc=com`, which is replicated across all servers.
- The data below the entry-balancing point of `ou=people,dc=example,dc=com` is distributed across two data sets, dataSet1 and dataSet2.
- Each data set is replicated between two directory servers. Each of these servers is associated with one of two locations, Austin or New York.

Configuration summary

To configure replication in an entry-balanced deployment:

1. Install two directory servers in an Austin location and two in a New York location.
2. Create a new backend, called `dataset`, to store the entry-balancing data set.
3. Define entry-balancing set names `dataSet1` and `dataSet2` for assignment to the `replication-set-name` Global Configuration Property of the PingDirectory server instances.
4. Import the data representing the global domain, stored in `userRoot`, into a server. Choose a server for each of the entry-balancing data sets, both stored in the backend named `dataset`.
5. Enable replication and initialize remaining servers.
6. Configure the proxies.
7. Check the status of replication.

Installing the PingDirectory server

About this task

Install four PingDirectory server instances, two in the Austin location and two in the New York location:

- austin1.example.com
- newyork1.example.com
- austin2.example.com
- newyork2.example.com

Steps

1. Install the first Austin server, `austin1`.

   Example:

   ```
   root@austin1# ./setup --baseDN dc=example,dc=com \
   --ldapPort 389 --rootUserDN "cn=Directory Manager" \
   --rootUserPassword pass --no-prompt --acceptLicense \
   --instanceName ds1 --location Austin
   ```

2. Install the second Austin server, `austin2`.

Copyright © 2025 Ping Identity Corporation

Example:

```
root@austin2 # ./setup --baseDN dc=example,dc=com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --no-prompt --acceptLicense \
--instanceName ds2 --location Austin
```

3. Install the first New York server, `newyork1`.

   Example:

   ```
   root@newyork1# ./setup --baseDN dc=example,dc=com \
   --ldapPort 389 --rootUserDN "cn=Directory Manager" \
   --rootUserPassword pass --no-prompt --acceptLicense \
   --instanceName ds3 --location NewYork
   ```

4. Install the second New York server, `newyork2`.

   Example:

   ```
   root@newyork# ./setup --baseDN dc=example,dc=com \
   --ldapPort 389 --rootUserDN "cn=Directory Manager" \
   --rootUserPassword pass --no-prompt --acceptLicense \
   --instanceName ds4 --location NewYork
   ```

Creating the database backends and defining the replication set name

About this task

To store the entry-balancing data set, create a new backend.

Steps

1. On each server, create a dataset backend named `dataset`.

   Example:

   ```
   ./bin/dsconfig --no-prompt create-backend \
   --backend-name dataset --type local-db --set enabled:true \
   --set base-dn:ou=people,dc=example,dc=com
   ```

2. Set the `replication-set-name` for `austin1.example.com` and `newyork1.example.com` to `dataset1`.

   Example:

   ```
   ./bin/dsconfig --no-prompt \
   set-global-configuration-prop \
   --set replication-set-name:dataset1
   ```

3. Set the `replication-set-name` for `austin2.example.com` and `newyork1.example.com` to `dataset2`.

   Example:

Copyright © 2025 Ping Identity Corporation

```
./bin/dsconfig --no-prompt \
set-global-configuration-prop \
--set replication-set-name:dataset2
```

Creating and setting the locations

About this task

Create and set the locations of the Austin and New York server instances.

Steps

1. On the Austin servers, create two instance locations, `newyork` and `austin`.

   Example:

   ```
   ./bin/dsconfig --no-prompt create-location --location-name austin

   ./bin/dsconfig --no-prompt create-location --location-name newyork \
   --set preferred-failover-location:austin
   ```

2. Set the location of the Austin server instances to `austin`.

   Example:

   ```
   ./bin/dsconfig --no-prompt set-location-prop --location-name austin \
   --add preferred-failover-location:newyork

   ./bin/dsconfig --no-prompt set-global-configuration-prop \
   --set location:austin
   ```

3. On the New York servers, create two instance locations, `newyork` and `austin`.

   Example:

   ```
   ./bin/dsconfig --no-prompt create-location \
   --location-name austin

   ./bin/dsconfig --no-prompt create-location \
   --location-name newyork \
   --set preferred-failover-location:austin
   ```

4. Set the location of on the New York server instances to `newyork`.

   Example:

Copyright © 2025 Ping Identity Corporation

```
./bin/dsconfig --no-prompt set-location-prop \
--location-name austin \
--add preferred-failover-location:newyork

./bin/dsconfig --no-prompt set-global-configuration-prop \
--set location:newyork
```

Importing the entries

Import the `userRoot` data based on data defined in the `userRoot.ldif` file into one server.

About this task

Choose a server for each of the entry-balancing data sets, both stored in the dataset backend.

> **Note**
>
> The `userRoot.ldif` file doesn't contain entries at or within the entry-balancing point, `ou=people,dc=example,dc=com`.

Steps

1. Import the userRoot data using the `import-ldif` command.

   Example:

   ```
   root@austin1# ./bin/import-ldif --backendID userRoot \
   --ldifFile /data/userRoot.ldif \
   --includeBranch dc=example,dc=com \
   --rejectFile /data/austin1-import-rejects \
   --port 389
   --hostname austin1.example.com
   ```

2. Import the `dataSet1` data that is assigned the `replication-set-name` on one server into the dataset backend.

   Example:

   ```
   root@austin1# ./bin/import-ldif --backendID dataset \
   --ldifFile /data/dataset1.ldif \
   --includeBranch ou=people,dc=example,dc=com \
   --rejectFile /data/austin1-dataset-import-rejects \
   --hostname austin1.example.com --port 389
   ```

3. Import the `dataSet2` data that is assigned the `replication-set-name` on one server into the dataset backend.

   Example:

   ```
   root@austin2# ./bin/import-ldif --backendID dataset \
   --ldifFile /data/dataset2.ldif \
   --includeBranch ou=people,dc=example,dc=com \
   --rejectFile /data/austin2-dataset-import-rejects \
   --hostname austin2.example.com --port 389
   ```

Copyright © 2025 Ping Identity Corporation

Enabling replication in an entry-balancing deployment

Enable replication between the servers and initialize the remaining servers without data.

About this task

> **Note**
>
> In this example, the `--restricted` domain is specified in the **`dsreplication`** command.

To enable replication on the servers in the topology:

Steps

1. Run **`dsreplication enable`**.

   Example:

   ```
   root@austin1# ./bin/dsreplication enable \
   --host1 austin1.example.com \
   --port1 389 --bindDN1 "cn=directory manager" \
   --bindPassword1 pass --host2 austin2.example.com \
   --port2 389 --bindDN2 "cn=directory manager" \
   --bindPassword2 pass \
   --replicationPort1 8989 \
   --replicationPort2 8989 \
   --baseDN dc=example,dc=com \
   --baseDN ou=people,dc=example,dc=com \
   --restricted ou=people,dc=example,dc=com \
   --adminUID admin --adminPassword pass --trustAll \
   --no-prompt
   ```

   > **Note**
   >
   > Running the **`dsreplication enable`** command for the first time creates the administrator account.

2. Enable replication between `austin1` and `newyork1`.

   Example:

   This procedure automatically also enables replication between `austin2` and `newyork1`.

Copyright © 2025 Ping Identity Corporation

```
root@austin1# ./bin/dsreplication enable \
--host1 austin1.example.com \
--port1 389 --bindDN1 "cn=directory manager" \
--bindPassword1 pass --host2 newyork1.example.com \
--port2 389 --bindDN2 "cn=directory manager" \
--bindPassword2 pass \
--replicationPort1 8989 \
--replicationPort2 8989 \
--baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--restricted ou=people,dc=example,dc=com \
--adminUID admin --adminPassword pass --trustAll \
--no-prompt
```

3. Enable replication between `austin1` and `newyork2`.

   Example:

   ```
   root@austin1# ./bin/dsreplication enable \
     --host1 austin1.example.com \
     --port1 389 --bindDN1 "cn=directory manager" \
     --bindPassword1 pass --host2 newyork2.example.com \
     --port2 389 --bindDN2 "cn=directory manager" \
     --bindPassword2 pass \
     --replicationPort1 8989 \
     --replicationPort2 8989 \
     --baseDN dc=example,dc=com \
     --baseDN ou=people,dc=example,dc=com \
     --restricted ou=people,dc=example,dc=com \
     --adminUID admin --adminPassword pass --trustAll \
     --no-prompt
   ```

   Result:

   The entry-balancing replication setup is complete.

4. Initialize the remaining servers without data.

   1. Initialize the global domain, `dc=example,dc=com` on `austin2`, `newyork1`, and `newyork2` servers.

      Example:

      ```
      root@austin1# ./bin/dsreplication initialize \
        --hostSource austin1.example.com --portSource 389 \
        --hostDestination austin2.example.com \
        --portDestination 389 --adminUID admin \
        --adminPassword password \
        --baseDN dc=example,dc=com \
        --no-prompt
      ```

   2. Initialize the entry-balancing domain, `ou=people,dc=example,dc=com`, from `austin1` to `newyork2`.

      Example:

Copyright © 2025 Ping Identity Corporation

```
root@austin1# ./bin/dsreplication initialize \
  --hostSource austin1.example.com --portSource 389 \
  --hostDestination newyork1.example.com \
  --portDestination 389 --adminUID admin \
  --adminPassword password \
  --baseDN dc=example,dc=com \
  --baseDN ou=people,dc=example,dc=com \
  --no-prompt
```

3. Initialize the entry-balancing domain, `ou=people,dc=example,dc=com`, from `austin2` to `newyork2`.

   Example:

```
root@austin2# ./bin/dsreplication initialize \
  --hostSource austin2.example.com --portSource 389 \
  --hostDestination newyork2.example.com \
  --portDestination 389 --adminUID admin \
  --adminPassword password \
  --baseDN dc=example,dc=com \
  --baseDN ou=people,dc=example,dc=com \
  --no-prompt
```

> **Note**
>
> After `austin2` is initialized with the global domain, you can combine steps 4b and 4c by initializing both domains with one invocation.

Checking the status of replication

After you have configured replication, check the status of the replication topology using the `dsreplication status` command.

Steps

- To check the replication topology status, run the `dsreplication status` command .

  Example:

```
root@austin1# ./bin/dsreplication status \
--adminPassword pass --no-prompt --port 389
```

Managing the PingDirectoryProxy server

After you have configured the PingDirectoryProxy server, you can manage the day-to-day operations of your deployment using the monitoring and logging features.

Copyright © 2025 Ping Identity Corporation

Managing logs

The PingDirectoryProxy server provides several different log publisher types that provide information about how the server is processing.

About the default logs

You can view all logs in the `PingDirectoryProxy/logs` directory. The following logs are documented in detail:

- Error Log
- server.out Log
- Debug Log
- Config Audit Log and the Configuration Archive
- Access Log
- Setup Log
- Tool Log
- LDAP SDK Debug Log

Error log

By default, this log file is available at `logs/errors` below the server install root and it provides information about warnings, errors, and other significant events that occur within the server. A number of messages are written to this file on startup and shutdown, but while the server is running there is normally little information written to it. In the event that a problem does occur, however, the server writes information about that problem to this file.

The following is an example of a message that might be written to the error log:

```
[11/Apr/2011:10:31:53.783 -0500] category=CORE severity=NOTICE msgID=458887 msg="The Directory Server has
started successfully"
```

The category field provides information about the area of the server from which the message was generated. Available categories include ACCESS_CONTROL, ADMIN, ADMIN_TOOL, BACKEND, CONFIG, CORE, DSCONFIG, EXTENSIONS, PROTOCOL, SCHEMA, JEB, SYNC, LOG, PLUGIN, PROXY, QUICKSETUP, REPLICATION, RUNTIME_INFORMATION, TASK, THIRD_PARTY, TOOLS, USER_DEFINED, UTIL, and VERSION.

The severity field provides information about how severe the server considers the problem to be. Available severities include:

- DEBUG – Used for messages that provide verbose debugging information and do not indicate any kind of problem. Note that this severity level is rarely used for error logging, because the server provides a separate debug logging facility.

Copyright © 2025 Ping Identity Corporation

- INFORMATION – Used for informational messages that can be useful from time to time but are not normally something that administrators need to see.
- MILD_WARNING – Used for problems that the server detects, which can indicate something unusual occurred, but the warning does not prevent the server from completing the task it was working on. These warnings are not normally something that should be of concern to administrators.
- MILD_ERROR – Used for problems detected by the server that prevented it from completing some processing normally but that are not considered to be a significant problem requiring administrative action.
- NOTICE – Used for information messages about significant events that occur within the server and are considered important enough to warrant making available to administrators under normal conditions.
- SEVERE_WARNING – Used for problems that the server detects that might lead to bigger problems in the future and should be addressed by administrators.
- SEVERE_ERROR – Used for significant problems that have prevented the server from successfully completing processing and are considered important.
- FATAL_ERROR – Used for critical problems that arise which might leave the server unable to continue processing operations normally.

The messages written to the error log can be filtered based on their severities in two ways. First, the error log publisher has a `default-severity` property, which can be used to specify the severity of messages logged regardless of their category. By default, this includes the NOTICE, SEVERE_WARNING, SEVERE_ERROR, and FATAL_ERROR severities.

You can override these severities on a per-category basis using the `override-severity` property. If this property is used, then each value should consist of a category name followed by an equal sign and a comma-delimited set of severities that should be logged for messages in that category. For example, the following override severity would enable logging at all severity levels in the PROTOCOL category:

```
protocol=debug,information,mild-warning,mild-error,notice,severe-warning,severe-error,fatal-error
```

Note that for the purposes of this configuration property, any underscores in category or severity names should be replaced with dashes. Also, severities are not inherently hierarchical, so enabling the DEBUG severity for a category will not automatically enable logging at the INFORMATION, MILD_WARNING, or MILD_ERROR severities.

The error log configuration can be altered on the fly using tools like **`dsconfig`**, the Administrative Console, or the LDIF connection handler, and changes will take effect immediately. You can configure multiple error logs that are active in the server at the same time, writing to different log files with different configurations. For example, a new error logger can be activated with a different set of default severities to debug a short-term problem, and then that logger can be removed after the problem is resolved, so that the normal error log does not contain any of the more verbose information.

server.out log

The `server.out` file holds any information written to standard output or standard error while the server is running. Normally, it includes a number of messages written at startup and shutdown, as well as information about any administrative alerts generated while the server is running. In most cases, this information is also written to the error log. The `server.out` file can also contain output generated by the JVM. For example, if garbage collection debugging is enabled, or if a stack trace is requested via "kill -QUIT" as described in a later section, then output is written to this file.

Copyright © 2025 Ping Identity Corporation

Debug log

The debug log provides a means of obtaining information that can be used for troubleshooting problems but is not necessary or desirable to have available while the server is functioning normally. As a result, the debug log is disabled by default, but it can be enabled and configured at any time.

Some of the most notable configuration properties for the debug log publisher include:

- enabled – Indicates whether debug logging is enabled. By default, it is disabled.
- log-file – Specifies the path to the file to be written. By default, debug messages are written to the `logs/debug` file.
- default-debug-level – Specifies the minimum log level for debug messages that should be written. The default value is "error," which only provides information about errors that occur during processing (for example, exception stack traces). Other supported debug levels include warning, info, and verbose. Note that unlike error log severities, the debug log levels are hierarchical. Configuring a specified debug level enables any debugging at any higher levels. For example, configuring the info debug level automatically enables the warning and error levels.
- default-debug-category – Specifies the categories for debug messages that should be written. Some of the most useful categories include caught (provides information and stack traces for any exceptions caught during processing), database-access (provides information about operations performed in the underlying database), protocol (provides information about ASN.1 and LDAP communication performed by the server), and data (provides information about raw data read from or written to clients).

As with the error and access logs, multiple debug loggers can be active in the server at any time with different configurations and log files to help isolate information that might be relevant to a particular problem. NOTE: Enabling one or more debug loggers can have a significant impact on server performance. We recommend that debug loggers be enabled only when necessary, and then be scoped so that only pertinent debug information is recorded.

Debug targets can be used to further pare down the set of messages generated. For example, you can specify that the debug logs be generated only within a specific class or package. If you need to enable the debug logger, you should work with your authorized support provider to best configure the debug target and interpret the output.

Audit log

The audit log is a specialized version of the access log used for troubleshooting problems that could occur in the course of processing.

The audit log records all changes to directory data in LDIF format so that administrators can quickly diagnose the changes an application made to the data or replay the changes to another server for testing purposes.

The audit log does not record authentication attempts but can be used in conjunction with the access log to troubleshoot security-related issues.

The audit log is disabled by default because it reduces the server's write performance.

By default, if you enable the audit log on the server, the `userPassword` and `authPassword` attribute values are obscured. Each value of an obscured attribute is replaced in the audit log with a string of the form `"***** OBSCURED VALUE *****"`. You can unobscure these attributes by deleting them from the `obscure-attribute` property.

Copyright © 2025 Ping Identity Corporation

Config audit log and the configuration archive

The configuration audit log provides a record of any changes made to the server configuration while the server is online. This information is written to the `logs/config-audit.log` file and provides information about the configuration change in the form that can be used to perform the operation in a non-interactive manner with the `dsconfig` command. Other information written for each change includes:

- Time that the configuration change was made.
- Connection ID and operation ID for the corresponding change, which can be used to correlate it with information in the access log.
- DN of the user requesting the configuration change and the method by which that user authenticated to the server.
- Source and destination addresses of the client connection.
- Command that can be used to undo the change and revert to the previous configuration for the associated configuration object.

In addition to information about the individual changes that are made to the configuration, the server maintains complete copies of all previous configurations. These configurations are provided in the `config/archived-configs` directory and are gzip-compressed copies of the `config/config.ldif` file in use before the configuration change was made. The file names contain timestamps that indicate when that configuration was first used.

Access and audit log

The access log provides information about operations processed within the server. The default access log file is written to `logs/access`, but multiple access loggers can be active at the same time, each writing to different log files and using different configurations.

By default, a single access log message is generated, which combines the elements of request, forward, and result messages. If an error is encountered while attempting to process the request, then one or more forward-failed messages can also be generated.

```
[01/Jun/2011:11:10:19.692 -0500] CONNECT conn=49 from="127.0.0.1" to="127.0.0.1"
  protocol="LDAP+TLS" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.764 -0500] BIND RESULT conn=49 op=0 msgID=1 version="3"
  dn="cn=Directory Manager" authType="SIMPLE" resultCode=0 etime=0.401
  authDN="cn=Directory Manager,cn=Root DNs,cn=config" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.769 -0500] SEARCH RESULT conn=49 op=1 msgID=2
  base="ou=People,dc=example,dc=com" scope=2 filter="(uid=1)" attrs="ALL"
  resultCode=0 etime=0.549 entriesReturned=1
[01/Jun/2011:11:10:19.788 -0500] DISCONNECT conn=49 reason="Client Unbind"
```

Each log message includes a timestamp indicating when it was written, followed by the operation type, the connection ID (which is used for all operations processed on the same client connection), the operation ID (which can be used to correlate the request and response log messages for the operation), and the message ID used in LDAP messages for this operation.

The remaining content for access log messages varies based on the type of operation being processed, and whether it is a request or a result message. Request messages generally include the most pertinent information from the request, but generally omit information that is sensitive or not useful.

Copyright © 2025 Ping Identity Corporation

Result messages include a `resultCode` element that indicates whether the operation was successful or if failed and an `etime` element that indicates the length of time in milliseconds that the server spent processing the operation. Other elements that might be present include the following:

- origin=replication – Operation that was processed as a result of data synchronization (for example, replication) rather than a request received directly from a client.
- message – Text that was included in the `diagnosticMessage` field of the response sent to the client.
- additionalInfo – Additional information about the operation that was not included in the response sent back to the client.
- authDN – DN of the user that authenticated to the server (typically only included in bind result messages).
- authzDN – DN of an alternate authorization identify used when processing the operation (for example, if the proxied authorization control was included in the request).
- authFailureID – Unique identifier associated with the authentication failure reason (only included in non-successful bind result messages).
- authFailureReason – Information about the reason that a bind operation failed that might be useful to administrators but was not included in the response to the client for security reasons.
- responseOID – OID included in an extended response returned to the client.
- entriesReturned – Number of matching entries returned to the client for a search operation.
- unindexed=true – Indicates that the associated search operation could not be sufficiently processed using server indexes and a significant traversal through the database was required.

Note that this is not an exhaustive list, and elements that are not listed here can also be present in access log messages. The LDAP SDK for Java provides an API for parsing access log messages and provides access to all elements that they can contain.

The server provides a second access log implementation called the audit log, which is used to provide detailed information about write operations (add, delete, modify, and modify DN) processed within the server. If the audit log is enabled, the entire content of the change is written to the audit log file (which defaults to `logs/audit`) in LDIF form.

The server also provides a very rich classification system that can be used to filter the content for access log files. This can be helpful when debugging problems with client applications, because it can restrict log information to operations processed only by a particular application (for example, based on IP address and/or authentication DN), only failed operations, or only operations taking a long time to complete, etc.

Setup log

The `setup` tool writes a log file providing information about the processing that it performs. By default, this log file is written to `logs/setup.log` although a different name may be used if a file with that name already exists, because the `setup` tool has already been run. The full path to the setup log file is provided when the `setup` tool has completed.

Copyright © 2025 Ping Identity Corporation

Tool log

Many of the administrative tools provided with the server (for example, `import-ldif`, `export-ldif`, `backup`, `restore`, etc.) can take a significant length of time to complete write information to standard output or standard error or both while the tool is running. They also write additional output to files in the `logs/tools` directory (for example, `logs/tools/ import-ldif.log`). The information written to these log files can be useful for diagnosing problems encountered while they were running. When running using the server tasks interface, log messages generated while the task is running can alternately be written to the server error log file.

LDAP SDK debug log

This log can be used to help examine the communication between the PingDirectory server and the PingDirectoryProxy server. It contains information about exceptions that occur during processing, problems establishing and terminating network connections, and problems that occur during the reading and writing of LDAP messages and LDIF entries. You can configure the types of debugging that should be enabled, the debug level that should be used, and whether debug messages should include stack traces. As for other file-based loggers, you can also specify the rotation and retention policies.

Types of log publishers

The PingDirectoryProxy server provides different types of loggers that get processing information about the server.

There are three primary types of loggers:

Access loggers

Provide information about operations processed within the server. They can be used for understanding the operations performed by clients, debugging problems with directory-enabled applications, and collecting usage information for performance and capacity planning purposes.

Error loggers

Provide information about warnings, errors, or significant events that occur within the server.

Debug loggers

Provide detailed information about processing performed by the server, including any exceptions caught during processing, detailed information about data read from or written to clients, and accesses to the underlying database.

By default, the following log publishers are enabled on the system:

- File-based access logger
- File-based error logger
- Failed-operations access logger

The following log publishers are available for the PingDirectoryProxy server but are disabled by default:

- File-based debug logger
- File-based audit logger

Copyright © 2025 Ping Identity Corporation

- Expensive operations access logger
- Successful searches with no entries returned access logger

Creating new log publishers

The server provides customization options to help you create your own log publishers with the `dsconfig` command.

When you create a new log publisher, you must also configure the log retention and rotation policies for each new publisher.

For more information, see Configuring Log Rotation and Configuring Log Retention.

Creating a new log publisher

Steps

1. Use the `dsconfig` command in non-interactive mode to create and configure the new log publisher.

   Example:

   This example shows how to create a logger that only logs disconnect operations.

   ```
   $ bin/dsconfig create-log-publisher \
     --type file-based-access --publisher-name "Disconnect Logger" \
     --set enabled:true \
     --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
     --set "rotation-policy:Size Limit Rotation Policy" \
     --set "retention-policy:File Count Retention Policy" \
     --set log-connects:false \
     --set log-requests:false --set log-results:false \
     --set log-file:logs/disconnect.log
   ```

   Note

   To configure compression on the logger, add the `--set compression-mechanism: gzip` option to the previous command.
   Because compression cannot be disabled or turned off after configured for the logger, plan carefully to determine your logging requirements, including log rotation and retention with regards to compressed logs.

2. View log publishers with the following command.

   ```
   $ bin/dsconfig list-log-publishers
   ```

Creating a log publisher using dsconfig interactive command-line mode

Steps

1. In the command line, enter `bin/dsconfig`.
2. Authenticate to the server by following the prompts.

Copyright © 2025 Ping Identity Corporation

3. In the main menu, select the option to configure the log publisher.
4. In the `Log Publisher menu`, select the option to create a new log publisher.
5. Select the Log Publisher type.

   For this example, select File-Based Access Log Publisher.
6. Enter a name for the log publisher.
7. Enable it.
8. Enter the path to the log file relative to the PingDirectory server root.

   For this example, `logs/disconnect.log`.
9. Select the rotation policy to use for this log publisher.
10. Select the retention policy to use for this log publisher.
11. In the `Log Publisher Properties menu`, select the option for `log-connects:false`, `log-disconnects:true`, `log-requests:false`, and `log-results:false`.
12. Enter `f` to apply the changes.

About log compression

The server supports the ability to compress log files as they are written.

This feature can significantly increase the amount of data that can be stored in a given amount of space so that log information can be kept for a longer period of time.

Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled at the time the logger is created. Compression cannot be turned on or off when the logger is configured. Because of problems in trying to append to an existing compressed file, if the server encounters an existing log file at startup, it rotates that file and begin a new one rather than attempting to append to the previous file.

Compression is performed using the standard gzip algorithm, so compressed log files can be accessed using readily available tools. The `summarize-access-log` tool can also work directly on compressed log files rather than requiring them to be uncompressed first.

However, because it can be useful to have a small amount of uncompressed log data available for troubleshooting purposes, administrators using compressed logging might want to have a second logger defined that does not use compression and has rotation and retention policies that minimizes the amount of space consumed by those logs while still making them useful for diagnostic purposes without the need to uncompress the files before examining them.

Configure compression by setting the `compression-mechanism` property to have the value of `gzip` when creating a new logger.

About log signing

The server supports the ability to cryptographically sign a log to ensure that it has not been modified in any way.

Copyright © 2025 Ping Identity Corporation

For example, financial institutions require audit logs for all transactions to check for correctness. Tamper-proof files are needed to ensure that these transactions can be properly validated and ensure that they have not been modified by any third-party entity or internally by unscrupulous employees.

Use the `dsconfig` tool to enable the `sign-log` property on a log publisher to turn on cryptographic signing.

When enabling signing for a logger that already exists and was enabled without signing, the first log file is not completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled are considered completely valid. For the same reason, if a log file is still open for writing, then signature validation does not indicate that the log is completely valid because the log doesn't include the necessary end signed content indicator at the end of the file.

To validate log file signatures, use the `validate-file-signature` tool provided in the `bin` directory of the server or the `bat` directory for Windows systems.

After you have enabled this property, you must disable and then re-enable the log publisher for the changes to take effect.

About encrypting log files

The server lets you encrypt log files as they are written.

The `encrypt-log` configuration property controls whether encryption is enabled for the logger. Enabling encryption causes the log file to have an `.encrypted` extension. If both encryption and compression are enabled, the extension is `.gz.encrypted`. Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption cannot be turned on or off after the logger is configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This reduces the overall size of the log file. The `encrypt-file` tool or custom code, using the LDAP SDK's `com.unboundid.util.PassphraseEncryptedInputStream`, is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the `encryption-settings create` command. By default, the encryption is performed with the server's preferred encryption settings definition.

To explicitly specify which definition should be used for the encryption, set the `encryption-settings-definition-id` property with the ID of that definition. You should set the encryption settings definition to be created from a passphrase so that the file can be decrypted by providing that passphrase even if the original encryption settings definition is no longer available. You can also create a randomly generated encryption settings definition, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data might remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it cannot write an incomplete block of data until the file is closed. This is not an issue for any log file that is not being actively written.

To examine the contents of a log file that is being actively written, use the `rotate-log` tool to force the file to be rotated before attempting to examine it.

Configuring log signing

Configure log signing for a log publisher.

Copyright © 2025 Ping Identity Corporation

Steps

1. To enable log signing for a log publisher, use `dsconfig`.

   Example:

   In this example, the `sign-log` property is set on the File-based Audit Log Publisher.

   ```
   $ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit Logger" \
     --set sign-log:true
   ```

2. Disable and then re-enable the log publisher for the change to take effect.

   Example:

   ```
   $ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit Logger" \
     --set enabled:false
   $ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit Logger" \
     --set enabled:true
   ```

Validating a signed file

The server provides a tool, `validate-file-signature`, that checks if a file has not been tampered with in any way.

Steps

- Run the `validate-file-signature` tool to check if a signed file has been tampered with.

  Example:

  For this example, assume that the `sign-log` property was enabled for the File-Based Audit Log Publisher.

  ```
  $ bin/validate-file-signature --file logs/audit
  ```

  Result:

  ```
  All signature information in file 'logs/audit' is valid
  ```

  Note

  If any validations errors occur, you will see a message similar to the one as follows.

  ```
  One or more signature validation errors were encountered
  while validating the contents of file 'logs/audit':
  * The end of the input stream was encountered without
    encountering the end of an active signature block.
    The contents of this signed block cannot be trusted
    because the signature cannot be verified
  ```

Copyright © 2025 Ping Identity Corporation

Configuring log file encryption

Configure log file encryption for a log publisher.

Steps

1. To enable encryption for a log publisher, use `dsconfig`.

   Example:

   In this example, the File-based Access Log Publisher `"Encrypted Access"` is created, compression is set, and rotation and retention policies are set.

   ```
   $ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted Access" \
     --type file-based-access \
     --set enabled:true \
     --set compression-mechanism:gzip \
     --set encryption-settings-definition-id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
     --set encrypt-log:true \
     --set log-file:logs/encrypted-access \
     --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
     --set "rotation-policy:Size Limit Rotation Policy" \
     --set "retention-policy:File Count Retention Policy" \
     --set "retention-policy:Free Disk Space Retention Policy" \
     --set "retention-policy:Size Limit Retention Policy"
   ```

2. Decrypt and decompress the file.

   Example:

   ```
   $ bin/encrypt-file --decrypt \
     --decompress-input \
     --input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
     --output-file decrypted-access
   Initializing the server's encryption framework...Done
   Writing decrypted data to file '/ds/Data-Sync/decrypted-access' using a
   key generated from encryption settings definition
   '332c846ef0dcd1d5187c1592e4c74cad33fc1e5fc20b726cd301cdd2b3ffbc2b'
   Successfully wrote 123,456,789 bytes of decrypted data
   ```

Configuring log rotation

The PingDirectory server allows you to configure the log rotation policy for the server.

About this task

When any rotation limit is reached, the server rotates the current log and starts a new log.

If you create a new log publisher, you must configure at least one log rotation policy.

You can select the following properties:

Copyright © 2025 Ping Identity Corporation

Time Limit Rotation Policy

Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every 7 days.

Fixed Time Rotation Policy

Rotates the logs every day at a specified time (based on 24-hour time). The default time is 2359.

Size Limit Rotation Policy

Rotates the logs when the file reaches the maximum size for each log. The default size limit is 100 MB.

Never Rotate Policy

Used in a rare event that does not require log rotation.

Steps

- Use `dsconfig` to modify the log rotation policy for the access logger.

  Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

Configuring log rotation listeners

The server provides two log file rotation listener, the copy log file rotation listener and the summarize log file rotation listener, which you can enable with a log publisher.

About this task

Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file is subject to deletion by a log file retention policy, but the copy is not automatically removed.

The summarize log file rotation listener invokes the `summarize-access-log` tool on a recently-rotated log file and writes its output to a file in a specified location. This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the `summarize-access-log` tool, including the `file-based-access` and `operation-timing-access` logger types.

Steps

- Use the following command to create a new copy log file rotation listener.

Copyright © 2025 Ping Identity Corporation

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Copy on Rotate" \
  --type copy \
  --set enabled:true \
  --set copy-to-directory:/path/to/archive/directory \
  --set compress-on-copy:true
```

Note

The path specified by the **copy-to-directory** property must exist, and the file system containing that directory must have enough space to hold all of the log files that are written there. The server automatically monitors free disk space on the target file system and generates administrative alerts if the amount of free space gets too low.

- **Use the following command to create a new summarize log file rotation listener.**

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Summarize on Rotate" \
  --type summarize \
  --set enabled:true \
  --set output-directory:/path/to/summary/directory
```

Note

The summary output files have the same name as the rotated log file, with an extension of **.summary**. If the **output-directory** property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.
As with the copy log file rotation listener, summary files are not automatically deleted. Although files are generally small in comparison to the log files themselves, make sure that enough space is available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

Configuring log retention

The server allows you to configure the log retention policy for each log on the server.

About this task

When a retention limit is reached, the server removes the oldest archived log before creating a new log. Log retention is only effective if you have a log rotation policy in place.

If you create a new log publisher, you must configure at least one log retention policy.

File Count Retention Policy

Sets the number of log files you want the server to retain. The default file count is 10 logs. If the file count is set to 1, then the log continues to grow indefinitely without being rotated.

Copyright © 2025 Ping Identity Corporation

Free Disk Space Retention Policy

Sets the minimum amount of free disk space. The default free disk space is 500 MBytes.

Size Limit Retention Policy

Sets the maximum size of the combined archived logs. The default size limit is 500 MBytes.

Time Limit Retention Policy

Sets the maximum length of time that rotated log files should be retained.

Custom Retention Policy

Create a new retention policy that meets your server's requirements. This requires developing custom code to implement the desired log retention policy

Never Delete Retention Policy

Used in a rare event that does not require log deletion.

Steps

- Use `dsconfig` to modify the log retention policy for the access logger.

  Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

Setting resource limits

You can set resource limits for the PingDirectoryProxy server using several global configuration properties as well as setting resource limits on specific client connection policies.

If you configure both global and client connection policy resource limits, the first limit reached is always honored. For example, if the server-wide maximum concurrent connections limit is reached, then all subsequent connections are rejected until existing connections are closed regardless of whether a client connection policy limit has been reached.

Setting global resource limits

You can specify the following types of global resource limits:

`maximum-concurrent-connections`

Specify the maximum number of client connections that can be established at any given time.

If the server already has the maximum number of connections established, then any new connection attempts from any clients are rejected until an existing connection is closed.

The default value of zero indicates that no limit is enforced.

Copyright © 2025 Ping Identity Corporation

`maximum-concurrent-connections-per-ip-address`

Specify the maximum number of client connections that can be established at any give time from the same client system.

If the server already has the maximum number of connections established from a given client, then any new connection attempts from that client are rejected until an existing connection from that client is closed. The server continues to accept connections from other clients that have not yet reached this limit.

The default value of zero indicates that no limit is enforced.

`maximum-concurrent-connections-per-bind-dn`

Specify the maximum number of client connections that can be established at any given time while authenticated as a particular user.

This property applies after the connection is established because the bind operation to authenticate the user happens after the connection is established rather than during the course of establishing the connection itself.

If a given user reaches the maximum number of connections, then any new attempt to authenticate as that user causes the connection performing the bind to be terminated.

> **Note**
>
> This limit applies only to authenticated connections and isn't enforced for clients that haven't authenticated or for clients that have authenticated as the anonymous user.

The default value of zero indicates that no limit is enforced.

Any changes to the `maximum-concurrent-connections` and `maximum-concurrent-connections-per-ip-address` properties take effect only for new connections established after the change is made. Any change to the `maximum-concurrent-connections-per-bind-dn` property applies only to connections, including existing connections, that perform authentication after the change is made.

Existing connections are allowed to remain established even if that would cause the new limit to be exceeded.

Setting client connection policy resource limits

Configure resource limits in a client connection policy using the following properties of the client connection policy:

`maximum-concurrent-connections`

This property specifies the maximum number of client connections that can be associated with a specific client connection policy at any given time. After this limit has been reached, any further attempts to associate a connection with this client connection policy result in the termination of the connection.

`maximum-connection-duration`

This property specifies the maximum length of time that a connection associated with a particular client connection policy can persist. After this period, the connection is terminated.

Copyright © 2025 Ping Identity Corporation

`maximum-idle-connection-duration`

This property specifies the maximum time that a connection associated with a particular client connection policy can persist after the completion of the last operation processed on that connection. Any new operation requested on the connection resets the timer. Connections that are idle for longer than the specified time are terminated.

`maximum-operation-count-per-connection`

This property specifies the maximum number of operations that can be requested by any client connection associated with this client connection policy. Attempts to process more than this number of operations on the connection will terminate the connection.

`maximum-concurrent-operations-per-connection`

This property specifies the maximum number of concurrent operations for any connection. This property can be used to prevent a single client connection from monopolizing server processing resources by sending a large number of concurrent asynchronous requests.

`maximum-connection-operation-rate`

This property specifies the maximum rate at which a client associated with a specific client connection policy can issue requests to the PingDirectoryProxy server. If a client attempts to request operations at a rate higher than this limit, then the server behaves as described by the `connection-operation-rate-exceeded-behavior` property.

`connection-operation-rate-exceeded-behavior`

This property describes how the server should behave if a client connection attempts to exceed a rate defined in the `maximum-connection-operation-rate` property.

`maximum-policy-operation-rate`

This property specifies the maximum rate at which all clients associated with a particular client connection policy can issue requests to the PingDirectoryProxy server. If this limit is exceeded, then the server responds as specified in the `policy-operation-rate-exceeded-behavior` property.

`policy-operation-rate-exceeded-behavior`

This property specifies the behavior of the PingDirectoryProxy server if a client connection attempts to exceed the rate defined in the `maximum-policy-operation-rate` property.

Monitoring the PingDirectoryProxy server

While the PingDirectoryProxy server is running, it generates a significant amount of information available through monitor entries.

This section contains information about the following:

- Monitoring server status using the status tool
- About the monitor entries
- Using the monitoring interfaces

Copyright © 2025 Ping Identity Corporation

- Monitoring with Java Management Extensions (JMX)

Monitoring system data using the PingDataMetrics server

The PingDataMetrics server provides collection and storage of performance data from your server topology. You can use the System Utilization Monitor with the PingDataMetrics server to collect information about the host system CPU, disk, and network utilization on any platform except Linux. If you are not using the PingDataMetrics server, you do not need to use the system utilization monitor. When data is being collected, it periodically forks the process and executes commands.

For more information about using the System Utilization Monitor, refer to the data collection chapter of the PingDataMetrics server documentation.

Monitoring the server using the status tool

The PingDirectoryProxy server provides a `status` tool that provides basic server status information, including version, connection handlers, a table of LDAP external servers, and the percent of the global index being used.

Steps

1. To view the current state of the server, run the `status` tool.

```
$ bin/status
```

2. Enter the LDAP connection parameters.

```
>>>> Specify LDAP connection parameters

Administrator user bind DN [cn=Directory Manager]:

Password for user 'cn=Directory Manager':

About the monitor entries

While the server is running, it generates a significant amount of information available through monitor entries. Monitor entries are available over LDAP in the `cn=monitor` subtree. The types of monitor entries that are available include:

- General Monitor Entry (cn=monitor) – Provides a basic set of general information about the server.
- Active Operations Monitor Entry (cn=Active Operations,cn=monitor) – Provides information about all operations currently in progress in the server.
- Backend Monitor Entries (cn={id} Backend,cn=monitor) – Provides information about the backend, including the number of entries, the base DN(s), and whether it is private.
- Client Connections Monitor Entry (cn=Client Connections,cn=monitor) – Provides information about all connections currently established to the server.
- Connection Handler Monitor Entry (cn={name},cn=monitor) – Provides information about the configuration of each connection handler and the client connections established to it.
- Database Environment Monitor Entries (cn={id} Database Environment,cn=monitor) – Provides statistics and other data from the Oracle Berkeley DB Java Edition database envi- ronment used by the associated backend.
- Disk Space Usage Monitor Entry (cn=Disk Space Usage,cn=monitor) – Provides information about the amount of usable disk space available to server components.
- JVM Memory Usage Monitor Entry (cn=JVM Memory Usage,cn=monitor) – Provides information about garbage collection activity, the amount of memory available to the server, and the amount of memory consumed by various server components.
- JVM Stack Trace Monitor Entry (cn=JVM Stack Trace,cn=monitor) – Provides a stack trace of all threads in the JVM.
- LDAP Statistics Monitor Entries (cn={name} Statistics,cn=monitor) – Provides information about the number of each type of operation requested and bytes transferred over the connection handler.
- Processing Time Histogram Monitor Entry (cn=Processing Time Histogram,cn=monitor) – Provides information about the number or percent of operations that completed in various response time categories.

Copyright © 2025 Ping Identity Corporation

- SSL Context Monitor Entry (cn=SSL Context,cn=monitor) – Provides information about the available and supported SSL Cipher Suites and Protocols on the server.
- System Information Monitor Entry (cn=System Information,cn=monitor) – Provides information about the underlying JVM and system.
- Version Monitor Entry (cn=Version,cn=monitor) – Provides information about the server version.
- Work Queue Monitor Entry (cn=Work Queue,cn=monitor) – Provides information about the state of the server's work queue, including the number of operations waiting on worker threads and the number of operations that have been rejected because the queue became full.

Working with alarms, alerts, and gauges

Alarms, alerts, and gauges alert administrators to changes in server conditions that might require attention.

Alarms

An alarm represents a stateful condition of the server or a resource that might indicate a problem, such as low disk space or external server unavailability.

Alarms have severity, name, and message. Alarms will always have a Condition property, and can have a Specific Problem or Resource property. If surfaced through SNMP, a Probable Cause property and Alarm Type property are also listed. You can configure alarms to generate alerts when the alarm's severity changes.

You can configure the Alarm Manager, which governs the actions performed when an alarm state is entered, through the `dsconfig` tool and the administrative console. A complete list of system alerts, alarms, and their severity is available in `<server-root>/docs/admin-alerts-list.csv`.

The server complies with the International Telecommunication Union CCITT Recommendation X.733 (1992) standard for generating and clearing alarms. If configured, entering or exiting an alarm state might result in one or more alerts.

An alarm state is exited when the condition no longer applies. An `alarm_cleared` alert type is generated by the system when an alarm's severity changes from a non-normal severity to any other severity. An `alarm_cleared` alert will correlate to a previous alarm when the Condition and Resource properties are the same. The Condition corresponds to the Summary column in the `admin-alerts-list.csv` file.

Like the Alerts Backend, which stores information in `cn=alerts`, the Alarm Backend stores information within the `cn=alarms` backend. Unlike alerts, alarm thresholds have a state over time that can change in severity and be cleared when a monitored value returns to normal. You can view alarms with the `status` tool. As with other alert types, you can configure alert handlers can to manage the alerts generated by alarms.

Alerts

There are two alert types supported by the server: standard and alarm-specific.

The server constantly monitors for conditions that might need administrator attention, such as low disk space. For this condition, the standard alert is `low-disk-space-warning`, and the alarm-specific alert is `alarm-warning`.

You can configure the server to generate alarm-specific alerts as well as standard alerts. By default, standard alerts are generated for conditions internally monitored by the server. However, gauges can only generate alarm-alerts.

Copyright © 2025 Ping Identity Corporation

Gauges

A gauge defines a set of threshold values with a specified severity that, when crossed, cause the server to enter or exit an alarm state.

Numeric gauges monitor continuous values like CPU load or free disk space. Indicator gauges monitor enumerated set of values such as `server available` or `server unavailable`. Gauges generate alarms when the gauge's severity changes due to changes in the monitored value.

The server installs a set of gauges that are specific to the product and that can be cloned or configured through the `dsconfig` tool. You can tailor existing gauges to fit each environment by adjusting the update interval and threshold values. Configuration of system gauges determines the criteria by which alarms are triggered.

Use the Stats Logger to view historical information about the value and severity of all system gauges. For more information, see Profiling server performance using the Stats Logger.

Testing alarms and alerts

Steps

1. Use `dsconfig` to configure a gauge and set the `override-severity` property to critical.

   The following example configures the CPU Usage (Percent) gauge.

   Example:

   ```
   $ dsconfig set-gauge-prop \
     --gauge-name "CPU Usage (Percent)" \
     --set override-severity:critical
   ```

2. Run the `status` tool to verify that an alarm was generated with corresponding alerts.

   The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts and alarms.

   Example:

   The sample output has been shortened to show just the alarms and alerts information.

Copyright © 2025 Ping Identity Corporation

```
$ bin/status

```

Indeterminate alarms

The server raises indeterminate alarms for a server condition for which a severity cannot be determined.

In most cases these alarms are benign and do not issue alerts, nor do they appear in the output of the `status` tool or Administrative Console by default.

These alarms are usually caused by an enabled gauge that is intended to measure an aspect of the server that is not currently enabled. For example, gauges intended to monitor metrics related to replication might produce indeterminate alarms if a server is not currently replicating data. The gauge can be disabled if needed.

For more information about indeterminate alarms, view the gauge's associated monitor entry. There might be messages that can help determine the issue.

The following is sample output from the `status` tool run with the `–alarmSeverity=indeterminate` option.

```

Administrative alert handlers

The server provides mechanisms to send alert notifications to administrators when significant problems or events occur during processing, such as problems during server startup or shutdown. The PingDirectory provides a number of alert handler implementations, including:

- Error Log Alert Handler. Sends administrative alerts to the configured server error logger(s).
- Exec Alert Handler. Executes a specified command on the local system if an administrative alert matching the criteria for this alert handler is generated by the PingDirectory. Information about the administrative alert will be made available to the executed application as arguments provided by the command.

Copyright © 2025 Ping Identity Corporation

- Groovy Scripted Alert Handler. Provides alert handler implementations defined in a dynamically-loaded Groovy script that implements the `ScriptedAlertHandler` class defined in the Server SDK.
- JMX Alert Handler. Sends administrative alerts to clients using the Java Management Extensions (JMX) protocol. Ping Identity uses JMX for monitoring entries and requires that the JMX connection handler be enabled.
- SMTP Alert Handler. Sends administrative alerts to clients via email using the Simple Mail Transfer Protocol (SMTP). The server requires that one or more SMTP servers be defined in the global configuration.
- SNMP Alert Handler. Sends administrative alerts to clients using the Simple Network Monitoring Protocol (SNMP). The server must have an SNMP agent capable of communicating via SNMP 2c.
- SNMP Subagent Alert Handler. Sends SNMP traps to a primary agent in response to administrative alerts generated within the server.
- Third Party Alert Handler. Provides alert handler implementations created in third-party code using the Server SDK.

Configuring the JMX connection handler and alert handler

You can configure the Java Management Extensions (JMX) connection handler and the alert handler using the **`dsconfig`** tool.

To allow users to receive JMX notifications, enable the `jmx-read` and `jmx-notify` privileges. By default, these privileges aren't granted to any users, including root users or global administrators.

For security reasons, you should create a separate user account that has only these privileges.

You can also configure the JMX connection handler and the alert handler using **`dsconfig`** in interactive command-line mode, which is visible in the `Standard object menu`.

Configuring the JMX connection handler

About this task

To enable the JMX connection handler:

Steps

1. Run **`dsconfig`**.

   Example:

   ```
   $ bin/dsconfig set-connection-handler-prop \
     --handler-name "JMX Connection Handler" \
     --set enabled:true \
     --set listen-port:1689
   ```

2. Add a new non-root user account with the `jmx-read` and `jmx-notify` privileges using the **`ldapmodify`** tool using an LDIF representation.

   Example:

Copyright © 2025 Ping Identity Corporation

```
dn: cn=JMX User,cn=Root DNs,cn=config
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-cfg-root-dn-user
givenName: JMX
sn: User
cn: JMX User
userPassword: password
ds-cfg-inherit-default-root-privileges: false
ds-cfg-alternate-bind-dn: cn=JMX User
ds-privilege-name: jmx-read
ds-privilege-name: jmx-notify
```

Configuring the JMX alert handler

About this task

To configure the Java Management Extensions (JMX) alert handler:

Steps

- Run `dsconfig`.

  Example:

  ```
  $ bin/dsconfig set-alert-handler-prop --handler-name "JMX Alert Handler" \
    --set enabled:true
  ```

Configuring the SMTP alert handler

To create a new instance of an SMTP alert handler, use the `dsconfig` tool.

About this task

By default, there is no configuration entry for an SMTP alert handler.

Steps

- Use the `dsconfig` tool to configure the SMTP Alert Handler.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-alert-handler \
  --handler-name "SMTP Alert Handler" \
  --type smtp \
  --set enabled:true \
  --set "sender-address:alerts@example.com" \
  --set "recipient-address:administrators@example.com" \
  --set "message-subject:Directory Admin Alert \%\%alert-type\%\%" \
  --set "message-body:Administrative alert:\\n\%\%alert-message\%\%"
```

Configuring the SNMP subagent alert handler

You can configure the SNMP subagent alert handler using the `dsconfig` tool, which is visible in the `Standard object menu`.

About this task

Before you begin, you need an SNMP subagent capable of communicating using SNMP2c. For more information about SNMP, see Monitoring using SNMP.

The PingDirectory server also supports an SNMP alert handler, which is used in deployments that do not enable an SNMP subagent.

To configure the SNMP subagent alert handler:

Steps

- Run `dsconfig`.

  Example:

  In this example:

  - The `server-host-name` is the address of the system running the SNMP subagent.
  - The `server-port` is the port number on which the subagent is running.
  - The `community-name` is the name of the SNMP community that is used for the traps.

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" \
  --set enabled:true \
  --set server-host-name:host2 \
  --set server-port:162 \
  --set community-name:public
```

Working with virtual attributes

The PingDirectoryProxy server provides dynamically generated attributes called virtual attributes for local PingDirectoryProxy server data.

The proxy virtual attributes apply to a local proxy backend, such as `cn=config` or the Root DSA-specific entry (DSE).

Copyright © 2025 Ping Identity Corporation

If you want virtual attributes in entries for proxied requests, they must be configured in the backend servers. Alternately, attributes can be inserted into those entries using proxy transformations. For more information, see Configuring proxy transformations.

For example, you can define a virtual attribute and assign it to the Root DSE using `create-virtual-sttribute`.

```
$ bin/dsconfig create-virtual-attribute \
  --name defineDescriptionOnRootDSE --type user-defined \
  --set enabled:true --set attribute-type:description \
  --set filter:objectclass=ds-root-dse --set value:PrimaryProxy
```

If you search the Root DSE using the following LDAP search, you see that the description attribute now has the value `Primary Proxy`.

```
$ bin/ldapsearch --baseDN "" --searchScope base --bindDN "" \
  --bindPassword "" --port 5389 -- hostname localhost \
  "objectclass=*" description

dn:
description:PrimaryProxy
```

Managing monitoring

The PingDirectoryProxy server provides a flexible monitoring framework that exposes its monitoring information under the `cn=monitor` entry.

It provides interfaces with:

- The PingDataMetrics server
- The administrative cosnole
- SNMP
- Java management extensions (JMX)
- LDAP

The PingDirectoryProxy server also provides a tool, the Periodic Stats Logger, to profile server performance.

The monitor backend

The server exposes its monitoring information under the `cn=monitor` entry.

Administrators can use various means to monitor the servers, including the PingDataMetrics server, through SNMP, the administrative console, JConsole, LDAP command-line tools, and the Periodic Stats Logger.

> **Note**
>
> To display server component activity and state, use the **`bin/status`** tool.

Copyright © 2025 Ping Identity Corporation

To see the list of all monitor entries, use `ldapsearch` as in the following example.

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
 --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
 --baseDN "cn=monitor" "(objectclass=*)" cn
```

The following table describes a subset of the monitor entries.

Component	Description
Active Operations	Provides information about the operations currently being processed by the server. Shows the number of operations, information on each operation, and the number of active persistent searches.
Backends	Provides general information about the state of a server backend, including the entry count. If the backend is a local database, there is a corresponding database environment monitor entry with information on cache usage and on-disk size.
Client Connections	Provides information about all client connections to the server. The client connection information contains a name followed by an equal sign and a quoted value, such as `connID="15", connectTime="20100308223038Z"` and so forth.
Connection Handlers	Provides information about the available connection handlers on the server, which includes the LDAP and LDIF connection handlers. These handlers are used to accept client connections and to read requests and send responses to those clients.
Disk Space Usage	Provides information about the disk space available to various components of the server.
General	Provides general information about the state of the server, including product name, vendor name, server version, etc.
Index	The monitor captures the number of keys preloaded, and counters for read/write/remove/open-cursor/read-for-search. These counters provide insight into how useful an index is for a given workload.
HTTP/HTTPS Connection Handler Statistics	Provides statistics about the interaction that the associated HTTP connection handler has had with its clients, including the number of connections accepted, average requests per connection, average connection duration, total bytes returned, and average processing time by status code.
JVM Stack Trace	Provides a stack trace of all threads processing within the Java virtual machine (JVM).
LDAP Connection Handler Statistics	Provides statistics about the interaction that the associated LDAP connection handler has had with its clients, including the number of connections established and closed, bytes read and written, LDAP messages read and written, operations initiated, completed, and abandoned, etc.

Copyright © 2025 Ping Identity Corporation

Component	Description
Processing Time Histogram	Categorizes operation processing times into a number of user-defined buckets of information, including the total number of operations processed, overall average response time in milliseconds (ms), number of processing times between 0ms and 1ms, and so forth.
System Information	Provides general information about the system and the JVM on which the server is running, including system host name, operation system, JVM architecture, Java home, Java version, and so forth.
Version	Provides information about the server version, including build ID, version, revision number, etc.
Work Queue	Provides information about the state of the PingDirectory server work queue, which holds requests until they can be processed by a worker thread, including the requests rejected, current work queue size, number of worker threads, and number of busy worker threads. The work queue configuration has a `monitor-queue-time` property set to `true` by default. This logs messages for new operations with a `qtime` attribute included in the log messages. Its value is expressed in milliseconds and represents the length of time that operations are held in the work queue. A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the `ldapsearch` command for example, use the `--useAdministrativeSession` option. The requester must have the `use-admin-session` privilege, which is included for root users. By default, eight threads are available for this purpose. This can be changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

Monitoring disk space usage

The disk space usage monitor provides information about the amount of usable disk space available for the server components.

The disk space usage monitor evaluates the free space at locations registered through the `DiskSpaceConsumer` interface by various components of the server. Disk space monitoring excludes disk locations that do not have server components registered. However, other disk locations might still impact server performance, such as the operating system disk, if it becomes full. When relevant to the server, these locations include the server root, the location of the `/config` directory, the location of every log file, all Java Runtime Environment (JRE) backend directories, the location of the changelog, the location of the replication environment database, and the location of any server extension that registers itself with the `DiskSpaceConsumer` interface.

The disk space usage monitor provides the ability to generate administrative alerts and take additional action if the amount of usable space drops below the defined thresholds.

You can configure three thresholds for this monitor:

Copyright © 2025 Ping Identity Corporation

Low space warning threshold

This threshold is defined as either a percentage or absolute amount of usable space. If the amount of usable space drops below this threshold, then the server generates an administrative alert but remains fully functional. It generates alerts at regular intervals that you configure (such as once a day) unless action is taken to increase the amount of usable space. The server generates additional alerts as the amount of usable space is further reduced, such as each time the amount of usable space drops below a value 10% closer to the low space error threshold. If an administrator frees up disk space or adds additional capacity, then the server should automatically recognize this and stop generating alerts.

Low space error threshold

This threshold is also defined as either a percentage or absolute size. If the amount of usable space drops below this threshold, the server generates an alert notification and begins rejecting all operations requested by non-root users with `UNAVAILABLE` results. The server should continue to generate alerts during this time. When the server enters this mode, an administrator has to take some kind of action, such as, running a command to invoke a task or removing a signal file, before the server resumes normal operation. This threshold must be less than or equal to the low space warning threshold. If they are equal, the server begins rejecting requests from non-root users immediately upon detecting low usable disk space.

Out of space error threshold

This threshold can also be defined as a percentage or absolute size. If the amount of usable space drops below this threshold, the server generates a final administrative alert and shuts itself down. This threshold must be less than or equal to the low space error threshold. If they are equal, the server shuts itself down rather than rejecting requests from non-root users.

The server monitors disk space consumption during processing for the `export-ldif`, `rebuild-index`, and `backup` tools. Space is monitored every 10 seconds if usable space for all monitored paths is greater than 15 percent of the capacity of those volumes. If usable space for any path drops below 15 percent, or below 10GB free, the space check frequency is increased to every second. Warning messages are generated if available space falls below 10 percent, or below 5GB free. If usable space for any path drops below two percent, or 1GB free, the tool processing is aborted and files can be removed to free up space.

The default configuration uses the same values for the low space error threshold and out of space error threshold. This is to prevent having the server online but rejecting requests, which causes problems with applications trying to interact with the server. The low space warning threshold generates an alert before the problem becomes serious, well in advance of available disk space dropping to a point that it is critical.

The default values might not be suitable for all disk sizes, and should be adjusted to fit the deployment. Determining the best values should factor in the size of the disk, how big the database might become, how much space log files might consume, and how many backups are stored.

The threshold values can be specified either as absolute sizes or as percentages of the total available disk space. You must specify all values as absolute values or as percentages. A mix of absolute values and percentages cannot be used. The low space warning threshold must be greater than or equal to the low space error threshold, the low space error threshold must be greater than or equal to the out of space error threshold, and the out of space error threshold must be greater than or equal to zero.

Copyright © 2025 Ping Identity Corporation

If the out of space error threshold is set to zero, then the server does not attempt to automatically shut itself down if it detects that usable disk space has become critically low. If the amount of usable space reaches zero, then the database preserves its integrity but might enter a state in which it rejects all operations with an error and requires the server, or at least the affected backends, to be restarted. If the low space error threshold is also set to zero, then the server generates periodic warnings about low available disk space but remains fully functional for as long as possible. If all three threshold values are set to zero, then the server does not attempt to warn about or otherwise react to a lack of usable disk space.

Monitoring with the PingDataMetrics server

The PingDataMetrics server is an invaluable tool for collecting, aggregating and exposing historical and instantaneous data from the various Ping Identity servers in a deployment.

The PingDataMetrics server relies on a captive PostgreSQL datastore for the metrics that it collects from internal instrumentation across the instances, replicas, and data centers in your environment. The data is available through a Monitoring API that can be used to build custom dashboards and monitoring applications to monitor the overall health of your PingData Platform system. For more information, see the PingDataMetrics Server Administration Guide.

Monitoring key performance indicators by application

PingDirectory server can be configured to track many key performance metrics, such as throughput and response-time, by the client applications requesting them.

This feature is invaluable for measuring whether the identify infrastructure meets all of your service-level agreements (SLA) that have been defined for client applications.

When enabled, the per-application monitoring data:

- Can be accessed in the `cn=monitor` backend
- Can be accessed in the Periodic Stats Logger
- Can be made available for collection by the Metrics server

For more information on using the Stats Logger, see Profiling server performance using the Stats Logger.

For details on configuring the server to expose metrics that interest you, see the PingDirectory server Configuration section of the PingDataMetrics Server Administration Guide.

Tracked application information is exposed in the PingDataMetrics server by metrics having the `application-name` dimension. For information on which metrics are available with the `application-name` dimension, see the documentation under `docs/metrics` of the PingDataMetrics server.

Configuring the external servers

Before you install the PingDataMetrics server, you must configure the servers you want to monitor:

- PingDirectory server
- PingDirectoryProxy server
- PingDataSync server

Copyright © 2025 Ping Identity Corporation

The PingDataMetrics server requires all servers to be 3.5.0 or later. See the administration guides for each product for installation instructions.

After you have installed the directory server, use the `dsconfig` tool to make configuration changes for the PingDataMetrics server. When using the `dsconfig` tool interactively, set the complexity level to `Advanced` so that you can make all the necessary configuration changes.

Preparing the servers monitored by the PingDataMetrics server

The Metrics Backend manages the storage of metrics and provides access to the stored blocks of metrics via LDAP. The Metrics Backend is configured to keep a maximum amount of metric history based on log retention policies.

The default retention policy uses the Default Size Limit Retention Policy, Free Disk Space Retention Policy, and the File Growth Limit Policy, limiting the total disk space used to 500 MB. This amount of disk typically contains more than 24 hours of metric history, which is ample. The directory server keeps a metric history so that the PingDataMetrics server can be down for a period and then catch up when it comes back online.

The following two commands create a Retention Policy that limits the number of files to 2000 and sets the Metrics Backend to flush data to a new file every 30 seconds.

```
$ bin/dsconfig create-log-retention-policy \
  --policy-name StatsCollectorRetentionPolicy \
  --type file-count --set number-of-files:2000

$ bin/dsconfig set-backend-prop \
  --backend-name metrics --set sample-flush-interval:30s \
  --set retention-policy:StatsCollectorRetentionPolicy
```

These commands configure the Metrics Backend to keep 16 hours of metric history, which consumes about 250 MB of disk, ensuring that captured metrics are available to the PingDataMetrics server within 30 seconds of when the metric was captured. The value of the `sample-flush-interval` attribute determines the maximum delay between when a metric is captured and when it can be picked up by the PingDataMetrics server.

You can set the flush interval between 15 seconds and 60 seconds, with longer values resulting in less processing load on the PingDataMetrics server. However, this flush interval increases the latency between when the metric was captured and when it becomes visible in the Dashboard Application. If you change the `sample-flush-interval` attribute to 60 seconds in the example above, then the PingDirectory server keeps 2000 minutes of history. Because the number of metrics produced per unit of time can vary depending on the configuration, no exact formula can be used to compute how much storage is required for each hour of history. However, 20 MB per hour is a reasonable estimate.

Configuring the Processing Time Histogram plugin

The Processing Time Histogram plugin is configured on each PingDirectory server and PingDirectoryProxy server as a set of histogram bucket ranges.

When the bucket ranges for a histogram change, the PingDataMetrics server notices the change and marks samples differently. This process allows for histograms with the same set of bucket definitions to be properly aggregated and understood when returned in a query. If different servers have different bucket definitions, then a single metric query cannot return histogram data from the servers.

Copyright © 2025 Ping Identity Corporation

You should try to keep the Processing Time Histogram bucket definitions the same on all servers. Having different definitions restricts the ability of the PingDataMetrics server API to aggregate histogram data across servers and makes the results of a query asking "What percentage of the search requests took less than 12 milliseconds?" harder to understand.

For each server in your topology, you must set the `separate-monitor-entry-per-tracked-application` property of the Processing Time Histogram plugin to true. This property must be set to expose per-application monitoring information under `cn=monitor`. When the `separate-monitor-entry-per-tracked-application` property is set to true, then the `per-application-ldap-stats` property must be set to `per-application-only` on the Stats Collector plugin and vice versa.

The following `dsconfig` command line sets the required properties of the Processing Time Histogram plugin.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Processing Time Histogram" \
  --set separate-monitor-entry-per-tracked-application:true
```

The following `dsconfig` command-line sets the `per-application-ldap-stats` property of the Stats Collector plugin to `per-application-only`.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Stats Collector" \
 --set per-application-ldap-stats:per-application-only
```

Setting the connection criteria to collect SLA statistics by application

To collect data about your service level agreements (SLAs), configure connection criteria for each SLA that you want to track.

The connection criteria are used in many areas within the server. They are used by the client connection policies, and are used when the server needs to perform matching based on connection-level properties, such as filtered logging. For assistance using connection criteria, contact a Ping Identity support representative.

For example, if you are interested in collecting statistics on data that is accessed by clients authenticating as the directory manager, you should create connection criteria on the server that identifies any user authenticating as the directory manager. The connection criteria name corresponds to the `application-name` dimension value that clients specify when accessing the data through the API. When you define the connection criteria, change the `included-user-base-dn` property to include the directory manager's full LDIF entry.

The following `dsconfig` command line creates connection criteria for the directory manager.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Directory Manager" \
  --type simple \
  --set "included-user-base-dn:cn=Directory Manager,cn=Root DNs,cn=config"
```

Updating the Global Configuration

You must create Global Configuration tracked applications for each application (connection criteria) you intend to track.

About this task

The `tracked-application` property allows individual applications to be identified in the server by connection criteria.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The name of the tracked application is the same as the name you defined for the connection criteria.

Steps

- To add connection criteria to the list of tracked applications, run `dsconfig` with the `set-global-configuration-prop` option.

  Example:

  This example adds the connection criteria you created in the example in Setting the connection criteria to collect SLA statistics by application to the list of tracked applications.

  ```
  $ bin/dsconfig set-global-configuration-prop \
    --set "tracked-application:Directory Manager"
  ```

  > **Note**
  >
  > The value of the `tracked-application` field corresponds to the value of the `application-name` dimension value that clients specify when accessing the data through the API.

Proxy considerations for tracked applications

In a proxy environment, the criteria should be defined in the PingDirectoryProxy server, because the PingDirectoryProxy server passes the application name through to the PingDirectory server in the intermediate client control.

If a client of the PingDirectoryProxy server or the PingDirectory server happens to use the intermediate client control, then the client name specified in the control is used as the application name regardless of the criteria listed in the `tracked-application` property.

Monitoring using SNMP

The PingDirectory server supports real-time monitoring using SNMP. The server provides an embedded SNMPv3 subagent plugin that, when enabled, sets up the server as a managed device and exchanges monitoring information with a primary agent based on the AgentX protocol.

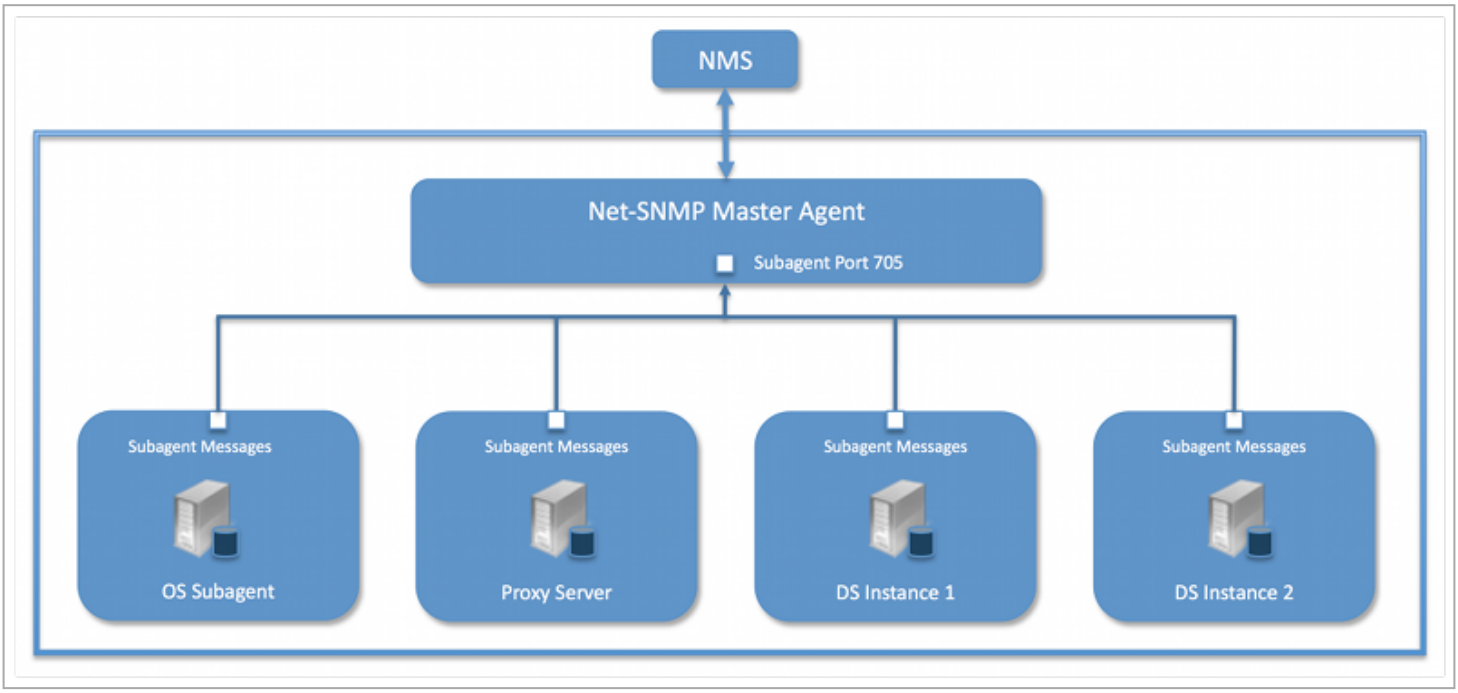
SNMP implementation

In a typical SNMP deployment, many production environments use a network management system (NMS) for a unified monitoring and administrative view of all SNMP-enabled devices.

The NMS communicates with a primary agent, whose main responsibility is to translate the SNMP protocol messages and multiplex any request messages to the subagent on each managed device, such as a PingDirectory server instance, a PingDirectoryProxy server, a PingDataSync server, or an OS Subagent. The primary agent also processes responses or traps from the agents. Many vendors provide commercial NMS systems. Consult with your NMS system for specific information.

Copyright © 2025 Ping Identity Corporation

The server contains an SNMP subagent plugin that connects to a Net-SNMP primary agent over TCP. The main configuration properties of the plugin are the address and port of the primary agent, which default to localhost and port 705, respectively. When the plugin is initialized, it creates an AgentX subagent and a managed object server and then registers as a management information base (MIB) server with the server instance. After the plugin's startup method is called, it starts a session thread with the primary agent. Whenever the connection is lost, the subagent automatically attempts to reconnect with the primary agent. The server's SNMP subagent plugin transmits only read-only values for polling or trap purposes. Set and inform operations are not supported. SNMP management applications cannot perform actions on the server on their own or through an NMS system.



Example SNMP Deployment

> **Note**
>
> The PingDirectory server was designed to interface with a Net-SNMP (5.3.2.2 or later) primary agent implementation with AgentX over TCP. Many operating systems provide their own Net-SNMP module. However, Service Management Automation (SMA) disables some features present in the Net-SNMP package and only enables AgentX over UNIX Domain Sockets, which cannot be supported by Java. If your operating system has a native Net-SNMP primary agent that only enables UNIX Domain Sockets, you should download and install a separate Net-SNMP binary from its website.

Configuring SNMP

Because all server instances provide information for a common set of management information bases (MIBs), each server instance provides its information under a unique SNMPv3 context name equal to the server instance name.

About this task

The server instance name is defined in the Global Configuration and is constructed from the host name and the server LDAP port by default. Information must be requested using SNMPv3, specifying the context name that pertains to the desired server instance.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The server supports SNMPv3, and only SNMPv3 can access the MIBs. For systems that implement SNMP v1 and v2c, Net-SNMP provides a proxy function to route requests in one version of SNMP to an agent using a different SNMP version.

Steps

1. **To enable the server's SNMP plugin, use the `dsconfig` tool.**

   > **Note**
   >
   > The SNMPv3 context name is limited to 30 bytes maximum. Any context name longer than 30 characters returns an error message when you attempt to enable the plugin.
   > The default context server name is the server instance name and the LDAP port number, so take note of the length of the fully-qualified DNS host name.

   1. **Specify the address and port of the SNMP primary agent.**
   2. **On each server instance, enable the SNMP subagent.**
   3. **Enable the SNMP Subagent Alert Handler so that the sub-agent sends traps for administrative alerts generated by the server.**

      Example:

      ```
      $ bin/dsconfig set-alert-handler-prop \
        --handler-name "SNMP Subagent Alert Handler" --set enabled:true
      ```

2. **View the error log.**

   Result:

   A message displays that the primary agent is not connected because it is not yet online.

   ```
   The SNMP sub-agent was unable to connect to the master
   agent at localhost/705: Timeout
   ```

3. **Edit the SNMP agent `snmpd.conf` configuration file and add the directive to run the agent as an AgentX primary agent.**

   The file is often located in `/etc/snmp/snmpd.conf`.

   Example:

   ```
   master agentx agentXSocket tcp:localhost:705
   ```

   > **Note**
   >
   > Using `localhost` means that only sub-agents running on the same host can connect to the primary agent. This is necessary because there are no security mechanisms in the AgentX protocol.

Copyright © 2025 Ping Identity Corporation

4. Add the trap directive to send SNMPv2 traps to `localhost` with the community name, public (or whatever SNMP community has been configured for your environment) and the port.

   Example:

   ```
   trap2sink localhost public 162
   ```

5. To create a SNMPv3 user, add the following lines to the `/etc/snmp/snmpd.conf` file.

   Example:

   ```
   rwuser initial
   createUser initial MD5 setup_passphrase DES
   ```

6. To create the SNMPv3 user, run `snmpusm`.

   Example:

   ```
   snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
   localhost create snmpuser initial
   ```

7. Start the `snmpd` daemon.

   Result:

   A message displays in the server's error log.

   ```
   The SNMP subagent connected successfully to the master agent
   at localhost:705. The SNMP context name is host.example.com:389
   ```

8. To see the alerts that are generated by the server, set up a trap client.

   1. Create a config file in `/tmp/snmptrapd.conf`.
   2. Add the `authcommunity log, execute public` directive to the file.

      > **Note**
      >
      > The directive specifies that the trap client can process traps using the public community string and can log and trigger executable actions.

9. Install the MIB definitions for the Net-SNMP client tools in the `/usr/share/snmp/mibs` directory.

   Example:

   ```
   $ cp resource/mib/* /usr/share/snmp/mibs
   ```

10. To run the trap client, run the `snmptrapd` command.

    Example:

Copyright © 2025 Ping Identity Corporation

This example specifies that the command should not create a new process using `fork()` from the calling shell (`-f`), should not read any configuration files (`-C`) except the one specified with the `-c` option, should print to standard output (`-Lo`), and then specifies that debugging output should be turned on for the User-based Security Module (`-Dusm`). The path after the `-M` option is a directory that contains the MIBs shipped with our product (`server-root/resource/mib`).

```
$ snmptrapd -f -C -c /tmp/snmptrapd.conf -Lf /root/trap.log -Dusm \
  -m all -M +/usr/share/snmp/mibs
```

11. To test the feature, run the Net-SNMP client tools.

    You must use the following options:

    - `-v` *<SNMP version>*
    - `-u` *<user name>*
    - `-l` *<security level>*
    - `-n` *<context name (instance name)>*
    - `-A` *<user password>*

      Example:

    In this example, the `-m all` option loads all MIBs in the default MIB directory in `/usr/share/snmp/mibs` so that MIB names can be used in place of numeric OIDs.

    +

```
$ snmpget -v 3 -u snmpuser -A password -l authNoPriv -n host.example.com:389 \
-m all localhost localDBBackendCount.0

$ snmpwalk -v 3 -u snmpuser -A password -l authNoPriv -n host.example.com:389 \
-m all localhost systemStatus
```

MIBS

The server provides SMIv2-compliant management information base (MIB) definitions (RFC 2578, 2579, 2580) for distinct monitoring statistics. These MIB definition text files are in the server's `/resource/mib` directory.

Each MIB provides managed object tables for each specific SNMP management information as follows:

LDAP Remote Server MIB

Provides information related to the health and status of the LDAP servers that the server connects to and statistics about the operations invoked by the server on those LDAP servers.

LDAP Statistics MIB

Provides a collection of connection-oriented performance data that is based on a connection handler in the server.

A server typically contain only one connection handler and therefore supplies only one table entry.

Copyright © 2025 Ping Identity Corporation

Local DB Backend MIB

Provides key metrics related to the state of the local database backends contained in the server.

Processing Time MIB

Provides a collection of key performance data related to the processing time of operations broken down by several criteria but reported as a single aggregated data set.

Replication MIB

Provides key metrics related to the current state of replication that can help diagnose how much outstanding work replication might have to do.

System Status MIB

Provides a set of critical metrics for determining the status and health of the system in relation to its work load.

For information on the available monitoring statistics for each MIB available on the PingDirectory server and the PingDirectoryProxy server, see the text files located in the server's `/resource/mib` directory.

The server generates an extensive set of SNMP traps for event monitoring. The traps display the severity, description, name, OID, and summary. For information about the available alert types for event monitoring, see the `resource/mib/UNBOUNDID-ALERT-MIB.txt` file.

Monitoring with the administrative console

Before you begin

Ensure that the server is running.

About this task

Administrators can use the administrative console to configure the server. The console also provides a status option that accesses the server's monitor content.

To view the Monitor Dashboard:

Steps

1. In your browser, enter http://<*server-name*>:8443/console.
2. Enter the root user distinguished name (DN) and password. Click Login.
3. In the top level navigation menu, select Status.
4. On the Status page, click the Monitors tab.

Result

The Monitors page opens, and you can monitor your server using the administrative console.

Copyright © 2025 Ping Identity Corporation

Accessing the Processing Time Histogram

The PingDirectory server provides a processing time histogram that classifies operation response time into user-defined buckets.

About this task

The histogram tracks the processing on a per-operation basis and as a percentage of the overall processing time for all operations. It also provides statistics for each operation type:

- `add`
- `bind`
- `compare`
- `delete`
- `modify`
- `modifyDN`
- `search`

Steps

1. From the administrative console, go to Configuration → Status → Monitors.
2. Select Processing Time Histogram.

> **Note**
>
> You can access other monitor entries in similar ways.

Monitoring with JMX

The PingDirectory server supports monitoring the Java virtual machine (JVM) through a Java Management Extensions (JMX) management agent, which can be accessed using JConsole or any other kind of JMX client.

The JMX interface provides JVM performance and resource utilization information for applications running Java. In addition to the monitor information that the server provides, you can monitor generic metrics exposed by the JVM, including:

- Memory pools
- Threads
- Loaded classes
- MBeans

You can also subscribe to receive JMX notifications for any administrative alerts that are generated within the server.

Copyright © 2025 Ping Identity Corporation

Running JConsole

Run `jconsole` to monitor the memory usage and thread activity of a Java virtual machine.

Before you begin

Before you can run `jconsole`, you must:

- Configure and enable the Java Management Extensions (JMX) Connection Handler for the server using the `dsconfig` tool.

  > **Note**
  >
  > For more information, see Configuring the JMX connection handler and alert handler.

- Invoke the `jconsole` executable by entering `jconsole` in your command-line interface or terminal.

  > **Note**
  >
  > If *<JDK_HOME>* is not set in your path, you can access `jconsole` in the `bin` directory of the `<JDK_HOME>` path.

Steps

1. To open the Java Monitoring & Management Console, run `jconsole`:

   Choose from:

   - To monitor a specific process ID for your application, run `jconsole <process ID>`.
   - To run `jconsole` remotely, run `jconsole <hostname:port>`.

     If SSL is configured on the JMX Connection Handler, you must specify the PingDirectory server `.jar` file in the class path when running `jconsole` over SSL, as in the following example:

     ```
     $ jconsole -J-Dcom.unboundid.directory.server.protocol.jmx.trustStorePath=$INSTANCE_ROOT/config/
     truststore -J-Dcom.unboundid.directory.server.protocol.jmx.trustStorePin=secret -J-
     Dcom.unboundid.directory.server.protocol.jmx.trustStoreType=JKS -J-classpath -J"$INSTANCE_ROOT/lib/*:/
     Library/Java/JavaVirtualMachines /jdk1.8.0_201.jdk/Contents/Home/lib/jconsole.jar"
     ```

     Set the following properties in the above command:

   - Set the `com.unboundid.directory.server.protocol.jmx.trustStorePath` property with the full trust store path.
   - Set the `com.unboundid.directory.server.protocol.jmx.trustStoreType` property if the default type, Java KeyStore (JKS), is not used.
   - Set the `com.unboundid.directory.server.protocol.jmx.trustStorePin` property with the trust store file password, if there is one.
   - Set the `com.unboundid.directory.server.protocol.jmx.trustStorePinFile` property with the file path containing the trust store password in plain text.

     Do not use this property if the `com.unboundid.directory.server.protocol.jmx.trustStorePin` property is used.

Copyright © 2025 Ping Identity Corporation

+

> **Note**
>
> When establishing a connection to `jconsole`, a window opens asking if you want to retry connecting insecurely. Click **Insecure connection**.
> Although `jconsole` considers anything other than `SslRmiClientSocketFactory` to be insecure, choosing to retry insecurely will enable PingDirectory's secure client socket factory.

2. **In the Java Monitoring & Administrative Console window, click Local Process, and then click the PID corresponding to the server.**
3. **Review the resource monitoring information.**

Monitoring the server using JConsole

Set up JConsole to monitor the server using a remote process.

Steps

1. **Start the server.**

   Example:

   ```
   $ bin/start-server
   ```

2. **Enable the Java Management Extensions (JMX) Connection handler using `dsconfig` with the `set-connection-handler-prop` option.**

   > **Note**
   >
   > The handler is disabled by default.
   > Include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

   Example:

   ```
   $ bin/dsconfig set-connection-handler-prop \
     --handler-name "JMX Connection Handler" --set enabled:true
   ```

3. **Assign privileges to a regular user account with the `ldapmodify` tool.**

   > **Warning**
   >
   > Do not use a root user account, as using a root user account would be a security risk.

   Example:

   This example grants `jmx-read`, `jmx-write`, and `jmx-notify` privileges to the user.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapmodify --hostname server1.example.com --port 1389 \
  --bindDN "cn=Directory Manager" --bindPassword secret
dn: uid=admin,dc=example,dc=com
changetype: modify
replace: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: jmx-write
ds-privilege-name: jmx-notify
```

4. In the Java Monitoring & Administrative Console, click Remote Process, and enter the following JMX URL using the host and port of your server.

```
service:jmx:rmi:///jndi/rmi://<host>:<port>/com.unboundid.directory.server.protocols.jmx.client-unknown
```

5. In the Username and Password fields, enter the bind distinguished name (DN) and password for a user that has at least the `jmx-read` privilege.
6. Click Connect.
7. Click com.unboundid.directory.server, and expand the `rootDSE` node and the `cn-monitor` sub-node.
8. Select a monitoring entry.

Monitoring using the LDAP SDK

You can use the monitoring API to retrieve monitor entries from the PingDirectoryProxy server and retrieve specific types of monitor entries.

For example, you can retrieve all monitor entries published by the server, and print the information contained in each using the generic API for accessing monitor entry data as follows.

```
for (MonitorEntry e : MonitorManager.getMonitorEntries(connection))
  {
    System.out.println("Monitor Name: " + e.getMonitorName());
    System.out.println("Monitor Type: " + e.getMonitorDisplayName());
    System.out.println("Monitor Data:");
    for (MonitorAttribute a : e.getMonitorAttributes().values())
    {
      for (Object value : a.getValues())
      {
        System.out.println(" " + a.getDisplayName() + ": " + String.valueOf(value));
      }
     }
     System.out.println();
  }
```

For more information about the LDAP SDK and the methods in this example, see the LDAP SDK repository on GitHub.

Copyright © 2025 Ping Identity Corporation

Monitoring over LDAP

The PingDirectory server exposes a majority of its information under the `cn=monitor` entry.

Steps

- To access these entries over LDAP, use the `ldapsearch` tool.

  Example:

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --baseDN "cn=monitor" "(objectclass=*)"
```

Profiling server performance using the Stats Logger

The PingDirectory server includes a built-in Stats Logger that is useful for profiling server performance for a given configuration.

At a specified interval, the Stats Logger can write server statistics to a JSON file or to a log file in a `.csv` file, which can be read by spreadsheet applications. The logger has a negligible impact on server performance unless the `log-interval` property is set to a value of less than 1 second. You can customize the statistics logged and their verbosity.

The Stats Logger can also be used to view historical information about server statistics, including:

- Replication
- LDAP operations
- Host information
- Gauges

To update the configuration of the existing Stats Logger Plugin, you can either:

- Set the advanced `gauge-info` property to `basic/extended` to include this information.
- Create a dedicated Periodic Stats Logger for information about statistics of interest.

For information about how to enable this logging and where to find the log file, see Enabling the Stats Logger.

Enabling the Stats Logger

About this task

By default, the PingDirectory server's built-in Stats Logger is disabled. To enable the Stats Logger:

Steps

1. Run `dsconfig` in interactive mode.

   When you are prompted, enter the LDAP or LDAPS connection parameters.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig
```

2. To change to the `Advanced Objects` menu, enter `o`.
3. On the main menu, enter the selection for `Plugins`.
4. On the `Plugin` menu, enter the selection for `View and edit an existing plugin`.
5. From the `Plugin` selection list, enter the selection for `Stats Logger`.
6. On the `Stats Logger Plugin` menu, enter the selection to set the `enabled` property to `TRUE`. To save and apply the configuration, enter `f`.

   Result:

   The default logger logs information about the server every second to `<server-root>/logs/dsstats.csv`. If the server is idle, nothing is logged.

   > **Note**
   >
   > To change the idle logging behavior, set the `suppress-if-idle` property to `FALSE`.

7. Run the PingDirectory server.

   Example:

   For example, if you are running in a test environment, you can run the `search-and-mod-rate` tool to apply some searches and modifications to the server.

   > **Tip**
   >
   > To see an example command, run **`search-and-mod-rate`** `--help`.

8. View the Stats Logger output at `<server-root>/logs/dsstats.csv`.

   You can open the file in a spreadsheet.

Configuring multiple Periodic Stats Loggers

About this task

You can create multiple Periodic Stats Loggers to:

- Log different statistics
- View historical information about gauges
- To create a log at different intervals, such as logging cumulative operations statistics every hour

To create a new log, use the existing Stats Logger as a template to get reasonable settings, including rotation and retention policy.

Copyright © 2025 Ping Identity Corporation

Steps

1. Run `dsconfig` in interactive mode.

   When prompted, enter the LDAP or LDAPS connection parameters.

   Example:

   ```
   $ bin/dsconfig
   ```

2. To change to the `Advanced Objects` menu, enter `o`.
3. In the main menu, enter the selection for `Plugins`.
4. In the `Plugin management` menu, enter the selection for `Create a new plugin`.
5. To use an existing plugin as a template, in the `Create a New Periodic Stats Logger Plugin` menu, enter `t`.
6. Enter the number corresponding to the existing stats logger as a template.
7. Enter a descriptive name for the new stats logger.

   For this example, enter `Stats Logger-10s`.

8. Enter the log file path to the file.

   For this example, enter `logs/dsstats2.csv`.

9. In the menu, make any other changes to the logger. To save and apply the configuration, enter `f`.

   Example:

   For this example, change the `log-interval` to `10s`, and the `suppress-if-idle` to `FALSE`.

Result

You should see two loggers, `dsstats.csv` and `dsstats2.csv`, in the `logs` directory.

Adding custom logged statistics to a Periodic Stats Logger

Add custom statistics based on any attribute in any entry under `cn=monitor` with the Custom Logged Stats object.

This configuration object provides powerful controls for how monitor attributes are written to the log. For example, you can extract a value from a monitor attribute using a regular expression. New Custom Logged Stats are automatically included in the Periodic Stats Logger output.

In addition to allowing a straight pass-through of the values using the raw statistic-type, you can configure attributes to be treated as any of the following:

- A counter, where the interval includes the difference in the value since the last interval
- An average value held by the attribute during the specified interval
- A minimum value held by the attribute during the specified interval

Copyright © 2025 Ping Identity Corporation

- A maximum value held by the attribute during the specified interval

The value of an attribute can also be scaled by a fixed value or by the value of another monitor attribute.

> **Note**
>
> Custom third-party server extensions written using the Server SDK can also expose interval statistics using a Periodic Stats Logger. The extension must first implement the SDK's `MonitorProvider` interface and register with the server. The monitor attributes produced by this custom `MonitorProvider` are then available to be referenced by a Custom Logged Stats object.

To illustrate how to configure a Custom Logged Statistics Logger, the following section reproduces the built-in `Consumer Total GB` column that displays in the output when the `included-resource-stat` property is set to memory-utilization on the Periodic Stats Logger.

The column is derived from the `total-bytes-used-by-memory-consumers` attribute of the `cn=JVM Memory Usage,cn=monitor` entry as follows.

```
dn: cn=JVM Memory Usage,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-memory-usage-monitor-entry
objectClass: extensibleObject
cn: JVM Memory Usage
...
total-bytes-used-by-memory-consumers: 3250017037
```

Configuring a custom logged statistic using dsconfig interactive

Steps

1. Run `dsconfig` and, when prompted, enter the LDAP or LDAPS connection parameters.

   Example:

   ```
   $ bin/dsconfig
   ```

2. In the server's `Advanced Objects menu`, enter the selection for `Custom Logged Stats`.
3. In the `Custom Logged Stats menu`, enter the selection for `Create a new Custom Logged Stats`.
4. Select the `Stats Logger Plugin` from the list if more than one is present on the system. If you only have one stats logger, press Enter to confirm that you want to use the existing plugin.
5. Enter a descriptive name for the `Custom Logged Stats`.

   For this example, enter `Memory Usage`.
6. From the `monitor-objectclass` property menu, enter the `objectclass` attribute to monitor.

   For this example, enter `ds-memory-usage-monitor-entry`.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> To view the entry, run **`ldapsearch`** using the base distinguished name (DN) `cn=JVM Memory Usage,cn=monitor` entry.

7. **Enter the attributes of the monitor entry that you want to log in the stats logger, and then press Enter again to continue.**

   For this example, enter `total-bytes-used-by-memory-consumers`.

8. **Specify the type of statistics for the monitored attribute to appear in the log file.**

   For this example, enter the option for `raw statistics` as recorded by the logger.

9. **In the `Custom Logged Stats menu,` review the configuration.**

10. **To set up a column name that lists the memory usage, enter the option to change the `column-name` property.**

11. **To add a specific label for the column name, enter the option to `add a value`, and then enter `Memory Consumer Total (GB)`. To continue, press Enter.**

12. **Confirm that you want to use the `column-name` value that you entered in the previous step. To use the value, press Enter.**

13. **To scale the `Memory Consumer Totals (GB)` by 1 gigabyte (GB), in the `Custom Logged Stats menu`, enter the option to change the `divide-value-by` property.**

14. **In the `divide-value-by` property menu, enter the option to change the value, and then enter `1073741824`.**

    1073741824 bytes is equivalent to 1 gigabyte.

15. **In the `Custom Logged Stats menu`, review your configuration. To save and apply the settings, enter `f`.**

    Example:

Copyright © 2025 Ping Identity Corporation

```
>>>> Configure the properties of the Custom Logged Stats
 >>>> via creating 'Memory Usage' Custom Logged Stats

         Property                  Value(s)
         ----------------------------------------------------------------
    1)   description               -
    2)   enabled                   true
    3)   monitor-objectclass       ds-memory-usage-monitor-entry
    4)   include-filter            -
    5)   attribute-to-log          total-bytes-used-by-memory-consumers
    6)   column-name               Memory Consumer Total (GB)
    7)   statistic-type            raw
    8)   header-prefix             -
    9)   header-prefix-attribute   -
    10)  regex-pattern             -
    11)  regex-replacement         -
    12)  divide-value-by           1073741824
    13)  divide-value-by-attribute -
    14)  decimal-format            .#
    15)  non-zero-implies-not-idle false

    ?)   help
    f)   finish - create the new Custom Logged Stats
    a)   hide advanced properties of the Custom Logged Stats
    d)   display the equivalent dsconfig arguments to create this object
    b)   back
    q)   quit

Enter choice [b]:
```

Result:

A message of `The Custom Logged Stats was created successfully` is returned.

After the Custom Logged Stats configuration change is completed, the new stats value should immediately show up in the Stats Logger output file.

Configuring a custom stats logger using dsconfig non-interactive

About this task

The following task replicates the previous procedure using `dsconfig` in non-interactive mode.

To create a custom stats logger:

Steps

- Run the `dsconfig` non-interactive command with the `create-custom-logged-stats` option.

  Example:

  In this example, the command produces a column named `Memory Consumer Total (GB)` that contains the value of the of `total-bytes-used-by-memory-consumers` attribute pulled from the entry with the `ds-memory-usage-monitor-entry` objectclass. This value is scaled by 1073741824 to get to a value represented in GBs.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-custom-logged-stats --plugin-name "Stats Logger" \
  --stats-name "Memory Usage" --type custom \
  --set monitor-objectclass:ds-memory-usage-monitor-entry \
  --set attribute-to-log:total-bytes-used-by-memory-consumers \
  --set "column-name:Memory Consumer Total (GB)" --set statistic-type:raw \
  --set divide-value-by:1073741824
```

Enabling and configuring the StatsD monitoring endpoint

The Monitoring Endpoint configuration type provides the StatsD endpoint type that you can use to transfer metrics data in the StatsD format.

About this task

You can configure the monitoring endpoint using the `dsconfig` command or the administrative console.

Steps

- To create the StatsD monitoring endpoint, use either of the following:

  Choose from:

  - To use the command-line, run `dsconfig` with the `create-monitoring-endpoint` option.

    This example configures a new StatsD monitoring endpoint to send UDP data to localhost port 8125 using `dsconfig`.

    ```
    dsconfig create-monitoring-endpoint \
        --type statsd \
        --endpoint-name StatsDEndpoint \
        --set enabled:true \
        --set hostname:localhost \
        --set server-port:8125 \
        --set connection-type:unencrypted-udp
    ```

  - To use the Administrative Console:

    1. From the Administrative Console, click Show Advanced Configuration.
    2. In the Logging, Monitoring, and Notifications section, click Monitoring Endpoints.
    3. Click New Monitoring Endpoint.

  When you configure a monitoring endpoint include:

  - The endpoint's host name
  - The endpoint's port
  - A toggle to use TCP or UDP
  - A toggle to use SSL if you use TCP

Copyright © 2025 Ping Identity Corporation

You can configure a StatsD Monitoring Endpoint with custom tags using the `additional-tags` property. This adds the defined tags to each metric message sent to the endpoint. Each tag should be created in a "key=value" format. Additional tags are appended to the end of the StatsD message. Here is a sample StatsD message with custom tags:

```
example.metric:123|g|#tag1:value1,tag2:value2
```

> **Note**
>
> You can send data to any number of monitoring endpoints.

Sending Metrics to Splunk with StatsD

About this task

Using the StatsD Endpoint type, you can send metric data to a Splunk installation. In Splunk, you can use Secure Sockets Layer (SSL) to secure ports that are open for StatsD. You can configure open UDP or TCP ports in Splunk to accept only connections from a certain hostname or IP address.

> **Note**
>
> StatsD metrics are typically sent over UDP. Using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost.

To securely send UDP or TCP data to Splunk:

Steps

1. Send the data to a Splunk Universal Forwarder.
2. Request that the forwarder use SSL to communicate with the Splunk Indexer.

DevOps and infrastructure as code

Derived from the words development and operations, the term DevOps refers to the practices that a company follows to ensure the production of high-quality products, while also minimizing the amount of time between the commitment of a system change and the implementation of that change in a production environment.

Most companies practice one of the following service models:

- Pets — With the pets service model, servers are built and managed manually, and are treated as unique and indispensable. Examples include mainframes, database systems, and load balancers.
- Cattle — With the cattle service model, arrays of multiple replaceable servers are built with automated tools. During a failure event, an array automatically restarts failed services and replicates data. Examples include web server arrays, search clusters, and multi-primary datastores.

Copyright © 2025 Ping Identity Corporation

Historically, servers have been treated like pets. The failure of one or multiple servers was often viewed as an emergency, and extensive resources were usually required to repair the damage. In the new DevOps paradigm, servers are recognized as dispensable and treated like cattle. When a server fails, the infrastructure replaces it immediately, configuring the replacement server identically to the failed one. Because no human intervention is required to fix them, the servers are considered self-healing.

To help treat your servers more like cattle than pets, PingDirectory supports server profiles and features like topology-management tools. For example, the `manage-profile setup` represents a single command that performs all the steps from the pet service model on a `server-profile` directory, a well-defined directory structure with all the necessary server configuration bits. Similarly, the `manage-profile replace-profile` command performs similar steps with a single command invocation after a server is updated to a new version.

The scripts in the `server-profile` directory are declarative of the environment. Consequently, what you define in the `server-profile` directory is what you get on the servers. No one needs to identify a server's current configuration and compute the differences that must be applied to attain the appropriate end state. Prior to server profiles, this problem was difficult to address, especially where no history was available. In such scenarios, an administrator might have needed to obtain the current configuration from the servers, to manually compute the difference between the current and desired configuration, and to apply the configuration changes, hoping all the while that nobody had changed the configuration during the process. Server profiles eliminate this procedural approach to applying configuration changes, and they simplify the steps associated with determining what is deployed in an environment. For more information on server profiles, see Server profiles.

Another principle that relates closely to DevOps is infrastructure as code (IaC), the concept of managing your operations in the same manner as your application and other code for general release with proper versioning, continuous integration, quality control, and release cycles. Customers who deploy PingDirectory servers as pets today can take advantage of current DevOps and IaC principles to turn them into cattle.

Server profiles

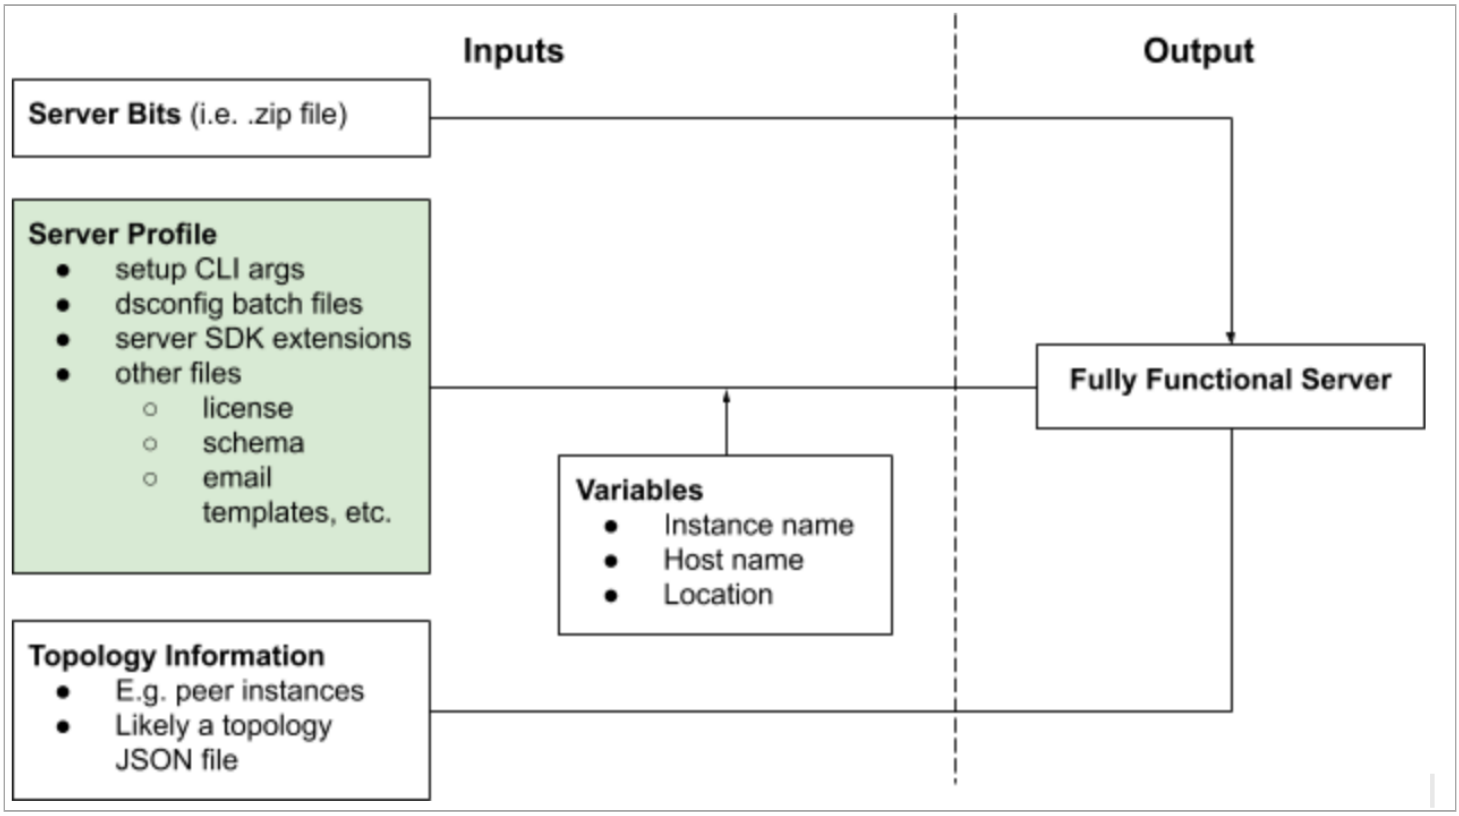
Regardless of the service model that your company follows, server profiles help you achieve your goals. At a basic level, a server profile defines a format for the configuration of a server by combining the following files into a single concrete structure:

- `dsconfig`
- Setup arguments
- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDataSync and related products by using deployment automation frameworks. When products support this capability, the amount of scripting that is required across automation frameworks — like Docker, Kubernetes, and Ansible — is reduced considerably.

The following image shows the role that a server profile plays in building a fully functional running server.

Copyright © 2025 Ping Identity Corporation



As a declarative form of a full server configuration, a server profile provides the following advantages:

- Provides a more complete and easily comparable way to define an individual server's configuration. Changes between different servers are easier to understand, and incremental changes to a server's configuration are easier to track.
- Ensures that each server instance is configured identically to its peers.
- Can be applied directly to new as well as previously installed instances.
- Shares a common configuration across a deployment pipeline of development, test, and production environments without unnecessary duplication. For information about substituting variables that differ by environment, see Variable substitution.
- Facilitates deployment automation by representing configuration as code.
- Reduces the number of additional configuration steps that are required to place a server into production.
- Makes the execution of various configuration changes more consistent and repeatable. The strategy of using a server profile to represent the final state of a server is less error-prone than recording a step-by-step process to attain that state.
- Can be managed easily in a version-control system.
- Simplifies the management of servers outside deployment automation frameworks.

A continuous deployment workflow can work with server profiles to make certain that changes to a server profile are moved automatically into production. In a stateful environment, the `manage-profile replace-profile` subcommand can be used to update existing servers. In a stateless environment, in which servers are considered immutable, `manage-profile setup` can be used to deploy new servers whenever a profile changes. With multiple environments, this deployment can be performed in a test environment before moving to production.

Copyright © 2025 Ping Identity Corporation

When working with zipped server SDK extensions and other files that might not be stored in a version-control system, the server profile can be modified to include these files prior to its use. For example, if the code for an extension is stored in a separate repository, it can be built and dropped into the server profile immediately before the `manage-profile` tool is run. This process is part of the deployment automation logic that uses the server profile, and it can be followed for any files that are needed by the server profile but whose versions are not controlled.

For more information about the `manage-profile` tool, see About the manage-profile tool.

Variable substitution

You can use the `manage-profile` tool to substitute different variables in server profiles.

The `manage-profile` tool uses the format `${VARIABLE}` to support the substitution of variables in profiles. This format can be escaped by using another `$`. For example, after substitution, `$${VARIABLE}` becomes `${VARIABLE}`.

Variable values can be read from a profile variables file or from environment variable values. If both options are used, the values that are specified in the file overwrite any environment variables.

The following code provides an example of how you can set user-defined variables by using a variables file in the server profile.

```
HOSTNAME=testserver.example.com
PORT=389
```

The following table describes built-in variables that can also be referenced in the server profile. Use these variables in the format previously described.

Built-in variable	Description
`PING_SERVER_ROOT`	Evaluates to the absolute path of the server's root directory
`PING_PROFILE_ROOT`	Evaluates to the individual profile's root directory **Note** Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using with the `PING_SERVER_ROOT` variable.

For more information about the tool's usage, run the command `bin/manage-profile --help`.

Copyright © 2025 Ping Identity Corporation

Profile structure

Use either of the following methods to create a server profile:

- Use the template named `server-profile-template.zip`, which is located in the `resource/` directory.
- Run the `manage-profile generate-profile` subcommand. The `manage-profile` tool references a file system directory structure rather than a ZIP file.

Files can be added to each directory as needed.

The following hierarchy represents the file structure of a basic server profile:

```
-server-profile/
  |-- dsconfig/
  |-- misc-files/
  |-- server-root/
  |   |-- post-setup/
  |   |-- pre-setup/
  |-- server-sdk-extensions/
  |-- setup-arguments.txt
  |-- variables-ignore.txt
```

setup-arguments.txt

When creating a profile, the first step is to add arguments to the `setup-arguments.txt` file, located in the `resources/server-profile-template.zip` archive.

When you run the `manage-profile setup` command, these arguments are passed to the server's setup tool. To view the arguments available in this file, run the server's `setup --help` command.

To provide the equivalent, non-interactive command-line interface (CLI) arguments after any prompts have been completed, run `setup` interactively. The `setup-arguments.txt` file in the server profile template contains an example set of arguments that can be changed.

`setup-arguments.txt` is the only required file in the profile.

dsconfig/

`dsconfig` batch files can be added to the `dsconfig` directory. These files, each of which must include a `.dsconfig` extension, contain `dsconfig` commands to apply to the server.

> **Note**
>
> `dsconfig` batch files in the server profile can't make changes to any topology configuration, including topology admin users and server instances. You should make topology configuration changes outside of the server profile.

Because the `dsconfig` batch files are ordered lexicographically, `00-base.dsconfig` runs before `01-second.dsconfig`, and so on.

Copyright © 2025 Ping Identity Corporation

> **Tip**
>
> To produce a `dsconfig` batch file that reproduces the current configuration, run `bin/config-diff`.

server-root/

Any server root files can be added to the `server-root` directory, including schema files, email template files, custom password dictionaries, and other files that must be present on the final server root. Add these files to the `server-root/pre-setup` or `server-root/post-setup` directory, depending on when they need to be copied to the server root. Most server root files are added to the server-root/pre-setup directory.

server-sdk-extensions/

Add server SDK extension `.zip` files to the `server-sdk-extensions` directory. Include any configuration that is necessary for the extensions in the profile's `dsconfig` batch files.

variables-ignore.txt

The `variables-ignore.txt` file is an optional component of the server profile. It is useful when adding bash scripts to the server root because such files often contain expressions that the `manage-profile` tool normally interprets as variables.

Add `variables-ignore.txt` to a profile's root directory to indicate the relative paths of any files that are not to have their variables substituted.

The following example shows the contents of a typical `variables-ignore.txt` file:

```
server-root/pre-setup/script-to-ignore.sh
server-root/post-setup/another-file-to-ignore.txt
```

server-root/permissions.properties

The `permissions.properties` file, located in the `server-root` directory, is an optional file that specifies the permissions to apply to files that are copied to the server root. These permissions are represented in octal notation. By default, server root files maintain their permissions when copied.

The following example shows the contents of a typical `permissions.properties` file:

```
default=700
file-with-special-permissions.txt=600
new-subdirectory/file-with-special-permissions.txt=644
bin/example-script.sh=760
```

Copyright © 2025 Ping Identity Corporation

misc-files/

Additional documentation and other files can be added to the `misc-files` directory, which the `manage-profile` tool does not use. Use the variable `PING_PROFILE_ROOT` to refer to files in this directory from other locations, such as `setup-arguments.txt`.

> **Note**
>
> Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using with the `PING_SERVER_ROOT` variable.

For example, a password file named `password.txt` in the `misc-files` directory could be referenced with `${PING_PROFILE_ROOT}/misc-files/password.txt` in `setup-arguments.txt`. Use a reference like this example to supply the file for the `--rootUserPasswordFile` argument in `setup-arguments.txt`.

About the manage-profile tool

The `manage-profile` tool is provided with the server to work with server profiles. It includes subcommands for creating, applying, and replacing server profiles, all of which significantly reduce the effort required by an administrator to configure a server appropriately.

The following sections describe these subcommands in more detail. For more information about the `manage-profile` tool, run `manage-profile --help`. For more information about each individual subcommand and its options, run `manage-profile <subcommand> --help`.

manage-profile generate-profile

To create a server profile from a configured server, use the `generate-profile` subcommand. The generated profile contains the following information, which provides a base for completing a profile:

- Command-line arguments that were used to set up the server
- `dsconfig` commands necessary to configure the server
- Installed server SDK extensions
- Files that are added to the server root

To produce a complete profile, some parts of the generated profile might require modifications, such as adding password files that `setup-arguments.txt` uses. The `--instanceName` and `--localHostName` arguments in `setup-arguments.txt` are made variables by `generate-profile`, and must be provided values when other `manage-profile` subcommands use the generated profile.

The `--excludeSetupArguments` option generates a server profile without a setup-arguments.txt file. This is useful when generating server profiles for use with Docker images.

Copyright © 2025 Ping Identity Corporation

manage-profile setup

To apply a server profile to a fresh, unconfigured server, use the `setup` subcommand, which replaces the normal setup tool when using a server profile. Run `manage-profile setup` to complete the following tasks:

- Copies the pre-setup files to the server root
- Runs the setup tool
- Copies the post-setup files to the server root
- Installs any server SDK extensions
- Runs any dsconfig batch files
- Imports any LDIF files
- Starts the server

While manage-profile setup is running, a copy of the profile is created in a temporary directory that can be specified by using the `--tempProfileDirectory` argument. The command leaves the server in a complete and running state when finished, unless the `--doNotStart` argument is specified.

manage-profile replace-profile

Run the `replace-profile` subcommand on a server that was originally set up with a server profile to replace its configuration with a new profile. The tool applies a specified server profile to an existing server while preserving its data, topology configuration, and replication configuration.

While `manage-profile replace-profile` is running, the existing server is stopped and moved to a temporary directory that the `--tempServerDirectory` argument can specify. A fresh, new server is subsequently installed and set up with the new profile. The final server is left running if it was running before the command was started, and remains stopped if it was stopped.

Run `manage-profile replace-profile` from a second unzipped server install package on the same host as the existing server, similar to the `update` tool. Use the `--serverRoot` argument to specify the root of the existing server that will have its profile replaced.

If files have been added or modified in the server root since the most recent `manage-profile setup` or `manage-profile replace-profile` was run, they are included in the final server with the replaced profile. Otherwise, files specifically added from the `server-root` directory of the previous server profile are absent from the final server with the replaced profile. If errors occur during the subcommand, such as the new profile having an invalid `setup-arguments.txt` file, the existing server returns to its original state from before `manage-profile replace-profile` was run.

The `--skipValidation` option which skips the validation step when running on an offline server

> **Note**
>
> When you run the **`manage-profile replace-profile`** tool with an SDK extension included in the new profile, the tool invokes the **`setup`** command.
>
> The **`manage-profile replace-profile`** tool can update the server version when needed. It can also directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to **`dsconfig`**.

Copyright © 2025 Ping Identity Corporation

Server profiles in a pets service model

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server. Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new pet server has been set up with a server profile, `manage-profile replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see About the manage-profile tool.

Troubleshooting the PingDirectoryProxy server

This section provides potential solutions for common problems that could occur when running the PingDirectoryProxy server.

It's primarily targeted at cases in which the PingDirectoryProxy server is running on Linux systems, but much of the information is useful for PingDirectoryProxy server running on other platforms.

Garbage collection diagnostic information

You can enable the JVM debugging options to track garbage collection data for your system. The options can impact JVM performance, but they provide valuable data to tune your server when troubleshooting garbage collection issues. While the `jstat` utility with the `-gc` option can be used to obtain some information about garbage collection activity, there are additional arguments that can be added to the JVM to use when running the server to provide additional detail.

```
-XX:+PrintGCDetails
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
-XX:+PrintGCDateStamps
```

To run the server with these options, edit the `config/java.properties` file and add them to the end of the line that begins with "`bin/start-server.java-args`". After the file has been saved, invoke the following command to make those new arguments take effect the next time the server is started:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsjavaproperties
```

Working with the Troubleshooting Tools

Problems might arise with the PingDirectoryProxy server, such as issues in the server or problems with the Java virtual machine (JVM), operating system, or hardware.

You must be able to diagnose problems quickly to determine the underlying cause and the best available solution.

Working with the collect-support-data tool

The PingDirectory server provides a significant amount of information about its current state including any problems that it has encountered during processing. If a problem occurs, the first step is to run the `collect-support-data` tool in the `bin` directory. The tool aggregates all relevant support files into a zip file that administrators can send to your authorized support provider for analysis. The tool also runs data collector utilities, such as `jps`, `jstack`, and `jstat` plus other diagnostic tools, and bundles the results in the zip file.

The tool may only archive portions of certain log files to conserve space, so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

The data collected by the `collect-support-data` tool varies between systems. However, the tool always tries to get the same information across all systems for the target PingDirectory server. The data collected includes the configuration directory, summaries and snippets from the `logs` directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

Available tool options

The `collect-support-data` tool has some important options that you should be aware of:

- --noLdap. Specifies that no effort should be made to collect any information over LDAP. This option should only be used if the server is completely unresponsive or will not start and only as a last resort.
- --pid {pid}. Specifies the ID of an additional process from which information is to be collected. This option is useful for troubleshooting external server tools and can be specified multiple times for each external server, respectively.
- --sequential. Use this option to diagnose "Out of Memory" errors. The tool collects data in parallel to minimize the collection time necessary for some analysis utilities. This option specifies that data collection should be run sequentially as opposed to in parallel. This action has the effect of reducing the initial memory footprint of this tool at a cost of taking longer to complete.
- --reportCount {count}. Specifies the number of reports generated for commands that supports sampling (for example, `vmstat`, `iostat`, or `mpstat`). A value of 0 (zero) indicates that no reports will be generated for these commands. If this option is not specified, it defaults to 10.
- --reportInterval {interval}. Specifies the number of seconds between reports for commands that support sampling (for example, `mpstat`). This option must have a value greater than 0 (zero). If this option is not specified, it default to 1.
- --maxJstacks {number}. Specifies the number of jstack samples to collect. If not specified, the default number of samples collected is 10.

Copyright © 2025 Ping Identity Corporation

- --collectExpensiveData. Specifies that data on expensive or long running processes be collected. These processes are not collected by default, because they will impact the performance of a running server.
- --comment {comment}. Provides the ability to submit any additional information about the collected data set. The comment will be added to the generated archive as a README file.
- --includeBinaryFiles. Specifies that binary files be included in the archive collection. By default, all binary files are automatically excluded in data collection.
- --adminPassword {adminPassword}. Specifies the global administrator password used to obtain `dsreplication status` information.
- --adminPasswordFile {adminPasswordFile}. Specifies the file containing the password of the global administrator used to obtain `dsreplication status` information.
- --outputPath. Specifies the path (and optionally, the name) for the support data archive file. If the path specifies a filename, the archive is written to that file. If the path specifies a directory, the file is written into that directory with a server-generated name.
- --useRemoteServer. Invokes the tool against a remote server instance and streams the output and resulting support data archive back to the client. This option can be especially useful when the server instance is running in a container because it might otherwise be difficult to invoke commands or access files in that container. See also: --proxyToServerAddress and --proxyToServerPort.
- --proxyToServerAddress and --proxyToServerPort. Use these options with --useRemoteServer to indicate that the support data archive should be retrieved from a server that is not directly accessible but can be accessed through a PingDirectoryProxy server.

Running the collect-support-data tool

Steps

1. Go to the server root directory.
2. Use the `collect-support-data` tool. Make sure to include the host, port number, bind DN, and bind password.

   Example:

   ```
   $ bin/collect-support-data --hostname 127.0.0.1 --port 389 \
     --bindDN "cn=Directory Manager" --bindPassword secret
   ```

3. Email the zip file to your Authorized Support Provider.

PingDirectory server troubleshooting tools

The Server provides a set of tools that can also be used to obtain information for diagnosing and solving problems.

Copyright © 2025 Ping Identity Corporation

Server version information

If it becomes necessary to contact your authorized support provider, then it will be important to provide precise information about the version of the PingDirectory server software that is in use. If the server is running, then this information can be obtained from the "`cn=Version,cn=monitor`" entry. It can also be obtained using the command:

```
$ bin/status --fullVersion
```

This command outputs a number of important pieces of information, including:

- Major, minor, point and patch version numbers for the server.
- Source revision number from which the server was built.
- Build information including build ID with timestamp, OS, user, Java and JVM version for the build.
- Auxiliary software versions: Jetty, JZlib, SNMP4j (SNMP4J, Agent, Agentx), Groovy, LDAP SDK for Java, and the Server SDK.

PingDirectory server gauges

The PingDirectory server provides a number of built-in gauges to monitor server performance. These gauges are listed in the following table:

Gauge Name	Enabled by default?	Description
Authentication Failure Rate	false	Rate of LDAP bind failures per second. A high rate of failures may indicate a misconfigured client application or a malicious attack.
Available File Descriptors	true	Monitors the number of file descriptors available to the server process. The server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. The number of file descriptors that the server will use can be configured by either using a `NUM_FILE_DESCRIPTORS` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as `NUM_FILE_DESCRIPTORS=12345`. If these are not set, the default of 65535 is used. Running out of available file descriptors can lead to unpredictable behavior and severe system instability.

Copyright © 2025 Ping Identity Corporation

Gauge Name	Enabled by default?	Description
Certificate Expiration (Days)	true	Monitors the expiration dates of key server certificates. A server certificate expiring may cause server unavailability, degradation, or loss of key server functionality. Certificates nearing the end of their validity should be replaced as soon as possible. See the status tool, or Status in the Administrative Console, for more information about server certificates and how they are managed.
CPU Usage (Percent)	true	Monitors server CPU use and provides an averaged percentage for the interval defined. The monitored resource is the host system's CPU, which does not include a resource identifier. If CPU use is high, check the server's current workload and other processes on this system and make any needed adjustments. Reducing the load on the system will lead to better response times.
Data Set Availability	true	For each data set, indicates whether there is at least one backend server available to fulfill requests. The resource identifier for this gauge is the name of the load-balancing algorithm used to define the set of backend servers fulfilling requests for the data set. Use the `dsconfig list-load-balancing-algorithms` command to see a list of load balancing algorithms. A data set may be included or excluded from monitoring by specifying its load-balancing algorithm name in the include resource and exclude resource properties respectively. A data set's availability depends upon the availability of the backend servers available to fulfill the PingDirectory server requests. The set of backend servers is defined by the set of servers configured in a data set's load-balancing algorithm. Make sure that backend servers are available to fulfill proxy requests.

Copyright © 2025 Ping Identity Corporation

Gauge Name	Enabled by default?	Description
Data Set Local Availability	true	For each data set, indicates whether there is at least one local backend server available to fulfill requests. The resource identifier for this gauge is the name of the load-balancing algorithm used to define the set of backend servers fulfilling requests for the data set. Use the `dsconfig list-load-balancing-algorithms` command to see a list of load balancing algorithms. A data set may be included or excluded from monitoring by specifying its load-balancing algorithm name in the `include resource` and `exclude resource` properties respectively. A data set's availability depends upon the availability of the backend servers available to fulfill the PingDirectory server requests. The set of backend servers is defined by the set of servers configured in a data set's load-balancing algorithm. Locations are used to indicate the set of preferred backend servers that should be used to fulfill requests. You can denote that a backend server is local by setting its external server configuration object's location attribute to be the same as this Directory Proxy Server instance's location set in its global configuration. Make sure that backend servers are available to fulfill proxy requests.
Disk Busy (Percent)	true	Monitors the percentage of disk use time averaged over the specified update interval. This gauge requires that the Host System Monitor Provider be enabled and that any monitored disks be registered using the disk-devices property of that configuration object. The resource identifier for this gauge is the disk device name. Use the iostat command or a similar system utility to see a list of disk device names. A separate gauge monitor entry will be created for each monitored disk.
HTTP Processing (Percent)	true	Monitors the percentage of time that request handler threads spend processing HTTP requests. This percentage represents the inverse of the server's ability to handle new requests without queuing.

Copyright © 2025 Ping Identity Corporation

Gauge Name	Enabled by default?	Description
JVM Memory Usage (Percent)	true	Monitors the percentage of Java Virtual Machine memory that is in use. This value naturally fluctuates due to garbage collection, so the minimum value within an interval is reported since it is a better indication of overall memory growth. When the memory usage exceeds 90%, this should be reported to customer support since the server is either misconfigured or has a memory leak. As memory usage approaches 100%, the server is more and more likely to experience garbage collection pauses, which leave the server unresponsive for a long time. Restarting the server is likely the only remedy for this situation. Prior to restarting the server, please run `collect-support-data` and capture the output of 'jmap -histo ' to provide to customer support. The pid of the server can be found from `/logs/server.pid`.
LDAP Operation Average Response Time (Milliseconds)	false	Monitors the average response time across all LDAP operations processed by this server since it was started. There is no resource identifier associated with this gauge. The monitored resource is overall response time of all LDAP operations processed by this server since it was started. High response times may be indicative of a number of factors including a disk-bound server, network latency, or misconfiguration. Enabling the Stats Logger plugin may help isolate problems. See the administration guide for more information on common problems and solutions.
LDAP Operations Failed (Percent)	false	Monitors the percentage of all LDAP operations processed by this server that have failed since it was started. There is no resource identifier associated with this gauge. The monitored resource is the overall number of failed LDAP operations processed by this server since it was started. A high percentage of failed operations may indicate misconfiguration of a client or server in a topology.
License Expiration (Days)	true	Monitors the expiration date of the product license. An expired license will cause warnings to appear in the server's logs and in the status tool output. Request a license key through the Ping Identity licensing website https://www.pingidentity.com/en/account/request-license-key.html or contact sales@pingidentity.com. Use the `dsconfig` tool to update the License configuration's license key property.

Copyright © 2025 Ping Identity Corporation

Gauge Name	Enabled by default?	Description
Memory Usage (Percent)	false	Monitors the percentage of memory use averaged over the update interval defined. The monitored resource is the host system's memory use, which does not have a resource identifier. Some operating systems, including Linux, use the majority of memory for file system cache, which is freed as applications need it. If memory use is high, check the applications that are running on the server.
Strong Encryption Not Available	true	The JVM does not appear to support strong encryption algorithms, like 256-bit AES. The server will fall back to using weaker algorithms, like 128-bit AES. To enable support for strong encryption, update your JVM to a newer version that supports it by default, or install or enable the unlimited encryption strength jurisdiction policy files in your Java installation.
Work Queue Size (Number Of Requests)	true	Number of requests in the server's work queue waiting to be processed, averaged over the update interval. There is no resource identifier associated with this gauge. The monitored resource is the server's work queue. If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available.

LDIF connection handler

The PingDirectory server provides an LDIF connection handler that provides a way to request operations that don't require any network communication with the server. This can be particularly helpful if a configuration problem or bug in the server has left a connection handler unusable, or if all worker threads are busy processing operations.

The LDIF connection handler is enabled by default and looks for LDIF files in the `config/auto-process-ldif` directory. This directory doesn't exist by default, but if you create it and place an LDIF file in it that contains one or more changes to be processed, the LDIF connection handler applies those changes.

Any changes that can be made over LDAP can be applied through the LDIF connection handler. It is primarily intended for administrative operations like updating the server configuration or scheduling tasks, although other types of changes (including changes to data contained in the server) can be processed. As the LDIF file is processed, a new file is written with comments for each change providing information about the result of processing that change.

Embedded profiler

If the PingDirectory server appears to be running slowly, then it is helpful to know what operations are being processed in the server. The JVM Stack Trace monitor entry can be used to obtain a point-in-time snapshot of what the server is doing, but in many cases, it might be useful to have information collected over a period of time.

Copyright © 2025 Ping Identity Corporation

The embedded profiler is configured so that it is always available but is not active by default so that it has no impact on the performance of the running server. Even when it is running, it has a relatively small impact on performance, but it is recommended that it remain inactive when it is not needed. It can be controlled using the `dsconfig` tool or the Administrative Console by managing the "Profiler" configuration object in the "Plugin" object type, available at the standard object level. The `profile-action` property for this configuration object can have one of the following values:

- start – Indicates that the embedded profiler should start capturing data in the background.
- stop – Indicates that the embedded profiler should stop capturing data and write the information that it has collected to a `logs/profile{timestamp}` file.
- cancel – Indicates that the embedded profiler should stop capturing data and discard any information that it has collected.

Any profiling data that has been captured can be examined using the `profiler-viewer` tool. This tool can operate in either a text-based mode, in which case it dumps a formatted text representation of the profile data to standard output, or it can be used in a graphical mode that allows the information to be more easily understood.

Invoking the profile viewer in text-based mode

Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option.

  Example:

  ```
  $ bin/profile-viewer --fileName logs/profile.20110101000000Z
  ```

Invoking the profile viewer in GUI mode

Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option. To invoke GUI mode, add the option `--useGUI`.

  Example:

  ```
  $ bin/profile-viewer --fileName logs/profile.20110101000000Z --useGUI
  ```

Troubleshooting resources for Java applications

Because the Server is written entirely in Java, it is possible to use standard Java debugging and instrumentation tools when troubleshooting problems with the PingDirectory server. In many cases, obtaining the full benefit of these tools requires access to the server source code. These Java tools should be used under the advisement of your authorized support provider.

Copyright © 2025 Ping Identity Corporation

Java troubleshooting tools

The Java Development Kit provides a number of very useful tools to obtain information about Java applications and diagnosing problems. These tools are not included with the Java Runtime Environment (JRE), so the full Java Development Environment (JDK) should always be installed and used to run the Server.

jps

The `jps` tool is a Java-specific version of the UNIX `ps` tool. It can be used to obtain a list of all Java processes currently running and their respective process identifiers. When invoked by a non-root user, it will list only Java processes running as that user. When invoked by a root user, then it lists all Java processes on the system.

This tool can be used to see if the PingDirectory server is running and if a process ID has been assigned to it. This process ID can be used in conjunction with other tools to perform further analysis.

This tool can be run without any arguments, but some of the more useful arguments that include:

- -v – Includes the arguments passed to the JVM for the processes that are listed.
- -m – Includes the arguments passed to the main method for the processes that are listed.
- -l – (lowercase L). Include the fully qualified name for the main class rather than only the base class name.

jstack

The `jstack` tool is used to obtain a stack trace of a running Java process, or optionally from a core file generated if the JVM happens to crash. A stack trace can be extremely valuable when trying to debug a problem, because it provides information about all threads running and exactly what each is doing at the point in time that the stack trace was obtained.

Stack traces are helpful when diagnosing problems in which the server appears to be hung or behaving slowly. Java stack traces are generally more helpful than native stack traces, because Java threads can have user-friendly names (as do the threads used by the Server), and the frame of the stack trace may include the line number of the source file to which it corresponds. This is useful when diagnosing problems and often allows them to be identified and resolved quickly.

To obtain a stack trace from a running JVM, use the command:

```
jstack {processID}
```

where {processID} is the process ID of the target JVM as returned by the `jps` command. To obtain a stack trace from a core file from a Java process, use the command:

```
jstack {pathToJava} {pathToCore}
```

where `{pathToJava}` is the path to the java command from which the core file was created, and `{pathToCore}` is the path to the core file to examine. In either case, the stack trace is written to standard output and includes the names and call stacks for each of the threads that were active in the JVM.

In many cases, no additional options are necessary. The "`-l`" option can be added to obtain a long listing, which includes additional information about locks owned by the threads. The "`-m`" option can be used to include native frames in the stack trace.

Copyright © 2025 Ping Identity Corporation

jmap

The `jmap` tool is used to obtain information about the memory consumed by the JVM. It is very similar to the native `pmap` tool provided by many operating systems. As with the `jstack` tool, `jmap` can be invoked against a running Java process by providing the process ID, or against a core file , like:

```
jmap {processID}
jmap {pathToJava} {pathToCore}
```

Some of the additional arguments include:

- -dump:live,format=b,file=filename – Dump the live heap data to a file that can be examined by the `jhat` tool
- -heap – Provides a summary of the memory used in the Java heap, along with information about the garbage collection algorithm in use.
- -histo:live – Provides a count of the number of objects of each type contained in the heap. If the "`:live`" portion is included, then only live objects are included; otherwise, the count include objects that are no longer in use and are garbage collected.

jhat

The `jhat` (Java Heap Analysis Tool) utility provides the ability to analyze the contents of the Java heap. It can be used to analyze a heap dump file, which is generated if the PingDirectory server encounters an out of memory error (as a result of the "`-XX:+HeapDumpOnOutOfMemoryError`" JVM option) or from the use of the `jmap` command with the "`-dump`" option.

The `jhat` tool acts as a web server that can be accessed by a browser in order to query the contents of the heap. Several predefined queries are available to help determine the types of objects consuming significant amounts of heap space, and it also provides a custom query language (OQL, the Object Query Language) for performing more advanced types of analysis.

The `jhat` tool can be launched with the path to the heap dump file, like:

```
jhat /path/to/heap.dump
```

This command causes the `jhat` web server to begin listening on port 7000. It can be accessed in a browser at `http://localhost:7000` (or `http://address:7000` from a remote system). An alternate port number can be specified using the "`-port`" option, like:

```
jhat -port 1234 /path/to/heap.dump
```

To issue custom OQL searches, access the web interface using the URL `http://localhost:7000/oql/` (the trailing slash must be provided). Additional information about the OQL syntax may be obtained in the web interface at `http://localhost:7000/oqlhelp/`.

jstat

The `jstat` tool is used to obtain a variety of statistical information from the JVM, much like the `vmstat` utility that can be used to obtain CPU utilization information from the operating system. The general manner to invoke it is as follows:

Copyright © 2025 Ping Identity Corporation

```
jstat {type} {processID} {interval}
```

The `{interval}` option specifies the length of time in milliseconds between lines of output. The `{processID}` option specifies the process ID of the JVM used to run the PingDirectory server, which can be obtained by running `jps` as mentioned previously. The `{type}` option specifies the type of output that should be provided. Some of the most useful types include:

- -class – Provides information about class loading and unloading.
- -compile – Provides information about the activity of the JIT complex.
- -printcompilation – Provides information about JIT method compilation.
- -gc – Provides information about the activity of the garbage collector.
- -gccapacity – Provides information about memory region capacities.

Java diagnostic information

In addition to the tools listed in the previous section, the JVM can provide additional diagnostic information in response to certain events.

Garbage collection diagnostic information

You can enable the JVM debugging options to track garbage collection data for your system. The options can impact JVM performance, but they provide valuable data to tune your server when troubleshooting garbage collection issues. While the `jstat` utility with the `-gc` option can be used to obtain some information about garbage collection activity, there are additional arguments that can be added to the JVM to use when running the server to provide additional detail.

```
-XX:+PrintGCDetails
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
-XX:+PrintGCDateStamps
```

To run the server with these options, edit the `config/java.properties` file and add them to the end of the line that begins with "`bin/start-server.java-args`". After the file has been saved, invoke the following command to make those new arguments take effect the next time the server is started:

```
$ bin/dsjavaproperties
```

JVM crash diagnostic information

If the JVM itself should happen to crash for some reason, then it generates a fatal error log with information about the state of the JVM at the time of the crash. By default, this file is named `hs_err_pid{processID}.log` and is written into the base directory of the PingDirectory server installation. This file includes information on the underlying cause of the JVM crash, information about the threads running and Java heap at the time of the crash, the options provided to the JVM, environment variables that were set, and information about the underlying system.

Copyright © 2025 Ping Identity Corporation

Troubleshooting resources in the operating system

The underlying operating system also provides a significant amount of information that can help diagnose issues that impact the performance and the stability of the PingDirectory server. In some cases, problems with the underlying system can be directly responsible for the issues seen with the server, and in others system, tools can help narrow down the cause of the problem.

Identifying problems with the underlying system

If the underlying system itself is experiencing problems, it can adversely impact the function of applications running on it. To look for problems in the underlying system view the system log file (`/var/log/messages` on Linux). Information about faulted or degraded devices or other unusual system conditions are written there.

Monitoring system data using the PingDataMetrics server

The PingDataMetrics server provides collection and storage of performance data from your server topology. You can use the System Utilization Monitor with the PingDataMetrics server to collect information about the host system CPU, disk, and network utilization on any platform except Linux. If you are not using the PingDataMetrics server, you do not need to use the system utilization monitor. When data is being collected, it periodically forks the process and executes commands.

For more information about using the System Utilization Monitor, refer to the data collection chapter of the PingDataMetrics server documentation.

Examining CPU utilization

Observing CPU utilization for the server process and the system as a whole provides clues as to the nature of the problem.

System-Wide CPU utilization

To investigate CPU consumption of the system as a whole, use the `vmstat` command with a time interval in seconds, like:

```
vmstat 5
```

The specific output of this command varies between different operating systems, but it includes the percentage of the time the CPU was spent executing user-space code (user time), the percentage of time spent executing kernel-space code (system time), and the percentage of time not executing any code (idle time).

Copyright © 2025 Ping Identity Corporation

If the CPUs are spending most of their time executing user-space code, the available processors are being well-utilized. If performance is poor or the server is unresponsive, it can indicate that the server is not optimally tuned. If there is a high system time, it can indicate that the system is performing excessive disk and/or network I/O, or in some cases, there can be some other system-wide problem like an interrupt storm. If the system is mostly idle but the server is performing poorly or is unresponsive, there can be a resource constraint elsewhere (for example, waiting on disk or memory access, or excessive lock contention), or the JVM can be performing other tasks like stop-the-world garbage collection that cannot be run heavily in parallel.

Per-CPU utilization

To investigate CPU consumption on a per-CPU basis, use the `mpstat` command with a time interval in seconds, like:

```
mpstat 5
```

On Linux systems, it might be necessary to add "`-P ALL`" to the command, like:

```
mpstat -P ALL 5
```

Among other things, this shows the percentage of time each CPU has spent in user time, system time, and idle time. If the overall CPU utilization is relatively low but `mpstat` reports that one CPU has a much higher utilization than the others, there might be a significant bottleneck within the server or the JVM might be performing certain types of garbage collection which cannot be run in parallel. On the other hand, if CPU utilization is relatively even across all CPUs, there is likely no such bottleneck and the issue might be elsewhere.

Per-process utilization

To investigate CPU consumption on a per-process basis, use a command such as the `top` utility on Linux. If a process other than the Java process used to run the PingDirectory server is consuming a significant amount of available CPU, it might be interfering with the ability of the server to run effectively.

Examining disk utilization

If the underlying system has a very high disk utilization, it can adversely impact server performance. It could delay the ability to read or write database files or write log files. It could also raise concerns for server stability if excessive disk I/O inhibits the ability of the cleaner threads to keep the database size under control.

The `iostat` tool can be used to obtain information about the disk activity on the system.

On Linux systems, `iostat` should be invoked with the "`-x`" argument, like:

Copyright © 2025 Ping Identity Corporation

```
iostat -x 5
```

A number of different types of information will be displayed, but to obtain an initial feel for how busy the underlying disks are, look at the "%util" column on Linux. This field shows the percentage of the time that the underlying disks are actively servicing I/O requests. A system with a high disk utilization likely exhibits poor server performance.

If the high disk utilization is on one or more disks that are used to provide swap space for the system, the system might not have enough free memory to process requests. As a result, it might have started swapping blocks of memory that have not been used recently to disk. This can cause very poor server performance. It is important to ensure that the server is configured appropriately to avoid this condition. If this problem occurs on a regular basis, then the server is likely configured to use too much memory. If swapping is not normally a problem but it does arise, then check to see if there are any other processes running, which are consuming a significant amount of memory, and check for other potential causes of significant memory consumption (for example, large files in a `tmpfs` file system).

Examining process details

There are a number of tools provided by the operating system that can help examine a process in detail.

ps

The standard `ps` tool can be used to provide a range of information about a particular process. For example, the command can be used to display the state of the process, the name of the user running the process, its process ID and parent process ID, the priority and nice value, resident and virtual memory sizes, the start time, the execution time, and the process name with arguments:

```
ps -fly -p {processID}
```

Note that for a process with a large number of arguments, the standard `ps` command displays only a limited set of the arguments based on available space in the terminal window.

pstack

The `pstack` command can be used to obtain a native stack trace of all threads in a process. While a native stack trace might not be as user-friendly as a Java stack trace obtained using `jstack`, it includes threads that are not available in a Java stack trace. For example, the command displays those threads used to perform garbage collection and other housekeeping tasks. The general usage for the `pstack` command is:

```
pstack {processID}
```

Copyright © 2025 Ping Identity Corporation

dbx / gdb

A process debugger provides the ability to examine a process in detail. Like `pstack`, a debugger can obtain a stack trace for all threads in the process, but it also provides the ability to examine a process (or core file) in much greater detail, including observing the contents of memory at a specified address and the values of CPU registers in different frames of execution. The GNU debugger `gdb` is widely-used on Linux systems.

Note that using a debugger against a live process interrupts that process and suspends its execution until it detaches from the process. In addition, when running against a live process, a debugger has the ability to actually alter the contents of the memory associated with that process, which can have adverse effects. As a result, it is recommended that the use of a process debugger be restricted to core files and only used to examine live processes under the direction of your authorized support provider.

pfiles / lsof

To examine the set of files that a process is using (including special types of files, like sockets), you can use a tool such as `lsof` on Linux systems, (

```
lsof -p {processID}
```

)

Tracing process execution

If a process is unresponsive but is consuming a nontrivial amount of CPU time, or if a process is consuming significantly more CPU time than is expected, it might be useful to examine the activity of that process in more detail than can be obtained using a point-in-time snapshot. For example, if a process is performing a significant amount of disk reads and/or writes, it can be useful to see which files are being accessed. Similarly, if a process is consistently exiting abnormally, then beginning tracing for that process just before it exits can help provide additional information that cannot be captured in a core file (and if the process is exiting rather than being terminated for an illegal operation, then no core file may be available).

This can be accomplished using the `strace` tool on Linux (

```
strace -f -p {processID}
```

).

Consult the `strace` manual page for additional information.

Problems with SSL communication

Enable TLS debugging in the server to troubleshoot SSL communication issues:

Copyright © 2025 Ping Identity Corporation

```
$ dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
  --set debug-level:verbose \
  --set include-throwable-cause:true
```

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true \
  --set default-debug-level:disabled
```

In the `java.properties` file, add `-Djavax.net.debug=ssl` to the `start-server` line, and run `bin/dsjavaproperties` to make the option take effect on a scheduled server restart.

Examining network communication

Because the server is a network-based application, it can be valuable to observe the network communication that it has with clients. The server itself can provide details about its interaction with clients by enabling debugging for the protocol or data debug categories, but there can be a number of cases in which it is useful to view information at a much lower level. A network sniffer, like the tcpdump tool on Linux, can be used to accomplish this.

There are many options that can be used with these tools, and their corresponding manual pages will provide a more thorough explanation of their use. However, to perform basic tracing to show the full details of the packets received for communication on port 389 with remote host 1.2.3.4, the following command can be used on Linux:

```
tcpdump -i {interface} -n -XX -s 0 host 1.2.3.4 and port 389
```

It does not appear that the `tcpdump` tool provides support for LDAP parsing. However, it is possible to write capture data to a file rather than displaying information on the terminal (using "`-w {path}`" with `tcpdump`), so that information can be later analyzed with a graphical tool like Wireshark, which provides the ability to interpret LDAP communication on any port.

Note that enabling network tracing generally requires privileges that are not available to normal users and therefore can require root access.

Common problems and potential solutions

This section describes a number of different types of problems that can occur and common potential causes for them.

General troubleshooting methodology

When a problem is detected, the following general methodology to isolate the problem are recommended.

1. Run the `bin/status` tool or look at the server status in the Administrative Console. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts.

Copyright © 2025 Ping Identity Corporation

2. Look in the server logs. In particular, view the following logs:
    - logs/errors
    - logs/failed-ops
    - logs/expensive-ops
3. Use system commands, such as `vmstat` and `iostat` to determine if the server is bottle-necked on a system resource like CPU or disk throughput.
4. For performance problem (especially intermittent ones like spikes in response time), enabling the `periodic-stats-logger` can help to isolate problems, because it stores important server performance information on a per-second basis. The `periodic-stats-logger` can save the information in a csv-formatted file that can be loaded into a spreadsheet. The information this logger makes available is very configurable. You can create multiple loggers for different types of information or a different frequency of logging (for example, hourly data in addition to per-second data). For more information, see "Profiling Server Performance Using the Periodic Stats Logger".
5. For replication problem, run `dsreplication status` and look at the `logs/replication` file.
6. For more advanced users, run the `collect-support-data` tool on the system, unzip the archive somewhere, and look through the collected information. This is often useful when administrators most familiar with the Data Platform do not have direct access to the systems where the production servers are running. They can examine the `collect-support-data` archive on a different server. For more information, see Using the Collect Support Data Tool.

> **Important**
>
> Run the `collect-support-data` tool whenever there is a problem whose cause is not easily identified, so that this information can be passed back to your authorized support provider before corrective action can be taken.

The server will not run setup

If the `setup` tool does not run properly, some of the most common reasons include the following.

A suitable Java environment is not available

The server requires that Java be installed on the system and made available to the server, and it must be installed prior to running `setup` . If the `setup` tool does not detect that a suitable Java environment is available, it will refuse to run.

To ensure that this does not happen, the `setup` tool should be invoked with an explicitly-defined value for the *JAVA_HOME* environment variable that specifies the path to the Java installation that should be used. For example:

```
env JAVA_HOME=/ds/java ./setup
```

If this still does not work for some reason, then it can be that the value specified in the provided *JAVA_HOME* environment variable can be overridden by another environment variable. If that occurs, try the following command, which should override any other environment variables that can be set:

Copyright © 2025 Ping Identity Corporation

```
env UNBOUNDID_JAVA_HOME="/ds/java" UNBOUNDID_JAVA_BIN="" ./setup
```

Unexpected arguments provided to the JVM

If the `setup` script attempts to launch the java command with an invalid set of Java arguments, it might prevent the JVM from starting. By default, no special options are provided to the JVM when running setup, but this might not be the case if either the *JAVA_ARGS* or *UNBOUNDID_JAVA_ARGS* environment variable is set. If the `setup` tool displays an error message that indicates that the Java environment could not be started with the provided set of arguments, then invoke the following command before trying to re-run `setup`:

```
unset JAVA_ARGS UNBOUNDID_JAVA_ARGS
```

The server has already been configured or used

The `setup` tool is only intended to provide the initial configuration for the server. It refuses to run if it detects that the `setup` tool has already been run, or if an attempt has been made to start the server prior to running the `setup` tool. This protects an existing server installation from being inadvertently updated in a manner that could harm an existing configuration or data set.

If the server has been previously used and if you want to perform a fresh installation, it is recommended that you first remove the existing installation, create a new one and run `setup` in that new installation. However, if you are confident that there is nothing of value in the existing installation (for example, if a previous attempt to run `setup` failed to complete successfully for some reason but it will refuse to run again), the following steps can be used to allow the `setup` program to run:

- Remove the `config/config.ldif` file and replace it with the `config/update/config.ldif.{revision}` file containing the initial configuration.
- If there are any files or subdirectories below the `db` directory, then remove them.
- If a `config/java.properties` file exists, then remove it.
- If a `lib/setup-java-home` script (or `` file on Microsoft Windows) exists, then remove it.

The server will not start

If the server does not start, then there are a number of potential causes.

Copyright © 2025 Ping Identity Corporation

The server or other administrative tool is already running

Only a single instance of the server can run at any time from the same installation root. If an instance is already running, then subsequent attempts to start the server will fail. Similarly, some other administrative operations can also prevent the server from being started. In such cases, the attempt to start the server should fail with a message like:

```
The Diretory Server could not acquire an exclusive lock on file
/ds/the/locks/server.lock: The exclusive lock requested for file
/ds/the/locks/ server.lock was not granted, which indicates
that another process already holds a shared or exclusive lock on that
file. This generally means that another instance of this server is already
running
```

If the server is not running (and is not in the process of starting up or shutting down) and there are no other tools running that could prevent the server from being started, and the server still believes that it is running, then it is possible that a previously-held lock was not properly released. In that case, you can try removing all of the files in the `locks` directory before attempting to start the server.

If you wish to have multiple instances running at the same time on the same system, then you should create a completely separate installation in another location on the file system.

There is not enough memory available

When the server is started, the JVM attempts to allocate all memory that it has been configured to use. If there is not enough free memory available on the system, then the server generates an error message that indicates that the server could not be started with the specified set of arguments. Note that it is possible that an invalid option was provided to the JVM (as described below), but if that same set of JVM arguments has already been used successfully to run the server, then it is more likely that the system does not have enough memory available.

There are a number of potential causes for this:

- If the amount of memory in the underlying system has changed (for example, system memory has been removed, or if the server is running in a zone or other type of virtualized container and a change has been made to the amount of memory that container will be allowed to use), then the server might need to be re-configured to use a smaller amount of memory than had been previously configured.
- Another process running on the system is consuming a significant amount of memory so that there is not enough free memory available to start the server. If this is the case, then either terminate the other process to make more memory available for the server, or reconfigure the server to reduce the amount of memory that it attempts to use.
- The server was just shut down and an attempt was made to immediately restart it. In some cases, if the server is configured to use a significant amount of memory, then it can take a few seconds for all of the memory that had been in use by the server, when it was previously running, to be released back to the operating system. In that case, run the `vmstat` command and wait until the amount of free memory stops growing before attempting to restart the server.

Copyright © 2025 Ping Identity Corporation

- If the system is configured with one or more memory-backed file systems, verify whether any large files might be consuming a significant amount of memory in any of those locations. If so, remove them or relocate them to a disk-based file system.
- For Linux systems only, if a mismatch exists between the huge pages setting for the JVM and the huge pages reserved in the operating system.

If nothing else works and there is still not enough free memory to allow the JVM to start, then as a last resort, try rebooting the system.

An invalid Java Environment or JVM option was used

If an attempt to start the server fails with an error message indicating that no valid Java environment could be found, or indicates that the Java environment could not be started with the configured set of options, then you should first ensure that enough memory is available on the system as described above. If there is a sufficient amount of memory available, then other causes for this error can include the following:

- The Java installation that was previously used to run the server no longer exists (for example, an updated Java environment was installed and the old installation was removed). In that case, update the `config/java.properties` file to reference to path to the new Java installation and run the `bin/dsjavaproperties` command to apply that change.
- The Java installation used to run the server has been updated and the server is trying to use the correct Java installation but one or more of the options that had worked with the previous Java version no longer work with the new version. In that case, it is recommended that the server be re-configured to use the previous Java version, so that it can be run while investigating which options should be used with the new installation.
- If an *UNBOUNDID_JAVA_HOME* or *UNBOUNDID_JAVA_BIN* environment variable is set, then its value might override the path to the Java installation used to run the server as defined in the `config/java.properties` file. Similarly, if an *UNBOUNDID_JAVA_ARGS* environment variable is set, then its value might override the arguments provided to the JVM. If this is the case, then explicitly unset the *UNBOUNDID_JAVA_HOME*, *UNBOUNDID_JAVA_BIN*, and *UNBOUNDID_JAVA_ARGS* environment variables before trying to start the server.

Note that any time the `config/java.properties` file is updated, the **`bin/dsjavaproperties`** tool must be run to apply the new configuration. If a problem with the previous Java configuration prevents the **`bin/dsjavaproperties`** tool from running properly, then it can be necessary to remove the `lib/set-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) and invoke the **`bin/dsjavaproperties`** tool with an explicitly-defined path to the Java environment, like:

```
env UNBOUNDID_JAVA_HOME=/ds/java bin/dsjavaproperties
```

Copyright © 2025 Ping Identity Corporation

An invalid command-line option was provided

There are a small number of arguments that are provided when running the `bin/start-server` command, but in most cases, none are required. If one or more command-line arguments were provided for the `bin/start-server` command and any of them is not recognized, then the server provides an error message indicating that an argument was not recognized and displays version information. In that case, correct or remove the invalid argument and try to start the server again.

The server has an invalid configuration

If a change is made to the server configuration using an officially-supported tool like `dsconfig` or the administrative console, the server should validate that configuration change before applying it. However, it is possible that a configuration change can appear to be valid at the time that it is applied, but does not work as expected when the server is restarted. Alternately, a change in the underlying system can cause a previously-valid configuration to become invalid.

In most cases involving an invalid configuration, the server displays (and writes to the error log) a message that explains the problem, and this can be sufficient to identify the problem and understand what action needs to be taken to correct it. If for some reason the startup failure does not provide enough information to identify the problem with the configuration, then look in the `logs/config-audit.log` file to see what recent configuration changes have been made with the server online, or in the `config/archived-configs` directory to see if there might have been a recent configuration change resulting from a direct change to the configuration file itself that was not made through a supported configuration interface.

If the server does not start as a result of a recent invalid configuration change, then it can be possible to start the server using the configuration that was in place the last time that the server started successfully (for example, the "last known good" configuration). This can be achieved using the `--useLastKnownGoodConfig` option:

```
$ bin/start-server --useLastKnownGoodConfig
```

Note that if it has been a long time since the last time the server was started and a number of configuration changes have been made since that time, then the last known good configuration can be significantly out of date. In such cases, it can be preferable to manually repair the configuration.

If there is no last known good configuration, if the server no longer starts with the last known good configuration, or if the last known good configuration is significantly out of date, then manually update the configuration by editing the `config/config.ldif` file. In that case, you should make sure that the server is offline and that you have made a copy of the existing configuration before beginning. You might wish to discuss the change with your authorized support representative before applying it to ensure that you understand the correct change that needs to be made.

> **Note**
>
> In addition to manually-editing the configuration file, you can look at previous archived configurations to see if the most recent one works. You can also use the **`ldif-diff`** tool to compare the configurations in the archive to the current configuration to see what is different.

Copyright © 2025 Ping Identity Corporation

You do not have sufficient permissions

The server should only be started by the user or role used to initially install the server. In most cases, if an attempt is made to start the server as a user or role other than the one used to create the initial configuration, then the server will fail to start, because the user will not have sufficient permissions to access files owned by the other user, such as database and log files. However, if the server was initially installed as a non-root user and then the server is started by the root account, then it can no longer be possible to start the server as a non-root user because new files that are created would be owned by root and could not be written by other users.

If the server was inadvertently started by root when it is intended to be run by a non-root user, or if you wish to change the user account that should be used to run the server, then it should be sufficient to simply change ownership on all files in the server installation, so that they are owned by the user or role under which the server should run. For example, if the server should be run as the "ds" user in the "other" group, then the following command can be used to accomplish this (invoked by the root user):

```
chown -R ds:other /ds/the
```

The server has crashed or shut itself down

You can first check the current server state by using the `bin/server-state` command. If the PingDirectory server was previously running but is no longer active, then the potential reasons include the following:

- The PingDirectory server was shut down by an administrator. Unless the server was forcefully terminated (for example, using "kill -9"), then messages are written to the `error` and `server.out` logs explaining the reason for the shutdown.
- The PingDirectory server was shut down when the underlying system crashed or was rebooted. If this is the case, then running the `uptime` command on the underlying system shows that it was recently booted.
- The PingDirectory server process was terminated by the underlying operating system for some reason (for example, the out of memory killer on Linux). If this happens, then a message will be written to the system error log.
- The PingDirectory server decided to shut itself down in response to a serious problem that had arisen. At present, this should only occur if the server has detected that the amount of usable disk space has become critically low, or if significant errors have been encountered during processing that left the server without any remaining worker threads to process operations. If this happens, then messages are written to the `error` and `server.out` logs (if disk space is available) to provide the reason for the shutdown.
- The JVM in which the PingDirectory server was running crashed. If this happens, then the JVM should dump a fatal error log (a `hs_err_pid{processID}.log` file) and potentially a core file.

In the event that the operating system itself crashed or terminated the process, then you should work with your operating system vendor to diagnose the underlying problem. If the JVM crashed or the server shut itself down for a reason that is not clear, then contact your authorized support provider for further assistance.

Copyright © 2025 Ping Identity Corporation

Conditions for automatic server shutdown

All PingDirectory servers will shut down in an out of memory condition, a low disk space error state, or for running out of file descriptors. The server will enter lockdown mode on unrecoverable database environment errors, but can be configured to shutdown instead with this setting:

```
$ dsconfig set-global-configuration-prop \
            --set unrecoverable-database-error-mode:initiate-server-shutdown
```

The server won't accept client connections

You can first check the current server state by using the `bin/server-state` command. If the server doesn't appear to be accepting connections from clients, then potential reasons include the following:

- The server isn't running.
- The underlying system on which the server is installed isn't running.
- The server is running but isn't reachable as a result of a network or firewall configuration problem. If that is the case, then connection attempts should time out rather than be rejected.
- If the server is configured to allow secure communication via SSL or StartTLS, then a problem with the key manager and/or trust manager configuration can cause connections to be rejected. If that is the case, then messages should be written to the server access log for each failed connection attempt.
- If the server has been configured with a maximum allowed number of connections, then it can be that the maximum number of allowed client connections are already established. If that is the case, then messages should be written to the server access log for each rejected connection attempt.
- If the server is configured to restrict access based on the address of the client, then messages should be written to the server access log for each rejected connection attempt.
- If a connection handler encounters a significant error, then it can stop listening for new requests. If this occurs, then a message should be written to the server error log with information about the problem. Another solution is to restart the server. A third option is to restart the connection handler using the LDIF connection handler to make it available again. To do this, create an LDIF file that disables and then re-enables the connection handler, create the `config/auto-process-ldif` directory if it doesn't already exist, and then copy the LDIF file into it.

The server is unresponsive

You can first check the current server state by using the `bin/server-state` command. If the server process is running and appears to be accepting connections but does not respond to requests received on those connections, then potential reasons for this behavior include:

Copyright © 2025 Ping Identity Corporation

If it appears that the problem is with the server software or the JVM in which it is running, then you need to work with your authorized support provider to fully diagnose the problem and determine the best course of action to correct it.

- If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available. If this is the case, then a stack trace obtained using the `jstack` command shows that all of the worker threads are busy and none of them are waiting for new requests to process.

  A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the `ldapsearch` command for example, use the `--useAdministrativeSession` option. The requester must have the `use-admin-session` privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

  > **Note**
  >
  > If all of the worker threads are tied up processing the same operation for a long time, the server will also issue an alert that it might be deadlocked, which might not actually be the case. All threads might be tied up processing unindexed searches.

- If a request handler is stuck performing some expensive processing for a client connection, then other requests sent to the server on connections associated with that request handler is forced to wait until the request handler is able to read data on those connections. If this is the case, then only some of the connections can experience this behavior (unless there is only a single request handler, in which it will impact all connections), and stack traces obtained using the `jstack` command shows that a request handler thread is continuously blocked rather than waiting for new requests to arrive. Note that this scenario is a theoretical problem and one that has not appeared in production.
- If the JVM in which the server is running is not properly configured, then it can be forced to spend a significant length of time performing garbage collection, and in severe cases, could cause significant interruptions in the execution of Java code. In such cases, a stack trace obtained from a `pstack` of the native process should show that most threads are idle but at least one thread performing garbage collection is active. It is also likely that one or a small number of CPUs is 100% busy while all other CPUs are mostly idle. The server will also issue an alert after detecting a long JVM pause (due to garbage collection). The alert will include details of the pause.
- If the JVM in which the server is running has hung for some reason, then the `pstack` utility should show that one or more threads are blocked and unable to make progress. In such cases, the system CPUs should be mostly idle.
- If a network or firewall configuration problem arises, then attempts to communicate with the server cannot be received by the server. In that case, a network sniffer like `snoop` or `tcpdump` should show that packets sent to the system on which the server is running are not receiving TCP acknowledgement.
- If the system on which the server is running has become hung or lost power with a graceful shutdown, then the behavior is often similar to that of a network or firewall configuration problem.

Copyright © 2025 Ping Identity Corporation

The server is slow to respond to client requests

If the server is running and does respond to clients, but clients take a long time to receive responses, then the problem can be attributable to a number of potential problems. In these cases, use the Periodic Stats Logger, which is a valuable tool to get per-second monitoring information on the server. The Periodic Stats Logger can save the information in csv format for easy viewing in a spreadsheet. For more information, see "Profiling Server Performance Using the Periodic Stats Logger". The potential problems that cause slow responses to client requests are as follows:

- The server is not optimally configured for the type of requests being processed, or clients are requesting inefficient operations. If this is the case, then the access log should show that operations are taking a long time to complete and they will likely be unindexed. In that case, updating the server configuration to better suit the requests, or altering the requests to make them more efficient, could help alleviate the problem. In this case, view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second. You can also run the `bin/status` command or view the status in the Administrative Console to see the server's Work Queue information (also see the next bullet point).
- The server is overwhelmed with client requests and has amassed a large backlog of requests in the work queue. This can be the result of a configuration problem (for example, too few worker thread configured), or it can be necessary to provision more systems on which to run the server software. Symptoms of this problem appear similar to those experienced when the server is asked to process inefficient requests, but looking at the details of the requests in the access log show that they are not necessarily inefficient requests. Run the `bin/status` command to view the Work Queue information. If everything is performing well, you should not see a large queue size or a server that is near 100% busy. The %Busy statistic is calculated as the percentage of worker threads that are busy processing operations.

```
           --- Work Queue ---
           : Recent : Average : Maximum
-----------:--------:---------:--------
Queue Size : 10   : 1       : 10
% Busy     : 17     : 14      : 100
```

You can also view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second.

- The server is not configured to fully cache all of the data in the server, or the cache is not yet primed. In this case, `iostat` reports a very high disk utilization. This can be resolved by configuring the server to fully cache all data, and to load database contents into memory on startup. If the underlying system does not have enough memory to fully cache the entire data set, then it might not be possible to achieve optimal performance for operations that need data which is not contained in the cache. For more information, see Disk-Bound Deployments.
- If the JVM is not properly configured, then it will need to perform frequent garbage collection and periodically pause execution of the Java code that it is running. In that case, the server error log should report that the server has detected a number of pauses and can include tuning recommendations to help alleviate the problem.
- If the server is configured to use a large percentage of the memory in the system, then it is possible that the system has gotten low on available memory and has begun swapping. In this case, `iostat` should report very high utilization for disks used to hold swap space, and commands like `cat /proc/meminfo` on Linux can report a large amount of swap memory in use. Another cause of swapping is if swappiness is not set to 0 on Linux. For more information, see Disable File System Swapping.

Copyright © 2025 Ping Identity Corporation

- If another process on the system is consuming a significant amount of CPU time, then it can adversely impact the ability of the server to process requests efficiently. Isolating the processes (for example, using processor sets) or separating them onto different systems can help eliminate this problem.

The server returns error responses to client requests

If a large number of client requests are receiving error responses, then view the `logs/failed-ops` log, which is an access log for only failed operations. The potential reasons for the error responses include the following:

- If clients are requesting operations that legitimately should fail (for example, they are targeting entries that do not exist, are attempting to update entries in a way that would violate the server schema, or are performing some other type of inappropriate operation), then the problem is likely with the client and not the server.
- If a portion of the PingDirectory server data is unavailable (for example, because an online LDIF import or restore is in progress), then operations targeting that data will fail. Those problems will be resolved when the backend containing that data is brought back online. During the outage, it might be desirable to update PingDirectoryProxy servers or load balancers or both to route requests away from the affected server. As of PingDirectory version 3.1 or later, the PingDirectory server will indicate that it is in a degraded status and the PingDirectoryProxy server will route around it.
- If the PingDirectory server work queue is configured with a maximum capacity and that capacity has been reached, then the server begins rejecting all new requests until space is available in the work queue. In this case, it might be necessary to alter the server configuration or the client requests or both, so that they can be processed more efficiently, or it might be necessary to add additional server instances to handle some of the workload.
- If an internal error occurs within the server while processing a client request, then the server terminates the connection to the client and logs a message about the problem that occurred. This should not happen under normal circumstances, so you will need to work with your authorized support provider to diagnose and correct the problem.
- If a problem is encountered while interacting with the underlying database (for example, an attempt to read from or write to disk failed because of a disk problem or lack of available disk space), then it can begin returning errors for all attempts to interact with the database until the backend is closed and re-opened and the database has been given a change to recover itself. In these cases, the `je.info.*` file in the database directory should provide information about the nature of the problem.

The server must disconnect a client connection

If a client connection must be disconnected due to the expense of the client's request, such as an unindexed search across a very large database, perform the following:

- Find the client's connection ID by looking in the `cn=Active Operations,cn=monitor monitor` entry.

```
$ bin/ldapsearch -baseDN cn=monitor "cn=active operations" \
  --bindDN "cn=directory manager"  \
  --bindPassword password
```

- The monitor entry will contain attribute values for `operation-in-progress`, which look like an access log message. Look for the value of `conn` in the client request that should be disconnected. In the following example, the client to be disconnected is requesting a search for `(description=expensive)`, which is on connection 6.

Copyright © 2025 Ping Identity Corporation

```
dn: cn=Active Operations,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-active-operations-monitor-entry
objectClass: extensibleObject
cn: Active Operations
num-operations-in-progress: 2
operation-in-progress: [15/Dec/2014:10:55:35 -0600] SEARCH conn=6 op=3 msgID=4
     clientIP="10.8.4.21" authDN="cn=app1,ou=applications,dc=example,dc=com" base="dc
     =example,dc=com" scope=wholeSubtree filter="(description=expensive)" attrs="A
     LL" unindexed=true
operation-in-progress: [15/Dec/2014:10:56:11 -0600] SEARCH conn=7 op=1 msgID=2
     clientIP="127.0.0.1" authDN="cn=Directory Manager,cn=Root DNs,cn=config" base="c
     n=monitor" scope=wholeSubtree filter="(cn=active operations)" attrs="ALL"
     num-persistent-searches-in-progress: 0
```

- With the connection ID value, create a file with the following contents, named `disconnect6.ldif`.

```
dn: ds-task-id=disconnect6,cn=scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-disconnect
ds-task-disconnect-connection-id: 6
ds-task-id: disconnect6
ds-task-class-name: com.unboundid.directory.server.tasks.DisconnectClientTask
```

- This LDIF file represents a task entry. The connection ID value 6 is assigned to `ds-task-disconnect-connection-id`. The value for `ds-task-id` value does not follow a specific convention. It must be unique among other task entries currently cached by the server.
- Disconnect the client and cancel the associated operation by adding the task entry to the server:

```
$ bin/ldapmodify --filename disconnect6.ldif  \
  --defaultAdd --bindDN "cn=directory manager" \
  --bindPassword password
```

Problems with the administrative console

If a problem arises when trying to use the administrative console, then potential reasons for the problem may include the following:

- The web application container used to host the console is not running. If an error occurs while trying to start it, then consult the logs for the web application container.
- If a problem occurs while trying to authenticate to the web application container, then make sure that the target PingDirectory server is online. If it is online, then the access log may provide information about the reasons for the authentication failure.

Copyright © 2025 Ping Identity Corporation

- If a problem occurs while attempting to interact with the PingDirectoryProxy server instance using the administrative console, then the access and error logs for that PingDirectory server instance might provide additional information about the underlying problem.

Problems with the administrative console: JVM memory issues

Console runs out of memory (PermGen). An inadequate PermSize setting in the server, while hosting web applications like the Administrative Console may result in errors like this in the error log:

```
[02/Mar/2016:07:50:27.017 -0600] threadID=2 category=UTIL
    severity=SEVERE_ERROR msgID=-1 msg="The server experienced an unexpected
    error. Please report this problem and include this log file.
    OutOfMemoryError: PermGen space
    ()\ncom.unboundid.directory.server.core.DirectoryServer.uncaughtException
    (DirectoryServer.java:15783)\njava.lang.ThreadGroup.uncaughtException
    (ThreadGroup.java:1057)\njava.lang.ThreadGroup.uncaughtException
    (ThreadGroup.java:1052)\njava.lang.ThreadGroup.uncaughtException
    (ThreadGroup.java:1052)\njava.lang.Thread.dispatchUncaughtException
    (Thread.java:1986)\nBuild revision: 22496\n"
```

This is only relevant for servers running Java 7.

Troubleshooting global index growing too large

About this task

If the global index appears to be growing too large, you can reload from the backend directory servers.

Steps

- To override the configuration of the `prime-index-source` property, run the `reload-index` tool with the `--fromDS` subcommand.

  Example:

  You can do this on a one-off basis if the global index appears to be growing too large.

  ```
  $ bin/reload-index \
    --bindPassword password \
    --baseDN "dc=example,dc=com" \
    --fromDS
  ```

Recovering forgotten Proxy User password

About this task

If you forget your `cn=Proxy User` password, you can recover it using different methods.

Copyright © 2025 Ping Identity Corporation

Steps

- To recover your password, do any of the following:

  Choose from:

  - The PingDirectory server supports a feature called password retirement that allows you to set a new password while allowing the current password to remain usable for a specified period of time. This can be used to set a new password for the account while still allowing the current password to remain temporarily available so that existing PingDirectoryProxy server instances will still be able to use the current password to authenticate until you can update them with the new password. To enable password retirement, update the `password-retirement-behavior` property in the root password policy for all PingDirectory server instances to include a value of `retire-on-administrative-reset`, and set the `max-retired-password-age` property to indicate how long you want the current password to remain valid after setting a new password. Then, reset the Proxy User password for all of the PingDirectory server instances, and update all of the PingDirectoryProxy server instances to use the new password in their LDAP external server configuration.
  - If you do not know the clear-text value for the password but you have other PingDirectoryProxy server instances set up to use that password, then you can use the encoded password value from the LDAP external server configuration entry of one of the existing PingDirectoryProxy servers when creating the LDAP external server for new PingDirectoryProxy server instances.
  - Create a new root user in the directory server instances with the appropriate set of privileges and have the new PingDirectoryProxy server instance use that account to authenticate. To use the new account, update all of the other PingDirectoryProxy instances.

Providing information for support cases

If a problem arises that you are unable to fully diagnose and correct on your own, then contact your authorized support provider for assistance. To ensure that the problem can be addressed as quickly as possible, be sure to provide all of the information that the support personnel may need to fully understand the underlying cause by running the `collect-support-data` tool, and then sending the generated zip file to your authorized support provider. It is good practice to run this tool and send the ZIP file to your authorized support provider before any corrective action has taken place.

SCIM 1.1 and 2.0 servlet extensions management

The server provides two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure, fast, and simple way. SCIM is an alternative to LDAP, allowing identity data provisioning between cloud-based applications over HTTPS. One servlet implements SCIM 1.1 and the other servlet implements SCIM 2.

This section describes fundamental SCIM concepts and provides information on configuring SCIM on your server.

Copyright © 2025 Ping Identity Corporation

Overview of SCIM 1.1 fundamentals

Understanding the basic concepts of SCIM can help you use the SCIM extension to meet your deployment needs. SCIM allows you to:

- Provision identities. Through the API, you have access to the basic create, read, update, and delete functions, as well as other special functions.
- Provision groups. SCIM also allows you to manage groups.
- Interoperate using a common schema. SCIM provides a well-defined, platform-neutral user and group schema, as well as a simple mechanism to extend it.

The SCIM extension implements the 1.1 version of the SCIM specification. Familiarize yourself with this specification to help you understand and make efficient use of the SCIM extension and the SCIM SDK. The SCIM specifications are located on the Simplecloud website. NOTE: SCIM 1.1 will be deprecated in a future release.

Summary of SCIM 1.1 protocol support

the server supports all required features of the SCIM 1.1 protocol and most optional features. The following table describes SCIM features and whether they are supported.

SCIM Protocol Support

SCIM Feature	Supported
Etags	Yes
JSON	Yes
XML*	Yes
Authentication/Authorization	Yes, via HTTP basic authentication or OAuth 2.0 bearer tokens
Service Provider Configuration	Yes
Schema	Yes
User resources	Yes
Group resources	Yes
User-defined resources	Yes
Resource retrieval via GET	Yes
List/query resources	Yes
Query filtering*	Yes

Copyright © 2025 Ping Identity Corporation

SCIM Feature	Supported
Query result sorting*	Yes
Query result pagination*	Yes (Directory server, not Directory Proxy server)
Resource updates via PUT	Yes
Partial resource updates via PATCH*	Yes
Resource deletes via DELETE	Yes
Resource versioning*	Yes (requires configuration for updated servers)
Bulk*	Yes
HTTP method overloading	Yes
Raw LDAP Endpoints**	Yes

`*` Denotes an optional feature of the SCIM protocol.

`**` Denotes a server extension to the basic SCIM functionality.

The Identity Access API

The PingDirectory server, PingDirectoryProxy server, and PingDataSync server support an extension to the SCIM 1.1 standard called the Identity Access API. The Identity Access API provides an alternative to LDAP by supporting CRUD (create, read, update, and delete) operations to access PingDirectory server data over an HTTP connection.

SCIM 1.1 and the Identity Access API are provided as a unified service through the SCIM HTTP Servlet Extension. The SCIM HTTP Servlet Extension can be configured to only enable core SCIM resources (for example, 'Users' and 'Groups'), only LDAP object classes (for example, `top`, `domain`, `inetOrgPerson`, or `groupOfUniqueNames`), or both. Because SCIM and the Identity Access API have different schemas, if both are enabled, there can be two representations with different schemas for any resources defined in the `scim-resources.xml` file: the SCIM representation and the raw LDAP representation. Likewise, because resources are exposed by an LDAP object class, and because these are hierarchical (e.g., `top` -→ `person` -→ `organizationalPerson` -→ `inetOrgPerson`, etc.), a client application can access an entry in multiple ways due to the different paths/URIs to a given resource.

This chapter provides information on configuring the SCIM and the Identity Access API services on the server.

Creating your own SCIM 1.1 application

To create your own System for Cross-domain Identity Management (SCIM) 1.1 application, you must download the SCIM 1.1 SDK.

SCIM is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

Copyright © 2025 Ping Identity Corporation

The SCIM 1.1 SDK is available for download at https://github.com/pingidentity/scim.

> **Note**
>
> The value of a read-only SCIM attribute can be set by a POST operation if the SCIM attribute is a custom attribute in the `scim-resource.xml` config file, but not if the SCIM attribute is a core SCIM attribute.

Configuring SCIM 1.1

This section discusses details about the PingDirectory server implementation of the SCIM protocol. Before reading this chapter, familiarize yourself with the SCIM Protocol specification, available on the Simplecloud website.

Before you begin

To set up your system for Cross-domain Identity Management (SCIM) servlet extension, the server provides a `dsconfig` batch file at `<server-root>/config/scim-config-proxy.dsconfig`.

The script runs a series of commands that:

- Enable the HTTP Connection Handler and SCIM HTTP Servlet Extension.
- Increase the level of detail logged by the HTTP Detailed Access Log Publisher.
- Add access controls to allow access to LDAP controls used by the SCIM servlet.
- Add support to the request processor for LDAP controls used by the SCIM servlet.
- Set the subordinate base distinguished name (DN) property of the root DSE so that SCIM requests can be authenticated using LDAP `uid` values.

> **Note**
>
> Edit the `dsconfig` batch file before running the details of your deployment.

Configuring the SCIM servlet extension

Steps

1. To allow read access to operational attributes used by the SCIM Servlet Extension, add access controls on each of the backend servers before you enable the System for Cross-domain Identity Management (SCIM) servlet extension.

   Example:

   Instead of the `dsconfig` interactive equivalent, the following example uses the non-interactive command to add access control instructions (ACIs) .

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id ||
    createTimestamp || modifyTimestamp")
    (version 3.0;acl "Authenticated read access to operational attributes \
    used by the SCIM servlet extension"; allow (read,search,compare)
    userdn="ldap:///all";)'
```

2. To enable the SCIM servlet extension, run the `dsconfig` batch file on the server.

   Example:

   ```
   $ bin/dsconfig --batch-file config/scim-config-proxy.dsconfig
   ```

3. Edit the `dsconfig` batch file to use the correct request processor name and base distingushed names (DNs) for the `set-request-processor-prop` and `set-root-dse-backend-prop` commands.

   For more information, see Configuring LDAP control support on all request processors (Proxy only) and SCIM 1.1 servlet extension authentication.

Enabling resource versioning

About this task

Resource versioning is enabled by default in new installations. Upgraded servers that had System for Cross-domain Identity Management (SCIM) enabled need additional configuration to enable resource versioning.

Steps

1. Enable the `ds-entry-checksum` virtual attribute.

   Example:

   ```
   $ bin/dsconfig set-virtual-attribute-prop \
   --name ds-entry-checksum \
   --set enabled:true
   ```

2. Remove any existing access controls required by SCIM for read access to operational attributes.

   Example:

   ```
   $ bin/dsconfig set-access-control-handler-prop \
   --remove 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimestamp || ds-create-
   time || modifyTimestamp || ds-update-time")
   (version 3.0;acl "Authenticated read access to operational attributes used by the SCIM servlet extension";
   allow (read,search,compare) userdn="ldap:///all"'
   ```

3. On the backend directory server, enable new access controls required by SCIM for read access to operational attributes with the following command.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If this access control instruction (ACI) is not present, problems will occur when a SCIM client tries to authenticate with a non-root distinguished name (DN).

```
$ bin/dsconfig set-access-control-handler-prop \
--add  'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimestamp || ds-create-
time || modifyTimestamp || ds-update-time || ds-entry-checksum")
(version 3.0;acl "Authenticated read access to operational attributes used by the SCIM servlet extension";
allow (read,search,compare) userdn="ldap:///all"'
```

Configuring LDAP control support on all request processors (Proxy only)

You must configure support for the required LDAP controls on all request processors handling LDAP requests that result from System for Cross-domain Identity Management (SCIM) requests.

About this task

Change the request processor name that was provided as an example and repeat the command for all additional request processors.

Steps

- Use `dsconfig` to change the request processor name (provided as an example) and repeat the command for all additional request processors.

  Use your deployment's request processor name.

  Example:

  ```
  $ bin/dsconfig set-request-processor-prop \
    --processor-name dc_example_dc_com-req-processor \
    --add supported-control-oid:1.2.840.113556.1.4.319 \
    --add supported-control-oid:1.2.840.113556.1.4.473 \
    --add supported-control-oid:2.16.840.1.113730.3.4.9
  ```

SCIM 1.1 servlet extension authentication

The SCIM 1.1 servlet supports authentication using either the HTTP Basic authentication scheme, or OAuth 2.0 bearer tokens. When authenticating using HTTP Basic authentication, the SCIM 1.1 servlet attempts to correlate the user name component of the Authorization header to a DN in the PingDirectory server. If the user name value cannot be parsed directly as a DN, it is correlated to a DN using an Identity Mapper. The DN is then used in a simple bind request to verify the password.

In deployments that use an OAuth authorization server, the SCIM 1.1 extension can be configured to authenticate requests using OAuth bearer tokens. The SCIM 1.1 extension supports authentication with OAuth 2.0 bearer tokens (per RFC 6750) using an OAuth Token Handler Server SDK Extension. Because the OAuth 2.0 specification does not specify how contents of a bearer token are formatted, the Server provides the token handler API to decode incoming bearer tokens and extract or correlate associated authorization DNs.

Copyright © 2025 Ping Identity Corporation

Neither HTTP Basic authentication nor OAuth 2.0 bearer token authentication are secure unless SSL is used to encrypt the HTTP traffic.

Enabling HTTPS communications

To make the System for Cross-domain Identity Management (SCIM) HTTP connection handler use SSL (which is mandated by the SCIM specification), enable a Key Manager provider and Trust Manager provider.

Steps

- To enable SSL during the server's initial setup, include the `--ldapsPort` and the `--generateSelfSignedCertificate` subcommands with the `setup` command.
- If your server already has a certificate that you would like to use:

  Choose from:

  - Set the `key-manager-provider` to the value you set when you enabled SSL in the server..
  - Define a new key manager provider.

  For more information, see Configuring HTTP connection handlers.

Configuring basic authentication using an identity mapper

About this task

By default, the SCIM servlet is configured to use the Exact Match Identity Mapper, which matches against the `uid` attribute. In this example, an alternate Identity Mapper is created so that clients can authenticate using `cn` values.

Steps

1. Create a new Identity Mapper that uses a match attribute of cn.

   Example:

   ```
   $ bin/dsconfig create-identity-mapper \
     --mapper-name "CN Identity Mapper" \
     --type exact-match \
     --set enabled:true \
     --set match-attribute:cn
   ```

2. Configure the SCIM servlet to use the new Identity Mapper.

   Example:

   ```
   $ bin/dsconfig set-http-servlet-extension-prop \
     --extension-name SCIM \
     --set "identity-mapper:CN Identity Mapper"
   ```

Enabling OAuth authentication

About this task

Copyright © 2025 Ping Identity Corporation

To enable OAuth authentication, you need to create an implementation of the `OAuthTokenHandler` using the API provided in the Server SDK. For details on creating an `OAuthTokenHandler` extension, see the Server SDK documentation.

Steps

1. Install your OAuth token handler on the server using `dsconfig`.

   Example:

   ```
   $ bin/dsconfig create-oauth-token-handler \
     --handler-name ExampleOAuthTokenHandler \
     --type third-party \
     --set extension-class:com.unboundid.directory.sdk.examples.ExampleOAuthTokenHandler
   ```

2. Configure the SCIM servlet extension to use it as follows:

   Example:

   ```
   $ bin/dsconfig set-http-servlet-extension-prop \
     --extension-name SCIM \
     --set oauth-token-handler:ExampleOAuthTokenHandler
   ```

Using HTTP basic authentication with bare UID on the PingDirectoryProxy server

Clients can authenticate to the System for Cross-domain Identity Management (SCIM) extension using HTTP basic authentication and a bare UID value.

About this task

When a SCIM extension is hosted by a PingDirectoryProxy server, you must explicitly configure the server with the names of subordinate base distinguished names (DNs) to search.

> **Note**
>
> Make sure to specify your deployment's subordinate base DN.

Steps

- To configure the server with the names of subordinate base DNs, run the following command on the PingDirectoryProxy server for every base DN that you can access using SCIM.

  ```
  $ bin/dsconfig set-root-dse-backend-prop \
    --set subordinate-base-dn:dc=example,dc=com
  ```

Verifying the SCIM 1.1 servlet extension configuration

About this task

You can verify the configuration of the SCIM 1.1 extension by navigating to a SCIM resource URL via the command line or through a browser window.

Copyright © 2025 Ping Identity Corporation

To verify the SCIM servlet extension configuration:

Steps

- Run `curl` to verify that the SCIM extension is running. The `-k` (or `--insecure`) option is used to turn off curl's verification of the server certificate, since the example PingDirectory server is using a self-signed certificate.

  Example:

```
$ curl -u "cn=Directory Manager:password" \
-k "https://localhost:8443/scim/ServiceProviderConfigs"

{"schemas":["urn:scim:schemas:core:1.0"],"id":"urn:scim:schemas:core:1.0",
"patch":{"supported":true},"bulk":{"supported":true,"maxOperations":10000,
"maxPayloadSize":10485760},"filter":{"supported":true,"maxResults":100},
"changePassword":{"supported":true},"sort":{"supported":true},
"etag":{"supported":false},"authenticationSchemes":[{"name":"HttpBasic",
"description":"The HTTP Basic Access Authentication scheme. This scheme is
not considered to be a secure method of user authentication (unless used in
conjunction with some external secure system such as SSL), as the user
name and password are passed over the network as cleartext.","specUrl":
"http://www.ietf.org/rfc/rfc2617","documentationUrl":
"http://en.wikipedia.org/wiki/Basic_access_authentication"}]}
```

- If the user ID is a valid DN (such as `cn=Directory Manager`), the SCIM extension authenticates by binding to the PingDirectory server as that user. If the user ID is not a valid DN, the SCIM extension searches for an entry with that `uid` value, and binds to the server as that user. To verify authentication to the server as the user with the `uid` of `user.0`, run the following command:

  Example:

```
$ curl -u "user.0:password" \
  -k "https://localhost:8443/scim/ServiceProviderConfigs"
```

Configuring advanced SCIM 1.1 extension features

The following sections show how to configure advanced SCIM 1.1 servlet extension features, such as bulk operation implementation, mapping SCIM resource IDs, and transformations.

About the SCIM schema

SCIM provides a common user schema and extension model, making it easier to interoperate with multiple Service Providers. The core SCIM schema defines a concrete schema for user and group resources that encompasses common attributes found in many existing schemas.

Each attribute is defined as either a single attribute, allowing only one instance per resource, or a multi-valued attribute, in which case several instances can be present for each resource. Attributes can be defined as simple, name-value pairs or as complex structures that define sub-attributes.

While the SCIM schema follows an object extension model similar to object classes in LDAP, it does not have an inheritance model. Instead, all extensions are additive, similar to LDAP Auxiliary Object Classes.

Copyright © 2025 Ping Identity Corporation

Mapping the LDAP schema to the SCIM resource schema

The resources configuration file is an XML file that is used to define the SCIM resource schema and its mapping to LDAP schema. The default configuration of the `scim-resources.xml` file provides definitions for the standard SCIM Users and Groups resources, and mappings to the standard LDAP `inetOrgPerson` and `groupOfUniqueNames` object classes.

The default configuration may be customized by adding extension attributes to the Users and Groups resources, or by adding new extension resources. The resources file is composed of a single `<resources>` element, containing one or more `<resource>` elements.

For any given SCIM resource endpoint, only one `<LDAPAdd>` template can be defined, and only one `<LDAPSearch>` element can be referenced. If entries of the same object class can be located under different subtrees or base DNs of the PingDirectory server, then a distinct SCIM resource must be defined for each unique entry location in the Directory Information Tree. This can be implemented in many ways. For example:

- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, and each running under a unique HTTP connection handler.
- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, each running under a single, shared HTTP connection handler, but each with a unique context path.

Note that LDAP attributes are allowed to contain characters that are invalid in XML (because not all valid UTF-8 characters are valid XML characters). The easiest and most-correct way to handle this is to make sure that any attributes that may contain binary data are declared using "dataType=binary" in the `scim-resources.xml` file. Likewise, when using the Identity Access API make sure that the underlying LDAP schema uses the Binary or Octet String attribute syntax for attributes which may contain binary data. This will cause the server to automatically base64-encode the data before returning it to clients and will also make it predictable for clients because they can assume the data will always be base64-encoded.

However, it is still possible that attributes that are not declared as binary in the schema may contain binary data (or just data that is invalid in XML), and the server will always check for this before returning them to the client. If the client has set the content-type to XML, then the server may choose to base64-encode any values which are found to include invalid XML characters. When this is done, a special attribute is added to the XML element to alert the client that the value is base64-encoded. For example:

```
<scim:value base64Encoded="true">AAABPB0EBZc=</scim:value>
```

The remainder of this section describes the mapping elements available in the `scim-resources.xml` file.

resource element">

About the `resource` element

A `resource` element has the following XML attributes:

- `schema`: a required attribute specifying the SCIM schema URN for the resource. Standard SCIM resources already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom resources using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the resource used to access it through the SCIM REST API.

Copyright © 2025 Ping Identity Corporation

- `mapping`: a custom Java class that provides the logic for the resource mapper. This class must extend the `com.unboundid.scim.ldap.ResourceMapper` class.

A resource element contains the following XML elements in sequence:

- `description`: a required element describing the resource.
- `endpoint`: a required element specifying the endpoint to access the resource using the SCIM REST API.
- `LDAPSearchRef`: a mandatory element that points to an `LDAPSearch` element. The `LDAPSearch` element allows a SCIM query for the resource to be handled by an LDAP service and also specifies how the SCIM resource ID is mapped to the LDAP server.
- `LDAPAdd`: an optional element specifying information to allow a new SCIM resource to be added through an LDAP service. If the element is not provided then new resources cannot be created through the SCIM service.
- `attribute`: one or more elements specifying the SCIM attributes for the resource.

attribute element">

About the `attribute` element

An `attribute` element has the following XML attributes:

- `schema`: a required attribute specifying the schema URN for the SCIM attribute. If omitted, the schema URN is assumed to be the same as that of the enclosing resource, so this only needs to be provided for SCIM extension attributes. Standard SCIM attributes already have URNs assigned for them, such as urn:scim:schemas:core:1.0. A new URN must be obtained for custom SCIM attributes using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the SCIM attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is false.
- `required`: an optional attribute indicating whether the SCIM attribute is required to be present in the resource. The default value is false.

An attribute element contains the following XML elements in sequence:

- `description`: a required element describing the attribute. Then just one of the following elements:
- `simple`: specifies a simple, singular SCIM attribute.
- `complex`: specifies a complex, singular SCIM attribute.
- `simpleMultiValued`: specifies a simple, multi-valued SCIM attribute.
- `complexMultiValued`: specifies a complex, multi-valued SCIM attribute.

simple element">

Copyright © 2025 Ping Identity Corporation

About the `simple` element

A `simple` element has the following XML attributes:

- `dataType`: a required attribute specifying the simple data type for the SCIM attribute. The following values are permitted: binary, boolean, dateTime, decimal, integer, string.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is false.

A simple element contains the following XML element:

- `mapping`: an optional element specifying a mapping between the SCIM attribute and an LDAP attribute. If this element is omitted, then the SCIM attribute has no mapping and the SCIM service ignores any values provided for the SCIM attribute.

complex element">

About the `complex` element

The `complex` element does not have any XML attributes. It contains the following XML element:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute, and an optional mapping to LDAP. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

simpleMultivalued element">

About the `simpleMultivalued` element

A `simpleMultiValued` element has the following XML attributes:

- `childName`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard emails SCIM attribute is email.
- `dataType`: a required attribute specifying the simple data type for the plural SCIM attribute (i.e. the data type for the value sub-attribute). The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is false.

A `simpleMultiValued` element contains the following XML elements in sequence:

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.
- `mapping`: an optional element specifying a default mapping between the SCIM attribute and an LDAP attribute.

complexMultiValued element">

Copyright © 2025 Ping Identity Corporation

About the `complexMultiValued` element

A `complexMultiValued` element has the following XML attribute:

- `tag`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard addresses SCIM attribute is address.

A `complexMultiValued` element contains the following XML elements in sequence:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute. The standard type, primary, and display sub-attributes do not need to be specified.
- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.

subAttribute element">

About the `subAttribute` element

A `subAttribute` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is false.
- `required`: an optional attribute indicating whether the SCIM sub-attribute is required to be present in the SCIM attribute. The default value is false.
- `dataType`: a required attribute specifying the simple data type for the SCIM sub-attribute. The following values are permitted: binary, boolean, dateTime, integer, string.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is false.

A `subAttribute` element contains the following XML elements in sequence:

- `description`: a required element describing the sub-attribute.
- `mapping`: an optional element specifying a mapping between the SCIM sub-attribute and an LDAP attribute. This element is not applicable within the `complexMultiValued` element.

canonicalValue element">

About the `canonicalValue` element

A `canonicalValue` element has the following XML attribute:

- `name`: specifies the value of the type sub-attribute. For example, work is the value for emails, phone numbers and addresses intended for business purposes.

Copyright © 2025 Ping Identity Corporation

A `canonicalValue` element contains the following XML element:

- `subMapping`: an optional element specifying mappings for one or more of the sub-attributes. Any sub-attributes that have no mappings will be ignored by the mapping service.

mapping element">

About the `mapping` element

A `mapping` element has the following XML attributes:

- `ldapAttribute`: A required element specifying the name of the LDAP attribute to which the SCIM attribute or sub-attribute map.
- `transform`: An optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described in Mapping LDAP entries to SCIM using the SCIM-LDAP API.

subMapping element">

About the `subMapping` element

A `subMapping` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute that is mapped.
- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM sub-attribute maps.
- `transform`: an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described later. The available transformations are described in Mapping LDAP Entries to SCIM Using the SCIM-LDAP API.

LDAPSearch element">

About the `LDAPSearch` element

An `LDAPSearch` element contains the following XML elements in sequence:

- `baseDN`: a required element specifying one or more LDAP search base DNs to be used when querying for the SCIM resource.
- `filter`: a required element specifying an LDAP filter that matches entries representing the SCIM resource. This filter is typically an equality filter on the LDAP object class.
- `resourceIDMapping`: an optional element specifying a mapping from the SCIM resource ID to an LDAP attribute. When the element is omitted, the resource ID maps to the LDAP entry DN. Note The `LDAPSearch` element can be added as a top-level element outside of any <Resource> elements, and then referenced within them via an ID attribute.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The `LDAPSearch` element can be added as a top-level element outside of any <Resource> elements, and then referenced within them via an ID attribute.

resourceIDMapping element">

About the `resourceIDMapping` element

The `resourceIDMapping` element has the following XML attributes:

- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM resource ID maps.
- `createdBy`: a required element specifying the source of the resource ID value when a new resource is created by the SCIM consumer using a POST operation. Allowable values for this element include `scim-consumer`, meaning that a value must be present in the initial resource content provided by the SCIM consumer, or the PingDirectory server, meaning that a value is automatically provided by the server (as would be the case if the mapped LDAP attribute is entryUUID).

The following example illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

```
<LDAPSearch id="userSearchParams">
  <baseDN>ou=people,dc=example,dc=com</baseDN>
  <filter>(objectClass=inetOrgPerson)</filter>
  <resourceIDMapping ldapAttribute="entryUUID" createdBy="directory"/>
</LDAPSearch>
```

LDAPAdd element">

About the `LDAPAdd` element

An `LDAPAdd` element contains the following XML elements in sequence:

- `DNTemplate`: a required element specifying a template that is used to construct the DN of an entry representing a SCIM resource when it is created. The template can reference values of the entry after it has been mapped using `{ldapAttr}`, where `ldapAttr` is the name of an LDAP attribute.
- `fixedAttribute`: zero or more elements specifying fixed LDAP values to be inserted into the entry after it has been mapped from the SCIM resource.

fixedAttribute element">

About the `fixedAttribute` element

A `fixedAttribute` element has the following XML attributes:

- `ldapAttribute`: a required attribute specifying the name of the LDAP attribute for the fixed values.

Copyright © 2025 Ping Identity Corporation

- `onConflict`: an optional attribute specifying the behavior when the LDAP entry already contains the specified LDAP attribute. The value merge indicates that the fixed values should be merged with the existing values. The value overwrite indicates that the existing values are to be overwritten by the fixed values. The value preserve indicates that no changes should be made. The default value is merge.

A `fixedAttribute` element contains one or more `fixedValue` XML element, which specify the fixed LDAP values.

Validating the updated SCIM schema

The Server SCIM extension is bundled with an XML Schema document, `resources.xsd`, which describes the structure of a `scim-resources.xml` resource configuration file. After updating the resource configuration file, you should confirm that its contents are well-formed and valid using a tool such as `xmllint`.

For example, you could validate your updated file as follows:

```
$ xmllint --noout --schema resources.xsd scim-resources.xml
scim-resources.xml validates
```

Mapping SCIM resource IDs

The default `scim-resources.xml` configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. The `entryUUID` attribute, whose read-only value is assigned by the server, meets the requirements of the SCIM specification regarding resource ID immutability. However, configuring a mapping to the attribute can result in inefficient group processing, since LDAP groups use the entry DN as the basis of group membership. The resource configuration allows the SCIM resource ID to be mapped to the LDAP entry DN. However, the entry DN does not meet the requirements of the SCIM specification regarding resource ID immutability. LDAP permits entries to be renamed or moved, thus modifying the DN. Likewise, you can use the Identity Access API to change the value of an entry's RDN attribute, thereby triggering a MODDN operation.

A resource can also be configured such that its SCIM resource ID is provided by an arbitrary attribute in the request body during POST operations. This SCIM attribute must be mapped to an LDAP attribute so that the SCIM resource ID can be stored in the server. By default, it is the responsibility of the SCIM client to guarantee ID uniqueness. However, the UID Unique Attribute Plugin can be used by the server to enforce attribute value uniqueness. For information about the UID Unique Attribute Plugin, see "Working with the UID Unique Attribute plugin" in the PingDirectory Server Administration Guide.

> **Note**
>
> Resource IDs cannot be mapped to virtual attributes. For more information about configuring SCIM Resource IDs, see "About the `<resourceIDMapping>` Element".

Using pre-defined transformations

Transformations are required to change SCIM data types to LDAP syntax values. The following pre-defined transformations may be referenced by the transform XML attribute:

- `com.unboundid.scim.ldap.BooleanTransformation`. Transforms SCIM boolean data type values to LDAP Boolean syntax values and vice-versa.

Copyright © 2025 Ping Identity Corporation

- `com.unboundid.scim.ldap.GeneralizedTimeTransformation`. Transforms SCIM dateTime data type values to LDAP Generalized Time syntax values and vice-versa.
- `com.unboundid.scim.ldap.PostalAddressTransformation`. Transforms SCIM formatted address values to LDAP Postal Address syntax values and vice-versa. SCIM formatted physical mailing addresses are represented as strings with embedded new lines, whereas LDAP uses the $ character to separate address lines. This transformation interprets new lines in SCIM values as address line separators.
- `com.unboundid.scim.ldap.TelephoneNumberTransformation`. Transforms LDAP Telephone Number syntax (E.123) to RFC3966 format and vice-versa.

You can also write your own transformations using the SCIM API described in the following section.

Mapping LDAP entries to SCIM using the SCIM-LDAP API

In addition to the SCIM SDK, the Server provides a library called SCIM-LDAP, which provides facilities for writing custom transformations and more advanced mapping.

You can add the SCIM-LDAP library to your project using the following dependency:

```
<dependency>
    <groupId>com.unboundid.product.scim</groupId>
    <artifactId>scim-ldap</artifactId>
    <version>1.5.0</version>
</dependency>
```

Create your custom transformation by extending the `com.unboundid.scim.ldap.Transformation` class. Place your custom transformation class in a jar file in the server's `lib` directory. NOTE: The Identity Access API automatically maps LDAP attribute syntaxes to the appropriate SCIM attribute types. For example, an LDAP DirectoryString is automatically mapped to a SCIM string.

SCIM authentication

SCIM requests to the LDAP endpoints will support HTTP Basic Authentication and OAuth2 Authentication using a bearer token. There is existing support for this feature in the PingDirectory server and the PingDirectoryProxy server using the OAuthTokenHandler API (meaning through a Server SDK extension, which requires some technical work to implement).

Note that our implementation only supports the HTTP Authorization header for this purpose; we do not support the form-encoded body parameter or URI query parameter mechanisms for specifying the credentials or bearer token.

SCIM logging

The PingDirectory server already provides a detailed HTTP log publisher to capture the SCIM and HTTP request details. To be able to correlate this data to the internal LDAP operations that are invoked behind the scenes, the Access Log Publisher will use "`origin=scim`" in access log messages that are generated by the SCIM servlet.

For example, you will see a message for operations invoked by replication:

Copyright © 2025 Ping Identity Corporation

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="replication" dn="uid=user.3,ou=people,dc=example,dc=com"
```

Likewise for SCIM messages, you will see a message like this:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="scim" dn="uid=user.3,ou=people,dc=example,dc=com"
```

SCIM monitoring

There are two facilities that can be used to monitor the SCIM activity in the server.

- HTTPConnectionHandlerStatisticsMonitorProvider — Provides statistics straight about total and average active connections, requests per connection, connection duration, processing time, invocation count, etc.
- SCIMServletMonitorProvider — Provides high level statistics about request methods (POST, PUT, GET, etc.), content types (JSON, XML), and response codes, for example, "`user-patch-404:26`".

The LDAP object class endpoints are treated as their own resource types, so that for requests using the Identity Access API, there will be statistics, such as `person-get-200` and `inetorgperson-post-401`.

Configuring the Identity Access API

Once you have run the `<server-root>/config/scim-config-ds.dsconfig` script, the resources defined in the `scim-resources.xml` will be available as well as the Identity Access API. However, to allow SCIM access to the raw LDAP data, you must set a combination of configuration properties on the SCIM Servlet Extension using the `dsconfig` tool.

- include-ldap-objectclass. Specifies a multi-valued property that lists the object classes for entries that will be exposed. The object class used here will be the one that clients need to use when referencing Identity Access API resources. This property allows the special value "*" to allow all object classes. If "*" is used, then the SCIM servlet uses the same case used in the server LDAP Schema.
- exclude-ldap-objectclass. Specifies a multi-valued property that lists the object classes for entries that will not be exposed. When this property is specified, all object classes will be exposed except those in this list.
- include-ldap-base-dn. Specifies a multi-valued property that lists the base DNs that will be exposed. If specified, only entries under these base DNs will be accessible. No parent-child relationships in the DNs are allowed here.
- exclude-ldap-base-dn. Specifies a multi-valued property that lists the base DNs that will not be exposed. If specified, entries under these base DNs will not be accessible. No parent-child relationships in the DNs are allowed here.

Using a combination of these properties, SCIM endpoints will be available for all included object classes, just as if they were SCIM Resources defined in the `scim-resources.xml` file.

Configuring the Identity Access API

Steps

1. Ensure that you have run the `scim-config-ds.dsconfig` script to configure the SCIM interface. Be sure to enable the entryDN virtual attribute.

Copyright © 2025 Ping Identity Corporation

2. Set a combination of properties to allow the SCIM clients access to the raw LDAP data: `include-ldap-objectclass`, `exclude-ldap-objectclass`, `include-ldap-base-dn`, or `exclude-ldap-base-dn`.

   Example:

   ```
   $ bin/dsconfig set-http-servlet-extension-prop \
     --extension-name SCIM --set 'include-ldap-objectclass:*' \
     --set include-ldap-base-dn:ou=People,dc=example,dc=com
   ```

   Result:

   The SCIM clients now have access to the raw LDAP data via LDAP object class-based resources as well as core SCIM resources as defined in the `scim.resource.xml` file.

Disabling core SCIM resources

Steps

1. Open the `config/scim-resources.xml` file, and comment out or remove the `<resource>` elements that you would like to disable.
2. Disable and re-enable the HTTP Connection Handler, or restart the server to make the changes take effect. In general, changing the `scim-resources.xml` file requires a HTTP Connection Handler restart or server restart.

> **Note**
>
> When making other changes to the SCIM configuration by modifying the SCIM HTTP Servlet Extension using **`dsconfig`**, the changes take effect immediately without any restart required.

Verifying the Identity Access API configuration

Steps

- Perform a curl request to verify the Identity Access API configuration.

  Result:

  ```
  $ curl -k -u "cn=directory manager:password" \
    -H "Accept: application/json" \
    "https://example.com/top/56c9fd6b-f870-35ef-9959-691c783b7318?
       attributes=entryDN,uid,givenName,sn,entryUUID"
       {"schemas":["urn:scim:schemas:core:1.0","urn:unboundid:schemas:scim:ldap:1.0"],
        "id":"56c9fd6b-f870-35ef-9959-691c783b7318",
        "meta":{"lastModified":"2013-01-11T23:38:26.489Z",
        "location":"https://example.com:443/v1/top/56c9fd6b-f870-35ef-9959-691c783b7318"},
        "urn:unboundid:schemas:scim:ldap:1.0":{"givenName":["Rufus"],"uid":["user.1"],
        "sn":["Firefly"],"entryUUID":["56c9fd6b-f870-35ef-9959-691c783b7318"],
        "entrydn":"uid=user.1,ou=people,dc=example,dc=com"}}
  ```

Copyright © 2025 Ping Identity Corporation

Monitoring the SCIM servlet extension

The SCIM SDK provides a command-line tool, `scim-query-rate`, that measures the SCIM query performance for your extension. The SCIM extension also exposes monitoring information for each SCIM resource, such as the number of successful operations per request, the number of failed operations per request, the number of operations with XML or JSON to and from the client. Finally, the server automatically logs SCIM-initiated LDAP operations to the default File-based Access Logger. These operations will have an `origin='scim'` attribute to distinguish them from operations initiated by LDAP clients. You can also create custom logger or request criteria objects that can track incoming HTTP requests, which the SCIM extension rewrites as internal LDAP operations.

Testing SCIM query performance

You can use the `scim-query-rate` tool, provided in the SCIM SDK, to test query performance, by performing repeated resource queries against the SCIM server.

The `scim-query-rate` tool performs searches using a query filter or can request resources by ID. For example, you can test performance by using a filter to query randomly across a set of one million users with eight concurrent threads. The user resources returned to the client in this example is in XML format and includes the `userName` and `name` attributes.

```
scim-query-rate --hostname server.example.com --port 80 \
--authID admin --authPassword password --xml \
--filter 'userName eq "user.[1-1000000]"' --attribute userName \
--attribute name --numThreads 8
```

You can request resources by specifying a resource ID pattern using the `--resourceID` argument as follows:

```
scim-query-rate --hostname server.example.com --port 443 \
--authID admin --authPassword password --useSSL --trustAll\
--resourceName User \
--resourceID 'uid=user.[1-150000],ou=people,dc=example,dc=com'
```

The `scim-query-rate` tool reports the error `"java.net.SocketException: Too many open files"` if the open file limit is too low. You can increase the open file limit to increase the number of file descriptors.

About the HTTP log publishers

HTTP operations may be logged using either a Common Log File HTTP Operation Log Publisher or a Detailed HTTP Operation Log Publisher. The Common Log File HTTP Operation Log Publisher is a built-in log publisher that records HTTP operation information to a file using the W3C common log format. Because the W3C common log format is used, logs produced by this log publisher can be parsed by many existing web analysis tools.

Log messages are formatted as follows:

- IP address of the client.
- RFC 1413 identification protocol. The Ident Protocol is used to format information about the client.
- The user ID provided by the client in an Authorization header, which is typically available server-side in the REMOTE_USER environment variable. A dash appears in this field if this information is not available.
- A timestamp, formatted as "'['dd/MM/yyyy:HH:mm:ss Z']'"

Copyright © 2025 Ping Identity Corporation

- Request information, with the HTTP method followed by the request path and HTTP protocol version.
- The HTTP status code value.
- The content size of the response body in bytes. This number does not include the size of the response headers.

The HTTP Detailed Access Log Publisher provides more information than the common log format in a format that is familiar to administrators who use the File-Based Access Log Publisher.

The HTTP Detailed Access Log Publisher generates log messages such as the following. The lines have been wrapped for readability.

```
[15/Feb/2012:21:17:04 -0600] RESULT requestID=10834128
from="10.2.1.114:57555" method="PUT"
url="https://10.2.1.129:443/Aleph/Users/6272c691-
38c6-012f-d227-0dfae261c79e" authorizationType="Basic"
requestContentType="application/json" statusCode=200
etime=3.544 responseContentLength=1063
redirectURI="https://server1.example.com:443/Aleph/Users/6272c691-38c6-012f-d227-0dfae261c79e"
responseContentType="application/json"
```

In this example, only default log publisher properties are used. Though this message is for a RESULT, it contains information about the request, such as the client address, the request method, the request URL, the authentication method used, and the Content-Type requested. For the response, it includes the response length, the redirect URI, the Content-Type, and the HTTP status code.

You can modify the information logged, including adding request parameters, cookies, and specific request and response headers. For more information, refer to the `dsconfig` command-line tool help.

Monitoring resources using the SCIM extension

The monitor provider exposes the following information for each resource:

- Number of successful operations per request type (such as GET, PUT, and POST).
- Number of failed operations and their error codes per request type.
- Number of operations with XML or JSON from client.
- Number of operations that sent XML or JSON to client.

In addition to the information about the user-defined resources, monitoring information is also generated for the schema, service provider configuration, and monitor resources. The attributes of the monitor entry are formatted as follows:

```
{resource name}-resource-{request type}-{successful or error status code}
```

You can search for one of these monitor providers using an `ldapsearch` such as the following:

```
$ bin/ldapsearch --port 1389 bindDN uid=admin,dc=example,dc=com \
  --bindPassword password --baseDN cn=monitor \
  --searchScope sub "(objectclass=scim-servlet-monitor-entry)"
```

Copyright © 2025 Ping Identity Corporation

For example, the following monitor output was produced by a test environment with three distinct SCIM servlet instances, Aleph, Beth, and Gimel. Note that the first instance has a custom resource type called host.

Managing the SCIM 2.0 servlet extension

The PingDirectoryProxy server provides a servlet extension that implements version 2 of the System for Cross-domain Identity Management (SCIM) specification.

The SCIM 2.0 extension doesn't replace the existing SCIM 1.1 extension, and there are significant differences in how they're configured.

> **Note**
>
> Configure your SCIM configurations, such as attribute mappings, on the PingDirectoryProxy server instead of on the backend PingDirectory servers.

Copyright © 2025 Ping Identity Corporation

Supported SCIM 2.0 endpoints

The PingDirectoryProxy server supports the following System for Cross-domain Identity Management (SCIM) 2.0 endpoints.

Endpoint	Description	Supported HTTP methods
`/ServiceProviderConfig`	Provides metadata that indicates the server's authentication scheme (OAuth 2.0) and its support for features that are optional in the SCIM standard. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
`/Schemas`	Lists the SCIM schemas that are configured for use on the server, and defines the various attributes available to resource types. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
`/Schemas/<schema>`	Retrieves a specific SCIM schema, as specified by the schema ID. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
`/ResourceTypes`	Lists all of the SCIM resource types that are configured for use on the server. Clients can use this information to determine the endpoint, core schema, and extension schemas of any resource types that the server supports. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
`/ResourceTypes/<resourceType>`	Retrieves a specific SCIM resource type, as specified by its ID. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
`/<resourceType>`	Creates a new resource (POST), or lists and filters resources (GET).	• GET • POST
`/<resourceType>/.search`	Lists and filters resources. This is used as an alternative to passing query parameters in the URL.	POST

Copyright © 2025 Ping Identity Corporation

Endpoint	Description	Supported HTTP methods
`/<resourceType>/<resourceId>`	Retrieves a single resource (GET), modifies a single resource (PUT, PATCH), or deletes a single resource (DELETE).	• GET • PUT • PATCH • DELETE

Configuring SCIM 2.0 on your server

Configure your SCIM configurations on the server.

This section includes the following topics:

- Creating your own SCIM 2.0 application
- Authentication requirements for SCIM 2.0 requests
- Defining permissions for SCIM 2.0 requests
- SCIM 2.0 Components
- Correlated LDAP data views
- Configuring an LDAP mapped SCIM resource type
- Configuring Permissions for SCIM 2.0 Operations
- SCIM 2.0 searches
- SCIM 2.0 PATCH operations
- Troubleshooting the SCIM 2.0 servlet Extension
- Disabling the SCIM 2.0 servlet extension

> **Note**
>
> There is a known issue with dot notation support for SCIM 2.0 sub-attributes.

Creating your own SCIM 2.0 application

To create your own System for Cross-domain Identity Management (SCIM) 2.0 application, you must download the SCIM 2 SDK.

SCIM is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 2 SDK is available for download at GitHub.

Copyright © 2025 Ping Identity Corporation

Authentication requirements for SCIM 2.0 requests

All System for Cross-domain Identity Management (SCIM) requests on a PingDirectoryProxy server must use OAuth 2.0 bearer token authentication.

Bearer tokens are evaluated using the SCIM 2 servlet extension's configured access token validators. Basic authentication is not supported.

In addition to requiring bearer tokens, the server does not process any SCIM requests unless it has at least one `encryption-settings` definition in its `encryption-settings` database. You can create the necessary definitions with the `encryption-settings` command-line tool.

For more information, see Encrypting sensitive data.

> **Note**
>
> You must define encryption settings and ensure they match on the proxy and all backend PingDirectory servers.

Defining permissions for SCIM 2.0 requests

Executing a System for Cross-domain Identity Management (SCIM) request on a server depends primarily on both the configured access control instructions (ACIs) in the server and the scopes used to authenticate the request present in the provided `OAuth` bearer token.

> **Note**
>
> You must define ACIs on the backend PingDirectory servers. Do not define ACIs on the PingDirectoryProxy server.

Internally, all SCIM 2.0 requests are processed using the `cn=SCIM2 Servlet,cn=Root DNs,cn=config` service account. Allowing a requested operation depends on the ACIs that apply to the operation. The `oauthscope` bind rule is useful because it allows the administrator to use the supplied `OAuth` scopes in ACI logic.

Because of implementation details, access to the `objectclass` operational LDAP attribute is necessary for SCIM requests to properly execute. Do not give the service account access to `objectclass` on a global level. Instead, add the ACI granting `objectclass` access to the LDAP subtree to expose to clients.

For more information, see Configuring permissions for SCIM 2.0 operations.

> **Note**
>
> ACIs that don't use the `oauthscope` bind rule can still apply to requested operations.
> An ACI that grants unconditional read access to any authenticated LDAP user also grants unconditional read access to SCIM requests regardless of the provided OAuth scopes. This is because the requests are processed through the service account.

SCIM 2.0 Components

Unlike the System for Cross-domain Identity Management (SCIM) 1.1 servlet extension, the SCIM 2.0 system is configured through the administrative console or with the `dsconfig` command-line tool.

The SCIM 2.0 system consists of the following components:

Copyright © 2025 Ping Identity Corporation

SCIM resource type

A SCIM resource type defines a class of resources, such as users or devices. Every SCIM resource type features at least one SCIM schema, which defines the attributes available to each resource. If you enable a SCIM resource type, it must have a designated LDAP structural objectclass and an associated base distinguished name (DN).The two types of SCIM resource types, mapping and pass-through, differ based on the definitions of the SCIM schema the resource types use:

LDAP mapping SCIM

Requires an explicitly defined SCIM schema with explicitly defined mappings of SCIM attributes to LDAP attributes. Use a mapping SCIM resource type to exercise detailed control over the SCIM schema and its attributes and mappings.

LDAP pass-through SCIM

Does not use an explicitly defined SCIM schema. Instead, an implicit schema is generated dynamically based on the underlying LDAP schema. Use a pass-through SCIM resource type when you need to get started quickly

SCIM schemas

Defines a collection of SCIM attributes, grouped under an identifier called a schema URN. Each SCIM resource type possesses a single core schema and can feature schema extensions, which act as secondary attribute groupings that the schema URN namespaces. SCIM Schemas are defined independently of SCIM resource types, and multiple SCIM resource types can use a single SCIM schema as a core schema or schema extension.

SCIM attributes

Defines an attribute that is available under a SCIM schema. The configuration for a SCIM attribute defines its data type, regardless of whether it's required, single-valued, or multi-valued. When a SCIM attribute consists of SCIM sub-attributes, it's defined as a complex attribute.

SCIM sub-attributes

When a SCIM attribute consists of SCIM sub-attributes, it's defined as a complex attribute.

SCIM attribute mappings (mapping resource types only)

Defines the manner in which a SCIM resource type maps the attributes in its SCIM schemas to native LDAP attributes of the PingDirectoryProxy server.

Correlated LDAP Data Views

Allows a single SCIM resource that consists of attributes that are retrieved from multiple LDAP entries. For more information, see Correlated LDAP data views.

Correlated LDAP data views

Correlated LDAP data views can be attached to a SCIM resource type to allow that resource type to use attributes from other LDAP entries. A SCIM resource type can have multiple data views configured.

Copyright © 2025 Ping Identity Corporation

Correlated LDAP data views share many configuration settings with SCIM resource types. The following exceptions are below:

- `primary-correlation-attribute`: The LDAP attribute from the SCIM Resource Type whose value will be used to match entries in the data view. This property must be defined.
- `secondary-correlation-attribute`: The LDAP attribute from the data view whose value will be matched with the primary-correlation-attribute. This property must be defined.
- `ldap-correlation-attribute-pair`: Optional correlation attribute pairs. If these are configured, entries between the SCIM resource type and the correlated LDAP data view must also have matching values for the specified attributes for them to be returned together.

> **Note**
>
> A correlated LDAP Data View cannot provide attributes from more than one LDAP entry at a time. If there are multiple LDAP entries with secondary-correlation-attribute values that match the primary-correlation-attribute from the SCIM resource type's entry, an error will be thrown.

Correlated LDAP data views share many configuration settings with SCIM resource types. The following exceptions are below:

If the correlated LDAP data view is attached to a pass-through SCIM resource type, its attributes will appear as schema extensions, similar to the following:

```
{
      ...
        "uid": [
        "user.8"
        ],
        "entryDN": "uid=user.8,ou=people,dc=example,dc=com",
        "urn:pingidentity:schemas:correlated:Document": {
            "documentIdentifier": [
            "user.8"
            ],
            "description": [
            "This is the description for the document user.8 under ou=Documents,dc=example,dc=com."
            ],
            ...
        },
        ...
        "schemas": [
        "urn:pingidentity:schemas:correlated:Document",
        "urn:pingidentity:schemas:passthrough:PassthroughUsers"
        ]
}
```

If the correlated LDAP data view is attached to a Mapping SCIM resource type, its attributes must be mapped to a schema used by the SCIM resource type. This is done through the `correlated-ldap-data-view` property in a SCIM attribute mapping.

Configuring an LDAP mapped SCIM resource type

Add a simple mapping System for Cross-domain Identity Management (SCIM) 2.0 resource type backed by the `inetOrgPerson` LDAP objectclass to a PingDirectoryProxy deployment.

Copyright © 2025 Ping Identity Corporation

About this task

To configure an LDAP mapped SCIM resource type:

Steps

1. Set up the PingDirectory backend server.
2. Export the `encryption-settings` definition with the tool's `export` subcommand.

   Example:

   For this example, use the default settings to use sample data and configured data encryption.

   ```
   encryption-settings export --output-file exported-key
   ```

3. Set up the PingDirectoryProxy server and import the `encryption-settings` definition file that was created in the previous step.
4. To configure the LDAP external server, use the `create-initial-proxy-config` tool.
5. Create the SCIM schema for the resource type to use.

   Example:

   ```
   dsconfig create-scim-schema \
   --schema-name urn:pingidentity:schemas:User:1.0 \
   --set display-name:User
   ```

6. Under this schema, add the following SCIM attributes.

   ```
   dsconfig create-scim-attribute \
   --schema-name urn:pingidentity:schemas:User:1.0 \
   --attribute-name displayName
   dsconfig create-scim-attribute \
   --schema-name urn:pingidentity:schemas:User:1.0 \
   --attribute-name name \
   --set type:complex
   dsconfig create-scim-subattribute \
   --schema-name urn:pingidentity:schemas:User:1.0 \
   --attribute-name name \
   --subattribute-name familyName
   dsconfig create-scim-subattribute \
   --schema-name urn:pingidentity:schemas:User:1.0 \
   --attribute-name name \
   --subattribute-name formatted
   dsconfig create-scim-attribute \
   --schema-name urn:pingidentity:schemas:User:1.0 \
   --attribute-name userName
   ```

7. Create the LDAP mapping SCIM resource type on the PingDirectoryProxy server.

   Example:

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-scim-resource-type \
--type-name Users \
--type ldap-mapping \
--set enabled:true \
--set endpoint:Users \
--set structural-ldap-objectclass:inetOrgPerson \
--set include-base-dn:ou=People,dc=example,dc=com \
--set lookthrough-limit:500 \
--set core-schema:urn:pingidentity:schemas:User:1.0
```

8. To create the SCIM attribute mappings, run the following commands.

```
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name displayName \
--set scim-resource-type-attribute:displayName \
--set ldap-attribute:displayName
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.formatted \
--set scim-resource-type-attribute:name.formatted \
--set ldap-attribute:cn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.familyName \
--set scim-resource-type-attribute:name.familyName \
--set ldap-attribute:sn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name userName \
--set scim-resource-type-attribute:userName \
--set ldap-attribute:uid \
--set searchable:true
```

9. Configure the SCIM2 HTTP Servlet Extension to use a Mock Access Token Validator.

> **Note**
>
> Never use Mock Access Token Validators in production environments or with sensitive data.

```
dsconfig create-access-token-validator \
--validator-name "SCIM2 Mock Validator" \
--type mock \
--set enabled:true
dsconfig set-http-servlet-extension-prop \
--extension-name SCIM2 \
--set "access-token-validator:SCIM2 Mock Validator"
```

Copyright © 2025 Ping Identity Corporation

10. To confirm that the new resource type is successfully added, send the following request to the PingDirectoryProxy server's SCIM `/ResourceTypes` endpoint.

> **Note**
>
> The HTTP port can vary depending on the deployment configuration.

```
curl -k -X GET \
https://localhost:8443/scim/v2/ResourceTypes \
-H 'Authorization: Bearer {"active":true}'
```

Result:

The following JSON object is displayed in the response in the `"Resources"` array.

```
{
...
"Resources": [{
"schemas":["urn:ietf:params:scim:schemas:core:2.0:ResourceType"],
"id":"Users",
"name":"Users",
"endpoint":"Users",
"schema":"urn:pingidentity:schemas:Users:1.0",
"meta":{
"resourceType":"ResourceType",
"location":"https://localhost:8443/scim/v2/ResourceTypes/Users"
}
}]
...
}
```

Configuring Permissions for SCIM 2.0 Operations

Configure permissions so that POST requests with the `userAdd` scope succeed on a PingDirectoryProxy deployment.

Before you begin

Set up an LDAP mapping System for Cross-domain Identity Management (SCIM) 2.0 resource type for the `inetOrgPerson` objectclass.

For more information, see Configuring an LDAP Mapping SCIM 2.0 resource type.

About this task

To configure permissions:

Steps

1. Set the SCIM resource type property:

Copyright © 2025 Ping Identity Corporation

Choose from:

- If the SCIM resource type being targeted already has a value for the `create-dn-pattern` property, skip to step 2.
- To set the SCIM resource type property, run the following `dsconfig` command on the PingDirectoryProxy server.

```
dsconfig set-scim-resource-type-prop \
--type-name Users \
--set create-dn-pattern:entryUUID=generated,ou=People,dc=example,dc=com
```

2. Send the following request to the PingDirectoryProxy server's SCIM `/Users` endpoint.

```
curl -k -X POST \
https://localhost:8443/scim/v2/Users/ \
-H 'Authorization: Bearer {"active":true}' \
-H 'Content-type: application/json' \
--data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'
```

> **Note**
>
> The HTTP port can vary depending on the deployment configuration.

Example:

The response from the server should have a status of `403` and should contain a correlation ID similar to the following.

```
{
"schemas":["urn:ietf:params:scim:api:messages:2.0:Error"],
"status":"403",
"detail":"Request failed:
correlationID='faa707b3-5d48-42e6-9e78-2c8dbb1e2cac'"
}
```

This is the expected response since this SCIM request does not have the permission needed to write to an entry. For more information on viewing the full server error message, see Troubleshooting the SCIM 2.0 servlet Extension.

3. Add an access control instruction (ACI) to the backend server's `ou=People,dc=example,dc=com` subtree.
    1. Run the following `ldapmodify` command for creating the ACI on the backend PingDirectory server (and not the PingDirectoryProxy) endpoint.

```
$ ldapmodify
dn:ou=People,dc=example,dc=com
changetype:modify
add:aci
aci:(version 3.0; acl "ACI for userAdd scope"; allow (add)
oauthscope="userAdd";)
```

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> This ACI doesn't grant write access to attributes, which means modify operations will not succeed. For more information on ACI configurations, see Overview of access control.
> This ACI grants permission to add entries to the specified subtree as long as the SCIM request contains the `userAdd` scope.

4. **Send the POST request to the SCIM `/Users` endpoint again, and include the `userAdd` scope in the bearer token.**

   Example:

   ```
   curl -k -X POST \
   https://localhost:8443/scim/v2/Users \
   -H 'Authorization: Bearer {"active":true, "scope":"userAdd"}' \
   -H 'Content-type: application/json' \
   --data '{"username":"user.test", "name":{"formatted":"Test",
   "familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'
   ```

   Result:

   The response from the server contains the created SCIM resource, which also contains values for the name and username attributes similar to the following.

   ```
   {
   "name":{
   "familyName":"User",
   "formatted":"Test"
   },
   "username":"user.test",
   "id":"6f9a89b8-e766-478c-9667-def049daf6bc",
   "meta":{
   "resourceType":"Users",
   "location":"https://localhost:8443/scim/v2/Users/6f9a89b8-e766-478c-9667-
   def049daf6bc"
   },
   "schemas":["urn:pingidentity:schemas:User:1.0"]
   }
   ```

SCIM 2.0 searches

You can cap the total number of resources that are matched by a search to prevent exhausting server resources.

The configuration for each System for Cross-domain Identity Management (SCIM) 2.0 resource type contains a `lookthrough-limit` property that defines this limit. The default `lookthrough-limit` value is 500.

If a search request exceeds the lookthrough limit, the client receives a `400` response with an error message similar to the following.

`{ "detail": "The search request matched too many results", "schemas": ["urn:ietf:params:scim:api:messages:2.0:Error"], "scimType": "tooMany", "status": "400" }`

Copyright © 2025 Ping Identity Corporation

To prevent this error:

- The client must refine its search filter to return fewer matches.
- You should configure paged searches as shown in Using paged SCIM searches.

Using paged SCIM searches

When searching large data sets, the results can be numerous and produce errors about a request matching too many results relative to the lookthrough limit. Paged searches avoid these errors and reduce memory usage.

Before you begin

> **Note**
>
> The paged System for Cross-domain Identity Management (SCIM) searches feature is not available for entry-balanced data sets. To use paged SCIM searches, your SCIM service's backend servers must be LDAP directory servers.

Complete the following one-time operation. You only need to run the command once per PingDirectoryProxy.

> **Tip**
>
> If you're not sure if you have run the command, you can run it again safely.

```
$ dsconfig set-request-processor-prop \
--processor-name  <proxying-request-processor>  \
--set supported-control-oid:2.16.840.1.113730.3.4.9 \
--set supported-control-oid:1.2.840.113556.1.4.473
```

`<proxying-request-processor>` is the request processor handling the entries targeted by the search.

About this task

The PingDirectoryProxy server does SCIM searches using LDAP requests. After you complete the following steps, the PingDirectoryProxy server creates LDAP requests that include request controls that ask the backend servers to sort and page the search results before returning the results.

These request controls are marked noncritical, meaning that if the backend server can't page the results, the backend server still returns the results. In this case, the PingDirectoryProxy server handles the sorting and paging itself.

If your SCIM searches result in an error because the request matched too many results, you can avoid the error by using paged searches. For more information, see SCIM 2.0 searches.

For each search:

Steps

1. Decide your SCIM search.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> To get paged results, your search must include at least one of these parameters: `startIndex`, `count`, or `sortBy`.

Example:

Your search might look like the following.

```
https://<proxy-hostname>:<proxy-port>/scim/v2/Users/?filter=st eq "TX"&sortBy=sn&sortOrder=ascending
```

This is the corresponding encoded version.

```
https://<proxy-hostname>:<proxy-port>/scim/v2/Users/?
filter=st%20eq%20%22TX%22&sortBy=sn&sortOrder=ascending
```

On your PingDirectoryProxy server, collect some information to use later. To find the SCIM resource type, `structural-ldap-objectclass`, `include-base-dn`, and `include-filter` values, run the following command.

```
$ dsconfig get-scim-resource-type-prop --type-name  <SCIM-resource-type-name>  \
--property structural-ldap-objectclass \
--property include-base-dn \
--property include-filter
```

2. For each backend server:

    1. Create a Virtual List View (VLV) index for your search using `dsconfig create-local-db-vlv-index` with the following options.

Option	Description
`--index-name`	Names the index.
`--backend-name`	Specifies the name of the local database backend in which to place the index. The default database backend for PingDirectory is userRoot.
`--set base-dn`	Specifies the desired base distinguished name (DN). This value must match the value of the `include-base-dn` property that you found in the previous step.
`--set scope`	Is always `whole-subtree`.

Copyright © 2025 Ping Identity Corporation

Option	Description
`--set filter`	Specifies the filter. Specify `(objectclass=<name-of-SCIM-resource-type-objectclass>)` where `<name-of-SCIM-resource-type-objectclass>` is the name of the objectclass used by the SCIM resource type property, which you found in the previous step. If the SCIM resource type has the `include-filter` property set, also specify that property value in the filter. For example, if the filter for the objectclass is `(objectclass=inetorgperson)` and the `include-filter` value is `(st=CA)`, specify the `--set filter` argument as `(&(objectclass=inetorgperson)(st=CA))`. Specify the LDAP attributes for all the components of your SCIM search filter. For example, if a mapping SCIM resource type maps the LDAP attribute `st` to the SCIM attribute `address.region` and the SCIM search filter requires that `address.region eq TX`, then this filter must include `(st = TX)` instead of `(address.region = TX)`.
`--set sort-order`	Specifies whether to sort ascending (+) or descending (-) and the LDAP attribute to sort by. If the SCIM search doesn't specify the `sortBy` parameter, specify the sort order as `+entryUUID`.

Example:

Each SCIM search that you want to produce paged results must have its own VLV index.

Recall the original, decoded SCIM search, shown here.

```
https://<proxy-hostname>:<proxy-port>/scim/v2/Users/?filter=st eq
"TX"&sortBy=sn&sortOrder=ascending
```

To create a VLV index for that search, run the following command:

```
$ dsconfig create-local-db-vlv-index --index-name sn \
--backend-name userRoot --set base-dn:ou=people,dc=example,dc=com \
--set scope:whole-subtree \
--set filter:"(&(objectclass=inetorgperson)(st=TX))" --set sort-order:+sn
```

2. Using the command line, stop the server, rebuild the index, start the server, and run the `rebuild-index` command specifying the base DN and the name of the index.

```
$ rebuild-index --baseDN  <baseDN-value>  --index  <name-of-index>
```

Example:

Copyright © 2025 Ping Identity Corporation

```
$ stop-server
$ rebuild-index --baseDN dc=example,dc=com --index vlv.sn
$ start-server
```

3. Run your SCIM search filter.

> **Note**
>
> The search can include only the filter you specified with `--set filter` in the earlier step without the `"(objectclass=<name-of-SCIM-resource-type-objectclass>)"` portion.

In addition to the Virtual List View request control, PingDirectoryProxy server adds a Server Side request control to the LDAP request. These request controls require certain parameters be set. To satisfy this requirement, PingDirectoryProxy server uses the following parameters.

Parameter	Default
`startIndex`	1
`count`	The value of the `lookthrough-limit` property of the SCIM resource type being searched. That default is 500.
`sortBy`	entryUUID With this default, the results appear unsorted.
`sortOrder`	ascending

If the client does not provide values for one of the parameters, the search uses the corresponding default value shown in the table.

SCIM 2.0 PATCH operations

You can use a PATCH request to modify a System for Cross-domain Identity Management (SCIM) 2.0 resource that has one or more required SCIM 2.0 attributes.

The requester needs permissions to read the values of these required attributes and to write permissions for the attributes being modified, even if the PATCH request does not alter the requirements.

Example

You can modify an LDAP Mapping SCIM 2.0 resource type using the following schema definition, where `uid` and `cn` are mapped to their LDAP equivalents.

Copyright © 2025 Ping Identity Corporation

```
{
        "schemas": ["urn:ietf:params:scim:schemas:core:2.0:Schema"],
        "id": "urn:test:schema:person",
        "attributes": [
        {
        "name": "uid",
        "type": "string",
        "multiValued": false,
        "required": true,
        "caseExact": false,
        "mutability": "readWrite",
        "returned": "default",
        "uniqueness": "none"
        },
        {
        "name": "cn",
        "type": "string",
        "multiValued": false,
        "required": false,
        "caseExact": false,
        "mutability": "readWrite",
        "returned": "default",
        "uniqueness": "none"
        }
                ],
                ...
                        }
```

The following PATCH operation fails if the SCIM 2 service account does not have access to both `uid` and `cn`.

```
{
        "schemas": ["urn:ietf:params:scim:api:messages:2.0:PatchOp"],
        "Operations":[{
        "op":"add",
        "path":"cn",
        "value": "new cn value"
        }]
                }
```

Troubleshooting the SCIM 2.0 servlet Extension

To troubleshoot the SCIM 2.0 servlet extension, you must enable the Debug Trace Logger.

About this task

For security reasons, error messages specifically regarding LDAP systems are suppressed and do not appear in the HTTP responses from the server. Instead, you will see something like the following.

Copyright © 2025 Ping Identity Corporation

```
{
        "schemas": [
        "urn:ietf:params:scim:api:messages:2.0:Error"
        ],
        "status": "400",
        "detail": "Request failed: correlationID='073eb1a8-8c51-48b3-83a0-380e1d4b4ab9'"
}
```

Steps

- To view these messages, enable the Debug Trace Logger through the administrative console or with the following `dsconfig` command.

  Example:

  ```
  dsconfig set-log-publisher-prop --publisher-name "Debug Trace Logger" \
                          --set enabled:true --add scim-message-type:error
  ```

  Result:

  After you enable the Debug Trace Logger, the server begins logging information related to SCIM operations to the `/logs/debug-trace` file, as in the following example.

  ```
  [09/Jun/2020:05:23:10.992 -0500] HTTP REQUEST requestID=3
  correlationID="073eb1a8-8c51-48b3-83a0-380e1d4b4ab9" product="Ping Identity
  Directory Server" instanceName="example" startupID="Xt9fJg==" threadID=173
  from=[0:0:0:0:0:0:0:1]:53978 method=POST
  url="https://0:0:0:0:0:0:0:1:9443/scim/v2/Users"
  ```

  > **Note**
  >
  > The presence of `correlationID` in these messages allows for matching the ID in the HTTP responses to the messages in the `debug-trace` log so that the appropriate LDAP error message can be determined.

Disabling the SCIM 2.0 servlet extension

If you do not need to expose data through the System for Cross-domain Identity Management (SCIM) 2 servlet, you can disable the SCIM 2.0 servlet extension.

Steps

1. Remove the SCIM 2 HTTP servlet extension from the HTTPS connection handler as well as from any other HTTP connection handlers.
2. Restart the handler.

Example

Copyright © 2025 Ping Identity Corporation

```
dsconfig set-connection-handler-prop \
        --handler-name "HTTPS Connection Handler" \
        --remove http-servlet-extension:SCIM2 \
        --set enabled:false

        dsconfig set-connection-handler-prop \
        --handler-name "HTTPS Connection Handler" \
        --set enabled:true
```

Managing Server SDK extensions

The server provides support for any custom extensions that you create using the Server SDK. This chapter summarizes the various features and extensions that can be developed using the Server SDK.

About the Server SDK

You can create extensions that use the Server SDK to extend the functionality of your server. Extension bundles are installed from a .zip archive or a file system directory. You can use the `manage-extension` tool to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

> **Note**
>
> The **`manage-extension`** tool can only be used with Java extensions packaged using the extension bundle format. Groovy extensions do not use the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation, which describes the extension bundle format and how to build an extension.

Available types of extensions

The Server SDK provides support for creating a number of different types of extensions for Ping Identity server products, including the PingDirectory server, the PingDirectoryProxy server, and the PingDataSync server. Some of those extensions include:

Cross-Product Extensions

- Access Loggers
- Alert Handlers
- Error Loggers
- Key Manager Providers
- Monitor Providers
- Trust Manager Providers
- OAuth Token Handlers

Copyright © 2025 Ping Identity Corporation

- Manage Extension Plugins

PingDirectory Server Extensions

- Certificate Mappers
- Change Subscription Handlers
- Extended Operation Handlers
- Identity Mappers
- Password Generators
- Password Storage Schemes
- Password Validators
- Plugins
- Tasks
- Virtual Attribute Providers

PingDirectoryProxy Server Extensions

- LDAP Health Checks
- Placement Algorithms
- Proxy Transformations

PingDataSync Server Extensions

- JDBC Sync Sources
- JDBC Sync Destinations
- LDAP Sync Source Plugins
- LDAP Sync Destination Plugins
- Sync SourcesSync Destinations
- Sync Pipe Plugins

For more information on the Server SDK, see the documentation available in the SDK build.

Command-line tools

The server provides a full suite of command-line tools necessary for administration. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

Copyright © 2025 Ping Identity Corporation

Available command-line tools

The PingDirectoryProxy server provides command-line tools you can run directly in interactive, non-interactive, or script mode.

Tools Help

For	Use this option	Example
Information about arguments and subcommands Usage examples	`--help`	`dsconfig --help`
A list of subcommands	`--help-subcommands`	`dsconfig --help-subcommands`
More information about a subcommand	`--help` with the subcommand	`dsconfig list-log-publishers --help`

> **Note**
>
> For more information about command-line tools, see Command-line tools.

Command-Line Tools

`authrate`	Perform repeated authentications against an LDAP directory server where each authentication consists of a search to find a user is followed by a bind to verify the credentials for that user.
`backup`	Back up one or more server backends. Each backend backup is stored in a separate backend backup directory. A backend backup directory can contain multiple backups of the backend. Each backend backup directory contains a `backup.info` file providing information about each backup in the directory and an archive file for each backup. The name of the archive file includes both the backend ID and the backup ID. The backup ID can be provided to the `backup` command, or an ID is generated from a current timestamp. Each backup can be optionally compressed, encrypted, hashed or signed. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`base64`	Encode raw data using the base64 algorithm or decode base64-encoded data back to its raw representation.

Copyright © 2025 Ping Identity Corporation

`collect-support-data`	Collect and package system information useful in troubleshooting problems. The information is packaged as a `.zip` archive that can be sent to a technical support representative. Information collected can include configuration files, server monitor entries, portions of log files, JVM thread stack dumps, system metrics, and other data that can be helpful in diagnosing problems, understanding server performance, or otherwise assisting with support requests. Although the tool will do its best to obscure or omit sensitive data, and the entire archive can be encrypted if you prefer, you might want to review the resulting support data archive to ensure verify its contents. Further, the archive will include a summary of any potential problems or concerns that are identified in the course of collecting the support data.
`config-diff`	Compares server configurations and produces a `dsconfig` batch file needed to bring the source inline with the target. Its uses include comparing multiple servers for configuration differences, producing a batch file to reconfigure a server from scratch from the out-of-the-box configuration, and comparing a local server against an expected configuration. Both the source and the target configurations can be retrieved over LDAP, accessed from the local server's file system, extracted from a specific file, or retrieved from every server in a configuration server group. Also, with the exception of accessing a configuration from a specific file, the source and/or target configurations can be compared as they existed at any point in the past, including the baseline, pre-installation configuration. Some configuration differences (those that will always differ between instances, like instance-name) are excluded by default to reduce the amount of spurious output, but these can be included by specifying the `--includeExpectedDifferences` command. Further differences can be excluded with the --exclude option. This tool attempts to generate a batch file that can be applied to the source server without any errors. However, there are some edge case configurations that the tool is not sophisticated enough to handle. For example, it cannot handle two peer configuration objects that would require swapping values for a property (for example, evaluation-order-index) that must be unique within the server. It will still generate a `dsconfig` batch file that includes these changes, but they might be rejected by the server. In these rare cases, the batch file can be hand edited so that it can be applied to a running server or it can be applied with the server shut down using `dsconfig --offline`.

Copyright © 2025 Ping Identity Corporation

`create-initial-proxy-config`	Create an initial server configuration. This tool is used to configure a basic PingDirectoryProxy server. The tool will prompt for basic information about your topology including directory server instances, their locations, and the credentials for communicating with them. This tool will record the configuration in a `dsconfig` batch file and apply the configuration to the local PingDirectoryProxy server. The following assumptions are made about the topology to expedite setup: • All servers will be accessible via a single user account. • All servers support the same communication security type. • All servers are Ping Identity, Sun Java System 5.x, 6.x, or 7.x, or Red Hat (including Fedora and 389) directory servers. If your topology does not meet these assumptions, use this tool to define a basic configuration and then use the `dsconfig` tool or the Administrative Console to customize the configuration.
`create-rc-script`	Create an RC script to start, stop, and restart the server on UNIX-based systems.
`create-systemd-script`	Create a `systemd` script to start and stop the server on Linux-based systems.
`deliver-one-time-password`	Generate and deliver a single-use token to a user through some out-of-band mechanism. The user can provide that token to the password modify extended request in lieu of the user's current password in order to select a new password.
`deliver-password-reset-token`	Generate and deliver a single-use token to a user through some out-of-band mechanism. The user can provide that token to the password modify extended request in place of the user's current password to select a new password.
`dsconfig`	View and edit the server configuration. This utility offers three primary modes of operation, the interactive mode, the non-interactive mode and batch mode. The interactive mode supports viewing and editing the configuration via an intuitive, menu driven environment. Running `dsconfig` in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the server. To start `dsconfig` in interactive command-line mode, simply invoke the `dsconfig` shell script or batch file without any arguments. The `dsconfig` non-interactive command-line mode provides a simple way to make arbitrary changes to the server by invoking it on the command-line. If you want to use administrative scripts to automate the configuration process, then run the `dsconfig` command in non-interactive mode. The `dsconfig` tool provides a batching mechanism that reads multiple `dsconfig` invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting in that it minimizes LDAP connections and JVM invocations that normally occur with each `dsconfig` call. You can view the logs/config-audit.log file to review the configuration changes made to the server and use them in the batch file.

Copyright © 2025 Ping Identity Corporation

`dsjavaproperties`	Configure the Java virtual machine (JVM) arguments used to run the server and associated tools. The options managed by this tool are stored in config/java.properties. Typically you should not edit that file directly but rather run this tool specifying `--jvmTuningParameter` arguments to customize JVM options appropriate for this system. It is necessary however that this tool be run in the event that config/java.properties must be edited by hand. Note that the changes will only apply to this PingDirectoryProxy server installation. No modifications will be made to your environment variables. Memory and other settings for the tool JVMs including the start-server tool can be tuned during initialization by specifying one or more instances of the `--jvmTuningParameter` option when invoking this tool. Supported values are as follows: • `NONE` Explicitly specify no parameters. • `PROXY_ENTRY_BALANCING` Increase the amount of memory used by the PingDirectoryProxy server in an entry-balanced environment in order to allow for better global index performance. • `AGGRESSIVE` This system is dedicated to running only this server. The amount of memory allocated to this server will be computed accordingly. • `SEMI_AGGRESSIVE` This system is shared by multiple server processes. The amount of memory allocated to this server will be computed accordingly If no parameters are specified the parameters specified by the previous invocation of this tool or setup will be used. Use the `NONE` option to explicitly specify no parameters.
`dump-dns`	Obtain a listing of all of the distinguished names (DNs) for all entries below a specified base DN in the server.
`encrypt-file`	Encrypt or decrypt data using a key generated from a user-supplied passphrase, a key generated from an encryption settings definition, or a key shared among servers in the topology. The data to be processed can be read from a file or standard input, and the resulting data can be written to a file or standard output. You can use this command to encrypt and subsequently decrypt arbitrary data, or to decrypt encrypted backups, LDIF exports, and log files generated by the server.
`encryption-settings`	Manage the server encryption settings database. More information about the cipher algorithms and transformations available for use can be found in the Java Cryptography Architecture Reference Guide, as well as the Standard Algorithm Name Documentation for your chosen JDK implementation used by this server.
`enter-lockdown-mode`	Request that the server enter lockdown mode, during which it only processes operations requested by users holding the `lockdown-mode` privilege. While in lockdown mode, the PingDirectoryProxy server rejects all requests from users that do not hold the `lockdown-mode` privilege.

Copyright © 2025 Ping Identity Corporation

`export-reversible-passwords`	Requests that the server export entries from a specified backend in LDIF form, including clear-text representations of any passwords encoded with a reversible storage scheme. This tool can only be used over a secure connection and when authenticated as a user with the `permit-export-reversible-passwords` privilege. The output will be encrypted using a key generated from either a user-supplied passphrase or an encryption settings definition.
`generate-totp-shared-secret`	Generate a shared secret that can be used to generate Time-based One-time Password (TOTP) authentication codes for use in authenticating with the `UNBOUNDID-TOTP SASL` mechanism, or in conjunction with the validate TOTP password extended operation.
`global-index-size`	Estimates the size in memory of one or more global indexes from the actual number of keys, the configured number of keys and the average key size. The estimate could be slightly higher or lower than the actual size. An estimate can be provided for more than one index in one invocation by providing multiple sets of options.
`identify-references-to-missing-entries`	This tool can be used to identify entries containing one or more attributes that reference entries that do not exist. This can require the ability to perform unindexed searches and/or the ability to use the simple paged results control.
`identify-unique-attribute-conflicts`	This tool can be used to identify unique attribute conflicts. That is, it can identify values of one or more attributes which are supposed to exist only in a single entry but are found in multiple entries.
`indent-ldap-filter`	Parse a provided LDAP filter string and displays it as a multi-line form that makes it easier to understand its hierarchy and embedded components. If possible, it also simplifies the provided filter in certain ways, such as removing unnecessary levels of hierarchy like an `AND` embedded in an `AND`.
`ldap-debugger`	Intercept and decode LDAP communication.

Copyright © 2025 Ping Identity Corporation

`ldap-diff`	**Compare the contents of two LDAP directory servers.** **The `ldap-diff` tool outputs the difference between data stored in two LDAP servers into an LDIF file. This file could be used with the `ldapmodify` command to bring the source directory server in sync with the target directory server. The specific entries to compare can be controlled with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. Specific attributes can also be excluded by prepending a `^` character to the attribute. On Windows operating systems, excluded attributes must be quoted, for example, `"^attrToExclude"`. When retrieving entries from a PingDirectory server, the `@objectClassName` notation can be used to compare only attributes that are defined for a given objectclass.** **This command can be used on servers actively being modified, without reporting false positives due to replication delays, by checking differing entries multiple times. By default, it will re-check each differing entry twice, pausing two seconds between checks. These settings can be configured with the `--numPasses` and `--secondsBetweenPass` options. The output is formatted so that delete operations come first, modify operations come next, and add operations come last. This gives the best chance that the resulting output file can be used to bring the source server into sync with the target server without causing any conflicts. This takes into account attribute uniqueness constraints as well as that child entries must be deleted before parents and parents must be added before children.** **The directory user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the PingDirectory server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry:** • `ds-cfg-default-root-privilege-name: unindexed-search` • `ds-cfg-default-root-privilege-name: bypass-acl` • `ds-rlim-size-limit: 0` • `ds-rlim-time-limit: 0` • `ds-rlim-idle-time-limit: 0` • `ds-rlim-lookthrough-limit: 0` **For servers from other vendors, consult their documentation for configuring the proper privileges.** **The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For directories that contain tens of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by `ldap-diff` can be customized by editing the `ldap-diff.java-args` setting in the `config/java.properties` file and running the `dsjavaproperties` command.**

Copyright © 2025 Ping Identity Corporation

`ldap-result-code`	Display and query LDAP result codes. This tool can be used to list all known defined LDAP result codes, retrieve the name of the result code with a given integer value, or search for all result codes with names containing a given substring. At most one of the `--list`, `--int-value`, and `--search` arguments can be provided. If none of them is provided, then the `--list` option will be chosen by default.
`ldapcompare`	Perform compare operations in an LDAP directory server. Compare operations can be used to efficiently determine whether a specified entry has a given value. The exit code for this tool will indicate whether processing was successful or unsuccessful, and to provide a basic indication of the reason for unsuccessful attempts. By default, it will use an exit code of zero (which corresponds to the LDAP 'success' result) if all compare operations completed with a result code of either 'compare false' or 'compare true' (integer values 5 and 6, respectively), but if the `--useCompareResultCodeAsExitCode` argument is provided, only one compare assertion is performed, and it yields an exit code of 'compare false' or 'compare true', then the numeric value for that result code will be used as the exit code. If any error occurs during processing, then the exit code will be a nonzero value that reflects the first error result that was encountered. The attribute type and assertion value to use for the compare operations will typically be provided as the first unnamed trailing argument provided on the command line. It should be formatted with the name or OID of the target attribute type followed by a single colon and the string representation of the assertion value. Alternatively, the attribute name or OID can be followed by two colons and the base64-encoded representation of the assertion value, or it can be followed by a colon and a less-than symbol to indicate that the assertion value should be read from a file (in which case the exact bytes of the file, including line breaks, will be used as the assertion value). The DNs of the entries to compare can either be provided on the command line as additional unnamed trailing arguments after the provided attribute-value assertion, or they can be read from a file whose path is provided using the `--dnFile` argument. If the attribute-value assertion is provided on the command line as an unnamed trailing argument, then the same assertion will be performed for all operations. If multiple types of assertions should be performed, then you can use the `--assertionFile` argument to specify the path to a file containing both attribute-value assertions and entry DNs.
`ldapdelete`	Delete one or more entries from an LDAP directory server. You can provide the DNs of the entries to delete using named arguments, as trailing arguments, from a file, or from standard input. Alternatively, you can identify entries to delete using a search base DN and filter.
`ldapmodify`	Apply a set of `add`, `delete`, `modify`, and/or `modify DN` operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the `ldifFile` argument. Change records must be separated by at least one blank line.

Copyright © 2025 Ping Identity Corporation

`ldappasswordmodify`	Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in RFC 3062), a standard LDAP modify operation, or an Active Directory-specific modification. Unless the password change method is explicitly specified (using the `--passwordChangeMethod` argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password change method will be selected, using a regular LDAP modify to update the `unicodePwd` attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute. The new password to set for the user can be specified in one of several ways. It can be directly provided on the command line, read from a specified file, interactively prompted from the user, or automatically generated by this tool. If the new password is not specified using any of those methods, and if the password is to be updated using the password modify extended operation, then the new password field of the request will be left blank to indicate that the server should generate a new password for the user and include it in the response to the client. If no new password is specified and some other password change method is selected, then the tool will exit with an error. The current password for the user can also be specified. This is optional, although some servers might require a user to provide their current password when setting a new one. If a current password is provided (whether given as a command-line argument, read from a specified file, or interactively requested from the user), and if a regular LDAP modify operation is used to change the password, then the resulting modify request will include a delete of the current value and an add of the new value. If no current password is provided, then the modify request will replace any existing password(s) with the new value.
`ldapsearch`	Process one or more searches in an LDAP directory server. The criteria for the search request can be specified in a number of different ways, including providing all of the details directly using command-line arguments, providing all of the arguments except the filter via command-line arguments and specifying a file that holds the filters to use, or specifying a file that includes a set of LDAP URLs with the base DN, scope, filter, and attributes to return. See the examples below for a number of sample command lines for this tool.

Copyright © 2025 Ping Identity Corporation

`ldif-diff`	Compare the contents of two files containing LDIF entries. The output is an LDIF file containing the `add`, `delete`, and `modify` change records needed to convert the data in the source LDIF file into the data in the target LDIF file. This tool works best with small LDIF files because it reads the entire contents of the source and target LDIF files into memory so they can be quickly compared. If you encounter an out of memory error while running the tool, you might need to increase the amount of memory available to the JVM used to invoke it. The amount of memory available to the JVM can be customized by invoking the JVM with the `-Xms` and `-Xmx` arguments, which specify the initial and maximum amounts of memory that it can use, respectively. These arguments should be immediately followed, without any intervening space, by an integer and a unit to specify the amount of memory that can be used. The unit can be either `m` to indicate that the size is in megabytes, or `g` to indicate that it is in gigabytes. For example, `-Xms512m` indicates that the JVM should be given an initial heap size of 512 megabytes, while `-Xmx2g` indicates that it should be given a maximum heap size of two gigabytes. When invoking the **`ldif-diff`** tool included in the installation of a Ping Identity server product, you can edit the `config/java.properties` file to specify the arguments to use when invoking the JVM. After modifying the file, run the **`dsjavaproperties`** tool to ensure that those changes will be used for subsequent tool invocations.
`ldifmodify`	Apply a set of changes (including add, delete, modify, and modify DN operations) to a set of entries contained in an LDIF file. The changes will be read from a second file (containing change records rather than entries), and the updated entries will be written to a third LDIF file. Unlike **`ldapmodify`**, the **`ldifmodify`** cannot read the changes to apply from standard input. All of the change records will be read into memory before processing begins, so it is important to ensure that the tool is given enough memory to hold those change records. However, it will only operate on a single source entry at a time, so the size of the source LDIF file does not significantly impact the amount of memory that the tool requires. Note that the tool will attempt to correctly handle multiple changes affecting the same entry. However, because it only operates on one entry at a time, it cannot always behave in exactly the same way as if it were applying the changes over LDAP to a server populated with the source LDIF file. For example, it is not possible to reject an attempt to delete an entry that has subordinates, so any delete will be treated as a subtree delete. Further, not all types of modify DN change records are supported. In particular, modify DN change records are not permitted if they target any entry that has been targeted by a previous change record (for example, renaming an entry that was created by a previous add change record). Finally, it cannot perform other types of validation, like ensuring that all of the necessary superior entries exist when adding a new entry, or ensuring that a modify DN will not introduce a conflict with an existing entry.
`ldifsearch`	Search one or more LDIF files to identify entries matching a given set of criteria.

Copyright © 2025 Ping Identity Corporation

`leave-lockdown-mode`	Request that the server leave lockdown mode and resume normal operation. While in lockdown mode, the PingDirectoryProxy server rejects all requests from users that do not hold the `lockdown-mode` privilege. Note that the PingDirectoryProxy server might place itself in lockdown mode under certain conditions; for example, if it detects a security problem like a malformed access control rule that might have otherwise resulted in exposure of sensitive data.
`list-backends`	List the backends and base DNs configured in the server.
`load-ldap-schema-file`	Load the schema definitions contained in a specified LDIF file into the schema for a running server. This tool can only be used in conjunction with a server instance running on the local system.
`make-ldif`	Generate LDIF data based on a definition in a template file. See the server's `config/MakeLDIF` directory for example template files. In particular, the `examples-of-all-tags.template` file shows how to use all of the tags for generating values.
`manage-account`	Retrieve or update information about the current state of a user account. Processing will be performed using the password policy state extended operation, and you must have the password-reset privilege to use this extended operation.
`manage-certificates`	Manage certificates and private keys in a JKS, PKCS #12, PKCS #11, or BCFKS key store.
`manage-extension`	Install or update server extension bundles. An extension bundle is a package of extension(s) that utilize the Server SDK to extend the functionality of the server. Extension bundles are installed from a zip archive or file system directory. The server will be restarted if running to activate the extension(s).
`manage-profile`	Generate, compare, install, and replace server profiles. Server profiles define a format for the configuration of a server, including `dsconfig`, initial DIT, setup arguments, server SDK extensions, and other files. These are combined into one concrete structure. This tool provides subcommands that can be used to generate a new profile from an existing server, to set up a new server, and to replace an existing server's profile with a different profile. A template server profile file structure can be found in the resource/ directory.
`manage-tasks`	Access information about pending, running, and completed tasks scheduled in the server.

Copyright © 2025 Ping Identity Corporation

`manage-topology`	Tool to manage the topology registry. The topology registry is a branch of the configuration DIT (`cn=Topology` , `cn=config`). It stores all metadata about server instances, including their instance and listener certificates, secret keys, server groups and administrative user accounts. In addition, it also stores information about the replication topology (replication server ID and replication domain ID) when replication is enabled among servers in a Directory topology. Last but not least, it stores the license key required to install the server. Changes to the topology registry on one server are automatically mirrored to other servers in the topology. The `dsconfig` tool, configuration API or the management console can be used to make changes to the topology registry. This tool allows some additional capability such as exporting the contents of the registry as a JSON file.
`modrate`	Perform repeated modifications against an LDAP directory server.
`move-subtree`	Move all entries in a specified subtree from one server to another.
`oid-lookup`	Search the OID registry to retrieve information about items that match a given OID or name. The string to use to search the OID registry should be provided as an unnamed trailing argument. All items in the OID registry will be examined, and any items that contain the provided string in its OID, name, type, origin, or URL will be matched. If no search string is provided, the entire OID registry will be displayed.
`parallel-update`	Use multiple concurrent threads to apply a set of add, delete, modify, and modify DN operations read from an LDIF file. As with other tools like `ldapmodify` , changes in the LDIF file to be processed should be ordered such that if there are any dependencies between changes (for example, if one add change record creates a parent entry and another add change record creates a child of that parent), prerequisite changes come before the changes that depend on them. When this tool is preparing to process a change, it will determine whether the new change depends on any other changes that are currently in progress, and if so, will delay processing that change until its dependencies have been satisfied. If a change does not depend on any other changes that are currently being processed, then it can be processed in parallel with those changes. This tool will keep track of any changes that fail in a way that indicates they succeed if re-tried later (for example, an attempt to add an entry that fails because its parent does not exist, but its parent can be created later in the set of LDIF changes), and can optionally re-try those changes after processing is complete. Any changes that are not retried, as well as changes that still fail after the retry attempts, will be written to a rejects file with information about the reason for the failure so that an administrator can take any necessary further action upon them.

Copyright © 2025 Ping Identity Corporation

`prepare-external-server`	Prepare a PingDirectoryProxy server and a directory server for communication. This tool performs several functions that update a directory server to be used as an external server by the PingDirectoryProxy server. If you use the `create-initial-proxy-config` tool to define and prepare directory server instances use of this tool is unnecessary. Among other functions, this tool creates the proxy user account, sets the correct password, and configures the account with required privileges. If necessary you are prompted for manager credentials in order that the tool can perform any required modifications to the external server. When using this tool, specify the LDAP connection options to establish a connection to the external server. Other options are used to specify information about the PingDirectoryProxy server which this tool uses to configure the external server. If a secure connection will be used by the PingDirectoryProxy server to communicate with the external server you can supply the path and password of the truststore to have this tool populate the PingDirectoryProxy server's truststore with the server certificate of the external server.
`profile-viewer`	View information in data files captured by the server profiler. Profiler data files are generated by the Profiler plugin. To create these data files, set the profile-action attribute of the Profiler configuration object to `start` to begin collection. Set the `profile-action` attribute to `stop` to end collection and have the plugin write the file to `logs/profile.{timestamp}`.
`register-yubikey-otp-device`	Registers a YubiKey OTP device with the PingDirectory server for a specified user so that the device can be used to authenticate that user in conjunction with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. Alternately, it can be used to unregister one or more YubiKey OTP devices for a user so that they can no longer be used to authenticate that user.
`reload-http-connection-handler-certificates`	Reload HTTPS Connection Handler certificates. This tool schedules an operation to run within the PingDirectoryProxy server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`reload-index`	Reload the contents of the global index. Reloads the contents of the global index for a given base DN. It is possible to reload all configured indexes in the global index (which includes the rdn index and all attribute indexes), or reload only those indexes specified by name. This tool schedules an operation to run within the PingDirectoryProxy server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.

Copyright © 2025 Ping Identity Corporation

`remove-attribute-type-from-schema`	Safely remove an attribute type definition from the server schema. The tool will perform an appropriate set of validation before actually removing the attribute type from the schema. The below conditions must be satisfied before the attribute type can be removed. • The requester must have the `update-schema` privilege. • The attribute type must not be referenced by any other schema element. • The attribute type must not be defined in any schema file that is included with the PingDirectoryProxy server. Only custom attribute types can be removed from the schema. • The attribute type must not be referenced in the server configuration (for example, it must not be indexed by any backend). • The attribute type must not be present in any entry that exists in any backend. This tool schedules an operation to run within the PingDirectoryProxy server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`remove-backup`	Safely remove a backup from the specified PingDirectory server backend. This tool deletes the specified backup archive and updates the backup descriptor accordingly. As an alternative to removing a specific backup, you can automatically remove backups outside of specified count or age criteria. The `--retainFullBackupCount` argument can be used to indicate that the specified number of full backups should be retained, and any other full backups in the directory are eligible to be removed. The `--retainFullBackupAge` argument can be used to indicate that any full backups older than the specified age are eligible to be removed.
`remove-defunct-server`	Remove a server from this server's topology. This tool will remove the specified server from the topology. In general, the uninstall tool should be used to remove a server from the topology. The remove-defunct-server tool should only be used if a prior attempt to uninstall a server was unsuccessful or the system where the server was installed is no longer available, leaving the server permanently inaccessible from the topology. If the defunct server is online and is able to reach other servers in the topology, running remove-defunct-server from it will cleanly remove it from the topology. If it cannot reach the other servers, then `remove-defunct-server` must also be run from one of the online servers.

Copyright © 2025 Ping Identity Corporation

`remove-object-class-from-schema`	Safely remove an object class definition from the server schema. The tool will perform an appropriate set of validation before actually removing the object class from the schema. The below conditions must be satisfied before the object class can be removed. • The requester must have the update-schema privilege. • The object class must not be referenced by any other schema element. • The object class must not be defined in any schema file that is included with the PingDirectoryProxy server. Only custom object classes can be removed from the schema. • The object class must not be referenced in the server configuration. • The object class must not be present in any entry that exists in any backend. This tool schedules an operation to run within the PingDirectoryProxy server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`replace-certificate`	Replace the listener certificate for this server instance. Only one backend can be restored at a time by the `restore` command. The PingDirectoryProxy server should be stopped unless task connection options are supplied for a running server. You can list the backups contained in a particular backend backup directory. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectoryProxy server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`restore`	Restore a backup of a server backend. Only one backend can be restored at a time by the `restore` command. The PingDirectoryProxy server should be stopped unless task connection options are supplied for a running server. You can list the backups contained in a particular backend backup directory. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectoryProxy server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`revert-update`	Revert this server package's most recent update.
`review-license`	Review and indicate your acceptance of the license agreement defined in `/legal/LICENSE.txt`.

Copyright © 2025 Ping Identity Corporation

`rotate-log`	Trigger the rotation of one or more log files. If the file argument is provided one or more times to specify the target log file paths, then only those log files will be rotated. If the file argument is not given, then the server will trigger rotation for all supported log files. You must have the `config-read` and `config-write` privileges to run this tool, and you must have the necessary access control rights to create and monitor entries in the task backend. This tool schedules an operation to run within the PingDirectoryProxy server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`sanitize-log`	Sanitize the contents of a server log file to remove potentially sensitive information while still attempting to retain enough information to make it useful for diagnosing problems or understanding load patterns. The sanitization process operates on fields that consist of name-value pairs. The field name is always preserved, but field values might be tokenized or redacted if they might include sensitive information. Supported log file types include the file-based access, error, sync, and resync logs, as well as the operation timing access log and the detailed HTTP operation log. Sanitize the audit log using the `scramble-ldif` tool.
`schedule-exec-task`	Schedule an exec task to run a specified command in the server. To run an exec task, a number of conditions must be satisfied: the server's global configuration must have been updated to include `com.unboundid.directory.server.tasks.ExecTask` in the set of allowed-task values, the requester must have the 'exec-task' privilege, and the command to execute must be listed in the `exec-command-whitelist.txt` file in the server's `config` directory. The absolute path (on the server system) of the command to execute must be specified as the first unnamed trailing argument to this program, and the arguments to provide to that command (if any) should be specified as the remaining trailing arguments. The server root is used as the command's working directory, so any arguments that represent relative paths are interpreted as relative to that directory.
`search-and-mod-rate`	Perform repeated searches against an LDAP directory server and modify each entry returned.
`search-logs`	Search across log files to extract lines matching the provided patterns, like the `grep` command-line tool. The benefits of using this tool over `grep` are its ability to handle multi-line log messages, extract log messages within a given time range, and the inclusion of rotated log files.
`searchrate`	Perform repeated searches against an LDAP directory server.
`server-state`	View information about the current state of the server process.

Copyright © 2025 Ping Identity Corporation

`set-delegated-admin-aci`	Request that the server assign appropriate access control instruction (ACI) for configured delegated administrators of the Delegated Admin API.
`setup`	Perform the initial setup for the server instance. This tool features both interactive and non-interactive modes for accepting the product license terms and initially configuring a server instance.
`start-server`	Start the server.
`status`	Display basic server information. This tool prints information about the server, such as version, connection handlers, and data sources. Some information canht not be available if the server is not running, or if authentication credentials are missing or do not have sufficient privileges, or if the invoking user does not have sufficient file system access rights.
`stop-server`	Stop or restart the server. This tool is used to stop or restart the local instance of the server (by omitting LDAP connection options), or a remote server (by interacting with it over LDAP). In addition, this tool is used to schedule the server for shutdown at a later time using the server's task interface.
`subtree-accessibility`	List or update the set of subtree accessibility restrictions defined in the server.
`sum-file-sizes`	Calculate the sum of the sizes for a set of files. This tool is used to find the sum of the sizes of one or more files. If any of the files specified is a directory then it will be recursively processed.
`summarize-access-log`	Examine one or more access log files to display a number of metrics about operations processed within the server.
`transform-ldif`	Apply one or more changes to entries or change records read from an LDIF file, writing the updating records to a new file. This tool can apply a variety of transformations, including scrambling attribute values, redacting attribute values, excluding attributes or entries, replacing existing attributes, adding new attributes, renaming attributes, and moving entries from one subtree to another.
`uninstall`	Uninstall server. This tool removes the entire server or individual server components from the file system. If this server is a member of an existing topology, you must first remove references to this server in the other servers using the remove-defunct-server tool.
`update`	Update a deployed server so its version matches the version of this package.

Copyright © 2025 Ping Identity Corporation

`validate-acis`	Validate a set of access control definitions contained in an LDAP server (including Oracle DSEE instances) or an LDIF file to determine whether they are acceptable for use in the server. **Note** Output generated by this tool is LDIF, but each entry in the output has exactly one ACI, so entries that have more than one ACI appear multiple times in the output with different ACI values.
`validate-file-signature`	Validate file signatures. For best results, file signatures should be validated by the same instance used to generate the file. However, it might be possible to validate signatures generated on other instances in a replicated topology.
`validate-ldap-schema`	Validate an LDAP schema read from one or more LDIF files.
`validate-ldif`	Validate the contents of an LDIF file against the server schema.

Saving options in a file

The PingDirectory server supports the use of a tools properties file (`config/tools.properties`) to simplify command-line invocations by reading in a set of options for each tool from a text file.

Properties files are convenient when quickly testing the PingDirectory server in multiple environments.

Each property takes the form of a name-value pair that defines predetermined values for a tool's options.

The PingDirectory server supports the following types of properties:

- Default properties that apply to all command-line utilities
- Tool-specific properties

Evaluation of command-line options and file options

You can specify options for a command-line tool on the command line, in a properties file, or both.

Options you specify on a tool's command line take priority over options in a properties file.

Consider the following scenarios.

Command-line options	Server uses ...
No command-line options	The options in the default `<server-root>/config/tools.properties` file.
Command-line options other than the `--propertiesFilePath <my-properties-file>` option	The command-line options, which take priority if the options are also in the `<server-root>/config/tools.properties` file. The file options for options that are only in the default `<server-root>/config/tools.properties` file.

Copyright © 2025 Ping Identity Corporation

Command-line options	Server uses ...
Only the `--propertiesFilePath <my-properties-file>` option	The options in `<my-properties-file>`.
The `--propertiesFilePath <my-properties-file>` option and other command-line options	The command-line options, which take priority if the options are also in `<my-properties-file>`. The file options for options that are only in `<my-properties-file>`.
The `--noPropertiesFile` option and other command-line options	Only the options you specify on the command line, ignoring the default properties file.

Example

Consider this example properties file that is saved as `<server-root>/bin/tools.properties`:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

The server checks command-line options and file options to determine the options to use, as explained below.

- All options presented with the tool on the command line take precedence over any options in a properties file.

  In the following example, the command runs with the options specified on the command line (`--port` and `--baseDN`). With the `port` value both on the command line and in the properties file, the command-line value takes priority. The command uses the `bindDN` and `bindPassword` values specified in the properties file.

  ```
  $ bin/ldapsearch --port 2389 --baseDN ou=People,dc=example,dc=com \
    --propertiesFilePath bin/tools.properties "(objectclass=*)"
  ```

- If you specify the properties file using the `--propertiesFilePath` option and no other command-line options, the server uses only the options in the specified properties file:

  ```
  $ bin/ldapsearch --propertiesFilePath bin/tools.properties \
    "(objectclass=*)"
  ```

- If you do not specify any command-line options, the server attempts to locate the default properties file in the following location:

  ```
  <server-root>/config/tools.properties
  ```

Copyright © 2025 Ping Identity Corporation

By moving your `tools.properties` file from `<server-root>/bin` to `<server-root>/config`, you do not have to specify the `--propertiesFilePath` option. That change shortens the previous command to the following command:

```
$ bin/ldapsearch "(objectclass=*)"
```

Creating a tools properties file

You can set properties that apply to all tools or are tool-specific. These properties serve as defaults for the command-line options they represent.

Steps

1. Use a text editor to open the default tools properties file (`config/tools.properties`) or a different properties file.

   > **Note**
   >
   > If you use a file other than `config/tools.properties`, invoke the tool with the `--propertiesFilePath` option to specify the path to your properties file.

2. Set or change properties that apply to all tools.

   Use the standard Java properties file format (name=value) to set properties. For example, the following properties define a set of Lightweight Directory Access Protocol (LDAP) connection parameters.

   ```
   hostname=server1.example.com
   port=1389
   bindDN=cn=Directory\ Manager
   bindPassword=secret
   baseDN=dc=example,dc=com
   ```

   > **Note**
   >
   > Properties files do not allow quotation marks of any kind around values.
   > Escape spaces and special characters.
   > Whenever you specify a path, do not use `~` to refer to the home directory. The server does not expand the `~` value when read from a properties file.

3. Set or change properties that apply to specific tools.

   Tool-specific properties start with the name of the tool followed by a period. These properties take precedence over properties that apply to all tools. The following example sets two ports: one that applies to all tools (`port=1389`) and a tool-specific one that `ldapsearch` uses instead (`ldapsearch.port=2389`).

   ```
   hostname=server1.example.com
   port=1389
   ldapsearch.port=2389
   bindDN=cn=Directory\ Manager
   ```

Copyright © 2025 Ping Identity Corporation

4. Save your changes and close the file.

dsconfig batch files">

Sample `dsconfig` batch files

The `config/sample-dsconfig-batch-files` directory contains `dsconfig` batch files that you can use to configure various aspects of the server. For example, these files can enable additional security capabilities or take advantage of features that might require customization from one environment to another.

Each file includes comments that describe the purpose and benefit of its configuration change. You can choose which of the changes you want to apply.

You need to customize some of the batch files to provide values that might vary from one environment to another. To apply a batch file that requires changes, copy it to another directory and edit the copy. Leave the files in the `config/sample-dsconfig-batch-files` directory unchanged so that they can be updated when you upgrade the server. To specify the path to the file that contains the changes to apply, use the `dsconfig` tool (`bin/dsconfig` on UNIX-based systems or `bat\dsconfig.bat` on Windows) with the `--batch-file` argument.

You should also provide the arguments needed to connect and authenticate to the server. The `--no-prompt` argument ensures that the tool does not block while waiting for input if any necessary arguments are missing. Consider this example.

```
bin/dsconfig --hostname localhost \
  --port 636 --useSSL --trustStorePath config/truststore \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPasswordFile admin-password.txt \
  --batch-file config/hardening-dsconfig-batch-files/reject-insecure-request.dsconfig \
  --no-prompt
```

Running task-based tools

The PingDirectory server has a Tasks subsystem that allows you to schedule basic operations, such as `backup`, `restore`, `rotate-log`, `schedule-exec-task`, `stop-server`, and others. All task-based tools require the `--task` option that explicitly indicates the tool is to run as a task rather than in offline mode.

The following table shows the options that you can use for task-based operations:

Options for task-based operations

Option	Description
`--task`	Indicates that the tool is invoked as a task. The `--task` option is required. If you invoke a tool as a task without this `--task` option, then a warning message is displayed stating that it must be used. If the `--task` option is provided but the tool was not given the appropriate set of authentication arguments to the server, then an error message is displayed and the tool exits with an error.

Copyright © 2025 Ping Identity Corporation

Option	Description
`--start <startTime>`	Indicates the date and time, expressed in the format 'YYYYMMDDhhmmss', when the operation is to start. A value of '0' causes the task to be scheduled for immediate execution. After the scheduled run, the tool exits immediately.
`--dependency <taskID>`	Specifies the ID of a task upon which this task depends. A task does not start execution until all its dependencies have completed execution. You can use this option multiple times in a single command.
`--failedDependencyAction <action>`	Specifies the action this task takes if one of its dependent tasks fail. Valid action values are: • `CANCEL` (the default) - Cancels the task. • `DISABLE` - Disables the task so that it is not eligible to run until you manually enable it again. • `PROCESS` - Runs the task.
`--startAlert`	Generates an administrative alert when the task starts running.
`--errorAlert`	Generates an administrative alert when the task fails to complete successfully.
`--successAlert`	Generates an administrative alert when the task completes successfully.
`--startNotify <emailAddress>`	Specifies an email address to notify when the task starts running. You can use this option multiple times in a single command.
`--completionNotify <emailAddress>`	Specifies an email address to notify when the task completes, regardless of whether it succeeded or failed. You can use this option multiple times in a single command.
`--errorNotify <emailAddress>`	Specifies an email address to notify if an error occurs when this task executes. You can use this option multiple times in a single command.
`--successNotify <emailAddress>`	Specifies an email address to notify when this task completes successfully. You can use this option multiple times in a single command.

Consent Solution Guide

This guide provides information for configuring and managing the PingDirectory server's Consent Service, which supports end-user control of personal data by collecting authorization from users and customers.

Introduction to the Consent Service and Consent API

Companies gain loyalty and trust when they offer transparency and control to their users and customers regarding the personal data that is collected, processed, or shared.

For example, in Europe, the General Data Protection Regulation (GDPR) was designed specifically for allowing companies to collect and use valuable data about its users, while protecting the rights of citizens to control what is collected and used.

To support the collection and end-user control of personal data, the PingDirectory server includes schema and REST APIs that provide the ability to collect fine-grained data authorizations (consents) from users and customers.

Consent Service overview

The Consent Service is an HTTP-based REST API hosted by the PingDirectory server or by the PingDirectoryProxy server.

Enterprises can integrate the following Consent Service features into their applications to give users transparency and control of their data privacy:

- The collection of consent from application users
- The enforcement of consent
- A user's management of his or her consent
- Auditing of consent actions

The following terms are used throughout this guide:

Collaborators

A list of individuals for whom access to this consent record is shared.

Consent definition

The terms of the fine-grained contract, which describes the data that can be processed or shared, and a purpose for processing or sharing the data. The consent definition is stored in the server configuration.

Consent localization

A child object of a definition that contains versioned, localized text for the consent definition, to be used when prompting an individual. This is stored in the server configuration.

Consent record

A record of a consent interaction with a user. Consent records are stored in the directory tree.

Subject

The individual whose data can be collected, processed, or shared.

Copyright © 2025 Ping Identity Corporation

Actor

The individual who granted, denied, or revoked consent. This is usually the same as the subject.

Audience

The entity, application, or service that is granted or denied access to a subject's data for a specific purpose.

Consent API overview

PingDirectory and PingDirectoryProxy provide a REST application programming interface (API) for managing an individual's consent to handle their data.

The PingDirectory Consent API enables the following authorization services for managing an individual's consent and data:

- Captures a user's consent for sharing or processing data
- Confirms a user's consent to share or process data has been granted
- The user can manage the consent that they have granted

The Consent REST API can be used as a component of a larger solution, such as a General Data Protection Regulation (GDPR) compliance system.

For more information on the Consent API, see the PingDirectory Consent API Reference and How applications use the Consent API.

How consents are collected

The Consent API allows the user to make the decision about sharing their data with other applications through a consent record.

User consent is collected by creating a consent record through the Consent API. In most cases, the Consent API client uses the consent localization data to construct an approval prompt that displays to the user. This prompt should include text describing what data is collected and for what purpose, allowing the user to make an informed decision about the value of sharing his or her data.

For example, a web application needing to collect consent for a user's browsing behavior uses the Consent API to look up the localizations for the `browsing-behavior` consent definition. It selects the localization appropriate for the user and use data from the localization resource to construct a consent prompt for display to the user. After the user is prompted and makes a decision, the client stores the decision by creating a new consent record through the Consent API.

How consents are enforced

The Consent API can be used as a data source for making access control decisions and enforcing the user's consent.

If a data usage scenario requires consent, then the application or service can't process or access the data unless the user has provided consent. The entity that performs this consent check can be the application itself or some other service.

Copyright © 2025 Ping Identity Corporation

To perform a consent check, the Consent API client tries to correlate a data access request type with a consent definition. For example, if a web application needs to collect a user's browsing behavior, it can use the `browsing-behavior` consent definition. In this data collection scenario, the application searches the Consent API and checks the an existing consent grant for a consent record that matches the user and the `browsing-behavior` consent definition. If a match is found, then the application proceeds. If a match is not found, the application must collect consent from the user.

How applications use the Consent API

The following example illustrates both consent capture and consent enforcement using the Consent API.

This example follows a user's journey on a website during which the company must gather consent to track the user's browsing behavior.

1. A user launches the company's application and authenticates.
2. The application wants to record the page visit but first checks if the user has granted consent to do so.
3. The application makes a call to the Consent API to determine if the `browsing-behavior` consent record exists for this user and whether consent been granted.
4. The API returns a result indicating that no consent record exists.
5. The application prompts the user for his or her consent.
6. The application calls the Consent API to retrieve the localization for the `browsing-behavior` consent, which includes the language that the application uses to produce a prompt for the user.
7. After the user makes a decision, the application stores the user's decision by creating a new consent record through a call to the Consent API.
8. Later, the user visits another page in the company's site, and the application wants to record the page visit, so it checks whether the user has granted consent to do so.
9. The application makes a call to the Consent API to get the `browsing-behavior` consent record for this user.
10. If the user's consent record agrees to have the company track his or her browsing behavior, the application can then make the appropriate calls to track browsing behavior.

Configuring the Consent Service

This section provides information for installing and configuring the components to support the Consent Service.

Installing and configuring the Consent Service includes the following topics:

- Configuration overview
- Example configuration scenarios
- Setting up with the configuration scripts
- Setting up in a replicated PingDirectory server environment
- Configuration reference

Copyright © 2025 Ping Identity Corporation

- Authorization

For more configuration information, see PingDataSync Server Administration Guide.

Configuration overview

Your Consent Service configuration can vary depending on client application capabilities, authentication methods used, and other factors.

By default, the Consent Service is not enabled. The setup and configuration process varies depending on the following factors:

- Whether client applications allow an individual to self-manage consents
- Whether some or all client applications can be privileged with the ability to manage all consents
- The HTTP authentication method used by client applications
- Whether consent records exist in the same directory as user entries

Example configuration scenarios

Review the following client application scenarios to determine how to configure the Consent Service to meet your business needs.

Directly managed consents

In this scenario, one or more client applications provide an interface for individuals to directly manage their own consent records. These applications can only manage consents for the currently authenticated user. In addition, there's a client application for consent administrators.

An OAuth 2 authorization server grants access tokens that the applications use to access the Consent API.

Configuration for this scenario includes:

1. Configure an OAuth 2 authorization server to issue a `urn:pingdirectory:consent` scope to individuals and a `urn:pingdirectory:consent_admin` scope to consent administrators.
2. Create an identity mapper to map subject identifiers used by the authorization server to Lightweight Directory Access Protocol (LDAP) distinguished names (DNs) used by the PingDirectory server.
3. Configure an access token validator to validate tokens issued by the OAuth 2 authorization server.
4. Configure the Consent HTTP Servlet Extension to disable HTTP basic authentication and restart the HTTPS Connection Handler.
5. Configure the Consent Service to use the OAuth scopes and token validator.

Indirectly managed consents (basic authentication)

In this scenario, an application uses a privileged service account to manage its users' consents. The application's privileged account can access any consent record, which gives the application the ability to perform operations that an individual user can't.

Copyright © 2025 Ping Identity Corporation

The following configuration steps describe the setup needed for the PingDirectory server's Open Banking Account Requests service to use the Consent Service as its backend.

Configuration for this scenario includes:

1. Create a service account for the application.
2. Configure the Consent HTTP Servlet Extension to enable HTTP basic authentication and restart the HTTPS Connection Handler.
3. Create an identity mapper to map the consent record subject and actor attribute values to LDAP DNs.
4. Configure the Consent Service to use the application's service account.
5. Configure the Consent Service to use the identity mapper.

Setting up with the configuration scripts

The PingDirectory server includes two configuration scripts that can serve as the starting point for setting up the Consent Service.

About this task

You can use one of the following two configuration scripts to start setting up the Consent Service:

- `consent-service-base-entries.ldif` - Import this LDIF script to create the base distinguished name (DN) where consent records are stored.
- `consent-service-cfg.dsconfig` - Import this script to configure and enable the Consent Service.

Both scripts are located in the `/resource/consent/` directory of the PingDirectory server root.

> **Tip**
>
> Carefully review and update both scripts to support your client application scenarios and business needs.

Steps

1. Choose a configuration script to set up the Consent Service.

   Choose from:

   - Basic configuration with the `consent-service-base-entries.ldif` file.
     1. Edit the LDIF script and change the location of where you want to store the consent records.
     2. Import the LDIF script using the `ldapmodify` command. See the following example.

        ```
        $ bin/ldapmodify --defaultAdd \
          --filename consent-service-base-entries.ldif
        ```

   - Basic configuration with the `consent-service-cfg.dsconfig` file.
     1. Search for `CHANGE-ME` and replace values.

Copyright © 2025 Ping Identity Corporation

2. Review configuration commands and make additional changes to match existing Ping environment parameters, application scenarios, and business needs.
3. Impost the script with the `dsconfig` command. See the following example.

```
$ bin/dsconfig --no-prompt \
  --batch-file consent-service-cfg.dsconfig
```

Setting up in a replicated PingDirectory server environment

Running the Consent Service setup script differs depending on if your environment has includes replicated PingDirectory servers.

About this task

Setting up the Consent Service requires different steps depending on if replication is enabled in your environment or not.

> **Tip**
>
> If possible, you should set up the Consent Service after replication is enabled for the PingDirectory servers.

For more information about server replication, see the PingDirectory Server Administration Guide.

Steps

1. Choose a Consent Service setup:

   Choose from:

   - If you are setting up the Consent Service after replication is enabled for PingDirectory servers:
     1. Configure the PingDirectory servers to use a configuration group called `all-servers`.

        > **Note**
        >
        > This ensures that configuration changes are applied to all servers in a topology.

        ```
        $ bin/dsconfig set-global-configuration-prop \
          --set configuration-server-group:all-servers
        ```

     2. Run the Consent Service setup script.

        ```
        $ bin/dsconfig --no-prompt \
          --batch-file resource/consent/consent-service-cfg.dsconfig
          --applyChangeTo server-group
        ```

   - If you have set up the Consent Service on a standalone PingDirectory server before enabling replication:

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> In this example, DS1 is the original PingDirectory server, and DS2 is the second server to be added as a replica.

1. Run the `config-diff` command without arguments on DS1 to produce a batch file that contains configuration changes that will be applied to DS2.

```
$ bin/config-diff > config-changes.dsconfig
```

2. Apply the `config-changes.dsconfig` file to DS2.

```
$ bin/dsconfig --no-prompt \
  --batch-file config-changes.dsconfig \
  --applyChangeTo single-server
```

3. Restart DS2.

4. Enable replication between the two servers.

Configuration reference

Use this section as a reference for information about the Consent Service properties and configuration.

There are many configuration options for the Consent Service and application integration. The configuration scripts included with PingDirectory server provide a starting point. Additional information about the Consent Service properties and configuration is provided as reference.

General Consent Service configuration

The Consent Service configuration is used to control authorization behavior and determines where consent records are stored in the PingDirectory server.

You configure the Consent Service properties using the `dsconfig set-consent-service-prop` command. You can use the Consent Service configuration script to configure the Consent Service properties, as show in the following example.

```
$ bin/dsconfig set-consent-service-prop \
  --set enabled:true \
  --set base-dn:ou=consents,dc=example,dc=com \
  --set "bind-dn:cn=consent service account" \
  --set unprivileged-consent-scope:urn:pingdirectory:consent \
  --set privileged-consent-scope:urn:pingdirectory:consent_admin \
  --set "consent-record-identity-mapper:User ID Identity Mapper"
```

Copyright © 2025 Ping Identity Corporation

Consent Service properties

Property	Description	Required to enable service
`enabled`	If set to `true`, the property enables the Consent Service for handling client requests.	Yes
`base-dn`	Specifies a container distinguished name (DN) for consent record entries.	Yes
`bind-dn`	Specifies an internal service account used by the Consent Service to perform LDAP operations.	Yes
`service-account-dn`	Specifies one or more DNs of requesters that are considered privileged when using basic authentication. If not defined, a requester is only considered privileged if it's mapped to a DN with the `bypass-acl` privilege.	No
`unprivileged-consent-scope`	Specifies the name of the scope required for bearer tokens representing unprivileged requesters.	Yes
`privileged-consent-scope`	Specifies the name of the scope required for bearer tokens representing privileged requesters.	Yes
`consent-record-identity-mapper`	Specifies one or more identity mappers used to map consent record `subject` and `actor` values to DNs. By default, these values are inferred from the authentication context, such as the bearer token subject.	No
`audience`	Specifies an `audience` claim value that the Consent Service requires to be present in bearer tokens that it accepts.	No

For the Consent Service to report itself as available to clients:

- The Consent Service must be enabled.
- The Consent Service base DN must be configured and must exist.
- The internal service account must be configured and exist.

Copyright © 2025 Ping Identity Corporation

- The internal service account must have the right to read, add, modify, and delete entries under the Consent Service base DN.

Creating a container entry for consent records

Each consent record is a distinct entry in the PingDirectory server. The Consent Service requires that these entries are stored under a common base distinguished name (DN).

About this task

The `base-dn` property of the Consent Service configuration defines the base DN. The Consent Service LDIF file sets the base DN.

To choose a different location to store consent records:

Steps

1. To create the Consent Service base DN, open a text editor and save the following to the `consent-service-base-dn.ldif` file.

   Example:

   ```
   dn: ou=consents,dc=example,dc=com
   objectClass: top
   objectClass: organizationalUnit
   ou: consents
   ```

2. Use `ldapmodify` to add the entry.

   Example:

   ```
   $ bin/ldapmodify --defaultAdd --filename consent-service-base-dn.ldif
   ```

Creating an internal service account

Create an internal LDAP connection to operate against consent records that are stored as LDAP entries.

About this task

The Consent Service uses an internal LDAP connection to operate against consent records that are stored as LDAP entries. The Consent Service authenticates the LDAP connection using a service account that must be created and dedicated solely to the Consent Service.

The Consent Service configuration script configures the internal service account using a topology administrator user. If needed, this can be changed to a root distinguished name (DN) user or a user DN whose entry is in the user backend. In all cases, the service account should exist in every LDAP server in the topology.

This service account must have:

- Full read and write access to the Consent Service base DN.

Copyright © 2025 Ping Identity Corporation

- The ability to read users' `isMemberOf` attribute.
- The right to use the following LDAP controls:
  - IntermediateClientRequestControl (1.3.6.1.4.1.30221.2.5.2)
  - NameWithEntryUUIDRequestControl (1.3.6.1.4.1.30221.2.5.44)
  - RejectUnindexedSearchRequestControl (1.3.6.1.4.1.30221.2.5.54)
  - PermissiveModifyRequestControl (1.2.840.113556.1.4.1413)
  - PostReadRequestControl (1.3.6.1.1.13.2)

For more information about configuring access, see Managing access control.

Steps

1. To ensure the correct access, create a user with the `bypass-acl` privilege.

   Example:

   The following `dsconfig` command creates a topology admin user with the `bypass-acl` privilege.

   ```
   $ dsconfig create-topology-admin-user \
     --user-name "Consent Service Account" \
     --set "description:Consent API service account" \
     --set "alternate-bind-dn:cn=consent service account" \
     --set first-name:Consent \
     --set inherit-default-root-privileges:false \
     --set last-name:Service \
     --set password:CHANGE-ME \
     --set privilege:bypass-acl
   ```

   Tip

   The `bypass-acl` privilege grants a broad level of access, so you might not want to grant this privilege to the Consent Service account.

2. Set this user as the `bind-dn` for the Consent Service.
3. To enable a targeted set of functionality for the Consent Service, add the following access control instruction (ACI).

   Example:

   The following example grants the access to the `cn=consent service account` DN using global ACIs.

Copyright © 2025 Ping Identity Corporation

```
# Grant access to the consent record base DN ou=consents,dc=example,dc=com
dsconfig set-access-control-handler-prop --add 'global-aci:(target="ldap:///
ou=consents,dc=example,dc=com")(targetattr="*||+")(version 3.0; acl "Consent Service account access
to consent record data"; allow(all) userdn="ldap:///cn=consent service account";)'

# Grant access to the LDAP request controls used by the Consent Service.
dsconfig set-access-control-handler-prop --add 'global-aci:(targetcontrol="1.3.6.1.4.1.30221.2.5.2||
1.3.6.1.4.1.30221.2.5.44||1.3.6.1.4.1.30221.2.5.54||1.2.840.113556.1.4.1413||1.3.6.1.1.13.2")
(version 3.0; acl "Consent Service account access to selected controls"; allow (read)
userdn="ldap:///cn=consent service account";)'
```

Configuring an identity mapper

The Consent Service uses identity mappers to map requester identities, subject values, and actor values to distinguished names (DNs).

An identity mapper takes a user identifier string and correlates the identifier with the DN of a user entry. The PingDirectory server provides four different types of identity mappers.

Identity mapper types and descriptions

Identity mapper type	Description
Exact match identity mapper	Maps a user identifier to a DN by searching for an entry with an attribute that exactly matches the identifier.
Regular expression identity mapper	Similar to an exact match identity mapper, but allows a regular expression to be specified for more flexible matching.
Third-party identity mapper	A custom Java identity mapper implementation written using the Server SDK.
Groovy scripted identity mapper	A custom Groovy identity mapper implementation written using the Server SDK.

The Consent Service can be configured to use identity mappers for each of the following scenarios:

Requesters authenticating using basic authentication

Use the Consent HTTP Servlet Extension `identity-mapper` property to configure an identity mapper that takes the HTTP Basic authorization user name string to find the corresponding user's identity in the PingDirectory server.

Requesters authenticating using bearer token authentication

Use the Access Token Validator `identity-mapper` property to configure an identity mapper that takes the subject or other claim value from the OAuth token to find the corresponding user's identity in the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

Consent record actor and subject values

Use the Consent Service `consent-record-identity-mapper` property to configure an identity mapper that takes these consent record attribute values and uses them to find the corresponding users' identities in the PingDirectory server.

The consent record identity mapper

By default, the Consent Service sets the `subject`, `subjectDN`, `actor`, and `actorDN` values to the identity of the authenticated requester. If the requester uses basic authentication, then all values are set to the auth DN determined by the basic authentication identity mapper. If the requester uses bearer token authentication, then the `subject` and `actor` values are set to the bearer token's subject claim value, while the `subjectDN` and `actorDN` values are set to the auth DN determined by the access token validator identity mapper.

Privileged clients can manually set a consent record's `subject` and `actor` values. In those cases, the Consent Service's `consent-record-identity-mapper` property is used to map a consent record's `subject` and `actor` values to `subjectDN` and `actorDN` values, respectively.

Identity mapper configuration options

The Consent Service configuration script configures a single identity mapper to be used for all three scenarios. The provided identity mapper searches by `uid`, `cn`, or `entryUUID` attributes under the base DNs `cn=config` and `ou=people,dc=example,dc=com`.

The following configuration provides an example of an identity mapper that matches a user identifier to an Lightweight Directory Access Protocol (LDAP) entry with the same value in its `uid` attribute.

```
$ bin/dsconfig create-identity-mapper --mapper-name "User ID Exact Match" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid
```

This configuration shows another typical example: an identity mapper that matches a user identifier to an LDAP entry with the same value in its `entryUUID` attribute.

```
$ bin/dsconfig create-identity-mapper --mapper-name "EntryUUID Exact Match" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:entryUUID
```

This final example creates an identity mapper that matches a user identifier to an LDAP entry with the same value in either its `uid`, `cn`, or `entryUUID` attribute. This identity mapper also constrains its search to the `cn=config` and `ou=people,dc=example,dc=com` and `cn=config` base DNs. By default, the `cn=config` base DN is not searched and must be explicitly listed to be searched.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-attribute:cn \
  --set match-attribute:entryUUID \
  --set match-base-dn:cn=config \
  --set match-base-dn:ou=people,dc=example,dc=com
```

Authentication methods

The Consent Service supports the following HTTP authentication methods and the use of token validators for authorization.

Supported HTTP authentication methods

The Consent Service supports the following HTTP authentication methods that are enabled by default:

Basic authentication

With basic authentication, the client provides an encoded user name-password pair in the HTTP Authorization request header. When the Consent Service receives a request using basic authentication, it maps the user name credential to a distinguished name (DN) using an identity mapper. This DN is designated the `auth DN` and is used to make subsequent authorization decisions. The Consent Service then performs an Lightweight Directory Access Protocol (LDAP) bind using the DN and password to determine if the request can be processed.

Bearer token authentication

With bearer token authentication, the client provides an access token in the HTTP Authorization request header. The access token is always obtained by the client from an external OAuth 2 authorization server and encapsulates information "claims" about a user identity, the client identity, and the requests that the client is authorized to make.

The Consent servlet looks at the request's Authorization header to determine which authentication type is being used by the client.

Configuring token validators

The PingDirectory server must be configured to accept access tokens using one or both of the following access token validators:

PingFederate access token validator

Supports access tokens issued by a PingFederate authorization server. This validator verifies an access token and discovers its claims by making a request to the PingFederate server's token introspection endpoint.

> **Note**
>
> If you are using PingFederate 10.0 or earlier, ensure that PingFederate is configured to respond to OAuth and OpenID Connect (OIDC) requests selecting the check boxes mentioned in steps 2 and 3 in Enabling the OAuth AS role. Starting with PingFederate 10.1, these items are always enabled.

Copyright © 2025 Ping Identity Corporation

JWT access token validator

Supports signed or encrypted JSON Web Token (JWT) access tokens issued by an arbitrary authorization server. This validator checks an access token by cryptographically verifying the token's signature using a trusted public certificate. The token's claims are encoded in the token itself, so discovering the token's claims does not require an outgoing token introspection request.

The token validator uses its identity mapper to map the subject claim to a DN. This DN is designated the `auth DN` and is used along with the token's claims to make subsequent authorization decisions.

If the PingDirectory server is configured with at least one access token validator, the Consent Service uses this access token validator. If the PingDirectory server is configured with more than one access token validator, the validators are consulted in order until one is able to successfully authenticate the request. If the PingDirectory server is configured with multiple access token validators, but only one should be used by the Consent Service, the access token validator can be configured by setting the `access-token-validator` property of the Consent HTTP Servlet Extension.

> **Note**
>
> Configuring an access token validator for the Consent Service requires the following from the authorization server configuration:
>
> - The values that the authorization server sets for **`subject`** claims must be mappable to a DN in the PingDirectory server.
> - The authorization server must be configured to authorize clients and grant scopes appropriately for privileged or unprivileged Consent API access.
> - The authorization server must be configured to issue tokens with scopes corresponding to the Consent Service's **`unprivileged-scope-name`** and **`privileged-scope-name`** configuration.
>
> See the authorization server's documentation for guidance.

Configuring basic authentication

Disable or enable basic authentication and configure an identity mapper for basic authentication.

About this task

By default, basic authentication is enabled. The settings are configured in the Consent HTTP Servlet Extension configuration.

> **Note**
>
> All of these configuration changes require the Consent servlet to be reloaded before they can take effect. To do this, see the last step.

Steps

- **To disable basic authentication, use the following command.**

  Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Consent \
  --set basic-auth-enabled:false
```

Copyright © 2025 Ping Identity Corporation

- To enable basic authentication, use the following command.

  Example:

  ```
  $ bin/dsconfig set-http-servlet-extension-prop \
    --extension-name Consent \
    --set basic-auth-enabled:true
  ```

- To configure an identity mapper for basic authentication, use the following command.

  Example:

  ```
  $ bin/dsconfig set-http-servlet-extension-prop \
    --extension-name Consent \
    --set "identity-mapper:User ID Exact Match"
  ```

- To restart the connection handler that hosts the Consent servlet, use the following commands.

  Example:

  ```
  $ bin/dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set enabled:false
  ```

  ```
  $ bin/dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set enabled:true
  ```

Configuring bearer token authentication

Configure an access token validator.

About this task

> **Note**
>
> You can configure the Consent Service to use a single validator.

Steps

- Configure an access token validator using `dsconfig`.

  Example:

  This example shows an access token validator configured on a PingDirectory server for a PingFederate server.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-external-server \
  --server-name PingFederate \
  --type http \
  --set base-url:https://my-ping-federate-server:1443/
```

```
$ bin/dsconfig create-access-token-validator \
  --validator-name "PingFederate Token Validator" \
  --type ping-federate \
  --set enabled:true \
  --set "identity-mapper:User ID Exact Match" \
  --set authorization-server:PingFederate \
  --set client-id:id \
  --set client-secret:secret
```

- (Optional) If more than one access token validator is configured on a PingDirectory server, you can configure the Consent Service to use a single validator with the following command.

  Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Consent \
  --set "access-token-validator:PingFederate Token Validator"
```

Configuring Consent Service scopes

Configure the `privileged-consent-scope` and `unprivileged-consent-scope` for the Consent Service.

About this task

The Consent Service checks access tokens for a `subject` claim and uses an identity mapper to map the value to a distinguished name (DN), called the request DN or auth DN. If no request DN can be mapped, the request is rejected.

The Consent Service only accepts an access token with a scope that it is configured to recognize.

`unprivileged-consent-scope`

An unprivileged consent scope designates the requester as unprivileged. The scope's name is configured with the Consent Service's `unprivileged-consent-scope` property.

`privileged-consent-scope`

A privileged consent scope designates the requester as privileged. This is configured using the Consent Service's `privileged-consent-scope` property.

> **Note**
>
> The authorization server must also be configured to issue tokens with these scopes.

Steps

- Configure the `privileged-consent-scope` and `unprivileged-consent-scope` for the Consent Service.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig set-consent-service-prop \
  --set unprivileged-consent-scope:consent \
  --set privileged-consent-scope:consent_admin
```

Authorization

The Consent Service's distinction between `privileged` and `unprivileged` requesters determines the type of operations that can be performed by requesters.

During the authorization phase, the Consent servlet performs checks on both the bearer token claims, if present, and the `auth DN` to determine if the requester is privileged or unprivileged. These are summarized in the following table.

Copyright © 2025 Ping Identity Corporation

Available operations per requester type

Requester type	Description	Access determined by	Can create consent records	Can update consent records	Can delete consent records
`Unprivileged`	Requesters with no authority to operate on consent records other than their own.	A requester is considered `unprivileged` if it does not meet any of the criteria for a `privileged` requester. If using bearer token authentication, the access token must include a scope named by the **`unprivileged-consent-scope`** property of the Consent Service configuration. Also, an unprivileged requester can only perform actions on consent records where the subject distinguished name (DN) matches the requester DN.	Yes. The subject/subjectDN and actor/actorDN values will be set based on the requester.	Yes, if the requester DN matches the subject DN.	No

Copyright © 2025 Ping Identity Corporation

Requester type	Description	Access determined by	Can create consent records	Can update consent records	Can delete consent records
`Privileged`	A requester with the authority to perform any operation on any consent record.	When using basic authentication, a requester is considered `privileged` if the requester DN either has the `bypass-acl` privilege or is listed in the `service-account-dn` property of the Consent Service configuration. If using bearer token authentication, the access token must include a scope named by the `privileged-consent-scope` property of the Consent Service configuration.	Yes	Yes	Yes

Bearer token check

If a bearer token was used, the following checks are performed:

- If the Consent Service's `audience` property is configured, the bearer token's audience claim must match the configured value.
- If the bearer token contains a scope matching the Consent Service's `privileged-scope-name` property, then the requester is considered privileged.
- If the bearer token doesn't contain a scope matching the Consent Service's `privileged-scope-name` property, the bearer token must have a scope matching the Consent Service's `unprivileged-scope-name` property, and the requester is considered unprivileged.

Basic authentication check

If basic authentication is used, the following checks are performed:

- If the `auth DN` has the Lightweight Directory Access Protocol (LDAP) privilege `bypass-acl`, the requester is `privileged`.

Copyright © 2025 Ping Identity Corporation

- If the `auth DN` is listed in the Consent Service's `service-account-dn` property, the requester is `privileged`.
- If the `auth DN` isn't listed in the Consent Service's `service-account-dn` property, the requester is considered `unprivileged`.

Managing Consents

This section provides information about the collection and end-user control of personal data as well as managing users' consents.

Managing users' consents includes the following topics:

- Overview of consent management
- Consent definitions and localizations
- Perform an audit on consents
- Logging
- Correlating user and consent data
- Troubleshooting the Consent Service

Overview of consent management

Consent management involves more than collecting the user's consent.

In the consent management life cycle:

1. The terms of each consent contract are centrally managed.
2. The user reviews previously granted consents and potentially revokes some of them.
3. Companies trace the history of updates to any consent in order to resolve a dispute or respond to audit.

Consent definitions and localizations

The Consent Service requires consent definitions and localizations, which collect and share a use's data and define the purpose for collecting and sharing this data.

Companies can centrally manage the language used when prompting a user to give consent to ensure a consistent user experience across multiple applications, such as mobile and web.

The Consent Service requires one or more consent definitions to be defined in the PingDirectory server configuration. Each consent definition represents the combination of:

- The data to be collected or shared
- The purpose for collecting or sharing the data

Copyright © 2025 Ping Identity Corporation

For example, a consent definition could represent users' email addresses that are used to deliver a third party's email newsletter. A consent definition could also represent access to a user's network-connected IoT device that could be used for a home automation task controlled by a third party.

Each consent definition must have one or more localizations. A localization is a versioned object consisting of the data that a Consent API client needs to prompt a user for consent. When a consent record is accepted or denied by a Consent Service client, it must include a reference to a consent definition, locale, and version.

Creating a consent definition and localization

Create and update a consent definition and localization.

Steps

- Create a consent definition using `dsconfig create-consent-definition`.

  Example:

  ```
  $ bin/dsconfig create-consent-definition \
    --definition-name email_newsletter \
    --set "display-name:Email newsletter"
  ```

- Create a localization for the consent definition using `dsconfig create-consent-definition-localization`.

  Example:

  ```
  $ bin/dsconfig create-consent-definition-localization \
    --definition-name email_newsletter \
    --localization-name en-US \
    --set version:1.0 \
    --set "data-text:Your email address" \
    --set "purpose-text:To receive newsletter updates"
  ```

- Update a localization and the version using `dsconfig set-consent-definition-localization-prop` and `set version`.

  Example:

  The following example updates a localization and its version.

  ```
  $ bin/dsconfig set-consent-definition-localization-prop \
    --definition-name email_newsletter \
    --localization-name en-US \
    --set version:1.1 \
    --set "data-text:Your preferred email address"
  ```

Perform an audit on consents

The Consent Service offers two types of audit logs to track changes and to perform audits on Consent Service resources.

Copyright © 2025 Ping Identity Corporation

For examples of configuring either type of log, see the `<server-root>/resource/consent-service-cfg.dsconfig` script bundled with the server or Logging.

This example uses the Consent Trace Logger, which represents Consent Service change events using the same field names used by the Consent API.

Log Publishers

Log publisher	Log publisher type	Description
collaborators	Trace logger key	The collaborators value, available only when the resource type is `consent`.
Consent Trace Logger	file-based-trace	Records Consent Service events at the Consent API level. Change events are recorded using messages of type `audit`.
Consent LDAP Audit Logger	file-based-audit	Records data changes at the LDAP level. In combination with a Request Criteria configuration object, an LDAP audit logger can be configured to record changes to Consent Service resources only.

Trace logger keys for auditing

Trace logger audit messages consist of a timestamp, the `CONSENT AUDIT` message type, and a set of key/value pairs.

> **Note**
>
> The keys used in trace log audit messages vary depending on the type of resource.

The following table describes a subset of important keys.

Trace logger key	Description
`requestID`	A server-specific HTTP request ID. This value can be correlated with messages produced by other loggers.
`resourceType`	The type of Consent Service resource that was changed. Possible values are `definition`, `localization`, or `consent`.
`changeType`	The type of change recorded by this message. Possible values are `create`, `update`, or `delete`.

Copyright © 2025 Ping Identity Corporation

Trace logger key	Description
`attrsAdded`	A comma-delimited list of the attributes that were added to the resource.
`attrsUpdated`	A comma-delimited list of the attributes that were modified on the resource.
`attrsDeleted`	A comma-delimited list of the attributes that were removed from the resource.
`requestDN`	The distinguished name (DN) of the requester, which is available only when the resource type is `consent`.
`definitionID`	The consent definition ID. The following list identifies the possible resource types and their definitions: **`definition`** Identifies the definition that was changed. **`localization`** Identifies the parent definition. **`consent`** Identifies the consent record's related definition.
`locale`	The locale. The following list identifies the possible resource types and their definitions: **`localization`** Identifies the localization in combination with the definition ID. **`consent`** Identifies the related localization combined with the definition ID.
`consentID`	The consent record ID, available only when the resource type is `consent`.
`subject`	The subject value, available only when the resource type is `consent`.
`subjectDN`	The subject's mapped LDAP DN. This is available only when the resource type is `consent`.
`actor`	The actor value. This is available only when the resource type is `consent`.

Copyright © 2025 Ping Identity Corporation

Trace logger key	Description
`actorDN`	The actor's mapped LDAP DN. This is available only when the resource type is `consent`.
`audience`	The audience value. This is available only when the resource type is `consent`.
`status`	The consent status. This is only available when the resource type is `consent`. Possible values are `pending`, `accepted`, `denied`, `revoked`, and `restricted`.
`previousStatus`	The previous consent status, if applicable. This is only available when the resource type is `consent`.
`msg`	A multiline value that includes the complete body of the changed resource. If the action is an `update` or a `delete`, the resource's body before the change is included.

Perform an audit

Consent resource changes for particular entities, such as a specific user or a specific consent definition, can be audited by searching the trace log using a combination of one of the message keys and the desired value.

For example, if an individual's LDAP distinguished name (DN) is known, the `subjectDN` key can be used to construct a text search for any audit log messages containing that DN. Any matching log messages constitute a history of that individual's consent activity.

New consent record example

This example shows an audit log message that provides important values in a parseable key/value format and includes a complete new consent record.

Copyright © 2025 Ping Identity Corporation

```
[22/May/2018:18:02:42.584 -0500] CONSENT AUDIT requestID=57 requestDN="uid=user.0,ou=people,
  dc=example,dc=com" consentID="6cff325b-e092-4094-b7f9-5a30864b0d24" subject="user.0" subjectDN="uid=user.
0,
  ou=People,dc=example,dc=com" actor="user.0" actorDN="uid=user.0,ou=People,dc=example,dc=com"

   'updatedDate':'2018-05-22T23:05:08.655Z'}"
```

Logging

Use the PingDirectory server trace log publisher for logging events generated by HTTP service operations.

About this task

You can use the trace logger to observe, debug, and audit consent requests.

Steps

- Create a trace logger for all consent events using `dsconfig create-log-publisher`.

> **Tip**
>
> To create a log of consent audit events only, remove all message types except for `consent-message-type:audit`.

Example:

The following example creates a trace logger for all consent events and summaries of HTTP requests and responses.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "Consent Trace Logger" \
  --type file-based-trace \
  --set "description:Records Consent API operations" \
  --set enabled:true \
  --set consent-message-type:audit \
  --set consent-message-type:consent-created \
  --set consent-message-type:consent-deleted \
  --set consent-message-type:consent-retrieved \
  --set consent-message-type:consent-search \
  --set consent-message-type:consent-updated \
  --set consent-message-type:definition-created \
  --set consent-message-type:definition-deleted \
  --set consent-message-type:definition-retrieved \
  --set consent-message-type:definition-search \
  --set consent-message-type:definition-updated \
  --set consent-message-type:error \
  --set consent-message-type:localization-created \
  --set consent-message-type:localization-deleted \
  --set consent-message-type:localization-retrieved \
  --set consent-message-type:localization-search \
  --set consent-message-type:localization-updated \
  --set http-message-type:request \
  --set http-message-type:response \
  --set 'exclude-path-pattern:/**/*.css' \
  --set 'exclude-path-pattern:/**/*.eot' \
  --set 'exclude-path-pattern:/**/*.gif' \
  --set 'exclude-path-pattern:/**/*.ico' \
  --set 'exclude-path-pattern:/**/*.jpg' \
  --set 'exclude-path-pattern:/**/*.js' \
  --set 'exclude-path-pattern:/**/*.png' \
  --set 'exclude-path-pattern:/**/*.svg' \
  --set 'exclude-path-pattern:/**/*.ttf' \
  --set 'exclude-path-pattern:/**/*.woff' \
  --set 'exclude-path-pattern:/**/*.woff2' \
  --set 'exclude-path-pattern:/console/**' \
  --set 'exclude-path-pattern:/console/**/template/**' \
  --set log-file:logs/consent-trace \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy"
```

Correlating user and consent data

An organization that has been granted consent by a group of users can perform an LDAP search so that they can use the consent data in the aggregate.

About this task

Copyright © 2025 Ping Identity Corporation

For this task, consider the example scenario where a marketing group has collected consent to send a newsletter by email. To find all the users that have granted consent to receive emails, the marketing group performs a search that lists all of the consent records where the consent definition is `email` and the status is `accepted`. Then, the marketing group must correlate these consent records to user entries and retrieve each user's email address.

Every consent record contains a `subject` field, the user whose data is collected and stored. You can configure the Consent Service so that it stores the subject's distinguished name (DN) in the **`subjectDN`** field.

Steps

- Perform a search using the **`ldapsearch`** command.

  Example:

  > **Note**
  >
  > The example includes the following modifications in the **`ldapsearch`** command:
  > - To correlate the consent record entries to user entries and retrieve each user entry's `mail` attribute value, **`ping-consent-subject-dn`** is used.
  > - To find all of the relevant consent record entries, the LDAP search specifies values where `ping-consent-definition.id` is `email` and the `ping-consent-status` is `accepted`.

  ```
  $ bin/ldapsearch \
     --baseDN "ou=consents,dc=example,dc=com" \
     --searchScope sub \
     --joinRule "dn:ping-consent-subject-dn" \
     --joinBaseDN "ou=people,dc=example,dc=com" \
     --joinScope sub \
     --joinRequestedAttribute mail
     '&(ping-consent-definition:jsonObjectFilterExtensibleMatch:={ "filterType" : "equals", "field" : "id",
  "value" : "email" })(ping-consent-state=accepted)' \
     1.1
  ```

  - A consent record's `subjectDN` field is the `ping-consent-subject-dn` attribute.
  - A consent record's status is in the `ping-consent-state` JSON attribute field.
  - A consent record's definition ID is in the `ping-consent-definition.id` JSON attribute field.
  - A user entry's email address is in the `mail` attribute.

    Result:

    The example LDAP search returns the following results.

Copyright © 2025 Ping Identity Corporation

```
# Join Result Control:
   #      OID:  1.3.6.1.4.1.30221.2.5.9
   #      Join Result Code:  0 (success)
   #      Joined With Entry:
   #           dn: uid=user.0,ou=People,dc=example,dc=com
   #           mail: user.0@example.com

   # Result Code:  0 (success)
   # Number of Entries Returned:  1
```

> **Note**
>
> The `Join Result Control:` output specifies the `mail` value.

Troubleshooting the Consent Service

This section provides general guidelines for troubleshooting the Consent Service and any connection issues.

When evaluating the configuration:

- Make sure that the Consent Service is enabled.
- Make sure that the Consent Service base distinguished name (DN) exists.
- Make sure that the Consent Service's service account has the correct permissions.
- If the Consent Service should accept bearer tokens, make sure that:
  - One or more access token validators are configured correctly.
  - The identity mappers for the access token validators are configured correctly.
  - The authorization servers are configured correctly to issue tokens that the Consent Service can accept. Check the `audience`, `privileged-consent-scope`, and `unprivileged-consent-scope` properties of the Consent Service configuration.
- If privileged users are defined, make sure that the members of the Lightweight Directory Access Protocol (LDAP) group are specified by the Consent Service configuration's `privileged-users-group-dn` property.
- If there are applications that allow individuals to manage their own consents, make sure that the system is properly configured to map `actor` and `subject` DNs. Check the Consent Service configuration's `consent-record-identity-mapper` property.

Error cases

The following topic discusses troubleshooting possible error cases and solutions.

Copyright © 2025 Ping Identity Corporation

Consent Service is unavailable

If the Consent Service is unavailable, check the following:

- Ensure that the service is enabled and that communication with the service is available.
- Confirm that the service account for the Consent Service has been properly provisioned.
- If the Consent Service resides on a PingDirectoryProxy server, make sure that the service account exists on the PingDirectoryProxy server and all PingDirectory servers behind the PingDirectoryProxy server.

Requester lacks sufficient rights to perform operation

A request might be rejected with a 403 for the following reasons:

- The bearer token does not contain a required scope. Check the `privileged-consent-scope` and `unprivileged-consent-scope` properties of the Consent Service configuration.
- The bearer token does not contain a required `audience` claim. Check the `audience` property of the Consent Service configuration.
- Authentication was successful, but the requester is `unprivileged` and attempted to perform an operation that only a `privileged` requester can perform. For example, the requester attempted to act upon a consent record that it does not own, or it attempted to delete a consent record.

When using basic authentication, the requester must be listed in the Consent Service configuration `service-account-dn` property to be considered `privileged`.

Subject and actor do not match

Only a `privileged` requester can `create` or `modify` a consent record whose `subject` and `actor` values do not match.

Unindexed search

The Consent Service doesn't allow a client to make an unindexed search. In most cases, a client should be able to fix this by refining the search. For example, if a search by `subject` is unindexed, perform a search by `subject` and `definition` ID.

Search size limit exceeded

The Consent Service caps the maximum number of records that can be returned in a search result using its `search-size-limit` configuration property. This limit can be increased, or the client might be able to refine the search to produce fewer results.

Copyright © 2025 Ping Identity Corporation

Delegated Admin Application Guide

Delegated Admin is an add-on to PingDirectory that enables the delegation of user and group management.

Introduction to Delegated Admin

Delegated Admin is an add-on to PingDirectory that enables the delegation of user and group management.

Delegated Admin lets organizations assign responsibilities associated with the management of identities in the PingDirectory server to a subset of administrators.

These delegated administrators can be any user outside the organization's IT department, including a customer.

The following employees typically fulfill roles that involve at least a basic level of identity management and represent strong candidates for inclusion in a group of delegated administrators:

- Help desk or customer service representatives who unlock and reset passwords
- Managers and Human Resources administrators who update employee profiles
- Application administrators who update identity attributes and manage access to applications

Features

Delegated Admin lets delegated administrators complete tasks across groups, subtrees, and entire organizations.

Tasks include:

- Create, view, and search user profiles.
- View user account information, including account status, last login time, and password expiration date.
- Update user attributes.
- Implement constructed attributes.
- Set attributes to `read-only`.
- Enable and disable accounts.
- Reset locked accounts.
- Create and edit groups.
- Manage the membership of groups and subgroups.
- Manage the roles of users and groups.
- Delete users, groups, and generic resource types.
- Implement custom UI form fields.
- Select user entries based on their distinguished names (DNs) without displaying the actual values of the DNs.
- Preview and download reports about user profiles. Reporting provides the following features:
    - Capability to report for resources of a given type or limited to members of a group

Copyright © 2025 Ping Identity Corporation

    - Ability to display multiple values per attribute for each user
    - Protection against spreadsheet formula injection
- Upload CSV files to add user, group membership, or organizational unit (OU) records.
- Trigger a password reset process for a user that invokes the self-service password reset process defined by the business.
- Configure REST Resource Types to correlate to other resource types to create one-to-many relationships without schema changes. Edit or delete linked entries from the edit page of the primary entry.

Installing Delegated Admin

Different options and procedures are available when you install Delegated Admin depending on your environment and the location of your installation.

To install Delegated Admin, read the following sections:

1. Check Installation requirements.
2. Prepare to install.
3. Obtain the installation files.
4. Install Delegated Admin:
    1. Install the application.
    2. Complete the installation.

Installation requirements

Before you install Delegated Admin, make sure you meet the requirements for the installation.

Before you begin

Regardless of the location of your Delegated Admin installation, ensure the following Ping Identity products are installed and configured before attempting to install Delegated Admin.

Product	Description	Version
PingDirectory server	Stores user-identity data. The HTTPS port that was configured during PingDirectory server setup is required to install Delegated Admin. For information about upgrading a PingDirectory server, see Upgrading the PingDirectory server. For information about installing and configuring a PingDirectory server, see the PingDirectory Server Administration Guide.	See Compatibility matrix.

Copyright © 2025 Ping Identity Corporation

Product	Description	Version
PingFederate Server	Provides identities for authentication and authorization. For information about installing and configuring PingFederate server, see Configuring the PingFederate server, or see thehttps://docs.pingidentity.com/csh?Product=pf-latest&context=pf_installing_pf[PingFederate Server Guide].	PingFederate 9.0.0 or later

Installation locations

The location that you choose determines the steps that you must perform to install Delegated Admin.

You can install Delegated Admin in any of the following locations:

- A PingDirectory server, including replicated instances
- A PingDirectoryProxy server
- External web server

Supported browsers

The following are the browsers supported by the Delegated Admin application and administrative console.

- Chrome
- Firefox
- Edge

Preparing to install Delegated Admin

To install Delegated Admin on a PingDirectory server or on a replicated instance of a PingDirectory server, complete the relevant tasks in this section before installing the application.

Copyright © 2025 Ping Identity Corporation

On a PingDirectory Server

Preparing to install Delegated Admin on a PingDirectory server
About this task

You can install Delegated Admin on a PingDirectory server with or without `Install with sample data` chosen as the installation option.

To install without `Install with sample data`, proceed to Obtaining the installation files.

To install with `Install with sample data`:

Steps

- Remove the relevant access control instruction (ACI) from the PingDirectory server base entry.

  For more information, see the `delegator/remove-sample-directory-data-aci.ldif` file.

On a replicated instance of PingDirectory Server

Preparing to install Delegated Admin on a replicated instance of the PingDirectory server
About this task

To install Delegated Admin on a replicated instance of the PingDirectory server:

Steps

1. Make sure that replication is enabled for the PingDirectory servers.

   For information about enabling server replication, see Managing replication.

2. To ensure that configuration changes are applied to all the servers in your topology, configure the PingDirectory servers to use a configuration group called `all-servers`.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --set configuration-server-group:all-servers
   ```

3. If you are installing Delegated Admin on a replicated PingDirectory server that had `Install with sample data` chosen as the installation option, remove the relevant ACI from the PingDirectory server base entry.

   > **Note**
   >
   > Because replicated instances share the same data, perform this step against only one of the servers. For more information, see the LDIF file `delegator/remove-sample-directory-data-aci.ldif`.

4. If you're installing Delegated Admin on a PingDirectory server installation that didn't have `Install with sample data` chosen as the installation option, proceed to Obtaining the installation files.

Copyright © 2025 Ping Identity Corporation

Obtaining the installation files

Obtain the Delegated Admin installation files from the Add-ons tab of the PingDirectory downloads page.

Steps

1. Download the Delegated Admin installation package, `pingdirectory-delegator-{version}.zip`, to the server on which you plan to install the application.
2. Extract the contents of the installation package.
3. Copy the folder named `/delegator` and its contents to the appropriate directory as shown in the following table.

Server	Directory
PingDirectory Server	`/webapps`
Replicated instance of PingDirectory Server	`/webapps`
PingDirectoryProxy Server	`/webapps`
External web server	Directory for web-based apps

Installing the application

The steps for installing Delegated Admin depend on whether you are setting up the application in a Unix or Linux environment or in a Windows environment.

> **Important**
>
> In all environments, if port 443 is used but not specified in the PingFederate Base URL, do not assign a value to `window.PF_PORT`.

Copyright © 2025 Ping Identity Corporation

Unix or Linux

Unix or Linux
About this task

To begin installing Delegated Admin in a Unix or Linux environment:

Steps

- Run the following script in the `/delegator` directory that you obtained in Obtaining the installation files.

```
$ ./set-up-delegator.sh
```

Result:

The system generates:

- A configuration file, `config.js`, located in the `/webapps/delegator/app` directory.
- A batch file, `delegated-admin.dsconfig`, in the `/webapps/delegator` directory.

The `setup` tool also generates several command-line prompts for completing the Delegated Admin installation. After you provide the distinguished name (DN) of the root user for your PingDirectory instance, you're prompted to enter information regarding your PingFederate server and the hosting location of the Delegated Admin web app. Enter your own values or press Enter to accept the default values.

> **Note**
>
> If you answer `y` to the **`setup`** script question `Is Delegated Admin being installed in a topology containing PingDirectoryProxy?`, the system also generates a batch file, `delegated-admin-for-proxy.dsconfig` in the `/webapps/delegator` directory.

Copyright © 2025 Ping Identity Corporation

Windows

Windows
About this task

To install Delegated Admin in a Windows environment:

Steps

1. In the Delegated Admin application directory, copy or rename the file `example.config.js` to `config.js`. `config.js` contains comments and placeholders for necessary information. For example, the Client ID that is required in this file must be one of the Client IDs that has been defined for the PingFederate configuration. This value represents the client intended for token issuance, such as `dadmin`.
2. Open `config.js` in a text editor.
3. Change the variable values to match your setup configuration.

config.jsVariable	Value
`window.PF_HOST`	Public address of the PingFederate server to which the application redirects the user's browser when signing on.
`window.PF_PORT`	PingFederate port number. **Note** If port 443 is used but not specified in the PingFederate Base URL, do not assign a value to `window.PF_PORT`.
`window.DADMIN_CLIENT_ID`	PingFederate Client ID for the application.

4. Save your changes to `config.js`.
5. Concatenate the following files into a single file named `delegated-admin.dsconfig`:
   - `delegated-admin-template-common.dsconfig`
   - `delegated-admin-template-ds.dsconfig`
   - `delegated-admin-template-ds-or-proxy.dsconfig`
   - `delegated-admin-template-webapp.dsconfig`
6. Open `delegated-admin.dsconfig` in a text editor and replace the variables, `${variable}`, with actual values.
7. Save your changes to `delegated-admin.dsconfig`.

Copyright © 2025 Ping Identity Corporation

Completing the installation

Regardless of whether you are installing Delegated Admin in a Unix or Linux or Windows environment, perform the relevant steps in this section after you complete the previous OS-specific tasks.

PingDirectoryProxy Server

The PingDirectoryProxy server
Before you begin

> **Note**
>
> The following task assumes that when you ran the **`setup`** command, you answered `y` to the question `Is Delegated Admin being installed in a topology containing PingDirectoryProxy?`

About this task

If you are installing Delegated Admin on the PingDirectoryProxy server, you must configure the proxy instance using the **`delegated-admin-for-proxy.dsconfig`** script as described in All locations except PingDirectoryProxy server.

To configure all instances of the PingDirectory server:

Steps

1. Apply the commands from the `delegated-admin.dsconfig` batch file to all instances of the PingDirectory server.

```
$ ./bin/dsconfig \
  --bindDN "cn=Directory Manager" \
  --bindPassword <password> \
  --no-prompt \
  --batch-file webapps/delegator/delegated-admin.dsconfig \
  --applyChangeTo server-group
```

2. Apply the commands from the `delegated-admin.dsconfig` batch file to all instances of the PingDirectory server, as explained in Replicated instances of the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

Replicated instances of PingDirectory Server

Replicated instances of the PingDirectory server
About this task

If you are installing Delegated Admin on one or more replicated instances of the PingDirectory server:

Steps

- **Apply the following commands in `delegated-admin.dsconfig` to each instance:**

```
$ ./bin/dsconfig \
  --bindDN "cn=Directory Manager" \
  --bindPassword <password> \
  --no-prompt \
  --batch-file webapps/delegator/delegated-admin.dsconfig \
  --applyChangeTo server-group
```

Copyright © 2025 Ping Identity Corporation

External web server

External web server
Before you begin

> **Note**
>
> The following steps assume that when you ran the **`setup`** command, you answered `n` to the question `Will the web app be hosted in PingDirectory?`

About this task

To install Delegated Admin on an external web server:

Steps

1. Open `config.js` in a text editor.
2. Change the variable values to specify the location of PingDirectory Server.

config.jsVariable	Value
`window.DS_HOST`	Host name of PingDirectory Server
`window.DS_PORT`	HTTPS port of PingDirectory Server

   To view an example outline that features these settings, see `example.config.js`.
3. Save your changes to `config.js`.
4. Create a CORS policy for the Delegated Admin HTTP servlet extension, where <*origin*> represents the public name of the host, proxy, or load balancer that presents the Delegated Admin web application:

   Example:

```
dsconfig create-http-servlet-cross-origin-policy
  --policy-name "Delegated Admin Cross-Origin Policy"
  --set "cors-allowed-methods: GET"
  --set "cors-allowed-methods: OPTIONS"
  --set "cors-allowed-methods: POST"
  --set "cors-allowed-methods: DELETE"
  --set "cors-allowed-methods: PATCH"
  --set "cors-allowed-origins: <origin>"

dsconfig set-http-servlet-extension-prop
  --extension-name "Delegated Admin"
  --set "cross-origin-policy:Delegated Admin Cross-Origin Policy"
```

5. (Optional) If you will be enabling administrators to run Delegated Admin reports in your configuration, run **`dsconfig`** with the `set-http-servlet-cross-origin-policy-prop` option:

Copyright © 2025 Ping Identity Corporation

Example:

```
dsconfig set-http-servlet-cross-origin-policy-prop \
  --policy-name "Delegated Admin Cross-Origin Policy" \
  --set cors-exposed-headers:Content-Disposition
```

All locations except PingDirectoryProxy server

About this task

To continue installing Delegated Admin on a PingDirectory server or an external web server:

Steps

- Run the following command with `delegated-admin.dsconfig` on the appropriate server:

```
$ ./bin/dsconfig \
  --bindDN "cn=Directory Manager" \
  --bindPassword <password> \
  --no-prompt \
  --batch-file webapps/delegator/delegated-admin.dsconfig
```

Next steps

> **Important**
>
> You cannot sign on to Delegated Admin until you configure the rights of the delegated administrators. For more information about configuring administrative rights, the REST resource type, session timeout values, and other properties, see Configuring Delegated Admin.

After you configure Delegated Admin, verify that the application is installed and working successfully.

Upgrading Delegated Admin

Ping Identity periodically issues software with new features, enhancements, and fixes for improved performance. Administrators can use the PingDirectory server's `update` tool to upgrade the current code version.

This section presents some update scenarios and the related implications when upgrading your version of Delegated Admin.

Upgrade considerations

Consider the following points when upgrading your version of Delegated Admin.

Copyright © 2025 Ping Identity Corporation

Considerations

> **Note**
>
> If you're running Delegated Admin 3.5 or earlier, upgrade it to the latest version to use PingDirectory 8.0 or later. For information about the compatibility between Delegated Admin and PingDirectory server versions, see the Compatibility matrix.

Upgrade considerations introduced in Delegated Admin 4.9

The default OpenID Connect (OIDC) grant type used by the `dadmin` client has been updated to Authorization Code with PKCE. The Delegated Admin application will continue to function normally with the Implicit grant type.

If you want to switch to Authorization Code with PKCE, see Changing the default OIDC grant type.

Upgrade considerations introduced in Delegated Admin 4.8

Two new permissions that affect user resource types have been added in Delegated Admin 4.8:

- `Update-profile` grants the ability to update user profiles without allowing password-related privileges.
- `Reset-password` grants the permission to reset passwords without the ability to change other user attributes.

To preserve current admin rights, no action is required after you upgrade.

For more information, see Configuring delegated administrator rights on the PingDirectory server.

Upgrade considerations introduced in Delegated Admin 4.6

To use the functionality that allows a help desk agent to trigger a password reset for a user, you must enable the Modifiable Password Policy State Plugin on the PingDirectory server that serves as a resource backend.

To enable the `Initiate Password Reset` menu option on user entries, perform the following steps:

1. Run the following command to enable the plugin needed for triggering Initiate Password Reset:

```
dsconfig set-plugin-prop \
--plugin-name "Modifiable Password Policy State Plugin" \
--set enabled:true --set "base-dn:${searchbasedn}" \
--set "filter:(|(objectClass=person)(objectClass=ds-cfg-user))"
```

2. Run the following command to add a Delegated Admin attribute to the users rest type for `ds-pwp-modifiable-state-json`:

```
dsconfig create-delegated-admin-attribute \
--type-name users  \
--attribute-type ds-pwp-modifiable-state-json  \
--set "display-name:Modifiable Password Policy State"  \
--set display-order-index:9999
```

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> When you install Delegated Admin 4.6 using the `delegated-admin.dsconfig` script, the Modifiable Password Policy State plugin is enabled. If you're upgrading from a previous version of Delegated Admin, you must manually enable the plugin and add the `ds-pwp-modifiable-state-json` attribute as a Delegated Admin attribute.

Upgrading the Delegated Admin application

Upgrade Delegated Admin to improve security.

Before you begin

If you are running Delegated Admin 4.3 or earlier, upgrade it to the latest version to use PingDirectory 8.2 or later. For information about the compatibility between Delegated Admin and PingDirectory server versions, see the Compatibility matrix.

About this task

To upgrade Delegated Admin on PingDirectory server:

Steps

1. Extract the contents of the Delegated Admin upgrade `.zip` archive.
2. Rename the original `delegator` folder to retain a backup copy of the earlier version.
3. Copy the extracted folder named `delegator` to the PingDirectory server folder named `webapps`.
4. Copy the `{OriginalDelegatorFolder}/app/config.js` configuration file to the new `delegator` folder.
5. Restart PingDirectory server by running `$ bin/stop-server --restart`

.

Configuring Delegated Admin

This section describes the necessary configuration to support Delegated Admin after the application is installed successfully.

At a minimum, you must configure the following properties on the PingDirectory server:

- Delegated administrator rights
- REST resource type
- Attributes and attribute searching

Configuration overview

Delegated Admin must have a PingDirectory server and PingFederate server installed.

For installation instructions, see the documentation for each product.

Copyright © 2025 Ping Identity Corporation

The process of configuring support for Delegated Admin on a PingDirectory server includes the following tasks:

- Configure users as Delegated Admin administrators.
- Configure attributes and attribute searching.
- Configure groups whose management requires delegation.

The process of configuring a PingFederate server includes the following tasks:

- Configure PingFederate as the identity provider for Delegated Admin.
- Configure PingFederate as the OAuth server for Delegated Admin.
- Register Delegated Admin as a client.
- Register the PingDirectory server as an OAuth token validator client.

Authentication configuration

The delegated administrator signs on to Delegated Admin through the PingFederate server, which is configured as the authentication server and OpenID Connect (OIDC) provider.

PingFederate validates the user's credentials against the PingDirectory server, encapsulates information `claims` about the user's identity, and issues an access token to Delegated Admin, which presents the token to the PingDirectory server in the HTTP Authorization request header.

Interaction with the PingDirectory server

The PingDirectory server is configured to accept access tokens by using access token validators. The values that the PingFederate server sets for the access token `sub` claim must be mappable to a distinguished name (DN) in the PingDirectory server. Setting up an access token validator for use with Delegated Admin requires some coordination with the server configuration. In the suggested default configuration, the access token contains the entryUUID of the administrator user entry in the `sub` claim. This value is mapped back to a PingDirectory server entry by using an Exact Match Identity Mapper.

Authorization by the PingDirectory server

After validation, the PingDirectory server checks the Delegated Admin configuration for authorization of the delegated administrator. Users or groups of users are authorized as delegated administrators in the PingDirectory server administrative console,or with the `dsconfig` tool.

Configure authentication

One of the prerequisites to installing Delegated Admin is to configure the following OAuth clients within PingFederate:

- Delegated Admin, which obtains an OIDC token that describes the authenticated user. For more information, see Configuring Delegated Admin as a new client (create OAuth client for Delegated Admin).
- The PingDirectory server itself, which calls PingFederate to validate the OIDC token that Delegated Admin passes to it. For more information, see Configuring the PingDirectory server as the token validator (create OAuth client for PingDirectory).

Copyright © 2025 Ping Identity Corporation

Configuring delegated administrator rights on the PingDirectory server

To delegate users or groups as administrators, use the PingDirectory Server Administrative Console (Delegated Admin rights and resource rights) or the `dsconfig create-delegated-admin-rights` and `create-delegated-admin-resource-rights` commands.

About this task

To use Delegated Admin, an administrator must possess rights that are designated through the PingDirectory server configuration in addition to valid credentials and an access token that the PingDirectory server can validate. Admin Permissions

`create`

The administrator can create new resources of this type.

`read`

The administrator can read resources of this type.

> **Note**
>
> The `create`, `delete`, `update`, `update-profile`, `reset-password`, and `manage-group-membership`, `update` permissions require the `read` permission.

`update`

The administrator can edit resources of this type.

`delete`

The administrator can delete resources of this type.

`update-profile`

The administrator can update user profiles but isn't allowed password- change-related privileges.

For group and generic type resources, the `update-profile` permission gives the same rights as the `update` permission.

`reset-password`

The administrator can reset passwords without the ability to change other user attributes.

`manage-group-membership`

The administrator can manage the membership of a group resource by adding or removing members. This permission is only applicable to group resource types.

Copyright © 2025 Ping Identity Corporation

`reference`

The administrator can reference resources when selecting a parent during the creation of another resource. With the reference permission specified, the administrator can use a parent REST resource type without seeing the option to manage the parent resource type. For example, if the parent type for users is Organizational Unit, the administrator can have reference rights to the Organizational Unit resource type only. The administrator can create users without seeing the Manage Organizational Unit navigation option.

The administrator can reference resource types in Delegated Admin attributes. For example, the administrator can select user entries from a list based on their distinguished names (DNs) without displaying the actual values of the DNs.

`download`

The administrator can download reports for resources of this type. With this permission, the Download Report button shows on the Reporting page for the administrator.

`upload`

The administrator can upload a `.csv` file to import resources of this type. With this permission, the Upload File button shows on the Reporting page for the administrator.

> **Note**
>
> For the parent resource type to be available for the creation of new entries under the parent, the `read` or `reference` permission must be specified.

To prevent changes that might break the configuration of the app, the app does not allow changes to RDN attributes of a resource entry DN, for resources referenced in the Delegated Admin server configuration. This includes the following configuration elements:

- `admin-user-DN` and `admin-group-DN` of Admin Rights
- `resource-subtree` and `resources-in-group` of Admin Resource Rights

For example, if an Admin Rights configuration contains `admin-group-DN: cn=Admin Group,dc=example,dc=com` and some administrator has rights to modify that particular group through the app, then the `cn` attribute of that group can't be changed without invalidating the configuration. The attribute label has a lock icon and a message indicating that the value can only be changed by a server administrator.

The example commands that follow illustrate the configuration options for delegated administration and are performed on the PingDirectory server.

> **Note**
>
> Administrators who manage only specific subtrees can't create users in an organization that does not reside under, or at the same level as, one of the subtrees.

Steps

- Restrict an administrator to manage users in specified subtrees.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name admin1 \
  --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com" \
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name admin1 \
  --rest-resource-type users \
  --set admin-scope:resources-in-specific-subtrees \
  --set "resource-subtree:ou=org1,dc=example,dc=com" \
  --set admin-permission:create \
  --set admin-permission:read \
  --set admin-permission:update \
  --set admin-permission:delete \
  --set enabled:true
```

- Restrict an administrator to managing the member users of one or more specified groups.

  Example:

  In the following example, assume the existence of a static or dynamic group entry whose members include the users to be managed.

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name admin1 \
  --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com"
  --set enabled:true
$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name admin1 \
  --rest-resource-type users \
  --set admin-scope:resources-in-specific-groups \
  --set "resources-in-group:cn=User Group,dc=example,dc=com" \
  --set admin-permission:read \
  --set admin-permission:update \
  --set enabled:true
```

- Assign the delegated admin rights to a group REST resource type that matches the specified group.

  For more information, see Manage groups.

- Rather than delegate a single user as an administrator, delegate an entire group of users as administrators.

  For more information about the PingDirectory server administrators and configuring dynamic and static groups, see the PingDirectory Server Administration Guide.

  Example:

  In this example, groups can be configured to manage specific subtrees or groups with the `resources-in-specific-subtrees` or `resources-in-group` setting for the `admin-scope`.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name admin-group1 \
  --set "admin-group-dn:cn=Admin Group,ou=people,dc=example,dc=com"
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name admin-group1 \
  --rest-resource-type users \
  --set admin-scope:all-resources-in-base \
  --set admin-permission:create \
  --set admin-permission:read \
  --set admin-permission:update \
  --set admin-permission:delete \
  --set enabled:true
```

Parameterized Delegated Administrator Rights

Delegated Admin rights can be parameterized so that a single definition provides a pattern for new administrators.

This allows a privileged administrator for a hosting company to use Delegated Admin to onboard a new tenant administrator to manage resources for the tenant's own organization. Using parameterized rights eliminates the need for the PingDirectory server configuration changes to create a new administrator.

In the following example, it's assumed that there are three REST resource types configured:

- `orgs`
- `groups`
- `users`

The users resource type has the parent resource type orgs.

```
$ bin/dsconfig create-delegated-admin-rights \
--rights-name "Tenant Admin" \
--set enabled:true \
--set 'admin-group-dn:cn=($1),ou=groups,dc=example,dc=com'

$ bin/dsconfig create-delegated-admin-resource-rights \
--rights-name "Tenant Admin" \
--rest-resource-type users --set enabled:true \
--set admin-permission:create \
--set admin-permission:read --set admin-permission:update \
--set 'resource-subtree:ou=($1),dc=example,dc=com'

$ bin/dsconfig create-delegated-admin-resource-rights \
--rights-name "Tenant Admin" \
--rest-resource-type orgs --set enabled:true \
--set admin-permission:reference \
--set 'resource-subtree:ou=($1),dc=example,dc=com'
```

Copyright © 2025 Ping Identity Corporation

A privileged admin can perform the following steps to onboard a new tenant in Delegated Admin:

- Add a new `org` for the tenant.
- Add a new `group` with the same name as the new `org`, representing the tenant admins.
- Add a new `user` representing an initial tenant admin.
- Add the new tenant admin user to the tenant admin group

The tenant admin user can now sign on to the app and manage users for their own organization.

Configuring user self-service

The PingFederate server provides end users with the ability to self-service their own profiles.

About this task

Additional configuration steps must be taken in both PingDirectory and PingFederate to enable users whom delegated administrators create to manage their own profiles through the PingFederate local identity profile-management feature.

> **Note**
>
> Import the Ping Federate LDIF first in PingDirectoryProxy and then in PingDirectory. Constructed attributes need to be created only in PingDirectoryProxy. Creating and rebuilding indexes (part of the self-service configuration) is done on PingDirectory.

Steps

1. Configure PingFederate for profile management.

   To allow users to change their passwords, enable Allow Password Changes in the HTML Form Adapter. You must make this change if you want to create passwords that the user must change on the first use. For example PingFederate configuration steps, see Customer IAM configuration.

   Setting up PingDirectory for customer identities in the PingFederate Administrator's Manual includes some of the following required steps on the PingDirectory server.

2. To create passwords that the user must change on the first use after account creation or a password reset, configure a PingDirectory password policy to force users to change their passwords.

   Example:

   This policy requires that you enable Allow Password Changes as mentioned above.

   ```
   dsconfig set-password-policy-prop --policy-name "Default Password Policy" \
   --set force-change-on-add:true --set force-change-on-reset:true
   ```

   Result:

   With these changes, when a user signs on to the PingFederate self-service page, the page prompts the user to change their password.

Copyright © 2025 Ping Identity Corporation

3. Import the required additional LDAP schema provided by PingFederate into PingDirectory.

    1. On the PingFederate server, copy the LDIF file `local-identity-pingdirectory.ldif` from the following location: `<pf_install>/pingfederate/server/default/conf/local-identity/ldif-scripts/local-identity-pingdirectory.ldif`.

    2. Use the `scopy` command to securely copy the LDIF file to your local machine.

4. Update the LDAP schema.

    1. Sign on to the PingDirectory administrative console.

    2. Go to LDAP Schema → Schema Utilities.

    3. Click Import Schema Element.

    4. Copy the schema changes from the file `<pf_install>/pingfederate/server/default/conf/local-identity/ldif-scripts/local-identity-pingdirectory.ldif`.

    5. Paste the schema changes into the text area.

    6. Click Import.

5. Create an equality index for the pf-connected-identity attribute.

```
$ bin/dsconfig create-local-db-index \
  --backend-name userRoot \
  --index-name pf-connected-identity \
  --set index-type:equality
```

6. After adding the index, use the rebuild-index utility to build the indexes.

    Example:

    For instance, the following sample builds the required index.

```
$ bin/rebuild-index \
  --baseDN "dc=example,dc=com" \
  --index pf-connected-identity
```

7. Configure PingDirectory Server Composed Attributes.

    In previous versions of Delegated Admin, the remaining configuration was achieved by setting a constructed attribute on the user REST resource type. In the latest version, composed attribute plugins should be used instead as they provide the following advantages:

    - The populate-composed-attribute-values tool can be used to enable self-service for any existing users.
    - Self-service is enabled for any users not created through the Delegated Admin app.

    Configure two Composed Attribute Plugins as follows:

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> *<users-base-dn>* and *<users-object-class>* must be replaced with the search base DN and structural object class of your REST Resource Type.

```
$ bin/dsconfig create-plugin \
  --plugin-name pf-connected-identities \
  --type composed-attribute \
  --set enabled:true \
  --set attribute-type:objectClass \
  --set value-pattern:pf-connected-identities \
  --set target-attribute-exists-during-initial-population-behavior:merge-existing-and-composed-values \
  --set "include-base-dn:<users-base-dn>" \
  --set "include-filter:(objectClass=<users-object-class>)"

$ bin/dsconfig create-plugin \
  --plugin-name pf-connected-identity \
  --type composed-attribute \
  --set enabled:true \
  --set attribute-type:pf-connected-identity \
  --set "value-pattern:auth-source=pf-local-identity:user-id={entryUUID}" \
  --set "include-base-dn:<users-base-dn>" \
  --set "include-filter:(objectClass=<users-object-class>)"
```

If you configure composed attribute plugins as described after upgrading an existing deployment, then you should remove the old constructed attribute configuration as follows.

```
$ bin/dsconfig set-rest-resource-type-prop --type-name users \
  --remove auxiliary-ldap-objectclass:pf-connected-identities \
  --remove post-create-constructed-attribute:pf-connected-identity \
  --remove update-constructed-attribute:pf-connected-identity
```

8. (Optional) Enable self-service for any existing users not already linked to PingFederate.

```
$ bin/populate-composed-attribute-values -h  <host>  -p  <port>  -D "cn=Directory Manager" -w  <password>
```

Configuring attributes and attribute search on the PingDirectory server

Use the Delegated Admin installation file to configure attributes and attribute search.

About this task

The file that installs Delegated Admin specifies the following values:

- Object class of user entries through `structural-ldap-objectclass:inetOrgPerson`
- Number of user attributes to expose

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Delegated Admin supports the following attribute types:
>
> - `Boolean`
> - `Integer`
> - `String`
> - `DateTime`
> - Distinguished name (DN)
> - Custom attributes
> - Constructed attributes
> - Multivalued attributes

Steps

1. **If necessary, change the attribute that is designated as the primary attribute.**

   Example:

   ```
   $ bin/dsconfig set-rest-resource-type-prop \
     --type-name users \
     --set primary-display-attribute-type:mail
   ```

2. **Configure any additional user attributes to appear in Delegated Admin by specifying the LDAP attribute type to expose and by providing a display name for it.**

   Example:

   ```
   $ bin/dsconfig create-delegated-admin-attribute \
     --type-name users \
     --attribute-type customAttr
     --set "display-name:My custom attribute"
   ```

3. **Configure attributes with distinguished name (DN) syntax on resource types to provide a reference from one resource to another.**

   Such an attribute is the standard LDAP `manager` attribute.

   The referencing resource doesn't have to be the same type of resource as the referenced resource. Delegated Admin allows the referenced resource to be selected without displaying the actual value of the DN.

   Example:

   In this example, the `manager` attribute is included in the users resource type, and its value is constrained to reference only resources of type `managers`. The `managers` REST Resource Type is assumed to have already been defined.

   ```
   $ bin/dsconfig create-delegated-admin-attribute \
     --type-name users \
     --attribute-type manager \
     --set display-name:Manager \
     --set reference-resource-type:managers
   ```

   Example:

Copyright © 2025 Ping Identity Corporation

Additionally, the Delegated Admin resource rights for the administrator must provide either read or reference permission to `managers`.

```
$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name Admin \
  --rest-resource-type managers \
  --set enabled:true \
  --set admin-permission:reference \
  --set admin-scope:all-resources-in-base
```

For more information about resource rights and permissions, see Configuring delegated administrator rights on the PingDirectory server.

4. Use the following command to set the search filter, where `%%` represents the search text entered in the web application.

   Example:

   ```
   $ bin/dsconfig set-rest-resource-type-prop \
     --type-name users \
     --set 'search-filter-pattern:(|(cn=%%)(mail=%%)(uid=%%))'
   ```

   When search text is entered in Delegated Admin, the property `search-filter-pattern` specifies which attributes to search in the PingDirectory server. To satisfy the query, define the appropriate attribute indexes for the PingDirectory server. For more information, see the PingDirectory Server Administration Guide.

5. To manage users whose profiles feature a large number of attributes, place the attributes in logical groupings, called attribute categories, and give them a specific display order.

   Example:

   The following commands create attribute categories and specify their display order.

   ```
   $ bin/dsconfig create-delegated-admin-attribute-category \
     --display-name "Basic Information" \
     --set display-order-index:1

   $ bin/dsconfig create-delegated-admin-attribute-category \
     --display-name "Contact Information" \
     --set display-order-index:2

   $ bin/dsconfig create-delegated-admin-attribute-category \
     --display-name "Other Attributes" \
     --set display-order-index:3
   ```

6. The following example commands assign attributes to a category and specify the display order of each attribute within its category.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-delegated-admin-attribute-prop \
  --type-name users \
  --attribute-type cn \
  --set "attribute-category:Basic Information" \
  --set display-order-index:1

$ bin/dsconfig set-delegated-admin-attribute-prop \
  --type-name users \
  --attribute-type sn \
  --set "attribute-category:Basic Information" \
  --set display-order-index:2
```

Unassigned attributes are displayed in a miscellaneous category.

7. For multivalued LDAP attributes, indicate whether the application should present them as multivalued.

   If not specified, the attributes are presented in the application as single-valued, even if the LDAP schema definition for the attribute allows multiple values.

   > **Note**
   >
   > This setting does not apply to attributes that are handled by custom UI form fields.

   Example:

```
$ bin/dsconfig set-delegated-admin-attribute-prop \
 --type-name users \
 --attribute-type mail \
 --set multi-valued:true
```

Constructed attributes

A constructed attribute is an attribute whose value is computed from values that are assigned to other attributes. For example, the system might construct a full- or common-name attribute, `cn`, from values that are assigned to the standard `givenName` and `sn` attributes, as follows.

```
dsconfig create-constructed-attribute
  --attribute-name ReqConstructedCN --set attribute-type:cn \
  --set 'value-pattern:{givenName} {sn}'
```

Beginning with Delegated Admin 3.5.0 and PingDirectory server 7.3.0.1, the value of a constructed attribute can be updated automatically whenever the value of a source attribute is not only creted, but also when it is edited.

```
dsconfig set-rest-resource-type-prop \
  --type-name users  \
  --set post-create-constructed-attribute:ReqConstructedCN  \
  --set update-constructed-attribute:ReqConstructedCN
```

Copyright © 2025 Ping Identity Corporation

In these examples, a change to the value of `givenName` or `sn` forces a corresponding change to the value of `cn`. Attributes that contribute to a required constructed attribute are identified in the UI as Required even if they were not originally designated as such. Because `cn` is a required attribute in this example, `givenName` and `sn` are also required.

> **Note**
>
> An attribute's capability of being changed after its creation is called its mutability.

As with standard attributes, constructed attributes are stored as LDAP attributes in a database like the PingDirectory server.

Setting an attribute to read-only

About this task

Beginning with Delegated Admin 3.5.0 and PingDirectory 7.3.0.1, you can set user access to standard and constructed attributes to `read-only` and `read/write`. You should restrict access to constructed attributes to `read-only`. Read-only attributes do not appear on the UI pages that are associated with the creation of users groups and other objects.

Steps

- Use the `dsconfig` tool to set a standard or constructed attribute as `read-only`.

  Example:

  ```
  dsconfig set-delegated-admin-attribute \
    --type-name users  \
    --attribute-type modifyTimestamp  \
    --set mutability:read-only
  ```

  Example:

  The following example resets a standard or constructed attribute from `read-only` to `read/write`.

  ```
  dsconfig set-delegated-admin-attribute \
    --type-name users  \
    --attribute-type modifyTimestamp  \
    --reset mutability
  ```

Users and groups

You can configure delegated administrators to manage users and groups in the PingDirectory server.

Configuring delegated administrators involves the following:

- Create new entries.
- Read, view, and search existing entries.
- Edit and update existing entries.
- Edit referenced items.

Copyright © 2025 Ping Identity Corporation

For example, if a delegated administrator is viewing an item that references a user, the delegated administrator can edit that user's information inline.

The following sections describe users and groups in more detail.

Enable user creation

Enable the creation of new users and resources by configuring either a parent entry distinguished name (DN) or parent resource type where new users will be located.

If you configure a parent DN, the entry that it references must exist in the PingDirectory server. All new users are created in this single location. If necessary, use `ldapmodify` to create the parent entry. For more information about the `ldapmodify` tool or about command-line help, see the PingDirectory Server Administration Guide. Alternatively, if a parent resource type is configured, the administrator can choose the specific resource where the new user is created.

> **Note**
>
> Delegated Admin cannot list organizations in which the delegated administrator is unable to manage user entries. Administrators who manage only specific subtrees cannot create users in an organization that does not reside under, or at the same level as, one of the subtrees.

The following example specifies a single location for new users on the PingDirectory server.

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set "parent-dn:ou=people,dc=example,dc=com" \
  --reset parent-resource-type
```

The setup script creates a resource type named `orgs`, which works with entries that feature the `organization objectClass`.

The following example shows that any organization resource can function as the location for new users on the PingDirectory server.

```
$ bin/dsconfig set-rest-resource-type-prop \
   --type-name users \
   --reset parent-dn \
   --set parent-resource-type:orgs
```

A different resource type can be created for `organizationalUnit objectClass` entries, as follows.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-rest-resource-type \
  --type-name orgUnits \
  --set "display-name:Organizational Units" \
  --set primary-display-attribute-type:ou \
  --set "search-filter-pattern:(&(objectClass=organizationalUnit)(ou=%%))" \
  --set structural-ldap-objectclass:organizationalUnit \
  --set enabled:false

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name orgUnits \
  --attribute-type ou \
  --set "display-name:Organizational Unit"

$ bin/dsconfig set-rest-resource-type-prop \
  --type-name orgUnits \
  --set enabled:true
```

The new resource type can be referenced as a `parent-resource-type`.

By default, new entries are named by their server-generated `entryUUID` values. To change this behavior, configure the LDAP `RDN` attribute.

> **Note**
>
> The `RDN` attribute type must also be configured as a Delegated Admin attribute. For more information, see Configuring attributes and attribute search on the PingDirectory server. Do not set read-only attributes as the `RDN` attribute.

In the following example, `uid` names new entries and becomes a required attribute.

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set create-rdn-attribute-type:uid
```

New users are always created with their configured structural LDAP `objectclass`. One or more auxiliary LDAP `objectclasses` can be specified, as the following example shows.

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set auxiliary-ldap-objectclass:ubidPersonAux
```

When existing users without all of the specified auxiliary `objectclasses` are edited, the missing `objectclasses` are updated automatically.

By default, the password field appears at the top of the Create User form outside any category. The next example adds the password field to the Required fields category and sets the location of the field to 2.

Copyright © 2025 Ping Identity Corporation

```
dsconfig set-rest-resource-type-prop \
    --type-name users \
    --set "password-attribute-category:Required fields" \
    --set password-display-order-index:2
```

> **Note**
>
> If the server does not require a password, you can leave the password field blank when you create a user. Without a password, the user can't sign on to Configuring user self-service.

Enabling Account Information tab content

The Delegated Admin GUI's Account Information tab provides information about a user account. For Delegated Admin to display the user account information, you must enable the `Password Policy State JSON` virtual attribute for the users object class. You can then configure the information that displays.

Steps

1. For each PingDirectory instance that contains users, enable the `Password Policy State JSON` virtual attribute for the users object class.

   > **Note**
   >
   > You don't need to enable this virtual attribute on PingDirectoryProxy instances.

   For example, the following command enables the virtual attribute for users with the `person` object class, which includes users whose REST resource type structural object class is derived from `person`, such as `inetOrgPerson`.

   ```
   $ bin/dsconfig set-virtual-attribute-prop \
        --name "Password Policy State JSON" \
        --set enabled:true \
        --set require-explicit-request-by-name:true \
        --set "filter:(objectClass=person)" \
        --no-prompt --applyChangeTo server-group
   ```

   After you enable the virtual attribute, delegated administrative users can access account information for a user in the Delegated Admin GUI.

   The Account Information tab provides account status by default. To display the last login time and the password expiration date, you must set their properties. You configure these items per password policy.

   When not configured, these entries appear as follows:

   ##### *LAST LOGIN*

   `Last login time not available.` (This entry also displays when the user hasn't logged in.)

   ##### *PASSWORD EXPIRATION*

   `Password expiration date has not been enabled.`

Copyright © 2025 Ping Identity Corporation

You can configure these items in the administrative console or by using the `dsconfig` tool interactively or non-interactively. The following steps use the non-interactive approach:

2. Select the password policy for which you want to enable the last login time and password expiration date.

   Learn more about Managing password policies.

   ```
   dsconfig list-password-policies
   ```

3. (Optional) Include the last login time.

   To include the last login time, choose which property to set. You can set either of the following properties:

   - `maximum-recent-login-history-successful-authentication-count`
   - `last-login-time-format`

     If you use this property, make sure the `last-login-time-attribute` has its default value `ds-pwp-last-login-time`.

     Values for `last-login-time-format` include:

     - `yyyyMMddHHmmss'Z'` for second-level accuracy
     - `yyyyMMdd` for day-level accuracy

   Learn more about last login time options.

4. (Optional) Include the password expiration date.

   To include this information, set the property `max-password-age`.

5. Set the desired password policy properties.

   Example:

   ```
   $ bin/dsconfig set-password-policy-prop \
        --policy-name "<password_policy_name>" \
        --set maximum-recent-login-history-successful-authentication-count:<count_value>  \
        --set "max-password-age:<password_age_value>" \
        --no-prompt --applyChangeTo server-group
   ```

Setting up initiate password reset for REST resource types

To initiate a password reset, a given REST resource type must have the `ds-pwp-modifiable-state-json` delegated admin attribute.

About this task

> **Note**
>
> The `ds-pwp-modifiable-state-json` delegated admin attribute is not visible on the **View/Edit** and **Reporting** pages. It's for internal use only, similar to the `ds-pwp-account-disabled` attribute.

Copyright © 2025 Ping Identity Corporation

To enable initiate password reset functionality for a specified REST resource type:

Steps

- Run `dsconfig` with the `create-delegated-admin-attribute` option.

  Example:

  The following example grants `"Tenant Users"` the initiate password reset functionality through the `ds-pwp-modifiable-state-json` delegated admin attribute.

  ```
  dsconfig create-delegated-admin-attribute \
      --type-name "Tenant Users"  \
      --attribute-type ds-pwp-modifiable-state-json  \
      --set "display-name:Modifiable Password Policy State"
  ```

Manage groups

The administrative scope for users determines which users are visible to the group administrator.

You can use `dsconfig` to delegate a user as a group administrator. An administrator can be configured to edit users and manage group memberships. When configuring an administrator, consider the following:

- The group administrator can view, add, and remove any of the users within their administrative scope to the membership of groups within the groups' administrative scope.
- Static groups can be nested.
- Users who belong indirectly to a group through nesting are visible as group members but cannot be removed.
- Users can be removed only from the groups of which they are a member. For example, an Employees group might include a Developers group as a nested member. In this scenario, a user in the Developers group is a direct member of that group and an indirect member of Employees. This member can be removed only when viewing the Developers group, not when viewing the Employees group.
- If a group is configured as a dynamic or virtual static group rather than a static group, then the group and its members are visible, but the group membership cannot be modified.

Example

In the following example, all users in the subtree `ou=org1,dc=example,dc=com` are visible:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name group-admin1 \
  --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com"
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name group-admin1 \
  --rest-resource-type groups \
  --set admin-scope:resources-in-specific-subtrees \
  --set "resource-subtree:ou=Groups,dc=example,dc=com" \
  --set admin-permission:manage-group-membership \
  --set admin-permission:create \
  --set admin-permission:read \
  --set admin-permission:update \
  --set admin-permission:delete \
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name group-admin1 \
  --rest-resource-type users \
  --set admin-scope:resources-in-specific-subtrees \
  --set "resource-subtree:ou=org1,dc=example,dc=com" \
  --set admin-permission:read \
  --set enabled:true
```

Set group attributes

The default settings for group attributes specify `cn` and `description` as group attributes, with `cn` used for the group title in Delegated Admin. To create the default settings, use the following commands with a search DN and parent DN (`"dc=example,dc=com"`):

```
$ bin/dsconfig create-rest-resource-type \
  --type group \
  --type-name groups \
  --set "display-name:Groups" \
  --set enabled:false \
  --set "search-base-dn:dc=example,dc=com" \
  --set primary-display-attribute-type:cn \
  --set resource-endpoint:groups \
  --set "search-filter-pattern:(cn=%%)" \
  --set structural-ldap-objectclass:groupOfUniqueNames
  --set parent-dn:dc=example,dc=com

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name groups \
  --attribute-type cn \
  --set "display-name:Name"

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name groups \
  --attribute-type description \
  --set "display-name:Description"

$ bin/dsconfig set-rest-resource-type-prop \
  --type-name groups \
  --set enabled:true
```

Copyright © 2025 Ping Identity Corporation

Set group search filter

When entering text to search for groups, the groups' `search-filter-pattern` property specifies the attributes to be searched in PingDirectory server.

To satisfy the query, define the appropriate attribute indexes for PingDirectory server. The default setting searches the attribute `cn` for the search text, which is represented by `%%`.

Use the following command to set the group search filter:

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name groups \
  --set 'search-filter-pattern:(cn=%%)'
```

Rename the Members and Nonmembers columns

An administrator can assign custom names for Members and Nonmembers columns in the Delegated Admin application for the following rest resource types:

- Groups
- Users
- Generic rest resource types

To set these column titles, run `dsconfig set-rest-resource-type-prop`:

```
dsconfig set-rest-resource-type-prop \
    --type-name users \
    --set "members-column-name:<custom member label>" \
    --set "nonmembers-column-name:<custom non member label>"
```

Viewing groups

Use the group `reference` right to grant delegated admins the right to see what groups a user is a member of without granting group resource management rights.

About this task

To grant a delegated admin the group `reference` right:

Steps

- Run `dsconfig` with the `create-delegated-admin-resource-rights` option.

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-delegated-admin-resource-rights \
    --rights-name DArights  \
    --rest-resource-type groups  \
    --set enabled:true  \
    --set admin-permission:reference  \
    --set admin-scope:all-resources-in-base
```

Result

The admin can see the user's group memberships on the entry preview's Group Membership tab.

Create a group

You can add users as members to groups that delegated administrators create and manage. You can also add subgroups as members to a group.

The configuration for each delegated group type consists of the following elements:

Group REST resource type

Defines the attributes to locate groups in the directory information tree (DIT).

Parent DN or Parent resource type

Specifies the location in which to create groups in the DIT.

- To specify a parent distinguished name (DN) for a resource type, enter the value in the Parent DN text box in the Resource Creation section. The parent DN is often identical to the search base DN, such as `ou=customers,ou=Groups, dc=example,dc=com`.
- To specify a parent resource type, select a value from the Parent Resource Type list in the Resource Creation section. Delegated administrators are subsequently presented with a list box that lets them select a resource, and the group is created under the selected parent resource. If you specify a parent resource type, set a value for the Primary Display Attribute Type in the Delegated Admin section. This setting determines the values that are displayed in the Delegated Admin GUI. For example, a primary display attribute type of `ou` displays the `ou` value in the list box for each resource within the parent resource type.

Attributes

These attributes are presented to the delegated administrators.

To configure a group REST resource type, go to Configuration → REST Resource Types page in the PingData Administrative Console.

When creating or editing a REST resource type, the Search Base DN field in the General Configuration section determines the data structure that is searched in Delegated Admin, and the Display Name field in the Delegated Admin section specifies the label of the REST resource in the Delegated Admin GUI.

`Display Name`	Configuration → REST Resource Types. Create or edit a REST resource type, and then go to the Delegated Admin section.	`Select a Type` label
`REST Resource Type`	Configuration → Delegated Admin Rights. Create or edit Delegated Admin rights, and then click New Delegated Admin Resource Rights.	`Select a Type` option
`Parent Resource Type`	Configuration → REST Resource Types. Create or edit a REST resource type, and then go to the Resource Creation section.	Display name for parent resource type
`Display Name`	Configuration → REST Resource Types. Create or edit a REST resource type, and then go to the Delegated Admin Attributes section. Click New Delegated Admin Attribute.	Additional fields such as `CN`, `Description`, `Business Category`, and `Organization`

Adding a user to a group

You can add users to groups from the Manage Users page and from the Manage Groups page in the Delegated Admin GUI.

When the delegated admin rights for a user REST resource type have the `resources-in-specific-groups` admin scope, a user is added to one of the configured groups when you create the user.

Adding a new user to a configured group

About this task

When the delegated admin rights for a user REST resource type has admin scope resources-in-specific-groups (and only in this case), a user is added to one of the configured groups when the user is created:

- For admins having rights to only one group, the new user is automatically added to that group. No field for `Select Group` displays.
- For admins having rights to more than one group, the admin selects a group to add the user to in the `Select Group` list.
- Admins can select from both static and dynamic groups.
- For dynamic groups, in addition to selecting the group, the new entry must also match criteria for membership of that group.

  For example, in a dynamic group of members with `uid=user.111*`, the `uid` starts with `user.111`.

In order for an administrator to create a new user in that group, they must:

Copyright © 2025 Ping Identity Corporation

Steps

1. In the `Select Group` list, select the group name.
2. Enter the value for `uid` that starts with `user.111`.

Adding a user from the Manage Users window

You can add users to groups using the Manage Users window in the Delegated Admin GUI.

Steps

1. In the Delegated Admin GUI, go to the Manage Users window.
2. Use to search field to search for the user to add to a group.
3. Click the Expand icon on the appropriate user profile.
4. To edit the user profile, click the Pencil icon.
5. Click the Group Membership tab.
6. Use the search field to search for the appropriate group.
7. To add the user to the respective group, in the Nonmember Groups list, click +.

   Result:

   The group moves to the Member Groups list.

Adding a user from the Manage Groups window

You can add users to groups using the Manage Groups window in the Delegated Admin GUI.

Steps

1. In the Delegated Admin GUI, go to the Manage Groups window.
2. To filter by group resource type, make a selection from the drop-down list for the group resource type you want to search within.
3. (Optional) To narrow your results, use the search field to search for the appropriate group.
4. Click the Expand icon on your chosen group.
5. To edit the group profile, click the Pencil icon.
6. Under the group name, click Group Membership.
7. (Optional) To filter entries by resource type, make a selection from the Select a Type drop-down list.

   > **Note**
   >
   > If there is a parent resource type, a second drop-down list appears. Make an additional selection, or leave it to **All** to see all entries in that resource type.

8. Use the search field to search for the appropriate entry.

Copyright © 2025 Ping Identity Corporation

9. To add an entry to the group, from the Nonmembers list, click +.

   Result:

   The user moves to the Members list.

Unlocking user accounts

To unlock a user account without requiring a password reset, use the Delegated Admin application.

About this task

> **Note**
>
> To require a password reset when unlocking a user, use the **Reset Password** or **Set Password** options in the Delegated Admin application.

To use Delegated Admin to unlock a user account without requiring a password reset:

Steps

1. In the Delegated Admin application, go to Manage Users.
2. In the Search box, enter the user ID of the user you need to unlock and press Enter.
3. (Optional) Click the Expand icon to expand the user entry.
4. Click the Locked toggle.

   Result:

   The toggle turns green and changes to Enabled.

Result

The user can access their account without resetting their password.

Enabling the Delegated Admin user REST resource type photo upload feature

In Delegated Admin 4.10.0 and later, you can add a photo to a user REST resource type profile in the Delegated Admin application.

To use the Delegated Admin photo upload feature, you must first enable the feature. You can use the PingData administrative console or `dsconfig` to perform this task.

For more information, see:

- Enabling the user profile photo upload feature using the administrative console
- Enabling the user profile photo upload feature using dsconfig

After you have enabled the feature, it's ready to use when creating a new user or when editing an existing user. To use the enabled photo upload feature, see Uploading a photo to a user REST resource type profile in Delegated Admin.

Copyright © 2025 Ping Identity Corporation

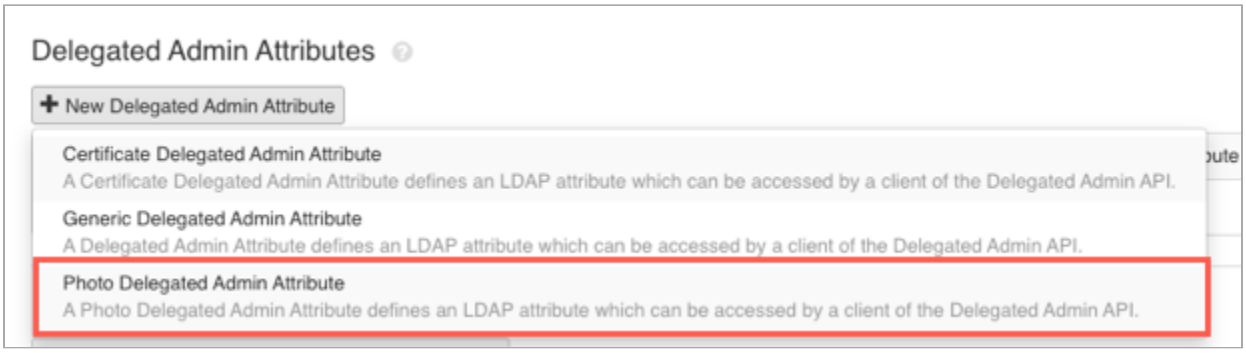
Enabling the user profile photo upload feature using the administrative console

About this task

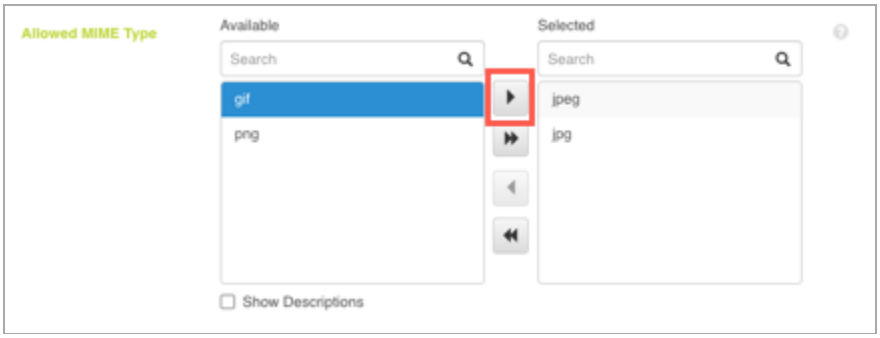
To enable the Delegated Admin user REST resource type photo upload feature using the PingData administrative console:

Steps

1. In the Web Services and Applications list, select REST Resource Types.
2. In the REST Resource Types list, select your user REST resource type.
3. Go to Delegated Admin Attributes and click New Delegated Admin Attribute.
4. In the New Delegated Admin Attribute list, select Photo Delegated Admin Attribute.



5. In the Attribute Type field, enter the attribute type, such as `jpegPhoto`.
6. Enter a Display Name for the attribute.
7. Keep the default value for Mutability.
8. (Optional) To allow multiple files to be uploaded for one user, enable Multi Valued.
9. Enter a Display Order Index or keep the default, `0`.
10. In the Allowed MIME Type list, select your desired allowed MIME file types from the Available column and use the arrows to add your selections to the Selected column.



11. Click Save.

Copyright © 2025 Ping Identity Corporation

Enabling the user profile photo upload feature using dsconfig

About this task

> **Tip**
>
> To allow multiple files to be uploaded for one user, set `multi-valued` to `true`, as in the second example.

To enable the Delegated Admin user REST resource type photo upload feature using `dsconfig`:

Steps

- Run `dsconfig create-delegated-admin-attribute`.

  Example:

  The following example creates a `jpegPhoto` Delegated Admin attribute with `.png` and `.jpg` set as accepted file types:

  ```
  bin/dsconfig create-delegated-admin-attribute \
      --type-name users  \
      --attribute-type jpegPhoto  \
      --type photo \
      --set display-name:Photo  \
      --set display-order-index:3  \
      --set allowed-mime-type:png  \
      --set allowed-mime-type:jpg  -n
  ```

  Example:

  The following example creates a multivalued `jpegPhoto` Delegated Admin attribute with `.png` and `.jpg` set as accepted file types:

  ```
  bin/dsconfig create-delegated-admin-attribute \
      --type-name users  \
      --attribute-type jpegPhoto  \
      --type photo \
      --set display-name:Photo  \
      --set multi-valued:true  \
      --set display-order-index:3  \
      --set allowed-mime-type:png  \
      --set allowed-mime-type:jpg  -n
  ```

Uploading a photo to a user REST resource type profile in Delegated Admin

After you have enabled the photo upload feature, you can use it to add a photo to a new or existing user REST resource type profile in Delegated Admin.

Copyright © 2025 Ping Identity Corporation

> **Important**
>
> You must enable the photo upload feature before you can use it in the Delegated Admin application. For more information and to enable the feature, see Enabling the Delegated Admin user REST resource type photo upload feature.

For information on using the photo upload feature, see the following topics:

- Uploading a photo to a new user profile in Delegated Admin
- Uploading a photo to an existing user profile in Delegated Admin

Uploading a photo to a new user profile in Delegated Admin

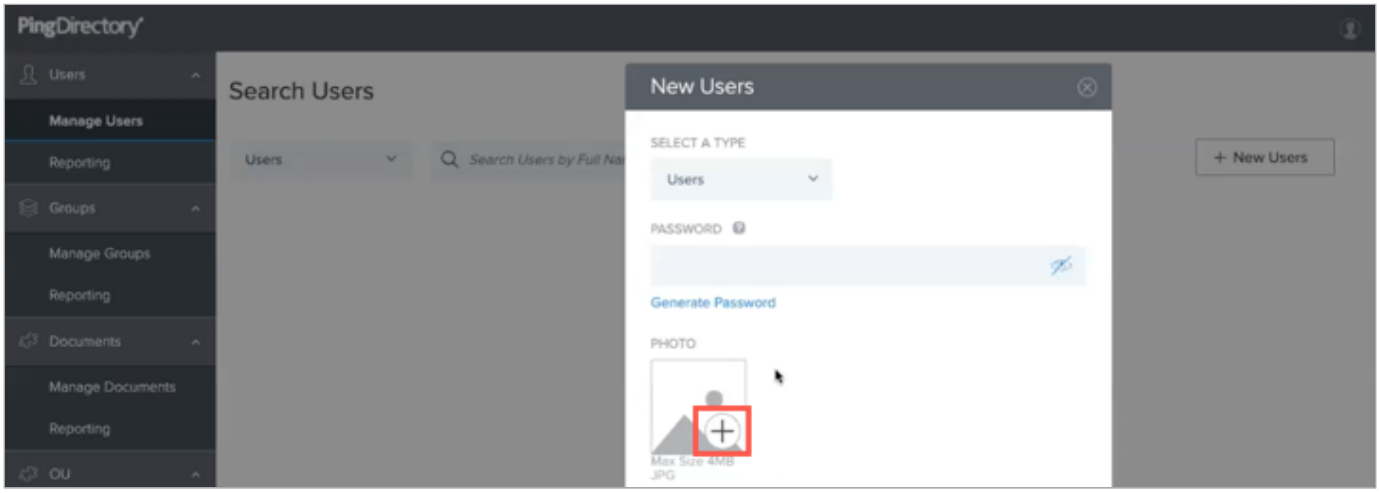
About this task

To add a photo to a new user profile in the Delegated Admin application:

Steps

1. **Click Users → Manage Users.**
2. **Click New Users.**

3. **To add a photo, click the + icon and select a photo.**



Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Due to a server limitation, only a thumbnail of the photo and not the file name is displayed after the upload. The maximum photo size is 4MB.

4. Complete all other required fields for the new user.
5. Click Save.

Uploading a photo to an existing user profile in Delegated Admin

About this task

To add a photo to an existing user profile in the Delegated Admin application:

Steps

1. Click Users → Manage Users.
2. To locate the user, enter the user information in the search field.
3. Click the Expand icon on the user profile.
4. To edit the profile, click the Pencil icon.
5. (Optional) If you already have a photo and want to replace it, click Remove to remove the original photo.
6. To add a photo, click the + icon and select a photo.

> **Note**
>
> Due to a server limitation, only a thumbnail of the photo and not the file name is displayed after the upload. The maximum photo size is 4MB.

7. Click Save.

Enabling the Delegated Admin user REST resource type certificate upload feature

In Delegated Admin 4.10.0 and later, you can add a certificate to a user REST resource type profile in the Delegated Admin application.

To use the Delegated Admin certificate upload feature, you must first enable the feature. You can use the PingData administrative console or `dsconfig` to perform this task.

For more information, see:

- Enabling the user profile certificate upload feature using the administrative console
- Enabling the user profile certificate upload feature using dsconfig

After you've enabled the feature, it's ready to use when creating a new user or when editing an existing user. To use the enabled certificate upload feature, see Uploading a certificate to a user REST resource type profile in Delegated Admin.

Copyright © 2025 Ping Identity Corporation

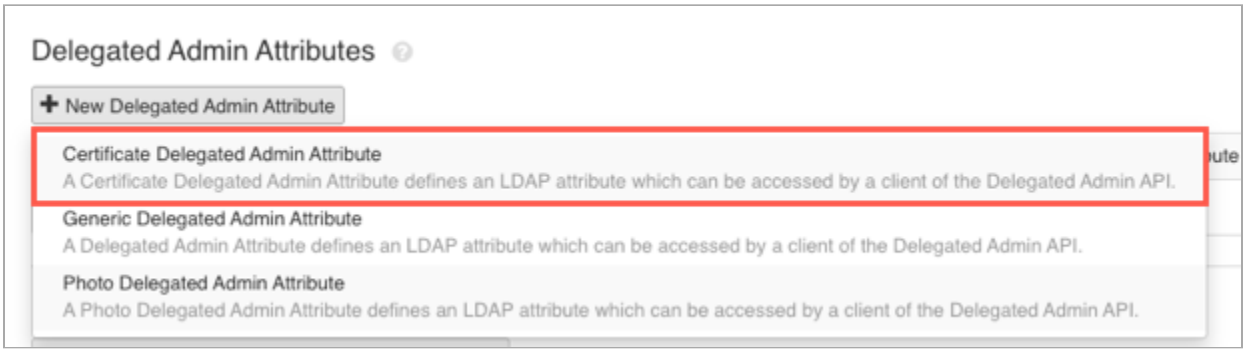
Enabling the user profile certificate upload feature using the administrative console

About this task

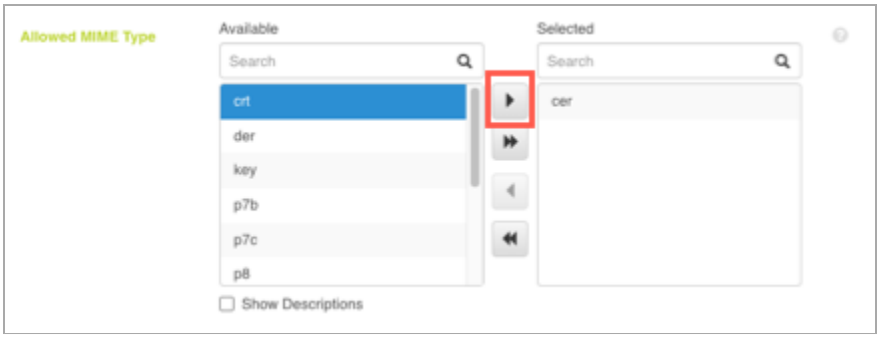
To enable the Delegated Admin user REST resource type certificate upload feature using the PingData administrative console:

Steps

1. In the Web Services and Applications list, select REST Resource Types.
2. In the REST Resource Types list, select your user REST resource type.
3. Go to Delegated Admin Attributes and click New Delegated Admin Attribute.
4. In the New Delegated Admin Attribute list, select Certificate Delegated Admin Attribute.



5. In the Attribute Type field, enter the attribute type, such as `userCertificate`.
6. Enter a Display Name for the attribute.
7. Keep the default values for Mutability.
8. (Optional) To allow multiple files to be uploaded for one user, enable Multi Valued.
9. Enter a Display Order Index or keep the default, `0`.
10. In the Allowed MIME Type list, select your desired allowed MIME file types in the Available column, and use the arrows to add your selections to the Selected column.



11. Click Save.

Enabling the user profile certificate upload feature using dsconfig

About this task

> **Tip**
>
> To allow multiple files to be uploaded for one user, set `multi-valued` to `true`, as in the second example.

To enable the Delegated Admin user REST resource type profile certificate upload feature using `dsconfig`:

Steps

- Run `dsconfig create-delegated-admin-attribute`.

  Example:

  The following example creates a `userCertificate` attribute with `.cer` and `.crt` set as accepted file types:

  ```
  bin/dsconfig create-delegated-admin-attribute \
      --type-name users  \
      --attribute-type userCertificate  \
      --type certificate  \
      --set "display-name:user certificate"  \
      --set display-order-index:3  \
      --set allowed-mime-type:cer  \
      --set allowed-mime-type:crt -n
  ```

  Example:

  The following example creates a multivalued `userCertificate` attribute with `.cer` and `.crt` set as accepted file types:

  ```
  bin/dsconfig create-delegated-admin-attribute \
      --type-name users  \
      --attribute-type userCertificate  \
      --type certificate  \
      --set "display-name:user certificate"  \
      --set multi-valued:true  \
      --set display-order-index:3  \
      --set allowed-mime-type:cer  \
      --set allowed-mime-type:crt -n
  ```

Uploading a certificate to a user REST resource type profile in Delegated Admin

After you have enabled the certificate upload feature, you can use it to add a certificate to a new or existing user REST Resource type profile in Delegated Admin.

Copyright © 2025 Ping Identity Corporation

Important

You must enable the certificate upload feature before you can use it in the Delegated Admin application. For more information and to enable the feature, see Enabling the Delegated Admin user REST resource type certificate upload feature.

For information on using the certificate upload feature, see:

- Uploading a certificate to a new user profile in Delegated Admin
- Uploading a certificate to an existing user profile in Delegated Admin

Uploading a certificate to a new user profile in Delegated Admin

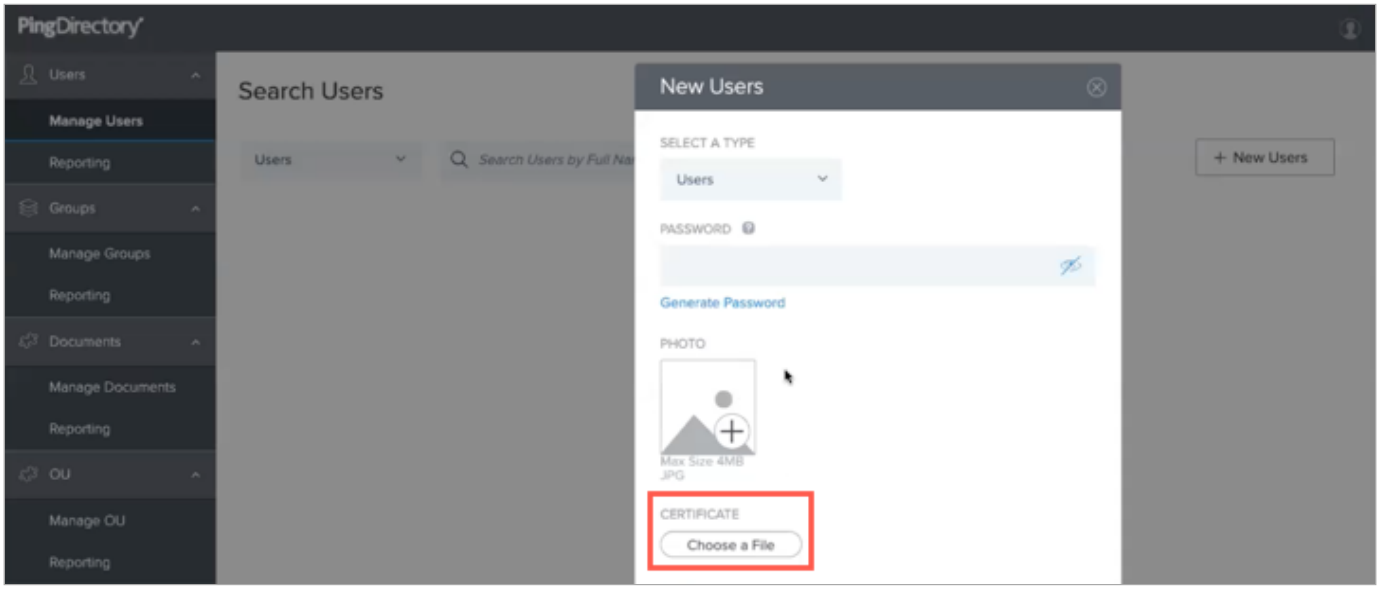
About this task

To add a certificate to a new user profile in the Delegated Admin application:

Steps

1. Click Users → Manage Users.
2. Click New Users.

3. To add a certificate, click Choose a File.



Copyright © 2025 Ping Identity Corporation

4. Complete all other required fields for the new user.
5. Click Save.

Uploading a certificate to an existing user profile in Delegated Admin

About this task

To add a certificate to an existing user profile in the Delegated Admin application:

Steps

1. Click Users → Manage Users.
2. To locate the user, enter the user information in the search field.
3. Click the Expand icon on the user profile.
4. To edit the profile, click the Pencil icon.
5. To add a certificate, click Choose a File and select a certificate file.
6. Click Save.

Generic resource types

Use generic resource types to manage LDAP entries that are neither users nor groups.

You can perform the following actions with generic resource types:

- Create new entries.
- Read, view, and search existing entries.
- Edit and update existing entries.
- Edit referenced items.

For example, a generic resource type can represent a device or used for organizational unit branch entries that are parents of other resources.

Defining a generic resource type

You can define generic resources for any structural LDAP object class, and they can function as members of a group.

Steps

1. Define a generic resource type.

   The following example enables the management of device entries.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-rest-resource-type \
  --type-name device \
  --set enabled:true \
  --set resource-endpoint:device \
  --set "display-name:Device" \
  --set structural-ldap-objectclass:device \
  --set search-base-dn:dc=example,dc=com \
  --set parent-dn:dc=example,dc=com \
  --set 'search-filter-pattern:(cn=%%)' \
  --set primary-display-attribute-type:cn

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name device \
  --attribute-type cn \
  --set "display-name:Device Name" \
  --set display-order-index:1

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name device \
  --attribute-type serialNumber \
  --set "display-name:Serial Number" \
  --set display-order-index:2
```

2. Create Delegated Admin resource rights for the generic resource type.

   Generic resource administrators must have read access to the user resource. For more information, see Configuring delegated administrator rights on the PingDirectory server.

Working with correlated REST resources

You can link resource types based on a common attribute value. When two or more resources are linked this way, they are known as correlated resources.

Correlated REST resources

When you retrieve a resource configured with correlated resources, any correlated resource with matching attribute values is included with the resource.

You can view, update, and delete a resource's correlated resources. You can also link them to and unlink them from a resource.

Configuration

The following example shows how to create a correlated resource by linking a `documents` resource type to a `users` resource type. When a user resource is retrieved, any document resources with the user's `entryUUID` in their `documentPublisher` attribute are included.

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-delegated-admin-correlated-rest-resource \
    --type-name users  \
    --resource-name Documents  \
    --set display-name:Documents  \
    --set correlated-rest-resource:Documents  \
    --set primary-rest-resource-correlation-attribute:entryUUID  \
    --set secondary-rest-resource-correlation-attribute:documentPublisher
```

Linking and unlinking

You can link resources to correlated resources by taking an attribute value from either the primary resource or the correlated resource and assigning it to the other. To control the direction that the linking value is assigned, use the `use-secondary-value-for-linking` property. If `use-secondary-value-for-linking` is `false` or isn't set, the primary correlation attribute's value is assigned to the secondary correlation attribute to create the link. If `use-secondary-value-for-linking` is `true`, the secondary correlation attribute's value is assigned to the primary correlation attribute.

The following is an example of a `users` resource type linked to a `documents` resource type by assigning the document's `entryUUID` value to the user's `description` attribute. The secondary correlation attribute's value is assigned to the primary correlation attribute, so `use-secondary-value-for-linking` is `true`.

```
dsconfig create-delegated-admin-correlated-rest-resource \
    --type-name users  \
    --resource-name ownedDocuments  \
    --set display-name:Owned Documents  \
    --set correlated-rest-resource:Documents  \
    --set primary-rest-resource-correlation-attribute:description  \
    --set secondary-rest-resource-correlation-attribute:entryUUID  \
    --set use-secondary-value-for-linking:true
```

If you inspected a user's `description` attribute with this setup, you see a list of all of the documents owned by the user.

The next example links the attributes in the other direction. Here, the user's `entryUUID` value is assigned to the `documentAuthor` attribute on the document.

```
dsconfig create-delegated-admin-correlated-rest-resource \
    --type-name users  \
    --resource-name authoredDocuments  \
    --set display-name:Authored Documents  \
    --set correlated-rest-resource:Documents  \
    --set primary-rest-resource-correlation-attribute:entryUUID  \
    --set secondary-rest-resource-correlation-attribute:documentAuthor  \
    --set use-secondary-value-for-linking:false
```

If you inspect a document's `documentAuthor` attribute with this setup, you see a list of all of the users who authored the document.

You can also unlink correlated resources from the primary resource. Resources are unlinked by removing the common attribute value using the logic based on the `use-secondary-value-for-linking` property described above.

Copyright © 2025 Ping Identity Corporation

Unlinking correlated resources differs from deleting correlated resources. When correlated resources are unlinked, the common attribute value is removed, but the correlated resource still exists in the directory. When a correlated resource is deleted, it is removed from the directory.

The attribute that the linking value is assigned to must be a writable attribute because the value must be updated to link and unlink correlated resources. The attributes should also have the same syntax so that the value of one can be assigned to the other successfully.

> **Note**
>
> When `use-secondary-value-for-linking` is enabled and a linked object is deleted, the linking value is not removed from the primary correlation attribute. This means that if a secondary object is recreated with the same value in the secondary correlation attribute, the secondary object is automatically linked to the primary object.

Permissions

The following table describes the permissions required to perform the specified actions.

Action	Permissions required
View	The `read` permission on the secondary resource type.
Update	The `update` or `update-profile` permission on the secondary resource type.
Delete	The `delete` permission on the secondary resource type.
Link or unlink	The `update` or `update-profile` permission. **Important** The required permission is dependent on the `use-secondary-value-for-linking` setting. If `use-secondary-value-for-linking` is set to `false`, the permission is required on the correlated resource type. If `use-secondary-value-for-linking` is set to `true`, the permission is required on the primary resource type.

Setting up a DN reference attribute

A REST resource type can reference or edit other REST resource types based on a distinguished name (DN) without the full DN value. The following task, performed by the system administrator, grants the Delegated Admin administrator this ability.

About this task

In this task, the Delegated Admin attribute used for reference must be in DN syntax, such as `manager`, `entryDN`, or `seeAlso`.

Steps

1. To use a resource type for DN reference, either:

Copyright © 2025 Ping Identity Corporation

Choose from:

- Use an existing REST resource type.
- Create a new REST resource type.

2. To add a `reference` Delegated Admin attribute, run `dsconfig` with the `create-delegated-admin-attribute` option using the following syntax.

Example:

```
dsconfig create-delegated-admin-attribute \
    --type-name users  \
    --attribute-type <attribute of DN syntax> \
    --set "display-name:<display name>"  \
    --set display-order-index: <>  \
    --set reference-resource-type:<rest-resource-type>
```

Example:

The following example uses the values from Creating and configuring a new REST resource type.

```
dsconfig create-delegated-admin-attribute \
    --type-name users  \
    --attribute-type manager  \
    --set "display-name:Select Manager"  \
    --set display-order-index:4  \
    --set reference-resource-type:Managers
```

Creating and configuring a new REST resource type

About this task

To set up a reference delegated admin attribute, you must have a REST resource type defined and configured.

This example task creates a new REST resource type called `Managers`.

Steps

1. To create the new REST resource type, run `dsconfig` with the `create-rest-resource-type` option.

Example:

In the following example, the new resource type of `Managers` is created.

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-rest-resource-type \
    --type-name Managers  \
    --type user  \
    --set 'description:Rest type for users who are managers\n\It is used as reference type for the
field Manager.'  \
    --set enabled:true  \
    --set resource-endpoint:managers  \
    --set structural-ldap-objectclass:inetOrgPerson  \
    --set search-base-dn:dc=example,dc=com  \
    --set "include-filter:(employeeType=manager)"  \
    --set parent-dn:ou=people,dc=example,dc=com  \
    --set create-rdn-attribute-type:uid  \
    --set display-name:Managers  \
    --set 'search-filter-pattern:(|(cn=%%)(mail=%%)(uid=%%)(sn=%%))'  \
    --set primary-display-attribute-type:cn
```

2. To add Delegated Admin attributes for the resource type, run `dsconfig` with the `create-delegated-admin-attribute` option.

   Example:

   The following example adds Delegated Admin attributes for the `Managers` resource type.

```
dsconfig create-delegated-admin-attribute
    --type-name Managers
    --attribute-type cn
    --set "display-name:Full Name"

dsconfig create-delegated-admin-attribute
    --type-name Managers
    --attribute-type uid
    --set "display-name:Manager ID"

dsconfig create-delegated-admin-attribute
    --type-name Managers
    --attribute-type mail
    --set display-name:Email

dsconfig create-delegated-admin-attribute
    --type-name Managers
    --attribute-type employeeType
    --set "display-name:Employee Type (must be manager)"

dsconfig create-delegated-admin-attribute
    --type-name Managers
    --attribute-type sn
    --set "display-name:Last name"

dsconfig create-delegated-admin-attribute
    --type-name Managers
    --attribute-type givenName
    --set "display-name:First Name"
```

Copyright © 2025 Ping Identity Corporation

3. To distinguish your resource type from other resources, run `dsconfig` with the `create-delegated-admin-attribute`.

   Example:

   In the following example, `Managers` are distinguished from other users using the `employeeType` attribute.

   ```
   dsconfig create-delegated-admin-attribute
       --type-name users
       --attribute-type employeeType
       --set "display-name:Employee type (manager, other)"
       --set display-order-index:4
   ```

4. To add Delegated Admin resource rights to your set of existing Delegated Admin rights, run `dsconfig` with the `create-delegated-admin-resource-rights` option.

   Example:

   In the following example, Delegated Admin are granted `reference` Admin Permission for the `Managers` REST resource type to allow viewing access.

   ```
   dsconfig create-delegated-admin-resource-rights
       --rights-name <existing-rights-name>
       --rest-resource-type Managers
       --set enabled:true
       --set admin-permission:reference
       --set admin-scope:all-resources-in-base
   ```

   Example:

   In the following example, Delegated Admin administrators are granted `read` and `update` Admin Permissions for `Managers` REST resource type to allow edit access.

   ```
   dsconfig create-delegated-admin-resource-rights
       --rights-name DArights
       --rest-resource-type Managers
       --set enabled:true
       --set admin-permission:read
       --set admin-permission:update
       --set admin-scope:all-resources-in-base
   ```

Next steps

After you have created and configured a new REST resource type, add a reference Delegated Admin attribute. See step 2 in Setting up a DN reference attribute.

Differentiating resource types within the same subtree

If you have resource types with the same object class and whose subtrees overlap, you can differentiate them through include filters.

About this task

Copyright © 2025 Ping Identity Corporation

An entry is categorized as a given resource type only if the entry's attributes match the resource type's include filters.

You can only create a new resource if the resource attributes match the include filters for the type of resource being created.

For example, to differentiate between two kinds of `organizationalUnit` resources stored in the same subtree, run the following commands.

```
$ bin/dsconfig create-constructed-attribute \
  --attribute-name businessCategoryHotel \
  --set attribute-type:businessCategory \
  --set value-pattern:Hotel

$ bin/dsconfig create-constructed-attribute \
  --attribute-name businessCategoryCruiseLine \
  --set attribute-type:businessCategory \
  --set value-pattern:CruiseLine

$ bin/dsconfig create-rest-resource-type \
  --type-name Hotel \
  --set enabled:true \
  --set resource-endpoint:hotels \
  --set "display-name:Hotel" \
  --set structural-ldap-objectclass:organizationalUnit \
  --set search-base-dn:dc=example,dc=com \
  --set parent-dn:dc=example,dc=com \
  --set 'search-filter-pattern:(&(objectClass=organizationalUnit)(ou=%%))' \
  --set primary-display-attribute-type:ou \
  --set include-filter:(businessCategory=Hotel) \
  --set post-create-constructed-attribute:businessCategoryHotel

$ bin/dsconfig create-rest-resource-type \
  --type-name "Cruise Line" \
  --set enabled:true \
  --set resource-endpoint:cruiselines \
  --set "display-name:Cruise Line" \
  --set structural-ldap-objectclass:organizationalUnit \
  --set search-base-dn:dc=example,dc=com \
  --set parent-dn:dc=example,dc=com \
  --set 'search-filter-pattern:(&(objectClass=organizationalUnit)(ou=%%))' \
  --set primary-display-attribute-type:ou \
  --set include-filter:(businessCategory=CruiseLine) \
  --set post-create-constructed-attribute:businessCategoryCruiseLine
```

Configuring a resource's summary display in the Delegated Admin GUI

The Delegated Admin GUI provides a summary of attributes for a resource. For example, the user and group resource profiles show a summary.

About this task

By default, a resource's summary shows all required attributes and all search attributes for the resource. However, you can explicitly set the items to include in the summary.

If you configure any attributes to appear in the summary, the default selection does not appear.

Copyright © 2025 Ping Identity Corporation

To configure an attribute to appear in the summary, either use `dsconfig` to set the `include-in-summary` property or use the PingDirectory administrative console to select the Include In Summary check box.

Steps

- For a given resource, configure each attribute to include in the summary.

  Choose from:

  - Use `dsconfig`.

    Use the `set-delegated-admin-attribute-prop` subcommand, where *<name_of_type>* is the resource type and *<type_of_attribute>* is the name of an existing attribute for the given resource.

    ```
    $ bin/dsconfig set-delegated-admin-attribute-prop \
      --type-name  <name_of_type>  \
      --attribute-type  <type_of_attribute>  \
      --set include-in-summary:true
    ```

    The following example includes the `cn` attribute in the summary for the `users` resource type.

    ```
    $ bin/dsconfig set-delegated-admin-attribute-prop \
      --type-name users \
      --attribute-type cn \
      --set include-in-summary:true
    ```

    Note

    To remove an attribute from the summary, use the same command but change `true` to `false`.

  - Use the PingDirectory administrative console.

    1. Sign on to the PingDirectory administrative console.
    2. From the Configuration page, click REST Resource Types.
    3. To edit a resource type, select it from the Name column.
    4. Go to the Delegated Admin Attributes section.
    5. To edit an attribute, click the Pencil icon.
    6. Select the Include In Summary check box.

       Note

       To remove an attribute from the summary, clear its **Include In Summary** check box.

Customizing UI form fields

You can customize the form field for a given attribute.

Copyright © 2025 Ping Identity Corporation

About this task

Although you can customize the presentation completely, Delegated Admin provides example files to demonstrate the functionality and capabilities.

> **Note**
>
> Because the example files most likely require modifications to address your specific needs, you should have a basic level of familiarity with HTML, CSS, and JavaScript when dealing with custom UI form fields.

The example files cover the following scenarios:

- **Single-selection lists, which allow users to select one item from multiple options**
- **Check boxes, which can be customized so that one check box is dependent on the other**
- **String fields with validation and error messages**
- **Custom, user-friendly display of a JSON attribute, such as `ubidEmailJSON`**
- **Multivalue string field, which allows users to enter multiple, comma-separated values**

To set up Delegated Admin to use the custom HTML files and to display custom UI form fields:

Steps

1. **Go to `PingDirectory/webapps/delegator/app/customAttributes`.**
2. **Use a text editor to open the relevant example HTML file, as shown in the following table.**

UI Form Field	Example File
Single selection list	`example-select.html`
Dependent check boxes	`example-dependent.html`
String field	`example-basic.html`
Custom display of a JSON attribute	`example-json.html`
Multivalue string field	`example-multivalue.html`

3. **Make the appropriate modifications to the example file.**

   For information about resizing and other custom capabilities, see the comments in `PingDirectory/webapps/delegator/app/assets/iframe-v1.js`.

4. **Save the example file as a new file named `attributeName.html`.**

   Example:

   For example, if you are setting up a custom attribute presentation for `cn`, name the file `cn.html`.

5. **(Optional) For further clarity, create a directory under the `customAttributes` directory with the name of the resource endpoint of the REST resource types.**

Copyright © 2025 Ping Identity Corporation

Example:

For example, because a `users` type exists with the endpoint `usersEndpoint`, you might place `cn.html` in a `customAttributes/usersEndpoint/` directory.

When locating the appropriate HTML file, Delegated Admin searches for the attribute name under the endpoint folder if one exists, and then searches under the `customAttributes` folder.

6. In the PingDirectory server, set the `attribute-presentation` field for the `Delegated Admin` attribute to `custom`.

   Example:

   ```
   dsconfig set-delegated-admin-attribute-prop \
     --type-name users  \
     --attribute-type cn  \
     --set attribute-presentation:custom
   ```

Next steps

Browsers that attempt to aggressively cache HTML files often save and reuse outdated versions of those files. Because such browsers might not display changes that are made to an example HTML file, include the following `<meta>` tag in the head of each custom HTML file.

```
<meta http-equiv="Cache-Control" content="no-cache"/>
```

If your browser still doesn't display the updated HTML file, try the following:

- Clear the browser's cache.
- Use a private browsing window.
- Try a different browser.

Setting up email invitations for a new user

About this task

To set up email invitations for a new user:

Steps

1. Set up PingFederate for local identity profile management.

   For more information, see Configuring user self-service.

   When you complete this task, the PingFederate configuration has a local identity profile.

2. Configure Delegated Admin profile management by users.

   For more information, see Configuring user self-service.

Copyright © 2025 Ping Identity Corporation

When you complete this task, users whom the Delegated Admin creates have the `pf-connected-identities` auxiliary object class and a `pf-connected-identity` attribute value, which provide integration with PingFederate's user self-service.

3. Instruct users to copy the email template to PingDirectory Server.

   For more information, see Editing and copying the email template to the PingDirectory server.

4. Create request criteria to match Delegated Admin user `ADD` requests.

   For more information, see Creating request criteria to match Delegated Admin user ADD requests.

5. Edit the provided email template and insert the URL to the PingFederate self-service profile management endpoint.

   For more information, see Editing and copying the email template to the PingDirectory server.

6. Create an SMTP external server.

   For more information, see Creating an SMTP external server.

7. Create a multi-part email account status notification handler for Delegated Admin user `ADD` requests.

   For more information, see Creating a multi-part Email Account Status notification handler for Delegated Admin user ADD requests.

Editing and copying the email template to the PingDirectory server

About this task

An example email template is provided in the Delegated Admin package at the top level in the file `delegated-admin-account-created.template`. This template provides a multi-part text and HTML email to the user with their user name and initial password along with a self-service link they can use to sign on to PingFederate and change their password and profile information.

Steps

1. Edit the template:
   1. Uncomment the line that sets the value for `profile_management_url`.
   2. Change the value of `profile_management_url` to the externally accessible URL of the profile management endpoint of your PingFederate local identity profile.
2. Copy the template file to the `config/account-status-notification-email-templates` folder of each instance of the PingDirectory server.

   By default, the email is sent to the address within the user's LDAP `mail` attribute.

   > **Note**
   >
   > You must provide a mail value for each user. For more information, see `common-header-fields.vm` in the email templates folder.

Next steps

For more information about the email format and further customization, see the `README` file in the templates folder.

Copyright © 2025 Ping Identity Corporation

Creating request criteria to match Delegated Admin user ADD requests

Steps

- For each user resource type for which new user email invites will be sent, create simple request criteria to match the parent DN and object classes for the resource type.

  > **Note**
  >
  > The setup script includes a request criteria for the user resource type that it creates.

  Example:

  ```
  $ dsconfig create-request-criteria --criteria-name \
  "Delegated Admin User Creation Request Criteria" --type simple \
  --set operation-type:add --set \
  "included-target-entry-dn:ou=people,dc=example,dc=com" \
  --set "any-included-target-entry-filter:(objectClass=inetOrgPerson)" \
  --set "included-application-name:PingDirectory Delegated Admin"
  ```

  The `included-application-name` property ensures that the criteria matches users whom the Delegated Admin created, but not users created through another interface, such as the Directory REST API. This application name value is visible in the LDAP access log for operations that the Delegated Admin HTTP servlet invokes.

Creating an SMTP external server

About this task

To send emails:

Steps

- Configure a PingDirectory server with an SMTP server in the global configuration.

  Example:

  ```
  $ dsconfig create-external-server --server-name \
  "SMTP Server" --type smtp --set server-host-name:smtp.example.com \
  --set user-name:example-smtp-user --set password:example-smtp-password
  $ dsconfig set-global-configuration-prop --set \
  "smtp-server:SMTP Server"
  ```

Creating a multi-part Email Account Status notification handler for Delegated Admin user ADD requests

You must set an Email Account Status notification handler in the password policy in force for new users. This handler is typically the default password policy.

About this task

The notification handler references the email template in the `config/account-status-notification-email-templates` folder.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The setup script creates an example notification handler in a disabled state. This handler cannot be enabled until an SMTP server becomes available in the global configuration.

Steps

1. Create or enable the handler:

   Choose from:

   - To create the handler from scratch, use the `dsconfig create-account-status-notification-handler` command.

     ```
     $ dsconfig create-account-status-notification-handler \
     --handler-name "Delegated Admin Email Account Status \
     Notification Handler" --type multi-part-email --set \
     enabled:true --set \
     "account-creation-notification-request-criteria:Delegated \
     Admin User Creation Request Criteria" --set \
     account-created-message-template:config/account-status-\
     notification-email-templates/delegated-admin-account-created.template
     ```

   - To enable the handler that is provided with the setup script, use the `dsconfig set-account-status-notification-handler-prop` command.

     ```
     $ dsconfig set-account-status-notification-handler-prop \
     --handler-name "Delegated Admin Email Account Status Notification \
     Handler" --set enabled:true
     ```

2. Set the handler in the password policy.

   Example:

   ```
   $ dsconfig set-password-policy-prop \
   --policy-name "Default Password Policy" --set \
   "account-status-notification-handler:Delegated Admin Email Account \
   Status Notification Handler"
   ```

Enabling the referential integrity plugin

When a REST resource type is set to create new entries using a relative distinguished name (RDN) attribute other than `entryUUID`, referential integrity issues can result when the entry's RDN attribute is edited.

About this task

To preserve the referential integrity of group memberships in such a scenario, enable the referential identity plugin.

Copyright © 2025 Ping Identity Corporation

Steps

- Enable the referential integrity plugin with the following command.

```
bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
  --set enabled:true
```

Result

After you enable the plugin, group memberships are preserved.

Enabling log tracing

You can enable log tracing for OAuth token processing, HTTP request and response actions, and API debugging.

Steps

- To view OAuth token processing and full HTTP request and response tracing, enable the debug trace logger with the following command.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name 'Debug Trace Logger' \
  --set enabled:true
```

- To enable `dadmin` API debug logging, use the following commands.

```
$ bin/dsconfig create-debug-target \
  --publisher-name 'File-Based Debug Logger' \
  --target-name com.unboundid.directory.server.http \
  --set debug-level:VERBOSE
```

```
$ bin/dsconfig create-debug-target \
  --publisher-name 'File-Based Debug Logger' \
  --target-name com.unboundid.directory.server.extensions.dadmin \
  --set debug-level:VERBOSE
```

```
$ bin/dsconfig create-debug-target \
  --publisher-name 'File-Based Debug Logger' \
  --target-name com.unboundid.directory.broker.api \
  --set debug-level:VERBOSE
```

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name 'File-Based Debug Logger' \
  --set enabled:true
```

Copyright © 2025 Ping Identity Corporation

Specify a custom hostname and port for your PingDirectory server

If an application is installed on a separate server from your PingDirectory server instance, you must specify where the PingDirectory server instance is found within the Delegated Admin application's `config.js` file.

The `DS_HOST` configuration variable should match your PingDirectory server's hostname. The `DS_PORT` configuration variable should match your PingDirectory server's HTTPS port.

> **Note**
>
> You don't need to specify these variables if you're hosting the Delegated Admin application alongside your PingDirectory server instance, as described in previous sections.

Changing the application logo

You can change the Ping Identity logo to your corporate logo.

About this task

Support for corporate logos includes, but is not limited to, the following file types:

- `JPG`
- `PNG`
- `SVG`

To maintain an appropriate aspect ratio, logo images are resized in Delegated Admin to a height of 22px and a maximum width of 150px.

Steps

1. To change the Ping Identity logo to your corporate logo, add the following line to the `config.js` configuration file.

   ```
   window.HEADER_BAR_LOGO = '<filename>';
   ```

2. Add the logo to the build directory.

   > **Note**
   >
   > Make sure to use the same file name specified in step 1.

Result

The corporate logo appears in the header, and the Ping Identity logo relegates to the sidebar in grayscale, preceded by "Powered by".

Copyright © 2025 Ping Identity Corporation

Configure the session timeout

By default, Delegated Admin has an idle session timeout value of 30 minutes. To adjust this value, perform the following steps.

Steps

1. Open the `config.js` configuration file in a text editor.
2. Add the following line to the configuration file.

   ```
   window.TIMEOUT_LENGTH_MINS=<TimeoutValue>;
   ```

   <*TimeoutValue*> is an integer that represents the session timeout value in minutes.

   To view an example outline that features this setting, see `example.config.js`.
3. Save your changes to `config.js`.

Verifying the installation

Steps

- To verify that Delegated Admin is installed successfully, go to `https://<webserverHost>:<httpPort>/delegator` and sign on to the application.

Troubleshooting

If your sign on attempt is unsuccessful, see Enabling log tracing and use your browser's debug feature to gain insight into the token-validation process.

Reporting

Reports provide information about users and group membership. You can preview a report and search, filter, and sort the content. When the preview meets your needs, you can download the resulting report.

About this task

In the Delegated Admin GUI, the left navigation pane provides a Reporting tab under the top-level sections, such as Users and Groups.

Administrators can also use the Reporting page to upload users and group members in bulk with a `.csv` file. The `.csv` file should contain headers with the exact attribute names of the users resource type. Users can be uploaded with missing info for some of the attributes but the required attributes must be present and specified. For a group administrator, uploading users will also add them to the appropriate group. Click `Upload` on the Reporting page and select a `.csv` file to upload.

On each Reporting tab, you can:

- Filter the columns or attributes to display.
- Filter the users returned, such as all users with the first name John. Only exact matches are returned.

Copyright © 2025 Ping Identity Corporation

- Sort columns by clicking the column name.

Steps

- To apply filters to the report, click Run.
- To download the report as currently filtered and sorted, click Download Report.
- To clear any filtering and sorting, click Reset.

Compatibility matrix

The following matrix identifies the minimum versions of the PingDirectory server required to access the full functionality provided by each release of Delegated Admin.

> **Note**
>
> All versions of Delegated Admin require PingFederate 9.0.0 or later.

Delegated Admin	PingDirectory server
4.10.0	9.1.0.0
4.9.0	9.1.0.0 EA
4.8.0	9.0.0.0
4.7.0	9.0.0.0 EA
4.6.0	8.3.0.0
4.5.0	8.3.0.0 EA
4.4.1	8.2.0.0
4.4.0	8.2.0.0
4.3.0	8.2.0.0 EA

Configuring the PingFederate server

PingFederate offers many configuration options. This section provides an example PingFederate configuration that supports Delegated Admin.

> **Note**
>
> The PingFederate information in this section is based on the PingFederate 10.1 interface.

Copyright © 2025 Ping Identity Corporation

Configuring the PingFederate server includes the following:

- Configuring PingFederate as the identity provider
- Configuring the OAuth server
- Configuring the PingDirectory server as the token validator (create OAuth client for PingDirectory)
- Configuring Delegated Admin as a new client (create OAuth client for Delegated Admin)
- Setting cross-origin resource sharing (CORS) settings
- Optional configuration tasks

Configuring PingFederate as the identity provider

The following task configures the PingFederate server as the identity provider (IdP) for the PingDirectory server.

Before you begin

Download the LDAPS certificate from the PingDirectory server. For more information, see Exporting certificates.

Steps

1. Sign on to the PingFederate administrative console.
2. Import the PingDirectory server LDAPS certificate:
    1. Go to Security → Certificate & Key Management → Trusted CAs.
    2. Click Import, click Choose File to browse to the certificate, click Next, and then click Save.
3. Add an LDAP datastore:
    1. Go to System → Data Stores.
    2. Click Add New Data Store.
    3. Specify a Name for the data store.
    4. Set Type to Directory (LDAP).
    5. Click Next.
    6. In the Hostname(s) field, enter the PingDirectory server host name and LDAPS port, separated by a colon (for example, 10.101.113.75:1636) and click Add.
    7. Select the Use LDAPS check box.
    8. Set LDAP Type to PingDirectory.
    9. In the User DN field, enter one of the following values based on your PingDirectory configuration:
        - `cn=dmanager`
        - `cn=Directory Manager`

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> These values are based on the assumption that Delegated Admin will run as the directory manager.

10. In the Password field, specify the root password.
11. Click Advanced and then Advanced LDAP Options.
    1. Select the Create New Connections If Necessary check box.
    2. Clear the Verify LDAPS Hostname check box.
    3. Click Done.
12. Click Test Connection.
13. Click Next.
14. Click Save.

4. Create the HTML form IdP Adapter.

   The adapter authenticates users against the PingDirectory server.

   1. Go to Authentication → IdP Adapters → Create New Instance
   2. In the Instance Name field, enter a name such as `PingDirectoryIdP`.
   3. Specify an Instance ID.
   4. Set Type to HTML Form IdP Adapter.
   5. Click Next.
   6. Go to the bottom of the page and click Manage Password Credential Validators.
   7. Create a validator to authenticate users against the PingDirectory server:
      1. Click Create New Instance.
      2. Specify an Instance Name.
      3. Specify an Instance ID.
      4. Set Type to LDAP User Name Password Credential Validator.
      5. Click Next.
      6. Specify an LDAP Datastore.
      7. Specify an Search Base.
      8. Enter the following text in the Search Filter field to use the email address or user name to sign on to the system.

         ```
         (|(uid=${username})(mail=${username}))
         ```

      9. Click Next and extend the contract with `entryUUID` and `cn`.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> These values are used later.

10. Click Next, Done, or Save until you reach the Create Adapter Instance screen.

8. Add a new row to Password Credential Validators, choose the new LDAP Password Credential Validator, and click Update.
9. Go to the Extended Contract tab and extend the adapter contract with `entryUUID` and `cn`.
10. Go to the Adapter Attributes tab, select `entryUUID` for a pseudonym, and then click Next, Next, Done, and Save.

    For more information, see Configuring the LDAP Username Password Credential Validator.

5. Enable session tracking:
    1. Go to Authentication → Sessions
    2. Select the Track Adapter Sessions For Logout check box.
    3. Select the Track Revoked Sessions On Logout check box.
    4. Select the Enable Authentication Sessions For All Sources check box.
    5. Click Save.

Configuring the OAuth server

The following task configures the PingFederate server for OAuth and OpenID Connect (OIDC) authentication.

Steps

1. Sign on to the PingFederate administrative console.
2. Set the identity provider (IdP) adapter mapping:
    1. Go to Authentication > OAuth > IdP Adapter Grant Mapping.
    2. From the Source Adapter Instance list, select the IdP adapter you created in Configuring PingFederate as the identity provider and click Add Mapping.
    3. Click Next.

    > **Note**
    >
    > No attribute source is needed.

    4. On the Contract Fulfillment tab, set the contracts as shown in the following table:

Contract	Source	Value
USER_KEY	Adapter	entryUUID

Copyright © 2025 Ping Identity Corporation

Contract	Source	Value
USER_NAME	Adapter	cn

5. Click Next and then click Next again.
6. Click Save.

3. Set up Access Token Management.

   Select an existing instance or click Applications > OAuth > Access Token Management > Create New Instance.

   Choose from:

   - If selecting an existing instance, click the Instance Configuration tab.

     > **Note**
     > With an existing instance, a JSON Web Token (JWT) is configured automatically.

   - If creating a new instance, specify the required fields and set Type to JSON Web Tokens.

     > **Note**
     > Take note of your new instance name. You'll need that information later.

     1. Use symmetric encryption for the JWT by adding a row in the Symmetric Keys section using 32 bytes or 64 characters of hex.

        > **Note**
        > This encryption only requires a symmetric key, not a certificate and private key. This step requires the client to validate the token by hitting the validation endpoint on the server.

     2. Set JWS Algorithm to HMAC Using SHA-256.
     3. Set Active Symmetric Key ID to your symmetric key and click Next.
     4. On the Session Validation tab, select all options and click Next.
     5. On the Access Token Attribute Contract tab, list at least one attribute to be defined in the access token, add `sub`, click Next until you reach the last section, and then click Save.

4. Set up access token mapping:

   1. Go to Applications > OAuth > Access Token Mappings.
   2. Set Context to Default, set Access Token Manager to the access token manager you created in the last step, and click Add Mapping.
   3. Click Next in the Attribute Source & User Lookup section to go to the Contract Fulfillment section.
   4. In the sub row, make the following selections:

      - In the Source list, select Persistent Grant.

Copyright © 2025 Ping Identity Corporation

- In the Value list, select USER_KEY.

5. Click Next until you reach the Summary section. Click Save.

5. Set up the OpenID Connect policy:
    1. Go to Applications > OAuth > OpenID Connect Policy Management.
    2. Click Add Policy.
    3. Specify a Policy ID.
    4. Specify a Name.
    5. Choose the previously created access token manager and click Next.
    6. Delete all extended contract attributes except `sub`.

       Other scopes are defined, if configured.
    7. Click Next to reach the Contract Fulfillment section.
    8. Fulfill the OpenID Connect (OIDC) contract sub with the access token attribute `sub`.
    9. Click Next and then click Done.
    10. If a default OIDC policy is not already defined, set this new policy as the default and click Save.
6. Add scopes for PingDirectory server APIs:
    1. Go to System > OAuth Settings > Scope Management.
    2. Click the Exclusive Scopes tab.
    3. Add a scope with a Scope Value of `urn:pingidentity:directory-delegated-admin` and a Scope Description of `DAScope`.
    4. Click Save.

Configuring the PingDirectory server as the token validator (create OAuth client for PingDirectory)

When creating a PingFederate access token validator in the PingDirectory server, use the `pingdirectory` client ID and secret.

About this task

The PingDirectory server uses an identity mapper to match the `sub` claim against the `entryUUID` attribute.

To configure the PingDirectory server as the token validator:

Steps

1. Sign on to the PingFederate administrative console.
2. Go to Applications → OAuth → Clients.
3. Click Add Client.

Copyright © 2025 Ping Identity Corporation

4. For both the Client ID and Name, specify `pingdirectory`.
5. In the Client Authentication section, select Client Secret.
6. In the Client Secret section, select Change Secret and then enter or generate a secret.
7. Copy the secret key.
8. In the Allowed Grant Types section, select Access Token Validation (Client is a Resource Server).
9. Set the Default Access Token Manager to the access token manager you created in step 3 of Configuring the OAuth server.
10. Click Save.

Configuring Delegated Admin as a new client (create OAuth client for Delegated Admin)

About this task

To configure Delegated Admin as a new client:

Steps

1. Sign on to the PingFederate administrative console.
2. Go to Applications → OAuth → Clients.
3. Click Add Client.
4. For both the Client ID and Name, specify `dadmin`.
5. Set Client Authentication to None.

> **Important**
>
> Do not set a client secret.

6. For Redirect URIS, enter the appropriate URI for your environment based on the following table and then click Add.

For Delegated Admin on a PingDirectory server or a PingDirectoryProxy server	`https://<server-host>:<server-port>/delegator/*`
For Delegated Admin on a web server hosted locally	`http://localhost:<server-port>/*`

7. Make the following selections:
    1. In the Bypass Authorization Approval section, select Bypass.
    2. In the Exclusive Scopes section, select Allow Exclusive Scopes and then select urn:pingidentity:directory-delegated-admin.
    3. In the Allowed Grant Types section, select Authorization Code.

Copyright © 2025 Ping Identity Corporation

4. In the Default Access Token Manager list, select the token manager that you created in step 3 of Configuring the OAuth server.
5. Select the check box for Require Proof Key for Code Exchange (PKCE).
6. In the OpenID Connect section, select the OpenID Connect (OIDC) policy that you created in step 5 of Configuring the OAuth server.

8. Click Save.

Next steps

After completing the previous steps, configure the following settings to display the name of the administrator who is signed on to the client application:

1. Add the `profile` scope and ensure it is available to the OAuth client used for the Delegated Admin application.
2. Add and fulfill the `name` attribute as part of the contract for both the access token and the ID token supplied to the Delegated Admin application.
3. Set the `PROFILE_SCOPE_ENABLED` configuration variable for Delegated Admin in the `config.js` file to `true`.

```
/**
 * Configuration wrapper object for Delegated Admin
 */
window.PD_DADMIN_CONFIG = {
  /**
   * Set to true if the "profile" scope is supported for the Delegated Admin OIDC client on
   * PingFederate and you wish to use it to show the current user's name in the navigation.
   * DEFAULT: false
   */
  PROFILE_SCOPE_ENABLED: true,
};
```

Setting cross-origin resource sharing (CORS) settings

The CORS settings can be set through the PingFederate administrative console.

Steps

1. Sign on to the PingFederate administrative console.
2. Click SYSTEM → OAuth Settings → Authorization Server Settings.
3. Go to the Cross-Origin Resource Sharing Settings section.
4. Add `https://${directoryServer:httpPort}` to Allowed Origin, using the host name and HTTPS listener port for the PingDirectory server.

> **Important**
>
> Don't include `/delegator` in the **Allowed Origin** field. Doing so causes Delegated Admin to throw a token validation error when you attempt to sign on.

Copyright © 2025 Ping Identity Corporation

For example, consider the following table:

For Delegated Admin on a PingDirectory server or a PingDirectoryProxy server	`https://<server-host>:<server-port>`
For Delegated Admin on a web server hosted locally	`http://localhost:5000/*`

5. Click Save.

Optional configuration tasks

For additional, optional configuration tasks, see the following topics.

- Configuring a local identity profile
- Configuring the HTML Form Adapter for customer identities
- Configuring local identity mapping

Changing the default OIDC grant type

To change the Delegated Admin application's default OpenID Connect (OIDC) grant type, use the PingFederate administrative console and the Delegated Admin `config.js` file.

About this task

To improve authentication security, switch your default OIDC grant type to Authorization Code with Require Proof Key for Code Exchange (PKCE). The Authorization Code with PKCE grant type hides access tokens during authentication with JavaScript applications, in comparison to the Implicit grant type that displays access tokens in the URL redirect during OIDC authentication.

> **Note**
>
> For more information, see OAuth Grant Types.

The following example changes the default OIDC grant type from Implicit to Authorization Code with Require Proof Key for Code Exchange (PKCE).

Steps

1. In the PingFederate administrative console, go to Applications → OAuth → Clients.
2. From the Clients list, select the dadmin client.
3. In the Allowed Grant Types section:
    1. Select the Authorization Code check box.
    2. Clear the Implicit check box.
    3. Select the Require Proof Key for Code Exchange (PKCE) check box.

Copyright © 2025 Ping Identity Corporation

4. Click Save.

4. From your `<server-root>` directory, open the Delegated Admin application's `config.js` file and set the `AUTHENTICATE_WITH_PKCE` variable to `true`.

Example:

```
/*
 * Indicates if this app should authenticate using the 'Authorization Code with PKCE' OAuth grant.
 * If true, the 'Authorization Code with PKCE grant will be used. If false, the 'Implicit' grant
 * will be used. * DEFAULT: window.AUTHENTICATE_WITH_PKCE = true;
 */
window.AUTHENTICATE_WITH_PKCE = true;
```

Note

If you don't already have the `AUTHENTICATE_WITH_PKCE` variable in your `config.js` file, you must add it.

Introduction to the PingDataSync server

The PingDataSync server is an efficient, Java-based server that provides high throughput, low latency, and bidirectional real-time synchronization between two endpoint topologies, such as PingDirectory servers, PingDirectoryProxy servers, PingOne, or relational database management systems (RDBMS) systems.

PingDataSync uses a dataless approach that synchronizes changes directly from the data sources in the background so that applications can continue to update their data sources directly. PingDataSync doesn’t store any data from the endpoints themselves, which reduces hardware and administration costs. The server’s high-availability mechanisms allow for easy failover from the main PingDataSync server to redundant instances.

PingDataSync server features

PingDataSync is designed to run with little administrative maintenance and includes the following features:

- High performance and availability with built-in redundancy.
- Dataless virtual architecture for a small-memory footprint and ease of maintenance.
- Comprehensive and straightforward setup that enables mapping attribute names, values, and distinguished names (DNs) between endpoints. For directory server endpoints, this enables schema and directory information tree (DIT) changes without custom coding and scripting.

Copyright © 2025 Ping Identity Corporation

- Multi-vendor directory server support, including:
  - PingDirectory server
  - PingDirectoryProxy server
  - Sun Directory Server Enterprise Edition
  - Sun Directory Server
  - Oracle Unified Directory
  - OpenDJ
  - Microsoft Active Directory (AD)
  - Generic LDAP directories
- RDBMS support, including Oracle Database and Microsoft SQL server systems.
- Proxy server support including PingDirectoryProxy server.
- A notification mode that sends real-time change notifications to the application or service of your choice through the server SDK.

The following topics present a general overview of the PingDataSync process and examples for use:

- Data synchronization process
- Synchronization modes
- PingDataSync operations
- Configuration components
- Synchronization flow examples
- Sample synchronization

Data synchronization process

PingDataSync performs point-to-point synchronization between a source endpoint and a destination endpoint. An endpoint is defined as any source or destination topology of directory or database servers.

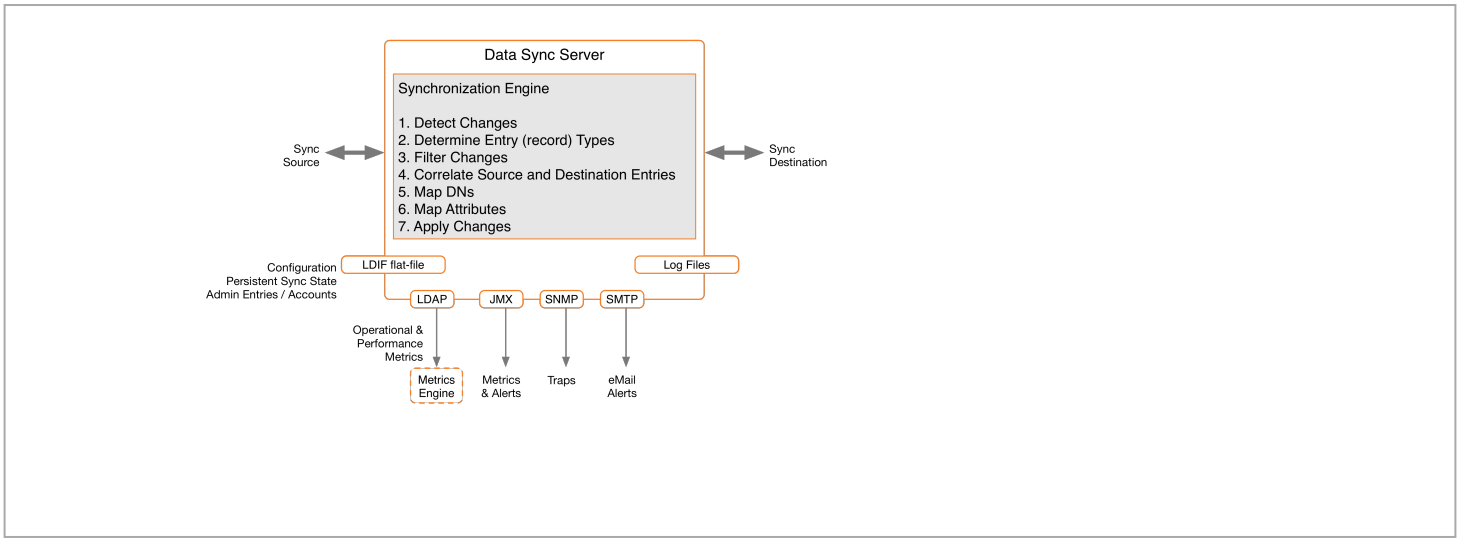
PingDataSync synchronizes data in one direction or bidirectionally between endpoints. For example, in a migration phase from Sun Directory server to a PingDirectory server, synchronization can occur in one direction from the source server to a staging server. With one-way synchronization, the source server is the authoritative endpoint for changes in the system. Bidirectional synchronization allows for parallel active installations between the source and the destination endpoints. With bidirectional synchronization, both endpoints are authoritative for the same set of attributes or for different sets of data.

Copyright © 2025 Ping Identity Corporation

PingDataSync also contains no single point of failure, either for detecting changes or for applying changes. PingDataSync instances themselves are redundant. There can be multiple instances running at a time, but only the server with the highest priority is actively synchronizing changes. The stand-by servers are constantly polling the active server instance to update their persistent state. This state contains the minimum amount of information needed to begin synchronization where the primary server left off, which logically is the last processed change number for the source server. In the case of a network partition, multiple servers can synchronize simultaneously without causing problems as they each verify the full entry before making changes.

Synchronization architecture

PingDataSync uses a virtualized, dataless approach that does not store directory data locally. The log files, administrator entries, configuration, sync state information are stored as flat files (LDIF format) within the system. No additional database is required.



Change tracking, monitoring, and logging

PingDataSync tracks and manages processes and server health with the following tools:

Change Tracking

Each directory instance stores a separate entry under cn=changelog for every modification made to the directory. PingDataSync provides full control over the synchronization process by determining which entries are synchronized, how they are correlated to the entries at the destination endpoint, and how they are transformed into the destination schema.

- For the PingDirectory server or Nokia 8661 Directory Server topologies, PingDataSync uses the server's LDAP Change Log for modification detection.
- For Oracle/Sun Directory Server, OpenDJ, Oracle Unified Directory, and generic LDAP directory topologies, PingDataSync uses the server's Retro Change Log, which provides a detailed summary of each change.
- For Active Directory (AD), PingDataSync uses the DirSync control, which polls for object attribute changes.

Copyright © 2025 Ping Identity Corporation

- For RDBMS systems, PingDataSync uses a Ping Identity Server SDK plugin to interface with a customized RDBMS change log table. The database triggers on each table record all INSERT, UPDATE, and DELETE operations to the change log table.

Monitoring, Alerts, and Alarms

PingDataSync supports several industry-standard, administrative protocols for monitoring, alarms, and alerts. System alarms and gauges can be configured to determine healthy performance thresholds and the server actions taken when performance values are outside the threshold. All administrative alarms are exposed over LDAP as entries under base DN `cn=alarms`. An administrative alert framework sends warnings, errors, or other server events through log messages, email, or JMX notifications. Administrative alerts are also exposed over LDAP as entries below base DN `cn=alerts`. Typical alert events are startup or shutdown, applied configuration changes, or synchronized resources unavailable.

Logging

PingDataSync provides standard logs (`sync, access, error, failed-operations, config-audit.log, debug`). The server can also be configured for multiple active sync logs. For example, each detected change, each dropped change, each applied change, or each failed change can be logged.

Synchronization modes

PingDataSync runs as a standalone Java process with two synchronization modes: standard and notification.

Standard synchronization

In standard synchronization mode, PingDataSync polls the directory server change log for create, modify, and delete operations on any entry. The server fetches the full entries from both the source and destination endpoints, and compares them to produce the minimal set of changes required to synchronize the destination with the source.

Notification synchronization

In notification synchronization mode, PingDataSync skips the fetch and compare phases of processing, notifies the destination that a change has happened, and provides the details of the change. Notification mode is currently available for the PingDirectory and Alcatel-Lucent 8661 directory and proxy servers only.

PingDataSync operations

PingDataSync provides seamless integration between disparate systems to transform data using attribute and DN mappings. A bulk resynchronization operation can be run verify mappings and test synchronization settings.

Copyright © 2025 Ping Identity Corporation

Real-time synchronization

Real-time synchronization is performed with the `realtime-sync` utility. The `realtime-sync` utility polls the source server for changes and synchronizes the destination entries immediately. Once the server determines that a change should be synchronized, it fetches the full entry from the source. It then searches for the corresponding entry in the destination endpoint using correlation rules and applies the minimum set of changes to synchronize the attributes. The server fetches and compares the full entries to make sure it does not synchronize any old data from the change log.

After a synchronization topology is configured, run `resync` to synchronize the endpoints, and then run `realtime-sync` to start global synchronization.

The `realtime-sync` tool is used for the following tasks:

- Start or stop synchronization globally or for specific sync pipes only.
- Set a start point at which synchronization should begin such as the beginning or end of the change log, at a specified change number, at a specified change sequence number, or at a specified time frame in the change log.

Data transformations

Data transformations alter the contents of synchronized entries between the source and destination directory server to handle variances in attribute names, attribute values, or DN structures. When entries are synchronized between a source and a destination server, the contents of these entries can be changed using attribute and DN mappings, so that neither server needs be aware of the transformations.

- Attribute Mapping – Any attribute in the entry can be renamed to fit the schema definitions from the source endpoint to the destination endpoint. This attribute mapping makes it possible to synchronize information stored in one directory's attribute to an attribute with a different name in another directory server, or to construct an attribute using portions of the source attribute values.
- DN Mapping – Any DNs referenced in the entries can be transparently altered. This mapping makes it possible to synchronize data from a topology that uses one DIT structure to a system that uses a different DIT structure.

Bulk resync

The `resync` tool performs a bulk comparison of entries on source topologies and destination topologies. PingDataSync streams entries from the source, and either updates the corresponding destination entries or reports those that are different. The `resync` utility resides in the `/bin` folder (UNIX or LINUX) or `\bat` folder (Windows), and can be used for the following tasks:

- Verify that the two endpoints are synchronized after an initial configuration.
- Initially populate a newly configured target endpoint.
- Validate that the server is behaving as expected. The `resync` tool has a `--dry-run` option that validates that synchronization is operating properly, without updating any entries. This option also can be used to check attribute or DN mappings.
- Perform scheduled synchronization.
- Recover from a failover by resynchronizing entries that were modified since the last backup was taken.

Copyright © 2025 Ping Identity Corporation

The `resync` tool also enables control over what can be synchronized, such as:

- Include or exclude any source and destination attributes.
- Apply an LDAP filter to only sync entries created since that last time the tool ran.
- Synchronize only creations or only modifications.
- Change the logging verbosity.
- Set a limit on `resync` operations (such as 2000 operations per second) to reduce impact on endpoint servers.

The sync retry mechanism

PingDataSync is designed to quickly synchronize data and attempt a retry should an operation fail for any reason. The retry mechanism involves two possible retry levels, which are configurable on the Sync Pipe configuration using advanced Sync Pipe properties. For detailed information, see the PingDataSync Reference Guide for the Sync Pipe configuration parameters.

Retry involves two possible levels:

First Level Retry

If an operation fails to synchronize, the server will attempt a configurable number of retries. The total number of retry attempts is set in the `max-operation-attempts` property on the Sync Pipe. The property indicates how many times a worker thread should retry the operation before putting the operation into the second level of retry, or failing the operation altogether.

Second Level Retry

Once the `max-operation-attempts` property has been exceeded, the retry is sent to the second level, called the delayed-retry queue. The delayed-retry queue uses two advanced Sync Pipe properties to determine the number of times an operation should be retried in the background after a specified delay.

Operations that make it to this level will be retried after the `failed-op-background-retrydelay` property (default: 1 minute). Next, PingDataSync checks the `max-failedop-background-retries` property to determine the number of times a failed operation should be retried in the background. By default, this property is set to 0, which indicates that no background retry should be attempted, and that the operation should be logged as failed.

> **Note**
>
> Background operations can hold up processing other changes, since PingDataSync will only process up to the next 5000 changes while waiting for a retried operation to complete.

Retry can be controlled by the custom endpoint based on the type of error exception. When throwing an exception, the endpoint code can signal that a change should be aborted, retried a limited number of times, or retried an unlimited number of times. Some errors, such as endpoint server down, should be retried indefinitely.

If the `max-failed-op-background-retries` property has been exceeded, the retry is logged as a failure and appears in the sync and the sync-failed-ops logs.

Copyright © 2025 Ping Identity Corporation

Configuration components

PingDataSync supports the following configuration parameters that determine how synchronization takes place between directories or databases:

Sync Pipe

Defines a single synchronization path between the source and destination topologies. Every Sync Pipe has one or more Sync Classes that control how and what is synchronized. Multiple Sync Pipes can run in a single server instance.

Sync Source

Defines the directory topology that is the source of the data to be synchronized. A Sync Source can reference one or more supported external servers.

Sync Destination

Defines the topology of directory servers where changes detected at the Sync Source are applied. A Sync Destination can reference one or more external servers.

External Server

Defines a single server in a topology of identical, replicated servers to be synchronized. A single external server configuration object can be referenced by multiple Sync Sources and Sync Destinations

Sync Class

Defines the operation types and attributes that are synchronized, how attributes and DNs are mapped, and how source and destination entries are correlated. A source entry is in one Sync Class and is determined by a base DN and LDAP filters. A Sync Class can reference zero or more Attribute Maps and DN Maps, respectively. Within a Sync Pipe, a Sync Class is defined for each type of entry that needs to be treated differently. For example, entries that define attribute mappings, or entries that should not be synchronized at all. A Sync Pipe must have at least one Sync Class but can refer to multiple Sync Class objects.

DN Map

Defines mappings for use when destination DNs differ from source DNs. These mappings allow the use of wild cards for DN transformations. A single wild card ("*") matches a single RDN component and can be used any number of times. The double wild card ("**") matches zero or more RDN components and can be used only once. The wild card values can be used in the `to-dn-pattern` attribute using `{1}` and their original index position in the pattern, or `{attr}` to match an attribute value. For example:

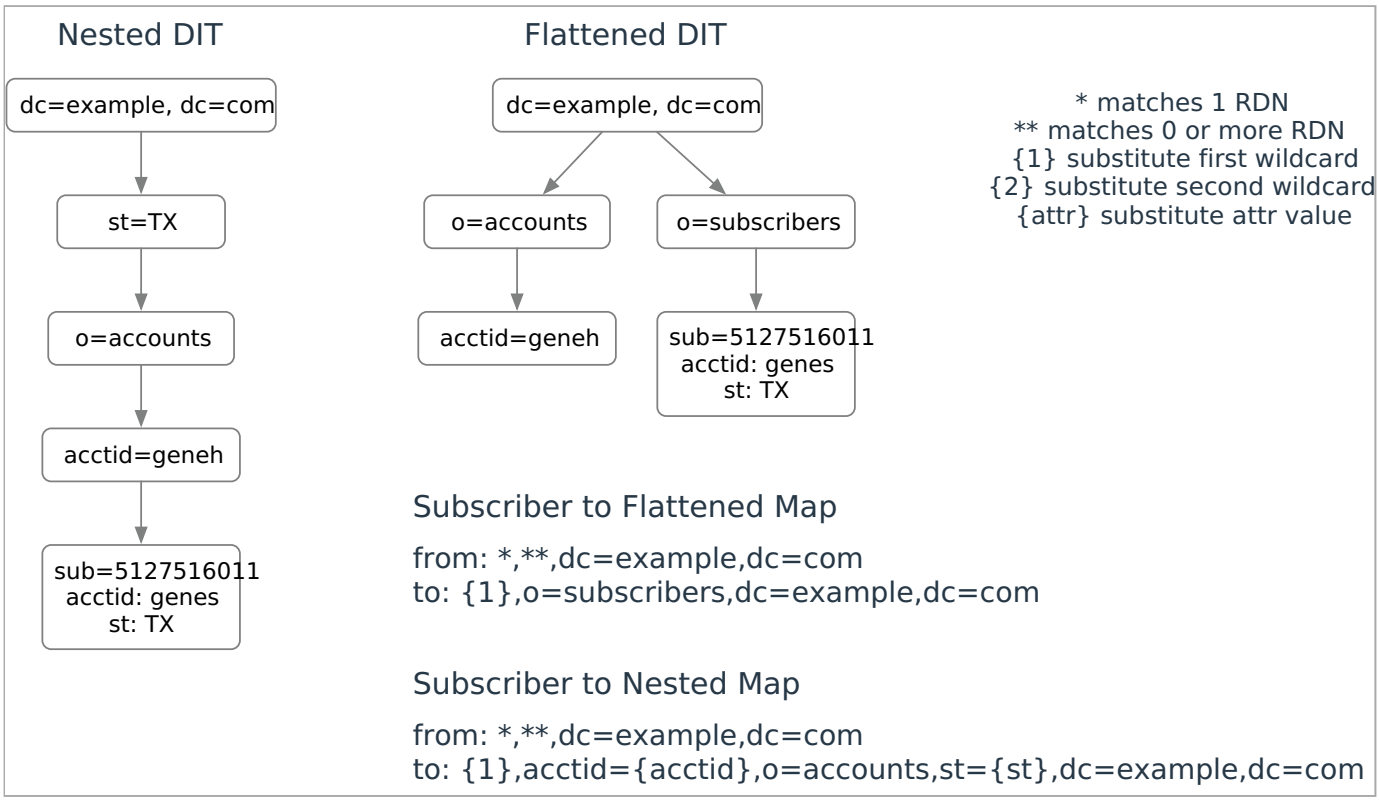
```
**,dc=myexample,dc=com->{1},o=example
```

Regular expressions and attributes from the user entry can also be used. For example, the following mapping constructs a value for the `uid` attribute, which is the RDN, out of the initials (first letter of `givenname` and `sn`) and the employee ID (`eid` attribute).

```
uid={givenname:/^(.)(.*)/$1/s}{sn:/^(.)(.*)/$1/s}{eid},{2},o=example
```

Copyright © 2025 Ping Identity Corporation

The following illustrates a how a nested DIT can be mapped to a flattened structure.



A diagram illustrating the mapping of a nested DIT to a flattened structure.

Attribute Map and Attribute Mappings

Defines a mapping for use when destination attributes differ from source attributes. A Sync Class can reference multiple attribute maps. Multiple Sync Classes can share the same attribute map. There are three types of attribute mappings:

- Direct Mapping – Attributes are directly mapped to another attribute: For example:

```
employeenumber->employeeid
```

- Constructed Mapping – Destination attribute values are derived from source attribute values and static text. For example:

```
{givenname}.{sn}@example.com->mail
```

- DN Mapping – Attributes are mapped for DN attributes. The same DN mappings that map entry DNs can be referenced. For example:

```
uid=jdoe,ou=People,dc=example,dc=com.
```

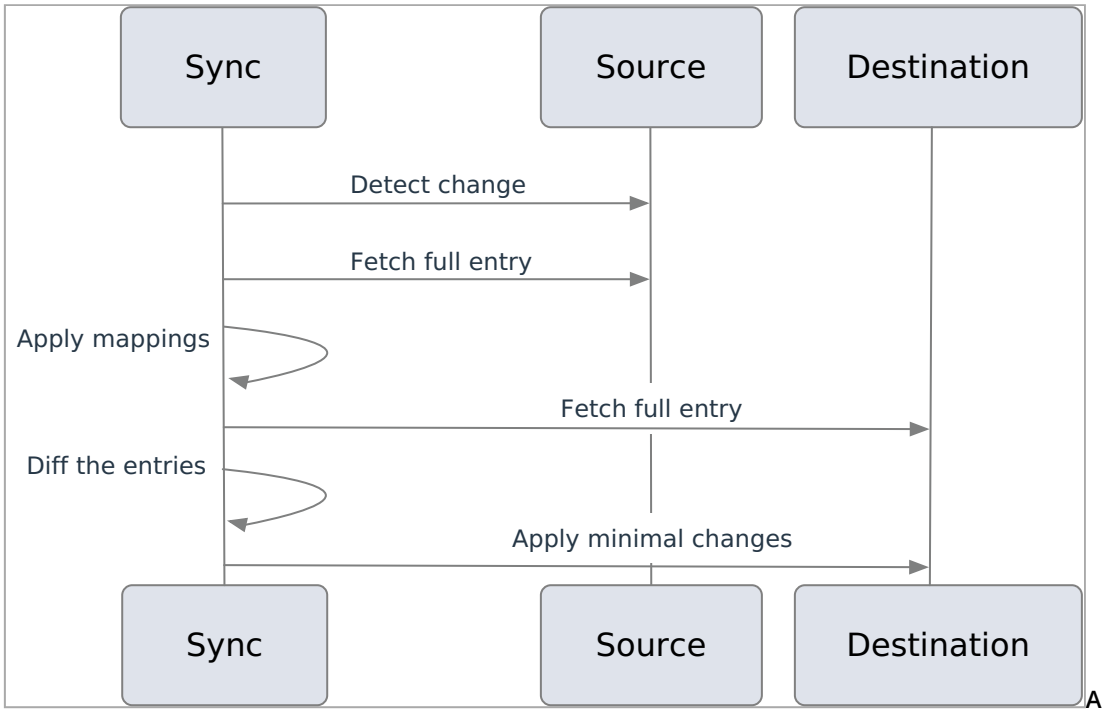
Sync flow examples

PingDataSync processes changes by fetching the most up-to-date, full entries from both sides and then compares them. This process flow is called standard synchronization mode. The processing flow differs depending on the type of PingDataSync change (`ADD, MODIFY, DELETE, MODDN`) that is requested. The following examples show the control flow diagrams for the sync operations, especially for those cases when a `MODIFY` or a `DELETE` operation is dropped. The sync log records all completed and failed operations.

Modify operation example

About this task



A process flow diagram that is described in detail in the following steps.

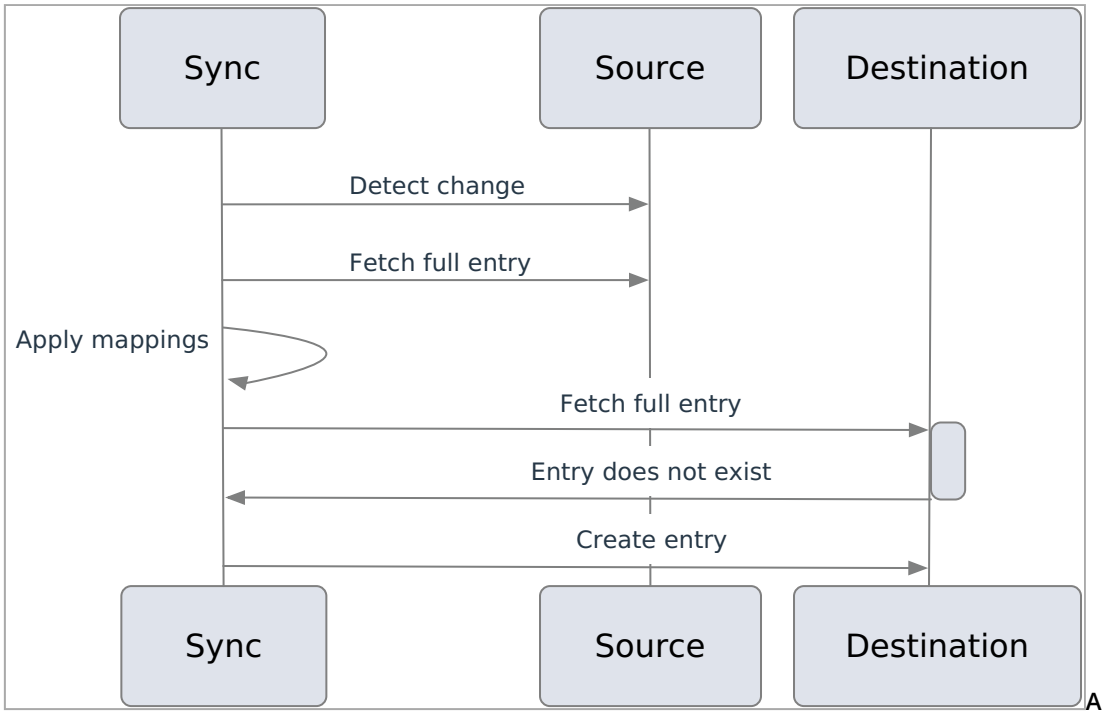
Steps

1. Detect change from the change log table on the source.
2. Fetch the entry or table rows from affected tables on the source.
3. Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.
4. Fetch the entry or table rows from affected tables on the destination.
5. Diff the computed destination entry and actual destination entry.
6. Apply the changes to the destination.

Copyright © 2025 Ping Identity Corporation

Add operation example

About this task



A process flow diagram that is described in detail in the following steps.

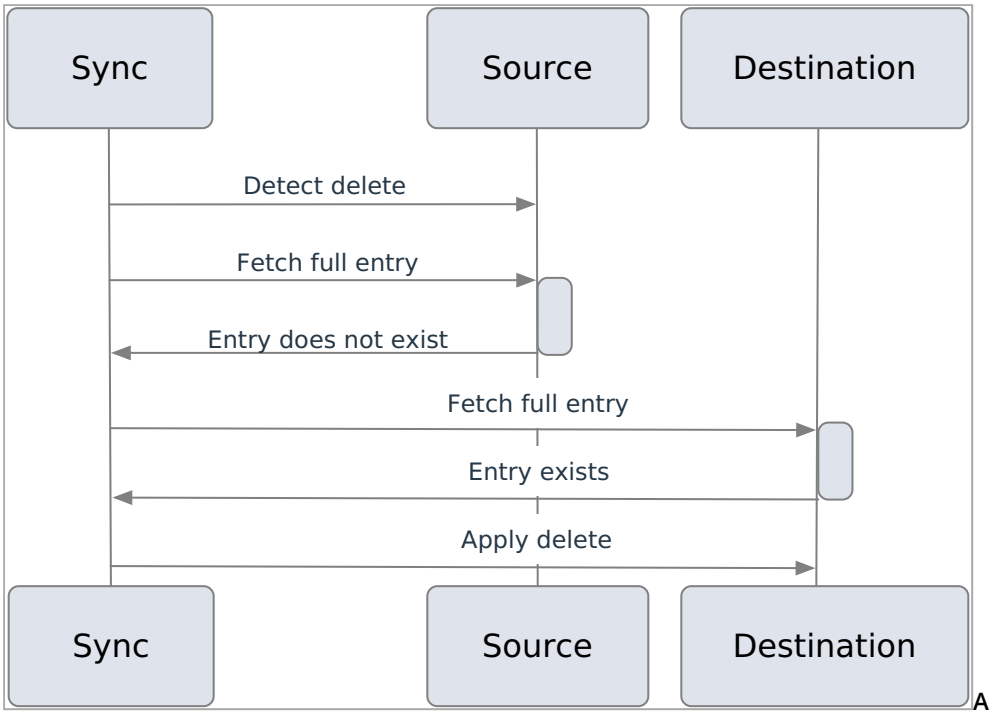
Steps

1. **Detect change from the change log table on the source.**
2. **Fetch the entry or table rows from affected tables on the source.**
3. **Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.**
4. **Fetch the entry or table rows from affected tables on the destination.**
5. **The entry or table row does not exist on the destination.**
6. **Create the entry or table row.**

Delete operation example

About this task

Copyright © 2025 Ping Identity Corporation



A process flow diagram that is described in detail in the following steps

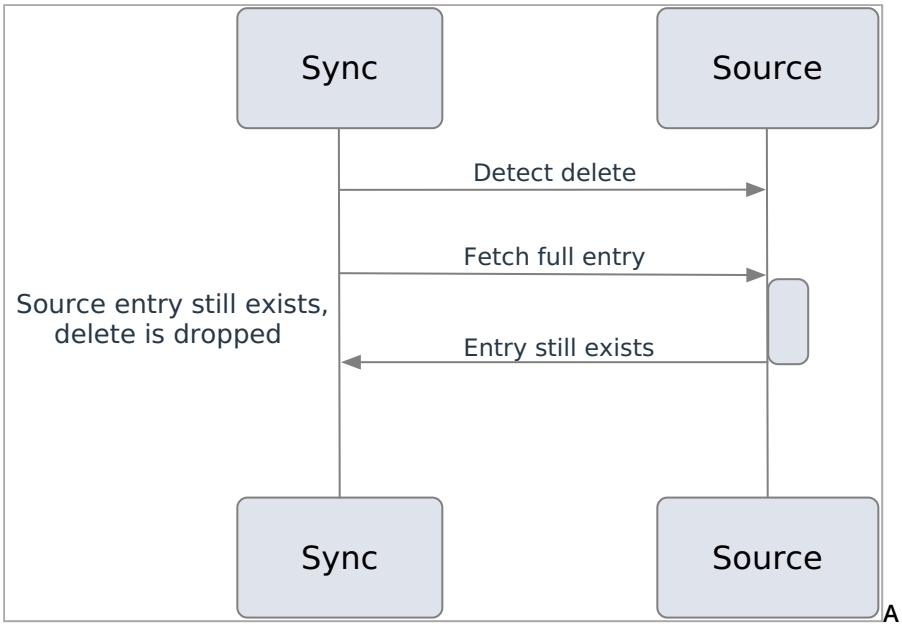
Steps

1. **Detect delete from the change log table on the source.**
2. **Fetch the entry or table rows from affected tables on the source.**
3. **Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.**
4. **Fetch the entry or table rows from affected tables on the destination.**
5. **The entry or table row exists on the destination.**
6. **Apply the delete on the destination.**

Delete after source entry is re-added

About this task

Copyright © 2025 Ping Identity Corporation



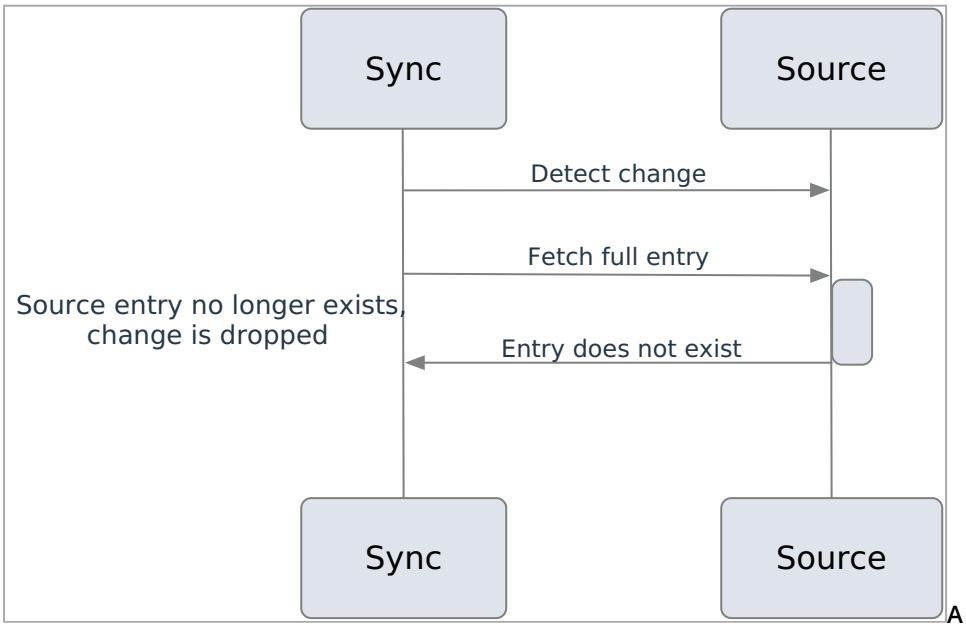
A process flow diagram that is described in detail in the following steps

Steps

1. **Detect delete from the change log table on the source.**
2. **Fetch the entry or table rows from affected tables on the source.**
3. **The entry or table row exists on the source.**
4. **Delete request is dropped.**

Standard modify after source entry is deleted

About this task



A process flow diagram that is described in detail in the following steps.

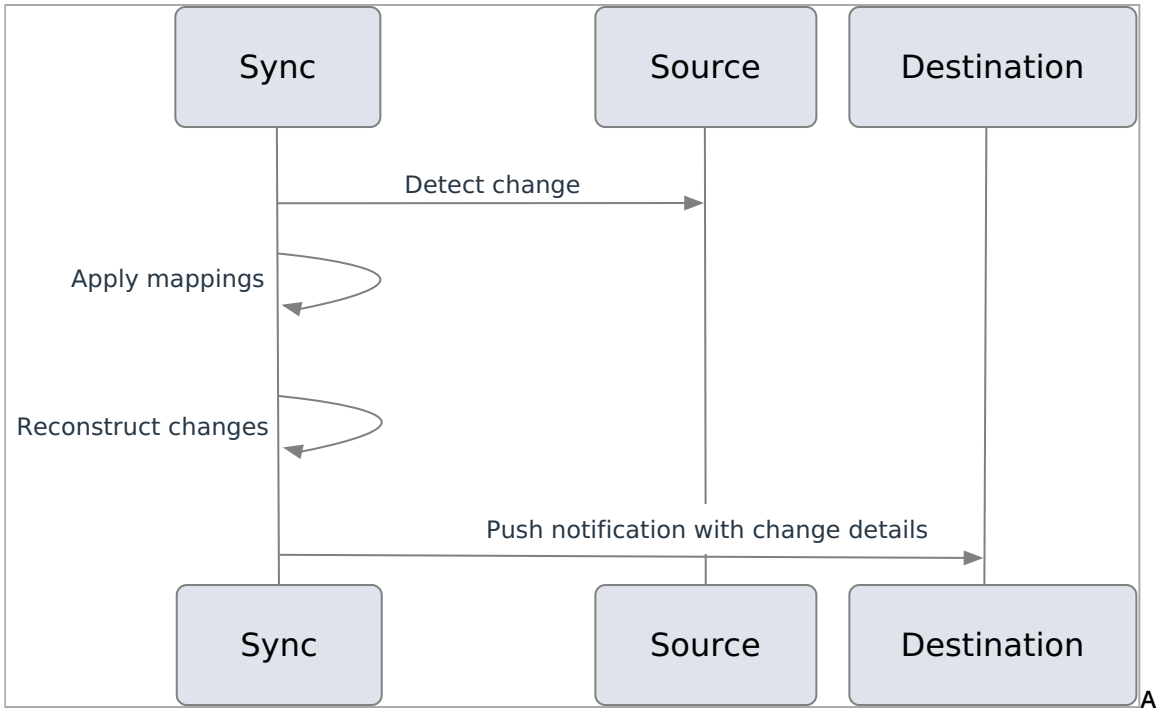
Copyright © 2025 Ping Identity Corporation

Steps

1. Detect change from the change log table on the source.
2. Fetch the entry or table rows from affected tables on the source.
3. The entry does not exist.
4. Change request is dropped because the source entry no longer exists.

Notification add, modify, modifyDN, and delete

About this task



A process flow diagram that is described in detail in the following steps.

Steps

1. Detect change from the change log table on the source.
2. Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.
3. Reconstruct changed entries.
4. Push notification with change details to the destination.

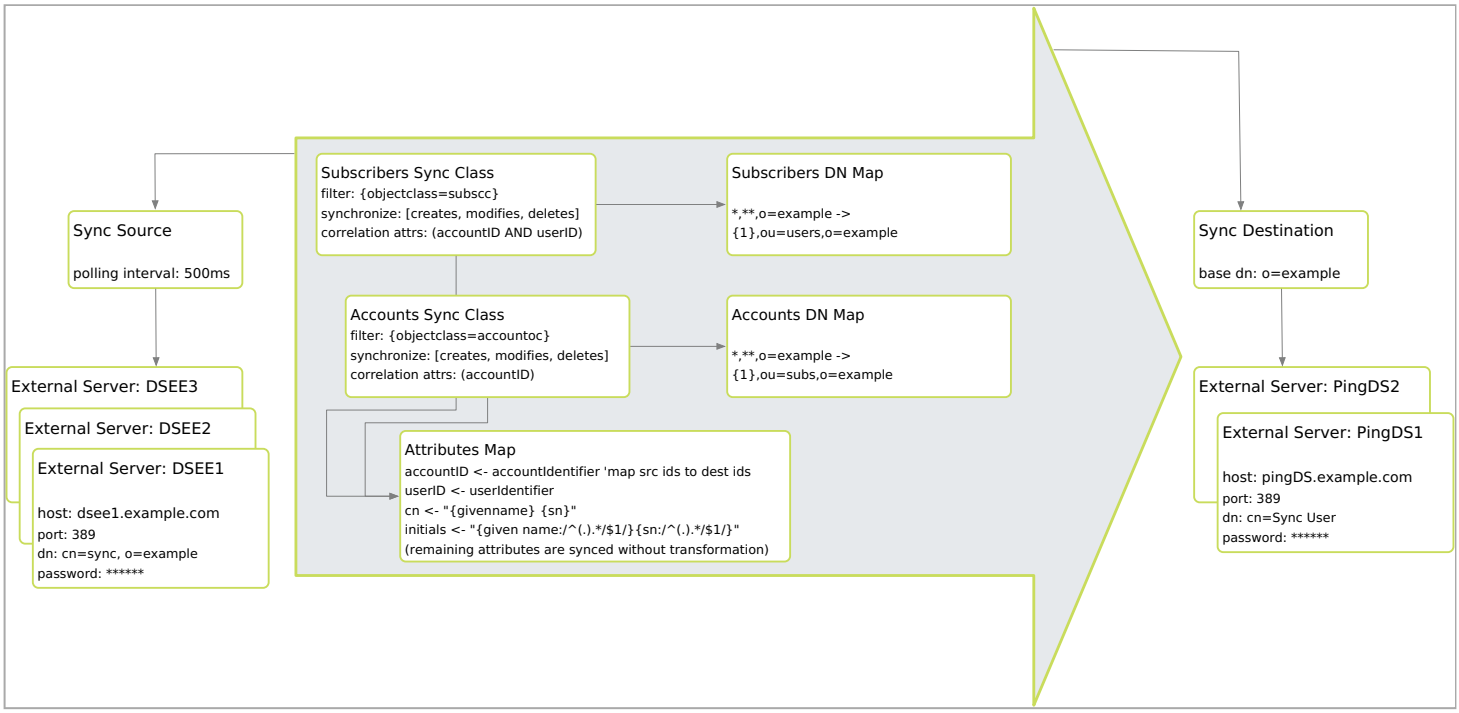
Sample synchronization

The following is a synchronization migration example from a Sun Directory Server Enterprise Edition (DSEE) topology to the PingDirectory server topology, including a change in the DIT structure to a flattened directory structure. The Sync Pipe connects the Sun Directory Server topology as the Sync Source and the PingDirectory server topology as the Sync Destination. Each endpoint is defined with three external servers in their respective topology. The Sync Pipe destination has its base DN set to `o=example`, which is used when performing LDAP searches for entries.

Two Sync Classes are defined: one for Subscribers, and one for Accounts. Each Sync Class uses a single "Sun DS to PingData Attribute Map" that has four attribute mappings defined. Each Sync Class also defines its own DN maps. For example, the Accounts Sync Class uses a DN map, called PingData Account Map, that is used to flatten a hierarchical DIT, so that the Account entries appear directly under `ou=accounts` as follows:

```
*,**,o=example ->{1},ou=accounts,o=example
```

With this mapping, if an entry DN has `uid=jsmith,ou=people,o=example`, then "*" matches `uid=jsmith`, "**" matches `ou=people`, and `{1}` matches `uid=jsmith`. Therefore, `uid=jsmith,ou=people,o=example` gets mapped to `uid=jsmith,ou=accounts,o=example`. A similar map is configured for the Subscribers Sync Class.



A diagram illustrating a sample synchronization topology configuration.

Installing the PingDataSync server

This section describes how to install and run PingDataSync. It includes pre-installation requirements and considerations.

Topics include:

- System requirements

Copyright © 2025 Ping Identity Corporation

- Install the JDK
- Optimize the Linux operating system
- Ping Identity license keys
- Installing PingDataSync
- Signing on to the administrative console
- Server folders and files
- Start and stop the server
- Run the server as a Microsoft Windows service
- Uninstall the server
- Update servers in a topology
- Revert an update
- Install a failover server
- Administrative accounts

System requirements

The PingDirectory server requires certain software packages to operate properly.

For optimal performance, the server requires Java for 64-bit architectures. To view the minimum required Java version, contact your authorized support provider for the latest supported software versions.

> **Tip**
>
> Implement a Network Time Protocol (NTP) system so that multi-server environments are synchronized and timestamps are accurate.

The following system requirements are qualified and certified to be compatible with the PingDirectory server.

Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software are suspected of causing issues.

CPU and memory

When sizing an instance of the PingDirectory server, provide at least the following minimum specs:

- 2 processor cores
- 4 GB of RAM

You can find more information about memory allocation in Memory allocation and database cache or Finding the optimal heap size (requires authentication).

Copyright © 2025 Ping Identity Corporation

Running PingDirectory on Amazon Web Services (AWS)

To take advantage of snapshots for backing up any important files, install the PingDirectory server on an Elastic Block Store (EBS) file system. You should also move any databases, logs, and other files to a high-performance file system that's separate from the rest of the server image and create an S3 bucket for storing backups, schema, and other artifacts.

The following guidelines and considerations apply to AWS environments:

- PingDirectory does not support the Elastic File System (EFS) for database persistence. For the best performance, use the local SSD.
- Using network load balancers (NLBs) can lead to severed connections, which could cause issues that are difficult to diagnose.

Platforms

The PingDirectory, PingDirectoryProxy, PingDataSync, and PingDataMetrics servers support the following operating systems for installation and deployment:

- Amazon Linux 2
- Canonical Ubuntu 18.04 LTS and 20.04 LTS
- CentOS 7.7 and 8.1
- Microsoft Windows Server 2016 and 2019
- Oracle Linux
  - Release 7 up to 7.9
  - Release 8 up to 8.6
- Red Hat Enterprise Linux ES
  - Release 7 up to 7.9
  - Release 8 up to 8.6
  - Release version 9.0
- SUSE Linux Enterprise 12 SP5 and 15 SP3

> **Important**
>
> The PingDirectory suite of products has been tested with the default configurations of all operating system components. Customized implementations or installed third-party plugins from your organization might affect the deployment of this product.

Docker

To deploy the PingDirectory server using Docker, you must have a supported version of Docker.

The following versions of Docker are supported:

- Docker 20.10.9

Copyright © 2025 Ping Identity Corporation

Learn more in the pingidentity/pingdirectory Docker image and the Ping Identity DevOps documentation.

> **Note**
>
> Only the PingDirectory server software is licensed under Ping Identity's end user license agreement, and any other software components contained within the image are liensed solely under the terms of the applicable open source or third-party license.
> Ping Identity accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

Java Runtime Environment

You must have one of the following versions of the Java Development Kit installed prior to installing the server:

- **Oracle JDK 8 64-bit**
- **Oracle JDK 11 LTS 64-bit**
- **Oracle JDK 17**
- **OpenJDK 8 64-bit**
- **OpenJDK 11 and 17**
- **Corretto 8, 11, and 17**

> **Important**
>
> Refer to the following with regard to Java support:
>
> - Due to the number of supported JDK variants, we do not explicitly list all of them here. The criteria for supported JDKs are:
> - They must be built from the OpenJDK codebase.
> - They must use the HotSpot JIT compiler. They cannot use OpenJ9 or other JIT implementations.
> - PingDataMetrics doesn't support Java 17.
> - The Java Support Policy applies to your Java Runtime Environment (JRE).

Browsers

The following browsers are supported by the PingDirectory server administrative console:

- **Chrome**
- **Firefox**
- **Edge**

Copyright © 2025 Ping Identity Corporation

Upgrade overview and considerations

Considerations when upgrading to 9.0.0.0 or later

Due to major updates to Spring dependencies, Spring configuration properties in PingData admin console configuration files prior to PingDirectory 9.0.0.0 are not compatible with the most recent admin console bundled with 9.0.0.0 and later versions of PingDirectory products. Attempting to use these older configuration files will result in the console failing to start.

If you are using older PingData admin console configuration files, these should be updated. Replace the following excerpt in the old `application.yml` file:

```
spring:
  profiles.active: default
  main.show-banner: false
  thymeleaf.cache: true
  thymeleaf.prefix: classpath:/public/app/
```

with the following:

```
spring:
  profiles.active: default
  web.resources:
    # 1 year. Update the corresponding value in MvcConfig if this changes.
    cache.period: 31536000
    add-mappings: false # use our custom mappings instead of the defaults
  main:
    banner-mode: "OFF"
  thymeleaf:
    prefix: classpath:/public/app/
```

Considerations when upgrading to 8.2.0.0

This upgrade moves to Jetty 9.4. As a result, the HTTPS connection handler will no longer support TLS_RSA ciphers by default. If you use any legacy HTTPS clients that still require TLS_RSA ciphers, modify the `ssl-cipher-suite` property of the HTTPS Connection Handler to include them.

Install the JDK

The Java 64-bit JDK is required on the server. Even if Java is already installed, create a separate Java installation for use by the server to ensure that updates to the system-wide Java installation do not inadvertently impact the installation.

Optimize the Linux operating system

Configure the Linux file system by making the following changes.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The server explicitly overrides environment variables like `PATH`, `LD_LIBRARY_PATH`, and `LD_PRELOAD` to ensure that settings used to start the server do not inadvertently impact its behavior. If these variables must be edited, set values by editing the `set_environment_vars` function of the `lib/_script-util.sh` script. Stop and restart the server for the change to take effect.

Setting the file descriptor limit

About this task

The server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. If needed, increase the file descriptor limit on the operating system with the following procedure.

> **Note**
>
> If the operating system relies on `systemd`, refer to the Linux operating system documentation for instructions on setting the file descriptor limit.

Steps

1. **Display the current `fs.file-max` limit of the system.**

   ```
   sysctl fs.file-max
   ```

   The `fs.file-max` limit is the maximum server-wide file limit you can set without tuning the kernel parameters in the `proc` file system.

2. **Edit the `/etc/sysctl.conf` file. If there is a line that sets the value of the `fs.file-max` property, make sure that its value is set to at least 1.5 times the per-process limit. If there is no line that sets a value for this property, add the following to the end of the file (100000 is just an example here; specify a value of at least 1.5 times the per-process limit):**

   Example:

   ```
   fs.file-max = 100000
   ```

3. **Display the current hard limit of the system.**

   ```
   ulimit -aH
   ```

   The `open files (-n)` value is the maximum number of open files per process limit.

   Verify that its value is set to at least 65535.

4. **Edit the `/etc/security/limits.conf` file. If the file has lines that set the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines to the end of the file (before "#End of file"), making certain to insert a tab between the columns.**

   Example:

Copyright © 2025 Ping Identity Corporation

```
*   soft   nofile   65535
*   hard   nofile   65535
```

Note

The number of open file descriptors is limited by the physical memory available to the host. You can determine this limit with the following command.
+

```
cat /proc/sys/fs/file-max
```

If the `file-max` value is significantly higher than the 65535 limit, consider increasing the file descriptor limit to between 10% and 15% of the system-wide file descriptor limit. For example, if the `file-max` value is 810752, you could set the file descriptor limit to 100000. If the `file-max` value is lower than 65535, the host is likely not sized appropriately.

5. **Reboot the system, and then use the `ulimit` command to verify that the file descriptor limit is set to `65535` with the following command:**

```
ulimit -n
```

Next steps

Once the operating system limit is set, the number of file descriptors that the server will use can be configured by either using a `NUM_FILE_DESCRIPTORS` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as, `NUM_FILE_ DESCRIPTORS=12345`. If these are not set, the default of `65535` is used. This is strictly optional if wanting to ensure that the server shuts down safely prior to reaching the file descriptor limit.

Note

For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits:

```
/etc/security/limits.d/20-nproc.conf

Add or edit the following lines if they do not already exist:
*      soft    nproc     65536
*      soft    nofile    65536
*      hard    nproc     65536
*      hard    nofile    65536
root   soft    nproc     unlimited
```

Set the file system flushes

Linux systems running the ext3 file system only flush data to disk every five seconds. If the server is on a Linux system, edit the mount options to include the following:

```
commit=1
```

Copyright © 2025 Ping Identity Corporation

This variable changes the flush frequency from five seconds to one. Also, set the flush frequency in the `/etc/fstab` file to make sure the configuration remains after reboot.

sysstat and `pstack` on Red Hat">

Install `sysstat` and `pstack` on Red Hat

The server troubleshooting tool `collect-support-data` relies on the `iostat`, `mpstat`, and `pstack` utilities to collect monitoring, performance statistics, and stack trace information on the server's processes. For Red Hat systems, make sure that these packages are installed, for example:

```
$ sudo yum install sysstat gdb dstat -y
```

dstat utility">

Install the `dstat` utility

The `dstat` utility is used by the `collect-support-data` tool.

Disable file system swapping

It is recommended that any performance tuning services like `tuned` be disabled. As root, change the current value in the operating system and by adding a line `vm.swappiness = 0` to `/etc/sysctl.conf` to ensure that the correct setting is applied when the system restarts.

If performance tuning is required, `vm.swappiness` can be set by cloning the existing performance profile then adding `vm.swappiness = 0` to the new profile's `tuned.conf` file in `/usr/lib/tuned/profile-name/tuned.conf`. The updated profile is then selected by running `tuned-adm profile customized_profile`.

Manage system entropy

Entropy is used to calculate random data that is used by the system in cryptographic operations. Some environments with low entropy may have intermittent performance issues with SSL-based communication. This is more typical on virtual machines, but can occur in physical instances as well. Monitor the `kernel.random.entropy_avail` in `sysctl` value for best results.

If necessary, update `$JAVA_HOME/jre/lib/security/java.security` to use `file:/dev/./urandom` for the `securerandom.source` property.

Set file system event monitoring (inotify)

An event monitoring tool such as `inotify` can be configured for notifying processes about file system events (including file creation, deletion, and updates). The Linux system puts a limit on the number of `inotify` watches assigned to each user. To increase the limit, edit `etc/sysctl.conf` to add a line:

Copyright © 2025 Ping Identity Corporation

```
fs.inotify.max_user_watches =524288
```

Run the command:

```
$ sudo sysctl -wfs.inotify.max_user_watches=524288
```

Tune IO scheduler

Using the correct IO scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load. For file systems running on an SSD, or in a virtualized environment, the `noop` scheduler is recommended. For all other systems, the `deadline` scheduler is recommended. To determine which scheduler is configured on your system, run this command:

```
$ cat /sys/block/<block-device>/queue/scheduler
```

For example:

```
$ cat /sys/block/sda/queue/scheduler
```

Changing the scheduler on a running system can be done with the following command:

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

The change will take effect after the system is restarted. The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

Enable the server to listen on privileged ports

Linux provides capabilities used to grant specific commands the ability to do things that are normally only allowed for a root account. Instead of granting the ability to a specific user, capabilities are granted to a specific command. It might be convenient to enable the server to listen on privileged ports while running as a non-root user.

The `setcap` command is used to assign capabilities to an application. The `cap_net_bind_service` capability enables a service to bind a socket to privileged ports (port numbers less than 1024). If Java is installed in `/ds/java` (and the Java command to run the server is `/ds/java/bin/java`), the Java binary can be granted the `cap_net_bind_service` capability with the following command:

```
$ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
```

Copyright © 2025 Ping Identity Corporation

The java binary needs an additional shared library (`libjli.so`) as part of the Java installation. More strict limitations are imposed on where the operating system will look for shared libraries to load for commands that have capabilities assigned. So it is also necessary to tell the operating system where to look for this library. This can be done by creating the file `/etc/ld.so.conf.d/libjli.conf` with the path to the directory that contains the `libjli.so` file. For example, if the Java installation is in `/ds/java` , the contents of that file should be:

```
/ds/java/lib/amd64/jli
```

Run the following command for the change to take effect:

```
$ sudo ldconfig -v
```

Ping Identity license keys

License keys are required to install, update, and renew all Ping Identity products.

How to obtain a license

To obtain a license key, contact your account representative or use the Ping Identity licensing portal.

When do you need a license

A license is required for setting up a new single server instance and can be used site-wide for all servers in an environment. Additionally, you must obtain a new license when updating a server to a new major version, such as when upgrading from 7.3 to 8.0. When cloning a server instance with a valid license, you do not need a new license.

> **Note**
>
> The update process displays a prompt for a new license.

How to specify a license

- Specify a license at setup.

  You have these options:

  - Use the `--licenseKeyFile` *<path-to-license>* option with `setup` .
  - Copy the license file to the server root directory and then run the `setup` tool. The tool discovers the license file.

- Specify a license after setup

  Use the administrative console or `dsconfig` (in the Topology section, select License).

  > **Note**
  >
  > Placing the new license file in the server root directory does not work in this case.

Copyright © 2025 Ping Identity Corporation

How to view the license status

To view the details of a license, including its expiration, you have these options:

- The server's `status` tool
- The administrative console's Status page (On the Monitors tab, search for License.)

License expiration

The server provides a notification as the expiration date approaches.

Before a license expires, obtain a new one and install it by using `dsconfig` or the administrative console.

> **Note**
>
> An expiring license causes alerts and alarms but does not affect the functionality of the product.

Installing PingDataSync

About this task

Use the `setup` tool to install the server. The server needs to be started and stopped by the user who installed it.

Steps

1. Log in as a user, other than root.
2. Obtain the latest zip release bundle from Ping Identity and unpack it in a directory owned by this user.

```
$ unzip  {pingdatasync}-<version>.zip
```

3. Change to the server root directory.

```
$ cd  {pingdatasync}
```

4. Run the `setup` command.

```
$ ./setup
```

5. Type `yes` to accept the End-User License Agreement and press Enter to continue.
6. If adding this server to an existing PingDataSync topology, type `yes`, or press Enter to accept the default (no).
7. Enter the fully qualified host name or IP address of the local host.
8. Create the initial root user DN for PingDataSync, or press Enter to accept the default (cn=Directory Manager).
9. Enter and confirm a password for this account.

Copyright © 2025 Ping Identity Corporation

10. Press Enter to enable server services and the administrative console.
11. Enter the port on which PingDataSync will accept connections from HTTPS clients, or press Enter to accept the default.
12. Enter the port on which PingDataSync will accept connections from LDAP clients, or press Enter to accept the default.
13. Press Enter to enable LDAPS, or enter no.
14. Press Enter to enable StartTLS, or enter no.
15. Select the certificate option for this server.
16. Choose the desired encryption for the directory data, backups, and log files from the choices provided:
    - Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments, and you should use the same encryption passphrase when setting up each server in the topology.
    - Encrypt data with a key generated from a passphrase read from a file.
    - Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
    - Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
    - Do not encrypt server data.
17. Choose the option for the amount of memory that should be allocated to the server.
18. To start the server when the configuration is complete, press Enter for (yes).
19. A Setup Summary is displayed. choose the option to setup the server with the listed parameters, change the parameters, or cancel the setup.

Next steps

After the server configuration is complete, the `create-sync-pipe-config` tool can be run to configure the synchronization environment.

The PingDataSync administrative console enables browser-based server management, the `dsconfig` tool enables command line management, and the Configuration API enables management by third-party interfaces.

Signing on to the administrative console

After you install the server, sign on to the administrative console to verify the configuration and manage the server.

Before you begin

To sign on to the administrative console, you must know the root user distinguished name (DN) or the common name (CN) of a root user DN.

For example, if the DN created when the server was installed is `cn=Directory Manager`, you can use `Directory Manager` as the username to sign on to the administrative console.

Copyright © 2025 Ping Identity Corporation

About this task

> **Note**
>
> To run the administrative console in an external container, such as Tomcat, see Deploying the administrative console.

Steps

- To access the administrative console, go to https://<*host*>:<*port*>/console/login. <*host*> is the hostname of the server, and <*port*> is the port on which the server accepts connections from HTTPS clients. This was configured during the install.

Setting the administrative console session timeout window

About this task

The default session timeout for the administrative console is 24 hours. You can adjust your session length to suit your organization's needs.

> **Note**
>
> When the session duration is exceeded, all inactive users are logged off automatically.

To change the default session timeout value:

Steps

1. To configure the `server.sessionTimeout` application parameter, which specifies the timeout duration in seconds, set the value as an `init` parameter either in the console or on the command line.

   Choose from:

   - Use the administrative console:

     1. Ensure that the Show Advanced Configuration check box is selected.

     
     2. In the Web Services and Applications list, select Web Application Extensions.
     3. In the Web Application Extension list, select Console.
     4. In the Init Parameter field, enter the desired timeout duration value in seconds.
     5. Click Save.

   - Use the command line:

Copyright © 2025 Ping Identity Corporation

- Run the following command:

```
dsconfig set-web-application-extension-prop --no-prompt \
        --extension-name Console \
        --add init-parameter:server.sessionTimeout=<value in seconds>
```

2. To save your changes, restart the HTTP(S) Connection Handler or the server.

   Choose from:

   - Restart the HTTP(S) Connection Handler:

```
dsconfig set-connection-handler-prop \
    --handler-name "<HTTPS Connection Handler>" \
    --set enabled:false

dsconfig set-connection-handler-prop \
    --handler-name "<HTTPS Connection Handler>" \
    --set enabled:true
```

   - Restart the server using `bin/stop-server` with the `-R` or `--restart` option:

```
bin/stop-server --restart
```

Server folders and files

After the distribution file is unzipped, the following folders and command-line utilities are available:

Directories/Files/Tools	Description
ldif	Stores any LDIF files that you might have created or imported.
import-tmp	Stores temporary imported items.
classes	Stores any external classes for server extensions.
bak	Stores the physical backup files used with the backup command-line tool.
velocity	Stores Velocity templates that define the server's application pages.
update.bat, and update	The update tool for UNIX/Linux systems and Windows systems.
uninstall.bat, and uninstall	The uninstall tool for UNIX/Linux systems and Windows systems.
ping_logo.png	The image file for the Ping Identity logo.
setup.bat, and setup	The setup tool for UNIX/Linux systems and Windows systems.

Copyright © 2025 Ping Identity Corporation

Directories/Files/Tools	Description
revert-update.bat, and revert-update	The revert-update tool for UNIX/Linux systems and Windows systems.
README	README file that describes the steps to set up and start the server.
License.txt	Licensing agreement for the product.
legal-notices	Stores any legal notices for dependent software used with the product.
docs	Provides the release notes, Configuration Reference (HTML), API Reference, and all other product documentation.
metrics	Stores the metrics that can be gathered for this server and surfaced in the PingDataMetrics server.
bin	Stores UNIX/Linux-based command-line tools.
bat	Stores Windows-based command-line tools.
lib	Stores any scripts, jar files, and library files needed for the server and its extensions.
collector	Used by the server to make monitored statistics available to the PingDataMetrics server.
locks	Stores any lock files in the backends.
tmp	Stores temporary files.
resource	Stores the MIB files for SNMP and can include ldif files, make-ldif templates, schema files, dsconfig batch files, and other items for configuring or managing the server.
config	Stores the configuration files for the backends (admin, config) as well as the directories for messages, schema, tools, and updates.
logs	Stores log files.
AD-Password-Sync-Agent.zip	The Active Directory Sync Agent package.

Start and stop the server

To start PingDataSync, run the `bin/start-sync-server` command on UNIX or Linux systems and the `bat\start-sync-server` on Microsoft Windows systems).

Copyright © 2025 Ping Identity Corporation

Start the server as a background process

Navigate to the server root directory, and run the following command:

```
$ bin/start-server
```

For Windows systems:

```
$ bat\start-server
```

Start the server at boot time

About this task

By default, the server does not start automatically when the system is booted. To configure the server to start automatically, use the `create-rc-script` tool to create a run control script as follows:

Steps

1. Create the startup script. In this example `ds` is the user.

   ```
   $ bin/create-rc-script \
     --outputFile Ping-Identity-Sync.sh \
     --userName ds
   ```

2. Log in as root and move the generated `Ping-Identity-Sync.sh` script into the `/etc/init.d` directory.

3. Create symlinks to it from the `/etc/rc3.d` directory (starting with an "S" to start the server) and `/etc/rc0.d` (starting with a "K" to stop the server).

   ```
   # mv Ping-Identity-Sync.sh /etc/init.d/
   # ln -s /etc/init.d/Ping-Identity-Sync.sh /etc/rc3.d/S50-Ping-IdentitySync.sh
   # ln -s /etc/init.d/Ping-Identity-Sync.sh /etc/rc0.d/K50-Ping-IdentitySync.sh
   ```

Stop the server

If PingDataSync has been configured to use a large amount of memory, it can take several seconds for the operating system to fully release the memory. Trying to start the server too quickly after shut down can fail because the system does not yet have enough free memory. On UNIX systems, run the `vmstat` command and watch the values in the `free` column increase until all memory held by PingDataSync is released back to the system.

A configuration option can also be set that specifies the maximum shutdown time a process can take.

To stop the server, navigate to the server root directory and run the following command:

Copyright © 2025 Ping Identity Corporation

```
$ bin/stop-server
```

Restart the server

Restart the server using the `bin/stop-server` command with the `--restart` or `-R` option. Running the command is equivalent to shutting down the server, exiting the JVM session, and then starting up again.

```
$ bin/stop-server --restart
```

Run the server as a Microsoft Windows service

The server can run as a Windows service on Windows Server 2016 and Windows Server 2019. This enables log out of a machine without the server being stopped.

Register the service

About this task

Perform the following steps to register the server as a service:

Steps

1. Stop the server with `bin\stop-server`. A server cannot be registered while it is running.
2. Register the server as a service. From a Windows command prompt, run `bat\register-windows-service.bat`.
3. After a server is registered, start the server from the Windows Services Control Panel or with the `bat\start-server.bat` command.

> **Note**
>
> Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

Run multiple service instances

Only one instance of a particular service can run at one time. Services are distinguished by the `wrapper.name` property in the `<server-root>\config\wrapper-product.conf` file. To run additional service instances, change the `wrapper.name` property on each additional instance. Descriptions of the services can also be added or changed in the `wrapper-product.conf` file.

Copyright © 2025 Ping Identity Corporation

Deregister and uninstall

While a server is registered as a service, it cannot run as a non-service process or be uninstalled. Use the `bat\deregister-windows-service.bat` file to remove the service from the Windows registry. The server can then be uninstalled with the `uninstall.bat` script.

Log files

The log files are stored in `<server-root>\logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or due to file size. Only the last three log files are retained. These configurations can be changed in the `<server-root>\config\wrapper.conf` file.

Uninstall the server

About this task

Use the `uninstall` command-line utility to uninstall the server using either interactive or non- interactive modes. Interactive mode provides options, progress, and a list of the files and directories that must be manually deleted if necessary.

Non-interactive mode, invoked with the `--no-prompt` option, suppresses progress information, except for fatal errors. All options for the `uninstall` command are listed with the `--help` option.

The `uninstall` command must be run as either the root user or the user account that installed the server.

Perform the following steps to uninstall in interactive mode:

Steps

1. Navigate to the server root directory.

```
$ cd PingData<server>
```

2. Start the uninstall command:

```
$ ./uninstall
```

3. Select the components to be removed, or press Enter to remove all components.
4. If the server is running, press Enter to shutdown the server before continuing.
5. Manually remove any remaining files or directories, if required.

Copyright © 2025 Ping Identity Corporation

Update servers in a topology

> **Note**
>
> This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than 7.x to a 7.x version, and is not applicable to any updates to server version 8.x or later.

> **Tip**
>
> For additional considerations, see the Planning your upgrade guide.

An update to the current release includes significant changes, and the introduction of a topology registry, which will store information previously stored in the admin backend (server instances, instance and secret keys, server groups, and administrator user accounts). For the admin backend to be migrated, the `update` tool must be provided LDAP authentication options to the peer servers of the server being updated.

The LDAP connection security options requested (either plain, TLS, StartTLS, or SASL) must be configured on every server in the topology. The LDAP credentials must be present on every server in the topology, and must have permissions to read from the admin backend and the config backend of every server in the topology. For example, a root DN user with the `inherit-default-privileges` set to `true` (such as the `cn=Directory Manager` user) that exists on every server can be used.

- Changes to clustered configurations are not allowed in mixed-version clusters. This applies to configuration in the `cn=Cluster,cn=config` subtree and only applies to servers with matching cluster names. Consider this when updating multiple servers in a cluster.
- To make clustered configuration changes in a mixed-version cluster, choose one of the following options:
  - Update each server to the same version.
  - Temporarily split up the cluster by changing the `cluster-name` property on the server instance configuration objects.
- After you have updated all the servers to the same version, you can again make clustered configuration changes and those changes will mirror across the topology.

The `update` tool will verify that the following conditions are satisfied on every server in the topology before allowing the update:

- When the first server is being updated, all other servers in the topology must be online. When updating additional servers, all topology information will be obtained from one of the servers that has already been updated. The `update` tool will connect to the peer servers of the server being updated to obtain the necessary information to populate the topology registry. The provided LDAP credentials must have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server, and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server will be uniquely identified by its instance name. Once set, the name cannot be changed. If needed, the following command can be used to set the instance name of a server prior to the update:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-global-configuration-prop \
  --set instance-name:uniqueName
```

- The cluster-wide configuration is synchronized on all servers in the topology. Older versions have some topology configuration under `cn=cluster,cn=config`. (JSON attribute and field constraints). These items did not support mirrored cluster-wide configuration data. An update should avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree primary. To synchronize the cluster-wide configuration data across all servers in the topology, run the `config- diff` tool on each pair of servers to determine the differences, and use `dsconfig` to update each instance using the `config-diff` output. For example:

```
$ bin/config-diff --sourceHost hostName \
  --sourcePort port \
  --sourceBindDN bindDN \
  --sourceBindPassword password \
  --targetHost hostName \
  --targetPort port \
  --targetBindDN bindDN \
  --targetBindPassword password
```

If any of these conditions are not satisfied, the `update` tool will list all of the errors encountered for each server, and provide instructions on how to fix them.

Update the server

About this task

This procedure assumes that an existing version of the server is stored at `PingData-server-old`. Make sure a complete, readable backup of the existing system is available before upgrading the server. Also, make sure there is a clear backout plan and schedule.

Steps

1. Download the latest version of the server software and unzip the file. For this example, the new server is located in the `PingData-server-new` directory.
2. Use the `update` tool of the newly unzipped build to update the server. Make sure to specify the server instance that is being upgrading with the `--serverRoot` option. The server must be stopped for the update to be applied.

Reverting an update

If necessary, a server can be reverted to the previous version using the `revert-update` tool. The tool accesses a log of file actions taken by the `update` tool to put the file system back to its prior state. If multiple updates have been run, the `revert-update` tool can be used multiple times to revert to each prior update sequentially. For example, the `revert-update` command can be run to revert to the server's previous state, then run again to return to its original state. The server is stopped during the revert-update process.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Reverting an update is not supported for upgrades to version 7.0, due to the topology backend changes.

Use the `revert-update` tool in the server root directory revert back to the most recent version of the server:

```
$ PingData-server-old/revert-update
```

Revert an update

Once the server has been updated, you can revert to the most recent version (one level back) using the revert-update tool. The `revert-update` tool accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the `revert-update` tool multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing the server, you can run the `revert-update` tool to revert to its previous state, then run the `revert-update` tool again to return to its original state.

Revert from version 7.x to a version earlier than 7.0

Reverting from version 7.0 or later to a pre-7.0 version can be done using the `revert-update` command with some extra steps. This is also the case when updating or reverting from a pre-6.2.0.2 to 6.2.0.2 or later. These steps are listed when the `update` and `revert-update` tool are run as well. You might need to perform one or more of the following tasks, depending on your installation and configuration:

- When updating or reverting from 6.2.0.2 or later to a pre-6.2.0.2 version, indexes might need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and use the `rebuild-index` tool to rebuild the indexes. The command for recreating an index will be in the "Undo" portion of the `logs/config-audit.log` file. If you wish to later revert to an older version, delete and recreate those composite indexes again after the revert has completed.
- When updating to 7.x for the first time, instance names will need to be set for each server in the topology if they were not previously set. This is done with the following `dsconfig` command:

  ```
  $ bin/dsconfig --bindDN "cn=Directory Manager" \
    --bindPassword secret \
    --no-prompt set-global-configuration-prop \
    --set instance-name:<name>
  ```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the `admin` backend. As long as new servers are not added to the topology after this update, the `revert-update` command can be used to return to the previous version.

  However, if new servers are added, then the restored `admin` backend of this server will not contain information about the new servers, and the local server will not be able to communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.

Copyright © 2025 Ping Identity Corporation

- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a pre-7.x version, any servers in the topology using the topology portion of the configuration (rather than the `admin` backend) will need to know that the reverted server was downgraded to the `admin` backend. This is done by running the following `dsconfig` command on one of the servers that has not been reverted:

```
$ bin/dsconfig set-server-instance-prop \
  --instance-name <Reverted server instance name> \
  --set server-version:<Version to which server is reverted>
```

- If the topology does not have a primary server when this command is run, it will not succeed. In this case, one of the remaining updated servers in the topology must be made primary with the following command. This will enable the chosen instance to run the first command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
  --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions (6.x or older). If you wish to later revert to an older version, the data must be exported to LDIF before performing the reversion. Re-import the data after the revert process has completed. In addition, the `changelogDb/` and `db/changelog/` directories in the reverted server root must be deleted after the revert has completed.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server will display warnings about "offline configuration changes," but they are not critical and will not appear on subsequent startups.

Revert to the most recent server version

Use `revert-update` in the server root directory revert back to the most recent version of the server.

```
$ <PingServer>-old/revert-update
```

Install a failover server

About this task

PingDataSync supports redundant failover servers that automatically become active when the primary server is not available. Multiple servers can be present in the topology in a configurable prioritized order.

Before installing a failover server, have a primary server already installed and configured. When installing the redundant server, the installer will copy the first server's configuration.

The primary and secondary server configuration remain identical. Both servers should be registered to the `allservers` group and all `dsconfig` changes need to be applied to the server group `allservers`.

Copyright © 2025 Ping Identity Corporation

Note

If the primary server has extensions defined, they should also be installed on any cloned or redundant servers. If extensions are missing from a secondary server, the following message is displayed during the installation:

```
Extension class <com.server.directory.sync.MissingSyncExtension> was not
found. Run manage-extension --install to install your extensions. Re-run setup to continue.
```

To remove a failover server, use the `uninstall` command.

Steps

1. Unpack the PingDataSync zip build. Name the unpacked directory something other than the first server instance directory.

```
$ unzip PingData<server>-<version>.zip -d <server2>
```

2. Navigate to the server root directory.
3. Use the `setup` tool in interactive mode in Install the Server, or in non-interactive mode as follows:

```
$ ./setup --localHostName <server2>.example.com --ldapPort 7389 \
  --masterHostName <server1>.example.com --masterPort 8389 \
  --masterUseNoSecurity \
  --acceptLicense \
  --rootUserPassword password \
  --no-prompt
```

   The secondary server is now ready to take over as a primary server in the event of a failover. No `realtime-sync` invocations are needed for this server.

4. Verify the configuration by using the `bin/status` tool. Each server instance is given a priority index. The server with the lowest priority index number has the highest priority.

```
$ bin/status --bindPassword secret

...(status output)...
                             --- Sync Topology ---
Host:Port                             :Status   :Priority
--------------------------------------:-------------:---------------
<server>.example.com:389 (this server) : Active      : 1
<server>.example.com:389        : Unavailable : 2
```

5. Obtain the name of a particular server, run the `dsconfig` tool with the `list-external-servers` option.

```
$ bin/dsconfig list-external-servers
```

6. To change the priority index of the server, use the `bin/dsconfig` tool:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-external-server-prop \
  --server-name <server2>.example.com:389 \
  --set <server>-priority-index:1
```

Administrative accounts

Users that authenticate to the Configuration API or the administrative console are stored in `cn=RootDNs,cn=config`. The `setup` tool automatically creates one administrative account when performing an installation. Accounts can be added or changed with the `dsconfig` tool.

Change the administrative password

About this task

Root users are governed by the Root Password Policy and by default, their passwords never expire. However, if a root user's password must be changed, use the `ldappasswordmodify` tool.

Steps

1. Open a text editor and create a text file containing the new password. In this example, name the file rootuser.txt.

```
$ echo password > rootuser.txt
```

2. Use `ldappasswordmodify` to change the root user's password.

```
$ bin/ldappasswordmodify --port 1389 --bindDN "cn=Directory Manager" \
--bindPassword secret --newPasswordFile rootuser.txt
```

3. Remove the text file.

```
$ rm rootuser.txt
```

Configuring the PingDataSync server

PingDataSync provides a suite of tools to configure a single server instance or server groups. All configuration changes to the server are recorded in the `config-audit.log`. Before configuring PingDataSync, review Sync Configuration Components.

Topics include:

- Configuation checklist
- Sync user account

Copyright © 2025 Ping Identity Corporation

- Configure PingDataSync in standard mode
- Use the Configuration API
- Configuration with the dsconfig tool
- Topology configuration
- Domain Name Service (DNS) caching
- IP address reverse name lookups
- Configure the synchronization environment with dsconfig
- Prepare external server communication
- HTTP connection handlers
- The resync tool
- The realtime-sync tool
- Configure the PingDirectory server backend for synchronizing deletes
- Configure DN maps
- Configure synchronization with JSON attribute values
- Configure fractional replication
- Configure failover behavior
- Configure traffic through a load balancer
- Configure authentication with a SASL external certificate
- Configure an LDAPv3 Sync Source
- Server SDK extensions

Configuration checklist

Before any deployment, determine the configuration parameters necessary for the synchronization topology.

For a better configuration experience, gather the following information before you start your configuration.

External servers

External server type

Determine the type of external servers included in the synchronization topology. Supported servers include:

- **PingDirectory server**
- **PingDirectoryProxy server**
- **Sun Directory Server Enterprise Edition**

Copyright © 2025 Ping Identity Corporation

- Sun Directory Server
- Oracle Unified Directory
- OpenDJ
- Microsoft Active Directory (AD)
- Generic LDAP directories

LDAP connection settings

Determine the following for each external server instance included in the synchronization topology:

- Host
- Port
- Bind distinguished name (DN)
- Bind password

Security and authentication settings

Determine the following:

- The secure connection types for each external server, such as SSL or StartTLS
- The authentication methods for external servers, such as simple authentication or external SASL mechanisms

> **Important**
>
> If you are synchronizing encoded passwords or clear-text passwords in particular, the connection should be secure. To synchronize to or from a Microsoft AD system, establish an SSL or StartTLS connection to PingDataSync. You should also enable password encryption for synchronization from AD or when synchronizing clear-text passwords. For more information, see Configuring password encryption.

Sync Pipes

A `Sync Pipe` defines a single synchronization path between the source and destination targets. One `Sync Pipe` is needed for each point-to-point synchronization path defined for a topology.

`Sync Source`

Determine which external server is the `Sync Source` for the synchronization topology. You can define a prioritized list of external servers for failover purposes.

`Sync Destination`

Determine which external server is the `Sync Destination` for the synchronization topology. You can define a prioritized list of external servers for failover purposes.

Sync Classes

A `Sync Class` defines how attributes and DNs are mapped and how source and destination entries are correlated. For each `Sync Pipe` defined, define one or more `Sync Classes` with the following information:

Copyright © 2025 Ping Identity Corporation

Evaluation order

If you are defining more than one `Sync Class`, the evaluation order of each `Sync Class` must be determined with the `evaluation-order-index` property. If there is an overlap between criteria used to identify a `Sync Class`, the `Sync Class` with the most specific criteria is used first.

Base DNs

Determine which base DNs contain entries needed in the `Sync Class`.

Include filters

Determine the filters to be used to search for entries in the `Sync Source`.

Synchronized entry operations

Determine which operations to synchronize:

- **`create`**
- **`modify`**
- **`delete`**

DNs

Determine the differences between the DNs from the `Sync Source` topology to the `Sync Destination` topology. For example, if there are structural differences in each directory information tree (DIT).

Destination correlation attributes

Determine the correlation attributes used to associate a source entry to a destination entry during synchronization. During the configuration setup, one or more comma-separated lists of destination correlation attributes are defined and used to search for corresponding source entries. PingDataSync maps all attributes in a detected change from source to destination attributes using the attribute maps defined in the `Sync Class`.

The correlation attributes are flexible enough that several destination searches with different combinations of attributes can be performed until an entry matches. For LDAP server endpoints, use the DN to correlate entries.

For example, to correlate entries in LDAP deployments, specify the attribute lists `dn,uid`, `uid,employeeNumber` and `cn,employeeNumber`. PingDataSync searches for a corresponding entry that has the same `dn` and `uid` values. If the search fails, it then searches for `uid` and `employeeNumber`. If that search fails, it searches for `cn` and `employeeNumber`. If none of these searches are successful, the synchronization change is aborted and a message is logged.

> **Note**
>
> To prevent incorrect matches, the most restrictive attribute lists (those that will never match the wrong entry) should be first in the list, followed by less restrictive attribute lists, which are used when the earlier lists fail. For LDAP-to-LDAP deployments, use the DN with a combination of other unique identifiers in the entry to guarantee correlation. For non-LDAP deployments, determine the attributes that can be synchronized across the network.

Copyright © 2025 Ping Identity Corporation

Attributes

Determine the differences between the attributes from the `Sync Source` to the `Sync Destination`.

Attribute consideration	Description
Attribute mappings	Determine how attributes are mapped from the `Sync Source` to the `Sync Destination`. For example, if they're mapped directly, mapped based on attribute values, or mapped based on attributes that store DN values.
Automatically mapped source attributes	Determine if there are attributes that can be automatically synchronized with the same name at the `Sync Source` to `Sync Destination`. For example, if you can set direct mappings for `cn`, `uid`, `telephoneNumber`, or for all attributes.
Non-auto mapped source attributes	Determine if there are attributes that shouldn't be automatically mapped. For example, the `Sync Source` might have an attribute, `employee`, while the `Sync Destination` has a corresponding attribute, `employeeNumber`. If an attribute isn't automatically mapped, you must provide a map to synchronize it.
Conditional value mapping	Determine if some mappings should only be applied some of the time as a function of the source attributes. **Note** You can use conditional value mappings with the `conditional-value-pattern` property, which conditionalizes the attribute mapping based on the subtype of the entry, or on the value of the attribute. For example, this might apply if the `adminName` attribute on the destination should be a copy of the `name` attribute on the source, but only if the `isAdmin` attribute on the source is set to `true`. Conditional mappings are multivalued. Each value is evaluated until one is matched (the condition is `true`). If none of the conditional mappings are matched, the ordinary mappings is used. If there isn't an ordinary mapping, the attribute is not created on the destination.

Sync user account

PingDataSync creates a Sync User account DN on each external server. The account (by default, `cn=Sync User`) is used exclusively by PingDataSync to communicate with external servers. The entry is important in that it contains the credentials (DN and password) used by PingDataSync to access the source and target servers. The Sync User account resides in different entries depending on the targeted system:

- For the PingDirectory server, PingDirectoryProxy server, Nokia 8661 Directory Server, Nokia 8661 Directory Proxy Server, the Sync User account resides in the configuration entry (`cn=Sync User,cn=Root DNs,cn=config`).

Copyright © 2025 Ping Identity Corporation

- For Sun Directory Server, Sun DSEE, OpenDJ, Oracle Unified Directory, and generic LDAP directory topologies, the Sync User account resides under the base DN in the `userRoot` backend (`cn=Sync User,dc=example,dc=com`).The Sync User account should not reside in the `cn=config` branch for Sun Directory Server and DSEE machines.
- For Microsoft Active Directory (AD) servers, the Sync User account resides in the Users container (`cn=Sync User,cn=Users,DC=adsync,DC=unboundid,DC=com`).
- For Oracle and Microsoft SQL Servers, the Sync User account is a login account (`SyncUser`)with the sufficient privileges to access the tables to be synchronized.

In most cases, modifications to this account are rare. Make sure that the entry is not synchronized by setting up an optional Sync Class if the account resides in the `userRoot` backend (Sun Directory Server or Sun DSEE) or Users container (Microsoft Active Directory). For example, a Sync Class can be configured to have all CREATE, MODIFY, and DELETE operations set to `false` .

Configure PingDataSync in standard mode

The `create-sync-pipe-config` tool is used to configure Sync Pipes and Sync Classes. For bidirectional deployments, configure two Sync Pipes, one for each directional path.

Use the create-sync-pipe tool to configure synchronization illustrates a bidirectional synchronization deployment in standard mode. The example assumes that two replicated topologies are configured:

- The first endpoint topology consists of two Sun LDAP servers: the main server and one failover. Both servers have Retro change logs enabled and contain the full DIT that will be synchronized to the second endpoint.
- The second endpoint topology consists of two PingDirectory servers: the main server and one failover. Both servers have change logs enabled and contain entries similar to the first endpoint servers, except that they use a `mail` attribute, instead of an `email` attribute.

A specific `mail` to `email` mapping must also be created to exclude the source attribute on the Sync Pipe going the other direction.

> **Note**
>
> If the source attribute is not excluded, PingDataSync will attempt to create an `email` attribute on the second endpoint, which could fail if the attribute is not present in the destination server's schema.

Then, two Sync Classes are defined:

- One to handle the customized `email` to `mail` attribute mapping.
- Another to handle all other cases (the default Sync Class).

The `dsconfig` command is used to create the specific attribute mappings. The `resync` command is used to test the mappings. Synchronization can start using the `realtime-sync` command.

Use the create-sync-pipe tool to configure synchronization

Use the `create-sync-pipe-config` utility to configure a Sync Pipe. After the configuration is completed, you can adjust settings using the `dsconfig` tool.

Copyright © 2025 Ping Identity Corporation

About this task

> **Important**
>
> If servers have no base entries or data, the `cn=Sync User,cn=Root DNs,cn=config` account needed to communicate cannot be created. Make sure that base entries are created on the destination servers.

If synchronizing pre-encoded passwords to a PingDirectory server destination, you must allow pre-encoded passwords in the default password policy. You must also configure password encryption on the destination. Make sure that the password encryption algorithm is supported by both source and destination servers with the following command:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set allow-pre-encoded-passwords:true
```

Encrypted and clear-text passwords can be synchronized by configuring the sync destination `password-synchronization-format` and `require-secure-connection-for-clear-text-passwords` properties.

> **Note**
>
> You can set the `require-secure-connection-for-clear-text-passwords` property to `false` when working in a test environment.
> If the `password-synchronization-format` property is set to `clear-text`, and the `require-secure-connection-for-clear-text-passwords` property is set to `true`, the connection must be secure. If a secure connection is not available, an error is generated and the password is not synchronized.

To configure PingDataSync with the `create-sync-pipe-config` command:

Steps

1. **Start PingDataSync:**

   ```
   $  <server-root>/bin/start-server
   ```

2. **From the `bin` directory, run the `create-sync-pipe-config` tool:**

   ```
   $bin/create-sync-pipe-config
   ```

3. **In the Initial Synchronization Configuration Tool menu, press Enter (yes) to continue the configuration.**
4. **In the Synchronization Mode menu, press Enter to select Standard Mode.**
5. **In the Synchronization Directory menu, select oneway(1) or bidirectional(2) for the synchronization topology.**

   This example assumes bidirectional synchronization.
6. **In the Source Endpoint Type menu, select the directory or database server for the first endpoint.**
7. **In the Source Endpoint Name menu, enter a name for the endpoint server, or press Enter to accept the default.**

Copyright © 2025 Ping Identity Corporation

8. In the Base DNs menu, enter the base distinguished name (DN) on the first endpoint topology where the entries will be searched.

   For example, `dc=example,dc=com`.

9. Select an option for the server security.

10. Enter the host name and listener port number for the source server, or accept the default.

    Make sure that the endpoint servers are online and running.

11. Enter another server host and port, or press Enter to continue.

12. Enter the SyncUser account DN for the endpoint servers, or press Enter to accept the default (`cn=Sync User,cn=RootDNs,cn=config`).

13. Enter and confirm a password for this account.

    Result:

    You can now configure the servers in the destination endpoint topology.

14. Repeat steps 6– 13 to configure the second server.

15. Define the maximum age of changelog log entries, or press Enter to accept the default.

    After you configure the source and destination topologies, PingDataSync prepares each external server by testing the connection to each server. Step 15 determines if each account has the necessary privileges (root privileges are required) to communicate with and transfer data to each endpoint during synchronization.

16. In the Sync Pipe Name menu, create a name for the Sync Pipe, or press Enter to accept the default.

    Because this configuration is bidirectional, the following step is setting up a Sync Pipe path from the source endpoint to the destination endpoint. A later step will define another Sync Pipe from the PingDirectory server to another server.

17. In the SyncClass Definitions menu, enter `Yes` to create a custom Sync Class.

    A Sync Class defines the operation types (creates, modifies, or deletes), attributes that are synchronized, how attributes and DNs are mapped, and how source and destination entries are correlated.

18. Enter a name for the new Sync Class, such as `server1_to_server2`.

19. In the Base DNs for Sync Class menu, enter one or more base DNs to synchronize specific subtrees of a directory information tree (DIT).

    > **Note**
    >
    > Entries outside of the specified base DNs are excluded from synchronization. Make sure the base DNs do not overlap.

20. In the Filters for Sync Class menu, define one or more LDAP search filters to restrict specific entries for synchronization, or press Enter to accept the default (no).

    Entries that do not match the filters are excluded from synchronization.

Copyright © 2025 Ping Identity Corporation

21. In the Synchronized Attributes for Sync Class menu, specify which user attributes will be automatically mapped from one system to another.

    This example will exclude the source attribute (`email`) from being auto-mapped to the target servers. Operational attributes are not included in any attribute mapping.

22. In the Operations for Sync Class menu, select the operations to synchronize for the Sync Class, or press Enter to accept the default (`1,2,3`).

23. Define a default Sync Class that specifies how the other entries are processed, or press Enter to create a Sync Class called `Default Sync Class` .

24. In the Default Sync Class Operations menu, specify the operations that the default Sync Class will handle during synchronization, or press Enter to accept the default.

25. Define a Sync Pipe going from the PingDirectory server to the Sun Directory Server and exclude the `mail` attribute from being synchronized to the other endpoint servers.

26. Review the Sync Pipe Configuration Summary, and press Enter to accept the default (write configuration), which records the commands in a batch file (`<server-root>/sync-pipe-cfg.txt`).

    You can reuse the batch file to set up other topologies.

Next steps

Apply the configuration changes to the local PingDataSync instance by using a `dsconfig` batch file. Any Server SDK extensions should be saved to the `<server-root>/lib/extensions` directory.

The next step is to configure the attribute mappings using the `dsconfig` command.

Configuring attribute mapping

About this task

The following procedure defines an attribute map from the `email` attribute in the source servers to a `mail` attribute in the target servers. Both attributes must be valid in the target servers and must be present in their respective schemas.

> **Note**
>
> The following can also be done with `dsconfig` in interactive mode. The attribute mapping options are available from the PingDataSync main menu.

Steps

1. On PingDataSync, run the `dsconfig` command to create an attribute map for the "SunDS>DS" Sync Class for the "Sun DS to Ping Identity DS" Sync Pipe, and then run the second `dsconfig` command to apply the new attribute map to the Sync Pipe and Sync Class.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig --no-prompt create-attribute-map \
  --map-name "SunDS>DS Attr Map" \
  --set "description:Attribute Map for SunDS>Ping Identity Sync Class" \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

```
$ bin/dsconfig --no-prompt set-sync-class-prop \
  --pipe-name "Sun DS to DS" \
  --class-name "SunDS>DS" \
  --set "attribute-map:SunDS>DS Attr Map" \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

2. Create an attribute mapping (from `email` to `mail`) for the new attribute map.

```
$ bin/dsconfig --no-prompt create-attribute-mapping \
  --map-name "SunDS>DS Attr Map" \
  --mapping-name mail --type direct \
  --set "description:Email>Mail Mapping" \
  --set from-attribute:email \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

3. For a bidirectional deployment, repeat steps 1–2 to create an attribute map for the DS>SunDS Sync Class for the Ping Identity DS to Sun DS Sync Pipe, and create an attribute mapping that maps `mail` to `email`.

```
$ bin/dsconfig --no-prompt create-attribute-map \
  --map-name "DS>SunDS Attr Map" \
  --set "description:Attribute Map for DS>SunDS Sync Class" \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

```
$ bin/dsconfig --no-prompt set-sync-class-prop \
  --pipe-name "Ping Identity DS to Sun DS" \
  --class-name "DS>SunDS" \
  --set "attribute-map:DS>SunDS Attr Map" \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig --no-prompt create-attribute-mapping \
  --map-name "DS>SunDS Attr Map" \
  --mapping-name email \
  --type direct \
  --set "description:Mail>Email Mapping" \
  --set from-attribute:mail \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

Configure server locations

About this task

PingDataSync supports endpoint failover, which is configurable using the `location` property on the external servers. By default, the server prefers to connect to, and failover to, endpoints in the same location as itself. If there are no location settings configured, PingDataSync will iterate through the configured list of external servers on the Sync Source and Sync Destination when failing over.

> **Note**
>
> Location-based failover is only applicable for LDAP endpoint servers.

Steps

1. On PingDataSync, run the `dsconfig` command to set the location for each external server in the Sync Source and Sync Destination. For example, the following command sets the location for six servers in two data centers, `austin` and `dallas`.

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:1389 \
  --set location:austin
```

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:2389 \
  --set location:austin
```

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:3389 \
  --set location:austin
```

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:4389 \
  --set location:dallas
```

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:5389 \
  --set location:dallas
```

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:6389 \
  --set location:dallas
```

2. Run `dsconfig` to set the location on the Global Configuration. This is the location of PingDataSync itself. In this example, set the location to `austin`.

```
$ bin/dsconfig set-global-configuration-prop \
  --set location:austin
```

Use the Configuration API

PingDataSync servers provide a Configuration API, which can be useful in situations where using LDAP to update the server configuration is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers should allow the `application/json` content type.

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP. The extension is enabled by default for new installations, and can be enabled for existing deployments by simply adding the extension to one of the server's HTTP Connection Handlers, as follows:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:Configuration
```

The API is made available on the HTTPS Connection handler's `host:port` in the `/config` context. Due to the potentially sensitive nature of the server's configuration, the HTTPS Connection Handler should be used, for hosting the Configuration extension.

Authentication and authorization

Clients must use HTTP Basic authentication to authenticate to the Configuration API. If the user name value is not a DN, then it will be resolved to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a user name. To customize this behavior, either customize the default identity mapper, or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. For example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Configuration \
  --set "identity-mapper:Alternative Identity Mapper"
```

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACI.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

dsconfig tool">

Relationship between the Configuration API and the `dsconfig` tool

The Configuration API is designed to mirror the `dsconfig` tool, using the same names for properties and object types. Property names are presented as hyphen case in `dsconfig` and as camel-case attributes in the API. In API requests that specify property names, case is not important. Therefore, `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the `dsconfig list-connection-handlers` command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a Local DB Backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the `dsconfig` tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the SCIM specification. Specific attributes can be requested using the `attributes` query parameter, whose value must be a comma-delimited list of properties to be returned, for example `attributes=baseDN,description`. Likewise, attributes can be excluded from responses by specifying the `excludedAttributes` parameter. See Sorting and filtering configuration objects for more information on query parameters.

Operations supported by the API are those typically found in REST APIs:

HTTP Method	Description	Related dsconfig Example
GET	Lists the attributes of an object when used with a path representing an object, such as `/config/global-configuration` or `/config/backends/userRoot`. Can also list objects when used with a path representing a parent relation, such as `/config/backends`.	`get-backend-prop` `list-backends` `get-global-configuration-prop`
POST	Creates a new instance of an object when used with a relation parent path, such as `config/backends`.	`create-backend`

Copyright © 2025 Ping Identity Corporation

HTTP Method	Description	Related dsconfig Example
PUT	Replaces the existing attributes of an object. A PUT operation is similar to a PATCH operation, except that the PATCH is determined by determining the difference between an existing target object and a supplied source object. Only those attributes in the source object are modified in the target object. The target object is specified using a path, such as `/config/backends/userRoot`.	`set-backend-prop` `set-global-configuration-prop`
PATCH	Updates the attributes of an existing object when used with a path representing an object, such as `/config/backends/userRoot`. See PATCH Example.	`set-backend-prop` `set-global-configuration-prop`
DELETE	Deletes an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	`delete-backend`

The OPTIONS method can also be used to determine the operations permitted for a particular path.

Object names, such as `userRoot` in the Description column, must be URL-encoded in the `path` segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent (%) character. So the URL for accessing the HTTP Connection Handler object is:

```
/config/connection-handlers/http%20connection%20handler
```

GET Example

The following is a sample GET request for information about the `userRoot` backend:

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

The response:

Copyright © 2025 Ping Identity Corporation

GET list example

The following is a sample GET request for all local backends:

```
GET /config/backends
Host: example.com:5033
Accept: application/scim+json
```

The response (which has been shortened):

Copyright © 2025 Ping Identity Corporation

```

```

PATCH Example

Configuration can be modified using the HTTP PATCH method. The PATCH request body is a JSON object formatted according to the SCIM patch request. The Configuration API supports a subset of possible values for the `path` attribute, used to indicate the configuration attribute to modify.

The configuration object's attributes can be modified in the following ways. These operations are analogous to the `dsconfig modify-[object]` options.

- An operation to set the single-valued `description` attribute to a new value:

  ```
  {
    "op" : "replace",
    "path" : "description",
    "value" : "A new backend."
  }
  ```

  is analogous to:

  ```
  $ dsconfig set-backend-prop --backend-name userRoot \
    --set "description:A new backend"
  ```

- An operation to add a new value to the multi-valued `jeProperty` attribute:

  ```
  {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }
  ```

  is analogous to:

  ```
  $ dsconfig set-backend-prop --backend-name userRoot \
    --add je-property:je.env.backgroundReadLimit=0
  ```

- An operation to remove a value from a multi-valued property. In this case, `path` specifies a SCIM filter identifying the value to remove:

Copyright © 2025 Ping Identity Corporation

```
{
  "op" : "remove",
  "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
  --remove je-property:je.cleaner.adjustUtilization=false
```

- A second operation to remove a value from a multi-valued property, where the `path` specifies both an attribute to modify, and a SCIM filter whose attribute is `value`:

```
{
  "op" : "remove",
  "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
  --remove je-property:je.nodeMaxEntries=32
```

- An option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value:

```
{
  "op" : "remove",
  "path" : "id2childrenIndexEntryLimit"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
  --reset id2childrenIndexEntryLimit
```

The following is the full example request. The API responds with the entire modified configuration object, which can include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions:

Example request:

Copyright © 2025 Ping Identity Corporation

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
  "schemas" : [ "urn:ietf:params:scim:api:messages:2.0:PatchOp" ],
  "Operations" : [ {
    "op" : "replace",
    "path" : "description",
    "value" : "A new backend."
  }, {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }, {
    "op" : "remove",
    "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
  }, {
    "op" : "remove",
    "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
  }, {
    "op" : "remove",
    "path" : "id2childrenIndexEntryLimit"
  } ]
}
```

          "type": "other",
          "synopsis": "If this limit is increased, then the contents
           of the backend must be exported to LDIF and re-imported to
           allow the new limit to be used for any id2children keys
           that had already hit the previous limit."
        }
      ]
    }
  }
```

API paths

The Configuration API is available under the `/config` path. A full listing of root sub-paths can be obtained from the `/config/ResourceTypes` endpoint:

```
GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json
```

Sample response (abbreviated):

Copyright © 2025 Ping Identity Corporation

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 520,
  "Resources": [
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "dsee-compat-access-control-handler",
      "name": "DSEE Compat Access Control Handler",
      "description": "The DSEE Compat Access Control
         Handler provides an implementation that uses syntax
         compatible with the Sun Java System Directory Server
         Enterprise Edition access control handler.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/dsee-compat-
access-control-handler"
      }
    },
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "access-control-handler",
      "name": "Access Control Handler",
      "description": "Access Control Handlers manage the
         application-wide access control. The server's access
         control handler is defined through an extensible
         interface, so that alternate implementations can be created.
         Only one access control handler may be active in the server
         at any given time.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/access-
control-handler"
      }
    },
    {
    ...
```

The response's `endpoint` elements enumerate all available sub-paths. The path `/config/access-control-handler` in the example can be used to get a list of existing access control handlers, and create new ones. A path containing an object name like `/config/backends/{backendName}`, where `{backendName}` corresponds to an existing backend (such as `userRoot`) can be used to obtain an object's properties, update the properties, or delete the object.

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted nor created. These paths can be differentiated from others by their singular, rather than plural, relation name (for example `global-configuration`).

Copyright © 2025 Ping Identity Corporation

Sorting and filtering configuration objects

The Configuration API supports SCIM parameters for filter, sorting, and pagination. Search operations can specify a SCIM filter used to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters or paging parameters, and attributes to include or exclude in both `get` and `list` operations.

GET Parameters for Sorting and Filtering

GET Parameter	Description
filter	Values can be simple SCIM filters such as `id eq "userRoot"` or compound filters like `meta.resourceType eq "Local DB Backend"` and `baseDn co"dc=example,dc=com"`.
sortBy	Specifies a property value by which to sort.
sortOrder	Specifies either `ascending` or `descending` alphabetical order.
startIndex	1-based index of the first result to return.
count	Indicates the number of results per page.

Update properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH. With PUT, the server computes the differences between the object in the request with the current version in the server, and performs modifications where necessary. The server will never remove attributes that are not specified in the request. The API responds with the entire modified object.

Request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
  "description" : "A new description."
}
```

  }
```

Administrative actions

Updating a property may require an administrative action before the change can take effect. If so, the server will return `200 Success`, and any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

For example, changing the `jeProperty` of a backend will result in the following:

```
"urn:unboundid:schemas:configuration:messages:2.0": {
  "requiredActions": [
    {
      "property": "baseContextPath",
      "type": "componentRestart",
      "synopsis": "In order for this modification to
         take effect, the component must be restarted,
         either by disabling and re-enabling it, or by
         restarting the server"
    },
    {
      "property": "id2childrenIndexEntryLimit",
      "type": "other",
      "synopsis": "If this limit is increased, then the
         contents of the backend must be exported to LDIF
         and re-imported to allow the new limit to be used
         for any id2children keys that had already hit the
         previous limit."
    }
  ]
}
...
```

Copyright © 2025 Ping Identity Corporation

Update servers and server groups

Servers can be configured as part of a server group, so that configuration changes that are applied to a single server, are then applied to all servers in a group. When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query parameter. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `singleServer` or `serverGroup` can be specified. For example:

```
https://example.com:5033/config/Backends/userRoot?applyChangeTo=singleServer
```

> **Note**
>
> This does not apply to mirrored subtree objects, which include Topology and Cluster level objects. Changes made to mirrored objects are applied to all objects in the subtree.

Configuration API responses

Clients of the API should examine the HTTP response code in order to determine the success or failure of a request. The following are response codes and their meanings:

.

Response Code	Description	Response Body
200 Success	The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the `urn:unboundid:schemas:configuration:messages:2.0` object.	List of objects, or object properties, administrative actions.
204 No Content	The requested operation succeeded and no further information has been provided, such as in the case of a DELETE operation.	None.
400 Bad Request	The request contents are incorrectly formatted or a request is made for an invalid API version.	Error summary and optional message.
401 Unauthorized	User authentication is required. Some user agents such as browsers may respond by prompting for credentials. If the request had specified credentials in an Authorization header, they are invalid.	None.
403 Forbidden	The requested operation is forbidden either because the user does not have sufficient privileges or some other constraint such as an object is edit-only and cannot be deleted.	None.

Copyright © 2025 Ping Identity Corporation

Response Code	Description	Response Body
404 Not Found	The requested path does not refer to an existing object or object relation.	Error summary and optional message.
409 Conflict	The requested operation could not be performed due to the current state of the configuration. For example, an attempt was made to create an object that already exists or an attempt was made to delete an object that is referred to by another object.	Error summary and optional message.
415 Unsupported Media Type	The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.	None.
500 Server Error	The server encountered an unexpected error. Please report server errors to customer support.	Error Summary and optional message.

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages may change, and their presence may depend on server configuration. Use the HTTP return code and the context of the request to create a client error message. The following is an example encoded error message:

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": 404,
  "scimType": null,
  "detail": "The Local DB Index does not exist."
}
```

dsconfig tool">

Configuration with the `dsconfig` tool

The Ping Identity servers provide several command-line tools for management and administration. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

The `dsconfig` tool is the text-based management tool used to configure the underlying server configuration. The tool has three operational modes:

- Interactive Mode
- Non-interactive mode
- Batch mode

The `dsconfig` tool also offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, the configuration should be accessed with the server running in order for the server to give the user feedback about the validity of the configuration.

Copyright © 2025 Ping Identity Corporation

Each command-line utility provides a description of the subcommands, arguments, and usage examples needed to run the tool. View detailed argument options and examples by typing `-- help` with the command.

```
$ bin/dsconfig --help
```

To list the subcommands for each command:

```
$ bin/dsconfig --help-subcommands
```

To list more detailed subcommand information:

```
$ bin/dsconfig list-log-publishers --help
```

Use dsconfig in interactive mode

Running `dsconfig` in interactive command-line mode provides a menu-driven interface for accessing and configuring the PingData server. To start `dsconfig` in interactive mode, run the tool without any arguments:

```
$ bin/dsconfig
```

Running the tool requires server connection and authentication information. After connection information is confirmed, a menu of the available operation types is displayed.

Use dsconfig in non-interactive mode

Non-interactive command-line mode provides a simple way to make arbitrary changes to the server, and to use administrative scripts to automate configuration changes. To make changes to multiple configuration objects at the same time, use batch mode.

The general format for the non-interactive command line is:

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

The `--no-prompt` argument specifies non-interactive mode. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on the implementation. The `{subcommand}` specifies which general action to perform. The following uses standard LDAP connections:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig --no-prompt list-backends \
  --hostname server.example.com \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --bindPassword password
```

The following uses SASL GSSAPI (Kerberos) parameters:

```
$ bin/dsconfig --no-prompt list-backends \
  --saslOption mech=GSSAPI \
  --saslOption authid=admin@example.com \
  --saslOption ticketcache=/tmp/krb5cc_1313 \
  --saslOption useticketcache=true
```

The `{subcommandArgs}` argument contains a set of arguments specific to the particular task. To always display the advanced properties, use the `--advanced` command-line option.

> **Note**
>
> Global arguments can appear anywhere on the command line. The subcommand-specific arguments can appear anywhere after the subcommand.

Use dsconfig batch mode

The `dsconfig` tool provides a batching mechanism that reads multiple invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting by minimizing LDAP connections and JVM invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment, or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

```
$ bin/dsconfig --no-prompt \
  --hostname host1 \
  --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret \
  --batch-file /path/to/sync-pipe-config.txt
```

If a `dsconfig` command has a missing or incorrect argument, the command will fail and stop the batch process without applying any changes to the server. A `--batch-continue-on-error` option is available, which instructs `dsconfig` to apply all changes and skip any errors.

View the `logs/config-audit.log` file to review the configuration changes made to the server, and use them in the batch file. The batch file can have blank lines for spacing, and lines starting with a pound sign (#) for comments. The batch file also supports a "\" line continuation character for long commands that require multiple lines.

PingDataSync also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Sun/Oracle to PingDataSync machines.

Topology configuration

Topology configuration enables grouping servers and mirroring configuration changes automatically. It uses a primary/secondary architecture for mirroring shared data across the topology.

All writes and updates are forwarded to the primary, which forwards them to all other servers. Reads can be served by any server in the group.

> **Note**
>
> To remove a server from the topology, it must be uninstalled with the `uninstall` tool.

Topology primary requirements and selection

A topology primary server receives any configuration change from other servers in the topology, verifies the change, then makes the change available to all connected servers when they poll the primary. The primary always sends a digest of its subtree contents on each update. If the node has a different digest than the primary, it knows it's not synchronized. The servers will pull the entire subtree from the primary if they detect that they are not synchronized. A server may detect it is not synchronized with the primary under the following conditions:

- At the end of its periodic polling interval, if a server's subtree digest differs from that of its primary, then it knows it's not synchronized.
- If one or more servers have been added to or removed from the topology, the servers will not be synchronized.

The primary of the topology is selected by prioritizing servers by minimum supported product version, most available, newest server version, earliest start time, and startup UUID (a smaller UUID is preferred).

After determining a primary, the topology data is reviewed from all available servers (every five seconds by default) to determine if any new information makes a server better suited to being the primary. If a new server can be the primary, it will communicate that to the other servers, if no other server has advertised that it should be the primary. This ensures that all servers accept the same primary at approximately the same time (within a few milliseconds of each other). If there is no better primary, the initial primary maintains the role.

After the best primary has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that primary. (The primary server itself is considered while determining this majority.)
- There is only a single primary in the entire topology.

If either of these conditions is not met, the topology is without a primary and the peer polling frequency is reduced to 100 milliseconds to find a new primary as quickly as possible. If there is no primary in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as primary with the `force-as-master-for-mirrored-data` option in the Global Configuration configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as primaries, then a `mirrored-subtree-manager-forced-as-master-error` critical alarm will be raised.

Copyright © 2025 Ping Identity Corporation

Topology components

When a server is installed, it can be added to an existing topology, which will clone the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

Server configuration settings

Configuration settings for the topology are configured in the Global Configuration and in the Config File Handler Backend. Though they are topology settings, they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The Global Configuration object contains a single topology setting, `force-as-master-for-mirrored-data`. This should be set to `true` on only one of the servers in the topology, and is used only if a situation occurs where the topology cannot determine a primary because a majority of servers is not available. A server with this setting enabled will be assigned the role of primary, if no suitable primary can be determined. See Topology primary requirements and selection for details about how a primary is selected for a topology.

The Config File Handler Backend defines three topology (`mirrored-subtree`) settings:

- `mirrored-subtree-peer-polling-interval` – Specifies the frequency at which the server polls its topology peers to determine if there are any changes that may warrant a new primary selection. A lower value will ensure a faster failover, but it will also cause more traffic among the peers. The default value is five seconds. If no suitable primary is found, the polling frequency is adjusted to 100 milliseconds until a new primary is selected.
- `mirrored-subtree-entry-update-timeout` – Specifies the maximum length of time to wait for an update operation (add, delete, modify or modify-dn) on an entry to be applied by the primary on all of the servers in the topology. The default is 10 seconds. In reality, updates can take up to twice as much time as this timeout value if primary selection is in progress at the time the update operation was received.
- `mirrored-subtree-search-timeout` – Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

Topology settings

Topology meta-data is stored under the `cn=topology,cn=config` subtree and cluster data is stored under the `cn=cluster,cn=config` subtree. The only setting that can be changed is the cluster name.

Monitor data for the topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to determine if there are changes in the topology. Topology data includes the following:

- The server ID of the current primary, if the primary is not known.
- The instance name of the current primary, or if a primary is not set, a description stating why a primary is not set.
- A flag indicating if this server thinks that it should be the primary.
- A flag indicating if this server is the current primary.
- A flag indicating if this server was forced as primary.

Copyright © 2025 Ping Identity Corporation

- The total number of configured peers in the topology group.
- The peers connected to this server.
- The current availability of this server.
- A flag indicating whether or not this server is not synchronized with its primary, or another node in the topology if the primary is unknown.
- The amount of time in milliseconds where multiple primaries were detected by this server.
- The amount of time in milliseconds where no suitable server is found to act as primary.
- A SHA-256 digest encoded as a base-64 string for the current subtree contents.

The following metrics are included if this server has processed any operations as primary:

- The number of operations processed by this server as primary.
- The number of operations processed by this server as primary that were successful.
- The number of operations processed by this server as primary that failed to validate.
- The number of operations processed by this server as primary that failed to apply.
- The average amount of time taken (in milliseconds) by this server to process operations as the primary.
- The maximum amount of time taken (in milliseconds) by this server to process an operation as the primary.

Servers and certificates

The following provides a detailed description of PingDirectory server certificate types.

The PingDirectory server uses two main types of certificates:

Listener certificates

Used to secure communication through TLS.

Inter-server certificates

Used to authenticate between server instances in a topology.

Listener certificates

When a client initiates TLS negotiation with the server, the server presents a certificate chain to the client and the certificate at the head of the chain functions as a listener certificate.

Because the client decides whether to trust the certificate chain, it is recommended that the chain be signed by an issuer whom the client is likely to trust or that the client can be easily configured to trust.

You can create self-signed certificates with long lifespans, but a certificate that a certification authority signs is likely to have a relatively short lifespan. Commercial authorities typically issue certificates that are valid for only one or two years, but some authorities use shorter validity windows.

Copyright © 2025 Ping Identity Corporation

Short certificate lifespans offer some security benefits. In particular, because most clients do not verify whether a certificate has been revoked, a shorter validity window minimizes the timeframe that a compromised certificate can be used. If the process for replacing certificates is streamlined or automated, administrative inconvenience can be kept to a minimum.

Listener certificates are stored in key stores that are referenced by key manager providers, which in turn provide the logic and configuration for accessing the key stores. If a server component, like a connection handler, requires access to a certificate that it presents to a peer during the TLS negotiation process, that component must reference the key manager provider that points to the key store containing the appropriate certificate. If the key store contains multiple certificates, and if the component referencing the key store includes a property specifying the certificate's nickname, the certificate with that alias is selected. Otherwise, the server lets the Java virtual machine (JVM) select a certificate that might not be well-defined.

The server also provides trust manager providers, which determine whether to trust the certificate chains with which it is presented. A trust manager provider can reference a specified trust store file, but other options include the JVM default trust store, which uses the Java installation's default set of trusted issuers, and the blind trust manager provider, which automatically trusts every certificate chain that is presented to it.

> **Note**
>
> Never use a blind trust manager in a production environment because it leaves the server vulnerable to impersonation and man-in-the-middle attacks. However, a blind trust manager can be convenient in test environments when troubleshooting certain types of problems.

Replacing listener certificates

Certificate authorities typically restrict the lifespans of the certificates that they sign. If you use a certification authority to issue listener certificates, you are likely replacing the certificates on a regular basis.

About this task

The `replace-certificate` tool performs the following steps:

1. Obtain a new certificate chain.
2. Make necessary updates to the key manager provider and the connection handler configurations
3. Update the server instance listener configuration with the new certificate.

The `replace-certificate` tool offers the following modes of operation:

Interactive mode

Walks you through the process of obtaining a new certificate and installing it in the server. Interactive mode also displays the non-interactive commands that are required to achieve the same result.

Non-interactive mode

Useful when scripting the process of replacing a certificate.

Steps

- To replace a listener certificate, run the `replace-listener-certificate` subcommand of the `replace-certificate` tool.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> You can replace certificates manually, but the **`replace-certificate`** tool automates the process. The **`replace-certificate`** tool provides information about multiple listener certificates during the transitional phase that occurs when you install them.
>
> The **`replace-listener-certificate`** subcommand takes arguments that provide the following information:
>
> - Arguments required to authenticate to PingDataSync, such as `--bindDN` and `--bindPasswordFile`
> - Details about the key store that contains the new certificate
> - Updates that must be made to the key and trust manager providers
> - Whether to signal the HTTP connection handler to reload its certificates after the update is complete

The following arguments are available:

Argument	Description
`--source-key-store-file {path}`	**Path to the Java KeyStore (JKS) or PKCS #12 file that contains the private key entry with the new certificate chain. This argument is required.**
`--source-key-store-password {password}`	**Clear-text password that is needed to access the contents of the source key store.**
`--source-key-store-password-file {path}`	**Path to the file that contains the password necessary to access the contents of the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database.**
`--source-certificate-alias {alias}`	**Password that is required to access the appropriate private key in the source key store. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, the key store password is used as the private key password.**
`--source-private-key-password-file {path}`	**Path to the file that contains the password needed to access the appropriate private key in the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, the key store password is used as the private key password.**
`--key-manager-provider {name}`	**Name of the key manager provider that is updated to use the new certificate chain. The value must identify a file-based key manager provider, and the new certificate chain must be enabled. Defaults to `JKS` if a value is not specified.**

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--trust-manager-provider {name}`	Name of the trust manager provider that is updated with the information required to trust the new certificate chain. The value must identify a file-based trust manager provider, and the new certificate chain must be enabled. If neither this argument nor the `--use-jvm-default-trust-manager-provider` argument is provided, the tool assumes that the name of the trust manager provider is identical to the name of the key manager provider, though these providers remain separate and distinct.
`--use-jvm-default-trust-manager-provider`	Indicates that the server must be configured to use the JVM-default trust manager provider, which trusts certificates signed by issuers in the `cacerts` trust store provided with the Java virtual machine (JVM), rather than updating an existing trust manager provider.
`--target-certificate-alias {alias}`	Alias to use for the new certificate in the key manager provider's key store, and for appropriate updates in the trust manager provider's trust store. Defaults to an alias of `server-cert` if a value is not specified. **Note** If the key manager provider's key store, or the trust manager provider's trust store, already contains an entry with the given alias, the existing entry is renamed.
`--reload-http-connection-handler-certificates`	Indicates that the tool is requesting that the server cause any HTTPS-based connection handlers to reload their certificates, so that the connection handlers can use the updated certificate. LDAP connection handlers react to the change immediately and start presenting the new certificate chain during subsequent TLS negotiations. HTTPS connection handlers continue using the former certificate until the connection handler is restarted or until the connection handler is asked specifically to reload its certificates. **Note** This option might prevent clients with existing TLS sessions that were negotiated with the former certificate from being resumed.

Copyright © 2025 Ping Identity Corporation

- To remove earlier certificates from the server instance listener configuration, run the `purge-retired-listener-certificates` subcommand.

> **Note**
>
> The `purge-retired-listener-certificates` subcommand does not take arguments other than the ones that are required to authenticate to the server.
> By default, the **`replace-certificate`** tool updates the server instance listener configuration object to include the new listener certificate, and it merges the old and new certificates residing in the configuration object.

Inter-server certificates

Each server instance in a topology has an inter-server certificate that is generated during the setup process.

The inter-server certificate is not exposed to clients, so a trusted issuer does not need to sign it. Instead, the topology registry, representing a mirrored portion of the configuration with information about every PingDirectory server instance in the environment, contains the information that each instance needs to trust the inter-server certificates for all other instances.

Inter-server certificates can be used to protect certain secrets that are shared among servers within the topology, like the secrets that are used to digitally sign log files, backups, and LDIF exports. Inter-server certificates include the encryption keys that reversible password-storage schemes use.

The inter-server certificate is generated with a long lifespan. Replace it only when you suspect that its private key is compromised.

Replacing the inter-server certificate

During the installation process, the inter-server certificate is generated with a long lifespan and does not require replacement under normal circumstances. You should replace the inter-server certificate only if you suspect that its private key is compromised.

About this task

The inter-server certificate is intended for use only between server instances within the same topology. Because it is not exposed to regular clients, the inter-server certificate does not need to be trusted.

The `replace-certificate replace-inter-server-certificate` command performs the following steps:

- Acquires the new inter-server certificate from a provided Java KeyStore (JKS) or PKCS #12 key store
- Makes the necessary updates to the `config/ads-truststore` file in the server key store
- Updates the server instance configuration object to include the new inter-server certificate

Copyright © 2025 Ping Identity Corporation

Note

To avoid the need to replace the inter-server certificate on a regular basis,use a self-signed certificate with a long lifespan. Each server instance must possess its own, unique inter-server certificate that satisfies the following conditions:

- Uses an RSA key pair
- Has a minimum key size of 2048 bits

The following types of certificates are not allowed:

- Certificates with an elliptic curve key pair
- Certificates with an RSA key that is smaller than 2048 bits

Steps

- **To replace the inter-server certificate, run the `replace-inter-server-certificate` subcommand of the `replace-certificate`.**

  The `replace-inter-server-certificate` subcommand takes a subset of the arguments that are used with the `replace-listener-certificate` subcommand, including the following arguments:

  - `--source-key-store-file {path}--source-key-store-password {password}`
  - `--source-key-store-password-file {path}`
  - `--source-certificate-alias {alias}`
  - `--source-private-key-password {password}`
  - `--source-private-key-password-file {path}`

- **To delete earlier values that are no longer needed, run the `purge-retired-inter-server-certificates` subcommand.**

  Note

  By default, the new inter-server certificate is merged with the existing values in the server instance configuration entry.

X.509 certificates

The server supports X.509 certificates, the most common type of certificates. RFC 5280 describes X.509v3, which provides the current version of the specification.

An X.509v3 certificate includes the following components:

X.509 encoding version

Enables the differentiation between an X.509v3 certificate and one that conforms to an earlier or later version of the specification.

Copyright © 2025 Ping Identity Corporation

Serial number of the certificate

Integer value that uniquely identifies a certificate as issued by a certification authority.

Subject DN

Distinguished name for the certificate, which often provides details about the context in which the certificate is to be used. For more information, see Certificate subject DNs.

Issuer DN

Distinguished name for the issuer certificate, which is the certificate used to sign the certificate. For a self-signed certificate, this value matches the subject DN.

Validity window

Indicates the timeframe during which the certificate is considered valid. This component includes the following elements:

- `notBefore`

  Specifies the earliest time at which the certificate is considered valid.

- `notAfter`

Specifies the latest time at which the certificate is considered valid.

Public key

Public portion of a pair of cryptographically linked keys. For more information, see Certificate key pairs.

Signature

A type of cryptographic proof that the certificate truly was sent from the issuer and has remained unaltered. A self-signed certificate is signed with its own private key. Otherwise, it is signed with the issuer's private key.

An X.509v3 certificate might also include the following optional components:

Subject unique ID

Uniquely identifies the certificate. This component has been deprecated in favor of the subject key identifier extension, so it is generally omitted from X.509v3 certificates.

Issuer unique ID

Subject unique ID of the issuer certificate, if available. This component has been deprecated in favor of the authority key identifier extension.

Set of extensions

Provides additional context for the certificate and the manner in which it is used. For more information, see Certificate extensions.

Copyright © 2025 Ping Identity Corporation

Certificate subject DNs

A certificate's subject distinguished name (DN) provides information about how the certificate should be used.

Like an LDAP DN, a certificate's subject DN consists of a comma-delimited series of attribute-value pairs. However, unlike an LDAP DN, the attribute names in a certificate subject DN are typically written in all uppercase characters.

A certificate's subject DN is also referred to as its subject. The following attributes commonly appear in a certificate subject.

Attribute name	Attribute description
`CN`	Common name **Note** For a listener certificate, the `CN` attribute typically identifies the host name that clients use to access the certificate. However, the subject alternative name extension is recommended more highly for accomplishing the same task. Most certificate subject DNs include at least the `CN` attribute.
`E`	Email address
`OU`	Name of the organizational unit, such as the relevant department
`O`	Name of the organization or company
`L`	Name of the locality, such as the appropriate city
`ST`	Full name of the state or province
`C`	ISO 3166 country code

A certificate subject includes at least one attribute-value pair, and the `CN` attribute is typically present. Other attributes can be omitted, although the `O` and `C` attributes are also common. For example, a listener certificate for a server with an address of `ldap.example.com`, which is run by the US-based company Example Corp, might have a subject of `CN=ldap.example.com,O=Example Corp,C=US`.

Certificate key pairs

Each certificate contains a key pair that consists of two keys that are linked cryptographically. If you encrypt data with one key, the data can be only decrypted with the other key.

Although a key pair can be created easily when both keys are generated simultaneously, the process of deriving one key from the other is extremely difficult, a process categorized in cryptographic terms as computationally infeasible.

When generating a key pair, one key is designated as the public key, and the other key is designated the private key. The public key can be made widely available, but the private key must be kept secret and not shared with anyone.

As long as the secrecy of the private key is maintained, the key pair can be used to perform the following functions:

- Encryption, sometimes referred to as confidentiality

Copyright © 2025 Ping Identity Corporation

If someone wants to send you a secret message without anyone else viewing it, the message can be encrypted with your public key. Only you possess the private key, so only you can decrypt the message.

- Digital signatures

  If you encrypt data with your private key, it can be decrypted only with your public key. Because your public key can be made widely available, this encryption method does not actually protect the content. However, digital signatures prove that a message came from you because only your private key could have generated it.

  > **Note**
  >
  > When generating a digital signature, the entire message is generally not encrypted. Only a hash of the message is encrypted, typically by using a digest algorithm like SHA-256.
  > This approach protects the integrity of a message. A decrypted signature that matches the digest of the original message guarantees that the message came from you and that it has remained unaltered since you signed it.

The following public key algorithms are used primarily in certificates that facilitate TLS communication:

- RSA, which is based on the multiplication of large prime numbers
- EC, which is based on computations that involve special types of elliptical curves

Although RSA is supported more widely than EC, it is slower and requires larger keys to achieve the same level of security. To support legacy clients, you should use an RSA certificate and choose a key size of at least 2,048 bits.

If all of your clients support EC certificates, you should use an EC certificate with a key size of at least 256 bits.

Certificate extensions

Extensions provide additional context for a certificate.

Some of the more common extension types include the following:

Subject key identifier

Holds a unique identifier for the certificate, which is generally derived from the certificate's public key.

Authority key identifier

Holds the subject key identifier for the issuer certificate. This extension type helps to identify the issuer certificate, especially when presented with an incomplete certificate chain.

Subject alternative name

Holds a list of ways that clients are expected to reference a server when establishing a connection to it.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Clients must take this information into account when deciding whether to trust a server's certificate.
> The most common types of values include DNS names, IP addresses, and URIs. DNS names must be fully qualified, but can optionally use an asterisk in the leftmost component to match any single name in that component. For example, `*.example.com` could match `www.example.com` or `ldap.example.com`, but would not match `ldap.east.example.com` or `example.com`.

Key usage

Provides information about the manner in which the certificate is expected to be used. The following key usages are allowed:

`digitalSignature`

Indicates that the certificate can be used for digitally signing data, excluding certificates and certificate revocation lists (CRL).

`nonRepudiation`

Indicates that the certificate can be used to prevent denying the authenticity of a message. `nonRepudiation` is also known as `contentCommitment`.

`keyEncipherment`

Indicates that the certificate can be used to protect encryption keys, such as symmetric keys that are derived during TLS key agreement.

`dataEncipherment`

Indicates that the certificate can be used for encrypting data directly.

`keyAgreement`

Indicates that the certificate's public key can be used for key agreement, such as deriving the symmetric key that protects TLS communication.

`keyCertSign`

Indicates that the certificate can act as a certification authority and be used for signing other certificates.

`cRLSign`

Indicates that the certificate can be used to sign CRLs.

`encipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for encrypting data during key agreement.

`decipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for decrypting data during key agreement.

Copyright © 2025 Ping Identity Corporation

Extended key usage

Acts as an alternative to the key usage extension and provides additional high-level functionality. The following extended key usages are allowed:

`serverAuth`

Indicates that the server can present the certificate to the client during TLS negotiation.

`clientAuth`

Indicates that the client can present the certificate to the server during TLS negotiation.

`codeSigning`

Indicates that the certificate can be used to sign source and compiled code.

`emailProtection`

Indicates that the certificate can be used to sign or encrypt email messages.

`timeStamping`

Indicates that the certificate can be used to assert the time that an event occurred.

`ocspSigning`

Indicates that the certificate can be used to sign an online certificate status protocol (OCSP) response.

Basic constraints

Indicates whether the certificate can act as a certification authority and, if so, the maximum number of intermediate certificates that can follow it in a certificate chain.

Certificate chains

A certificate chain is an ordered list of one or more certificates. In such a chain, each subsequent certificate is the issuer of the previous certificate.

During TLS negotiation, the server presents a certificate chain to the client, which determines whether to trust the chain and continue with the negotiation. The client can also present its own certificate chain to the server.

If a certificate is self-signed, its chain contains only that single certificate. If a certificate is signed by a self-signed certificate authority (CA) certificate, such as a root CA, the chain contains two certificates: the server certificate and the CA certificate that follows it. If a single intermediate CA (a CA certificate that is signed by a root CA) is present, the chain contains the server certificate, followed by the intermediate CA, and then the root CA.

Intermediate certificate authorities are useful for security purposes, especially in commercial authorities. If a client trusts a root CA certificate, it is likely to trust anything with that root CA certificate at the base of its chain. Consequently, the root CA certificate must be kept secure.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If the root CA certificate is compromised, any certificate that is directly or indirectly signed by it can no longer be trusted.

With intermediate CA certificates, the root certificate can be kept offline in secure storage and used only when a new intermediate CA certificate must be signed. The intermediate CA certificates can be used to sign end-entity certificates, but must be protected to avoid compromising any of the certificates. A compromised certificate must be revoked along with all of the certificates that it signed. In such a scenario, the root CA can be used to sign a new certificate.

> **Note**
>
> The certificate chain that the server presents to the client, or that the client presents to the server, during TLS negotiation does not always need to be the complete chain. If the root CA at the end of the chain is widely trusted, the server can assume that the client already has that root CA in its default set of trusted certificates. The server can leave that root CA off the chain with the assumption that the client will retrieve it from its default trust store. While the same assumption could theoretically be true for intermediate CA certificates, only the root CA certificate is commonly omitted. When a client receives an incomplete chain, the client looks in its default trust store to determine whether the trust store contains the issuer certificate, which it can identify by using properties like the issuer distinguished name (DN) or an authority key identifier extension.

The certificate at the head of a certificate chain, which appears as the first one in the list, is often called the end-entity certificate. If this certificate appears at the head of the chain that a server presents during TLS negotiation, it is referred to as the server certificate. If the certificate appears at the head of a chain that a client presents, it is referred to as a client certificate. The certificate at the end of a complete chain must be a root CA certificate. In the case of a self-signed certificate, the chain contains only a single certificate that serves both roles.

About representing certificates, private keys, and certificate signing requests

X.509 is an encoding format that uses the ASN.1 distinguished encoding rules (DER), which exist in binary format. When writing a certificate to a file, either a raw DER format or a plain-text format called PEM can be used.

PEM encoding consists of a line that contains the text `-----BEGIN CERTIFICATE-----`, followed by a set of lines that contains the base64-encoded representation of the raw DER bytes (typically with no more than 64 characters per line), followed by a line that contains the text `-----END CERTIFICATE-----`.

The X.509 encoding contains a certificate's public key, but not its private key. The PKCS #8 specification in RFC 5958 describes the encoding for private keys. This approach uses a DER encoding with a PEM variant that instead uses the following header and footer, respectively.

```
 -----BEGIN PRIVATE KEY-----
-----END PRIVATE KEY-----
```

RFC 5958 also describes an encrypted representation of the private key, but that format is currently unsupported.

The PKCS #10 specification in RFC 2986 describes the CSR format. This format uses a DER encoding with a PEM variant that uses the following header and footer, respectively.

Copyright © 2025 Ping Identity Corporation

```
-----BEGIN CERTIFICATE REQUEST-----
-----END CERTIFICATE REQUEST-----
```

Some implementations use the following alternate, nonstandard forms.

```
-----BEGIN NEW CERTIFICATE REQUEST-----
-----END NEW CERTIFICATE REQUEST-----
```

Certificate trust

When a server presents its certificate chain to a client during TLS negotiation, the client decides whether to trust the certificate chain and concludes whether it is communicating with a legitimate server instead of an impostor.

If a client is tricked through DNS hijacking into communicating with a rogue application instead of with a legitimate server, the application can steal the client's credentials, or can fool the client into concluding that it has performed an action that it has not performed. If a rogue application acts as a broker between the client and the legitimate server, the client might be unable to detect the change, and the malicious application might be capable of stealing data or altering the communication. Consequently, you should avoid `trust all` or `blind trust` options in a production environment.

When determining whether to trust a server certificate chain, a client performs the following steps.

Processing steps

1. Verifies that it has received the complete certificate chain.

   If a server presents an incomplete chain, the client must ensure that it can complete the chain with information in an explicitly provided trust store or default trust store. If the client cannot complete the certificate chain, the chain is not trusted.

2. Verifies that each subsequent certificate in the chain is the issuer certificate for, and that its private key was used to sign, the certificate that precedes it.

   > **Note**
   >
   > If a certificate chain contains extraneous certificates, or if a subsequent certificate did not issue the certificate that precedes it, the chain is not trusted.

3. Confirms that it has a reason to trust the certificate at the root of the chain.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> This step is generally performed by ensuring that the root certificate authority (CA) certificate can be found in either a default trust store or a trust store that is configured for use by the client. If the client has no prior knowledge of the root CA certificate, the chain is not trusted.

4. **Verifies that the current time lies within the validity window for each certificate in the chain.**

> **Note**
>
> The chain is not trusted under the following conditions:
> - When the `notBefore` value of any certificate in the chain is later than the current time.
> - When the `notAfter` value of any certificate in the chain is earlier than the current time.

5. **Verifies that the server certificate at the head of the chain is suitable for the server with which the client thinks it is communicating.**

> **Note**
>
> The client must verify that the address used to connect to the server matches one of the following values:
> - The `CN` attribute of the certificate's subject.
> - One of the values of any subject alternative name extension.

These steps represent a starting point. If necessary, the client can perform additional types of validation. For example, if a root or intermediate certification authority maintains a certificate revocation list (CRL) or supports the online certificate status protocol (OCSP), the client must verify that none of the certificates in the chain has been revoked. The client can also verify that the CA certificates include the basic constraints extension, and that the server certificate does not contain too many levels. Other checks, like those that use certificate policy extensions, can also be performed.

Keystores and truststores

A keystore is a type of database that holds certificates.

The following examples represent the most common forms of keystores:

- **File that uses the Java-specific Java KeyStore (JKS) format**
- **File that uses the standard PKCS #12 format**
- **Collection of files that holds certificates and private keys, typically in PEM or DER format**
- **Hardware security module (HSM) that makes the certificate information available through an interface like PKCS #11**

The server supports file-based keystores by using the JKS and PKCS #12 formats and by using hardware security modules that are accessible through PKCS #11. The server does not currently support a keystore format that consists of individual certificate and private key files. To import these files into a JKS or PKCS #12 keystore, use the `manage-certificates` tool.

A keystore also represents a collection of entries, each of which is identified by a name that an alias calls. Keystores can have the following entry types:

Copyright © 2025 Ping Identity Corporation

Private key entries

Contain a certificate chain and a private key. When a server accepts a TLS-based connection, it uses a private key entry to obtain the certificate chain that it presents to the client. The server can also use the private key from the same entry to process its key agreement. Similarly, a client uses a private key entry when presenting its own certificate chain to a server.

Trusted certificate entries

Contain a single certificate without a private key. As the name implies, a trusted certificate entry is intended primarily for use when determining whether to trust a certificate chain that is presented during TLS negotiation.

Secret key entries

Contain a secret key only, without an associated certificate. These types of entries are not used for TLS processing. Instead, they hold symmetric encryption keys or other types of secrets.

A password, sometimes called a PIN, protects the contents of a keystore. In some cases, like with JKS keystores, some content might be accessible without a password, and a password might be required only when trying to access private keys or secret keys. In other cases, like with PKCS #12 keystores, you might need a password for any interaction with the keystore.

Additional passwords can further protect private keys. This approach is often the same as with the keystore password, but the password can be different. This tactic is useful when a single keystore is shared for multiple purposes, for example, and when merely having access to the keystore does not guarantee access to all of the data that it contains.

> **Note**
>
> A truststore is another name for a keystore that is intended primarily for use when determining whether to trust a certificate chain that has been presented. Truststores generally contain primarily trusted certificate entries, but that case is not required.

Java runtime environments typically include a default truststore, often `jre/lib/security/cacerts` or `lib/security/cacerts`, that is pre-populated with several widely trusted certification authority certificates. When presented with a certificate that one of these authorities has signed, the default truststore can allow the certificate to be trusted without any additional configuration. When presented with a self-signed certificate, or when presented with a certificate that is signed by an issuer not in the default truststore, such as a private corporate certification authority, a separate truststore is required.

Transport Layer Security (TLS)

TLS describes a mechanism for securely communicating between two parties that might have no prior knowledge of each other.

TLS is the successor to SSL, and the two terms are often used interchangeably, even though such usage might not technically be correct.

> **Note**
>
> SSL remains the more widely recognized term. The abbreviation TLS occasionally generates confusion with the StartTLS extended operation, particularly in LDAP.

TLS provides security in the form of the following main components:

Copyright © 2025 Ping Identity Corporation

Certificate trust

Is about reassuring a connection-initiating client that it is communicating with the server to which it intended to connect. To ensure that the server shares the same degree of confidence in the identity and legitimacy of the client, it can ask the client to present its own certificate chain. For more information, see Certificate Trust.

Cipher selection

Involves choosing the cipher and the key to protect the bulk of the communication. Although a client can use a server certificate's public key to encrypt data before sending it, this approach can lead to the following issues:

- Unless the client presents its own certificate chain to the server, the server cannot encrypt the data that it sends back to the client.
- Public key encryption is considerably slower than symmetric encryption, in which the same key is used for both encryption and decryption. Public key encryption is also called asymmetric encryption because different keys are used to encrypt and decrypt data.
- If you rely entirely on the security of a private key to ensure the secrecy of a communication, and if the private key becomes compromised, data that has been encrypted with the private key must also be considered compromised.

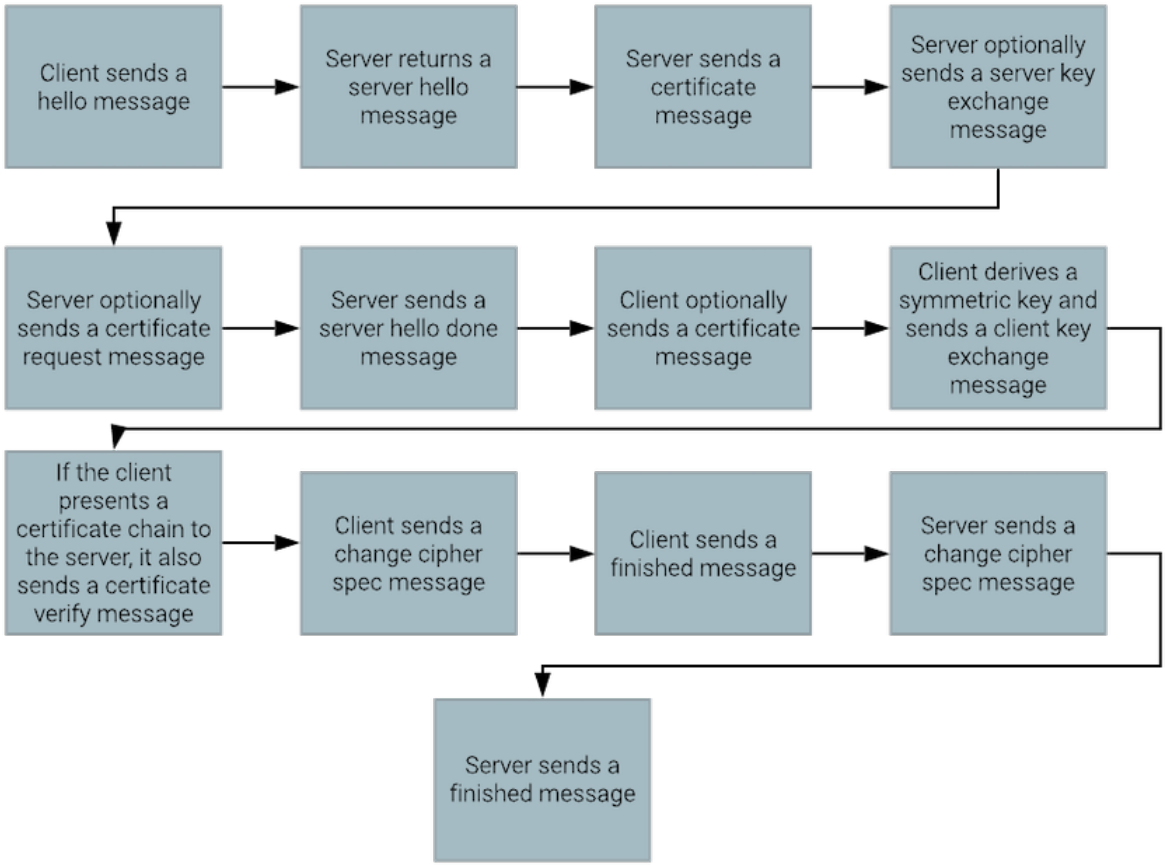
Rather than relying solely on public key encryption to protect communication between a client and server, the TLS negotiation process allows a client and server to agree on the type of encryption and the secret key to use after completing the negotiation process.

TLS handshakes

The process of negotiating the TLS is referred to as the handshake.

Copyright © 2025 Ping Identity Corporation

Although the exact process depends on the TLS version that is ultimately chosen, the following steps represent the basic components of a TLS 1.2 handshake:



TLS processing steps

1. The client sends a `hello` message that provides the server with the following information:
    - Highest supported version of the TLS protocol
    - The cipher suites that the client uses
    - Set of extensions with additional information:
        - The address that the client uses to communicate with the server
        - The signature algorithms and elliptic curves that the client supports
        - Whether the client supports secure renegotiation
2. The server returns a `server hello` message that provides the client with the following information:
    - The TLS protocol version that the server uses

Copyright © 2025 Ping Identity Corporation

- The cipher suite that the server selects

The server can also provide its own extensions to the client.

3. The server sends a `certificate` message that provides its certificate chain to the client.
4. The server can optionally send a `server key exchange` message with additional information that the client might need to securely derive the same symmetric encryption key that the server generates.
5. The server can optionally send a `certificate request` message that asks the client to present its own certificate chain to the server.
6. The server sends a `server hello done` message to inform the client that it has completed its `hello` sequence.
7. The client can optionally send a `certificate` message to the server with its own certificate chain.

> **Note**
>
> The client sends a `certificate` message only when the server initially sends a certificate request. If the client receives such a request, it can refuse to, and probably will not, send a certificate chain. The server decides whether to require a client certificate chain. In LDAP, the server commonly asks the client to present a certificate, but continues with TLS negotiation even if the client does not present one. This approach supports authentication methods like SASL EXTERNAL, in which a client uses the certificate chain that it presents during TLS negotiation as proof of its identity.

8. The client derives a symmetric key to use for the remainder of the encrypted processing, and sends a `client key exchange` message to the server. The `client key exchange` message includes the information that the server needs to generate the same key. Only the client and server know the value of the key, even if another entity can observe the communication that passes between the client and the server.
9. If the client presents a certificate chain to the server, it also sends a `certificate verify` message to prove that the private key for the certificate is included at the head of the chain.
10. The client sends a `change cipher spec` message to the server, which informs the server that the client will use the agreed-upon symmetric key to encrypt everything else that it sends to the server.
11. The client sends a `finished` message to the server to indicate that it has completed its portion of the handshake.
12. The server sends a `change cipher spec` message to the client, which informs the client that the server will use the agreed-upon symmetric key to encrypt everything else that it sends to the client.
13. The server sends a `finished` message to the client to indicate that it has completed its portion of the handshake.

TLS 1.3 uses a different handshake sequence that can require only a single round-trip to exchange the necessary information between the client and the server. TLS 1.2 requires two round-trips. To accomplish this task, TLS 1.3 tries to guess the type of key agreement that the server wants to use, and sends the relevant information to the server up front instead of waiting to hear from the server.

Because an extra round of communication between the client and server is eliminated, the server finishes its portion of the negotiation before the client. The server must assume that the client trusts its certificate chain. Because the server might log a successful negotiation only to discover late, through a TLS alert, that the client rejected the certificate, this approach might complicate certain types of troubleshooting.

Copyright © 2025 Ping Identity Corporation

Key agreement

Key agreement processing provides a critical component of TLS negotiation.

It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

RSA key exchange

The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.

Diffie-Hellman (DH) key exchange

The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, use ECHDE over DHE, and either of those options over RSA. The DH algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. The use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

LDAP StartTLS extended operation

In most scenarios, a client that uses TLS establishes a connection to a port that is dedicated to its use, like 636 (LDAPS) or 443 (HTTPS).

The client begins the TLS-negotiation process by sending a `client hello` message over the connection. In some scenarios, the client establishes a non-secure connection and later converts it to a secure one. In LDAP, this task is accomplished by using the `StartTLS` extended operation.

The `StartTLS` extended operation provides the following advantages over a dedicated LDAPS connection:

- To enable secure as well as insecure communication, only one port needs to be opened through a firewall.
- A client can use opportunistic encryption, in which the client performs the following steps:

    1. Queries the root DSE to determine whether the server supports StartTLS.
    2. Secures the connection, if possible.

  Opportunistic encryption is useful in scenarios like following referrals because LDAP URLs do not officially support LDAPS as a scheme.

Copyright © 2025 Ping Identity Corporation

To ensure that a communication is always secure, use LDAPS instead of establishing an insecure connection that you secure later with the `StartTLS` extended operation. If you enable support for unencrypted LDAP communication, as `StartTLS` requires, a client might send a password-containing bind request or other sensitive data over an unencrypted connection. A server can be configured to reject unencrypted communication, but it cannot prevent a client from sending an unencrypted request.

> **Note**
>
> Although you can use `StartTLS` to temporarily secure a connection before falling back on an unencrypted LDAP communication, the server does not support this strategy.

The manage-certificates tool

The server offers a `manage-certificates` tool that enables interaction with Java KeyStore (JKS) and PKCS #12 key stores.

Although it behaves similarly to the `keytool` utility that accompanies most Java distributions, `manage-certificates` is easier to use, provides improved usage information, and offers additional functionality.

Available subcommands

The `manage-certificates` tool uses the following subcommands to indicate which function to invoke:

Subcommand	Function
`list-certificates`	Lists the certificates in a keystore.
`import-certificate`	Imports a certificate into a trusted certificate entry or imports a certificate chain and private key into a private key entry.
`export-certificate`	Exports a certificate from a keystore.
`export-private-key`	Exports a private key from a keystore.
`generate-self-signed-certificate`	Generates a self-signed certificate.
`generate-certificate-signing-request`	Generates a certificate-signing request that can be provided to a certification authority.
`sign-certificate-signing-request`	Signs a certificate-signing request with a specified issuer certificate.
`check-certificate-usability`	Checks a specified certificate in a keystore to verify whether it is suitable for use as a listener certificate.
`trust-server-certificate`	Initiates the TLS-negotiation process with a specified server to obtain its certificate chain so that a truststore can be updated with the necessary information to trust the chain.

Copyright © 2025 Ping Identity Corporation

Subcommand	Function
`display-certificate-file`	Displays the contents of a file that contains one or more PEM-encoded or DER-encoded X.509 certificates.
`display-certificate-signing-request-file`	Displays the contents of a file that contains a PEM-encoded or DER-encoded PKCS #10 certificate-signing request (CSR).
`change-certificate-alias`	Changes the alias for an entry in a keystore.
`change-keystore-password`	Changes the password for a keystore.
`change-private-key-password`	Changes the password that protects the private key for a specified entry in a keystore.

Common arguments

Most of the `manage-certificates` subcommands require access to a Java KeyStore (JKS) or PKCS #12 keystore. In such instances, use the `--keystore` argument to specify the path to the keystore.

If the keystore already exists, the tool detects automatically whether it is a JKS or PKCS #12 keystore. If the operation creates a new keystore, you can specify the type explicitly by using the `--keystore-type` argument, followed by a value of `JKS` or `PKCS12`. If you do not specify the keystore type, a default value of `JKS` is used.

Some situations require you to provide the password that is needed to access the keystore. For a JKS keystore, you might need to provide a keystore password only for operations that involve creating a keystore or accessing a private key. However, you will likely need to provide the password for all operations that involve a PKCS #12 keystore.

To provide a keystore password, use one of the following arguments:

- `--keystore-password`, followed by the clear-text password for the keystore.
- `--keystore-password-file`, followed by the path to a file that contains the password for the keystore. The file might contain the password in the clear, or it might be encrypted with a definition from the server's encryption-settings database.
- `--prompt-for-keystore-password`. If this argument is provided, the tool prompts you interactively to provide the password.

If a private key is protected with a different password than the keystore itself, specify one of the following arguments to provide the private key password:

- `--private-key-password`, followed by the plain-text password.
- `--private-key-password-file`, followed by the path to a file that contains the clear-text or encrypted password.
- `--prompt-for-private-key-password`, which causes the tool to prompt interactively for the password.

Several operations require you to specify the keystore entry to target. In such scenarios, provide the `--alias` argument, followed by the name of the alias for that entry.

Copyright © 2025 Ping Identity Corporation

Listing the certificates in a keystore

List the certificates available in a keystore.

Steps

- To list the certificates in a keystore, use the `list-certificates` subcommand.

  This subcommand requires you to specify the path to the keystore file, and possibly the password that is needed to access the keystore. The following options are also available:

Option	Description
`--alias {alias}`	Specifies the alias of the certificate to display. If this value is not provided, all certificates are displayed. To list more than one specific certificate, specify this value multiple times.
`--display-pem-certificate`	Includes a PEM-encoded representation of each certificate as part of the output.
`--verbose`	Includes details about each certificate.

  Example:

  The following command demonstrates the basic listing of a keystore that contains a single certificate chain.

Generating self-signed certificates

The process of creating a self-signed certificate is straightforward because a self-signed certificate claims itself as its own issuer.

Copyright © 2025 Ping Identity Corporation

Although self-signed certificates are convenient for testing environments, clients do not trust them by default. Consequently, you should not use them as listener certificates in production environments.

The `manage-certificates` tool offers a `generate-self-signed-certificate` subcommand that can create a self-signed certificate. In addition to the arguments that provide information about the keystore, certificate alias, and optional private key password, the following arguments are available.

Argument	Description
`--subject-dn {subject}`	Subject DN for the certificate to create. This value is required.
`--days-valid {number}`	Number of days that the certificate remains valid. Defaults to `365` if no value is specified.
`--validity-start-time {timestamp}`	Indicates the time at which the certificate begins its validity window. This value is assumed to reflect the local time zone, and must be expressed in the form `YYYYMMDDhhmmss`, where a value of `20190102030405` indicates January 2, 2019, at 3:04:05 AM. Defaults to the current time if no value is specified.
`--key-algorithm {name}`	Name of the algorithm to use when generating the key pair. For a listener certificate, this value is typically `RSA` or `EC`. Defaults to `RSA` if no value is specified. **Note** This argument cannot be used in conjunction with the `--replace-existing-certificate` argument.
`--key-size-bits {number}`	Length of the key, in bits, to generate. If the `--key-algorithm` argument is given, then `--key-size-bits {number}` must also be specified. Conversely, if the `--replace-existing-certificate` argument is given, then `--key-size-bits {number}` must not be specified. Typical key sizes are: • RSA key – 2048 or 4096 bits If a default RSA key is used but this argument is not provided, a default key size of 2048 bits is used. • Elliptic curve key – 256 or 384 bits

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--signature-algorithm {name}`	Name of the algorithm to use to sign the certificate. If the `--key-algorithm` argument is used to specify an algorithm other than `RSA`, then `--signature-algorithm {name}` must also be specified. If the `--replace-existing-certificate` argument is used, then `--signature-algorithm {name}` must not be specified. Typical signature algorithms include `SHA256withRSA` for certificates with RSA keys, and `SHA256withECDSA` for certificates with elliptic curve keys. If a default key algorithm is used but the `--signature-algorithm {name}` argument is not provided, a default value of `SHA256withRSA` is used.
`--replace-existing-certificate`	Uses the new certificate to replace an existing certificate in the key store (within the same alias), and reuses the key for that certificate.
`--inherit-extensions`	Indicates that, when replacing an existing certificate, the new certificate contains the same set of extensions as the existing certificate. If the `--replace-existing-certificate` argument is provided, but the `--inherit-extensions` argument is omitted, the new certificate contains only arguments that are provided explicitly.
`--subject-alternative-name-dns {name}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided DNS name. The given name must be fully qualified, although it can contain an asterisk (`*`) as a wildcard in the leftmost component. To include multiple DNS names in the subject alternative name extension, specify the `--subject-alternative-name-dns {name}` argument multiple times.
`--subject-alternative-name-ip-address {address}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided IP address. The given address must be a valid IPv4 or IPv6 address. No wildcards are allowed. To include multiple IP addresses in the subject alternative name extension, specify the `--subject-alternative-name-ip-address {address}` argument multiple times.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--subject-alternative-name-email-address {address}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided email address. To include multiple email addresses in the subject alternative name extension, specify the `--subject-alternative-name-email-address {address}` argument multiple times.
`--subject-alternative-name-uri {uri}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided URI. To include multiple URIs in the subject alternative name extension, specify the `--subject-alternative-name-uri {uri}` argument multiple times.
`--subject-alternative-name-oid {oid}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided object identifier (OID). The given value must be a valid OID. To include multiple OIDs in the subject alternative name extension, specify the `--subject-alternative-name-oid {oid}` argument multiple times.
`--basic-constraints-is-ca {value}`	Indicates that the certificate is expected to have a basic constraints extension, with a specified value of `true` or `false`, for the flag indicating whether to consider the certificate a certification authority that can be used to sign other certificates. • For root and intermediate certificate authority (CA) certificates, the `--basic-constraints-is-ca {value}` argument must be present with a value of `true`. • For end-entity certificates, the `--basic-constraints-is-ca {value}` argument can optionally be present with a value of `false`. • For a self-signed certificate, specify the `--basic-constraints-is-ca {value}` argument with a value of `false` to indicate that the certificate is not considered a CA certificate.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--basic-constraints-maximum-path-length {number}`	Indicates that the basic constraints extension is expected to include a path length constraint element with the specified value. Use this argument only if `--basic-constraints-is-ca` is provided with a value of `true`. A path length constraint value of `0` indicates that the certificate can be used to issue only end-entity certificates. A path length constraint value of `1` indicates that the certificate can be used to sign end-entity certificates or intermediate CA certificates, the latter of which can be used to sign only end-entity certificates. A value greater than `1` indicates the presence of several intermediate CA certificates between it and the end-entity certificate at the head of the chain.
`--key-usage {value}`	Indicates that the certificate is expected to have a key usage extension with the specified value. The following values are allowed: • `digital-signature` • `non-repudiation` • `key-encipherment` • `data-encipherment` • `key-agreement` • `key-cert-sign` • `crl-sign` • `encipher-only` • `decipher-only` To include multiple key usages, specify the `--key-usage {value}` argument multiple times.
`--extended-key-usage {value}`	Indicates that the certificate is expected to have an extended key usage extension with the specified value. The following values are allowed: • `server-auth` • `client-auth` • `code-signing` • `email-protection` • `time-stamping` • `ocsp-signing`

Example

For example, the following command can be used to generate a self-signed server certificate.

Copyright © 2025 Ping Identity Corporation

```
bin/manage-certificates generate-self-signed-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --keystore-type JKS \
     --alias server-cert \
     --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
     --key-algorithm EC \
     --key-length-bits 256 \
     --signature-algorithm SHA256withECDSA \
     --subject-alternative-name-dns ds.example.com \
     --subject-alternative-name-dns ds1.example.com \
     --subject-alternative-name-dns localhost \
     --subject-alternative-name-ip-address 1.2.3.4 \
     --subject-alternative-name-ip-address 127.0.0.1 \
     --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
     --key-usage digital-signature \
     --key-usage key-encipherment \
     --key-usage key-agreement \
     --extended-key-usage server-auth \
     --extended-key-usage client-auth

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=ds.example.com,O=Example Corp,C=US

```

Generating certificate signing requests

A certificate signing request (CSR) contains all of the information that a certification authority requires to issue a certificate.

RFC 2986 defines the request format, also known as PKCS #10, and includes the following elements:

- Certificate signing request version
- Requested subject distinguished name (DN) for the certificate
- Public key for the requested certificate
- Requested set of extensions for the certificate
- Signature that proves the requester has the private key for the given public key

Copyright © 2025 Ping Identity Corporation

To create a certificate signing request, use the `manage-certificates generate-certificate-signing-request` command, which performs the following steps:

1. Generated a public and private key pair.
2. Stores the key pair in a key store with a given alias.
3. Outputs the certificate signing request to the terminal.
4. Optionally writes the certificate signing request to a file.

Because a certificate signing request contains many of the same elements as a certificate, the command to generate one takes most of the same arguments as for generating a self-signed certificate. The following arguments are unavailable when generating a CSR:

- `--replace-existing-certificate`
- `--days-valid {number}`
- `--validity-start-time {timestamp}`

The following arguments are available when generating a certificate signing request but not when generating a self-signed certificate:

`--output-file {path}`

Path to a file to which the certificate signing request is written. If this value is not provided, the request is written only to the terminal in PEM form.

`--output-format {value}`

Format to use when writing the certificate signing request. This value can be `PEM` or `DER`, but the DER format is used only in conjunction with the `--output-file` argument. Defaults to `PEM` if the `--output-format {value}` argument is not provided.

`--use-existing-key-pair`

Indicates that the CSR uses a key pair that already exists in the key store with the given alias, rather than generating a new key pair, in which case the specified alias must not already be in use in the key store.

The following example command creates a CSR.

Copyright © 2025 Ping Identity Corporation

```
bin/manage-certificates generate-certificate-signing-request \
     --output-file ds1-cert.csr \
     --output-format PEM \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --keystore-type JKS \
     --alias server-cert \
     --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
     --key-algorithm EC \
     --key-length-bits 256 \
     --signature-algorithm SHA256withECDSA \
     --subject-alternative-name-dns ds.example.com \
     --subject-alternative-name-dns ds1.example.com \
     --subject-alternative-name-dns localhost \
     --subject-alternative-name-ip-address 1.2.3.4 \
     --subject-alternative-name-ip-address 127.0.0.1 \
     --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
     --key-usage digital-signature \
     --key-usage key-encipherment \
     --key-usage key-agreement \
     --extended-key-usage server-auth \
     --extended-key-usage client-auth

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing
request.

Successfully wrote the certificate signing request to file
'/ds/build/package/PingDirectory/ds1-cert.csr'.
```

If the contents of the resulting CSR file are made available to a certification authority to be signed, the resulting signed certificate can be imported into the key store.

To print the contents of a certificate signing request file, use the `display-certificate-signing-request-file` subcommand, which supports the following arguments:

`--certificate-signing-request-file {path}`

Path to the file that contains the certificate signing request to display.

`--verbose`

Indicates that the command is expected to display verbose information about the request, rather than a basic information set.

The following example demonstrates the basic output from the command.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates display-certificate-signing-request-file \
                                --certificate-signing-request-file ds1-cert.csr

                                PKCS #10 Certificate Signing Request Version:  v1
                                Subject DN:  CN=ds.example.com,O=Example Corp,C=US
                                Signature Algorithm:  SHA-256 with ECDSA
                                Public Key Algorithm:  EC (secP256r1)
```

The following example demonstrates the verbose output.

```
$ bin/manage-certificates display-certificate-signing-request-file \
     --certificate-signing-request-file ds1-cert.csr \
     --verbose

Importing signed and trusted certificates

Use the `manage-certificates import-certificate` command to import certificates into a keystore.

This command is used to accomplish the following tasks:

- Import a certificate that a certification authority has signed into the keystore in which the key pair was generated. In this scenario, the certificate is imported into a private key entry and must be imported as a certificate chain rather than an end-entity certificate.
- Import a trusted issuer certificate into a trust store. In this scenario, the certificate is imported into a trusted certificate entry as a single certificate instead of as a chain.
- Import a certificate chain, along with the private key for the end-entity certificate. This approach imports certificates that were generated through another library, like OpenSSL.

In addition to the arguments that provide information about the key store and the alias into which the certificate or certificate chain is imported, the `manage-certificates import-certificate` command accepts the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to import. The certificate can be in PEM or DER format and can be a single certificate or a certificate chain. If the certificates in the chain reside in separate files, specify the `--certificate-file {path}` argument multiple times when you import a certificate chain.

`--private-key-file {path}`

Path to the file containing the private key that corresponds to the certificate at the head of the imported chain. The private key can be in PEM or DER format.

`--no-prompt`

Indicates that the certificate is to be imported without prompting for confirmation. By default, a summary of the certificate is displayed, and you must confirm that you want to import it.

The following example command imports a signed certificate into the key store that generates the certificate signing request.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates import-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --certificate-file ds1-cert.pem \
     --certificate-file ca-cert.pem

The following certificate chain will be imported into the keystore into alias
'server-cert', preserving the existing private key associated with that alias:

Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
                     (4 minutes, 16 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
                   (364 days, 23 hours, 55 minutes, 43 seconds from now)
Validity State:  The certificate is currently within the validity window.

Do you want to import this certificate chain into the keystore? yes

Successfully imported the certificate chain.
```

If you do not provide the `--no-prompt` argument, the `manage-certificates import-certificate` tool still displays information about the certificates to import. To view additional information about a certificate before you import it, use the `display-certificate-file` subcommand, which supports the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to view.

`--verbose`

Displays verbose information about the certificate.

The output of the `display-certificate-file` subcommand has the same format and content as the `list-certificates` subcommand.

Copyright © 2025 Ping Identity Corporation

Exporting certificates

Use the `export-certificate` subcommand to export a single certificate or a certificate chain from a key store to a file in PEM or DER format.

The `export-certificate` subcommand supports the normal arguments about the key store and certificate alias, in addition to the following arguments:

`--output-file {path}`

Path to the file to which exported certificates are written. If this value is not provided, the certificates are written to standard output rather than a file.

`--output-format {format}`

Format in which exported certificates are written. The value can be `PEM` or `DER`, but the DER format can be used only if the output is written to a file. Defaults to `PEM` if no value is specified.

`--export-certificate-chain`

Indicates that a certificate chain, rather than the end-entity certificate only, is to be exported.

`--separate-file-per-certificate`

Indicates the use of separate output files for each exported certificate, rather than placing all of the certificates in a single file. If this argument is provided and multiple certificates are to be exported, then `.1` is appended to the path for the indicated output file for the first certificate in the chain, `.2` is appended for the second certificate, and so on.

The following example exports a certificate chain.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates export-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \

```

The `export-certificate` subcommand exports only the public portion of a certificate. Its private key is not included. To export the private key, use the `export-private-key` subcommand, which supports the following arguments, in addition to the usual key store and alias arguments:

`--output-file {path}`

Path to the file to which the exported private key is written. If this value is not provided, the key is written to standard output rather than a file.

`--output-format {format}`

Format in which the exported private key is written. The value can be `PEM` or `DER`, but the DER format is used only if the output is written to a file. Defaults to `PEM` if no value is specified.

The following code provides an example of the `export-private-key` subcommand .

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates export-private-key \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --output-file server-cert-key.pem \
     --output-format PEM

Successfully exported the private key.
```

Using manage-certificates as a simple certification authority

If your server instances need to support an arbitrary or unknown set of clients, configure them with certificates from a trusted issuer, such as a commercial authority or the free Let's Encrypt service.

About this task

If you control every client that accesses the servers, you might want to create your own internal certification authority so that you have a common issuer for all servers. In such a scenario, the clients need to trust only the certificates that the issuer signs. Commercial and open-source software packages provide full-featured certification authority functionality, but you can use the `manage-certificates` tool to create a certificate authority (CA) certificate that you can use to sign certificate-signing requests.

Steps

1. Create a CA certificate.

   A CA certificate is a self-signed certificate that possesses the following extensions:

   - A key usage extension that includes at least the keyCertSign usage
   - A basic constraints extension that identifies the certificate as a CA certificate

     If you do not plan to use an intermediate CA certificate, the basic constraints extension must have a path length constraint of `0`. If you plan to use an intermediate CA certificate, the path length constraint must be `1`. Because certificates that the CA certificate signs are valid only for as long as all certificates in the chain remain valid, we recommend that you specify a long lifespan for the CA certificate.

     Example:

     The following example creates a new root CA certificate.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates generate-self-signed-certificate \
     --keystore /ca/root-ca-keystore \
     --keystore-password-file /ca/root-ca-keystore.pin \
     --keystore-type JKS \
     --alias root-ca-cert \
     --subject-dn "CN=Example Root CA,O=Example Corp,C=US" \
     --days-valid 7300 \
     --key-algorithm RSA \
     --key-size-bits 4096 \
     --signature-algorithm SHA256withRSA \
     --basic-constraints-is-ca true \
     --basic-constraints-maximum-path-length 1 \
     --key-usage key-cert-sign \
     --key-usage crl-sign

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:
Subject DN:  CN=Example Root CA,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Monday, January 27, 2020 at 03:47:29 PM CST (0 seconds ago)
Validity End Time: Sunday, January 22, 2040 at 03:47:29 PM CST
                   (7299 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
SHA-1 Fingerprint: bc:8e:5b:30:52:ec:03:63:b4:9a:aa:1a:45:a0:fc:84:49:dd:e8:64
SHA-256 Fingerprint:
   d5:47:06:cd:a2:95:42:61:1f:c7:aa:04:16:1e:c1:70:41:c4:44:48:bf:74:20:5f:1c:
   61:e2:aa:40:08:3a:ff
```

2. Export the public portion of the root CA certificate for future reference.

   When you import a signed certificate, you can import the public portion of the root CA certificate as a standalone certificate into trust stores as well as into part of a certificate chain.

3. Create a new certificate signing request to create an intermediate CA certificate,

   The certificate signing request uses essentially the same settings as the root CA. If you anticipate only a single intermediate CA, its basic constraints extension must have a path length constraint of `0`, rather than `1`, to indicate that it is used only to sign end-entity certificates and that it cannot create subordinate CA certificates by itself.

   Example:

   The following example command creates a certificate signing request.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates generate-certificate-signing-request \
     --keystore /ca/intermediate-ca-keystore \
     --keystore-password-file /ca/intermediate-ca-keystore.pin \
     --keystore-type JKS \
     --alias intermediate-ca-cert \
     --subject-dn "CN=Example Intermediate CA,O=Example Corp,C=US" \
     --key-algorithm RSA \
     --key-size-bits 4096 \
     --signature-algorithm SHA256withRSA \
     --basic-constraints-is-ca true \
     --basic-constraints-maximum-path-length 0 \
     --key-usage key-cert-sign \
     --key-usage crl-sign \
     --output-file /ca/intermediate-ca-cert.csr \
     --output-format PEM

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing
request.

Successfully wrote the certificate signing request to file
'/ca/intermediate-ca-cert.csr'.
```

4. Use the root CA certificate to sign the certificate signing request for the intermediate CA certificate with the `sign-certificate-signing-request` subcommand.

   The `sign-certificate-signing-request` subcommand takes most of the same arguments as generating a self-signed certificate. The primary differences between the argument sets are as follows:

   - The key store that contains the certificate uses the provided key store arguments to sign the request. To specify the name of the certificate to use when signing the request, use the `--signing-certificate-alias` argument.
   - To specify the path to the file that contains the certificate signing request file to generate, provide a `--request-input-file` argument.
   - To specify the path to the file to which the signed certificate is written, provide a `--certificate-output-file` argument. If this argument is omitted, the PEM representation of the certificate is written to standard output.
   - To specify the format, `PEM` or `DER`, in which the certificate is written to the output file, provide an `--output-format` argument.
   - To specify the subject to use for the signed certificate, use the `--subject-dn` argument. To use the subject DN from the certificate signing request, omit this argument.
   - To specify the name of the signature algorithm, use the `--signature-algorithm` argument.

     > **Note**
     >
     > Because the requester generated the key, you cannot specify the key algorithm or the key length.

   - To indicate that the signed certificate includes every extension that is listed in the certificate signing request, use the `--include-requested-extensions` argument. If this argument is not provided, explicitly specify the set of extensions to include.

Copyright © 2025 Ping Identity Corporation

Example:

The following example command signs the certificate signing request for an intermediate CA certificate.

```
$ bin/manage-certificates sign-certificate-signing-request \
     --keystore /ca/root-ca-keystore \
     --keystore-password-file /ca/root-ca-keystore.pin \
     --signing-certificate-alias root-ca-cert \
     --days-valid 7300 \
     --include-requested-extensions \
     --request-input-file /ca/intermediate-ca-cert.csr \
     --certificate-output-file /ca/intermediate-ca-cert.pem \
     --output-format PEM

Read the following certificate signing request:

PKCS #10 Certificate Signing Request Version:  v1
Subject DN:  CN=Example Intermediate CA,O=Example Corp,C=US
Signature Algorithm:  SHA-256 with RSA
Public Key Algorithm:  RSA (4096-bit)

Do you really want to sign this request? yes

Successfully wrote the signed certificate to file
'/ca/intermediate-ca-cert.pem'.
```

5. After you obtain the intermediate CA certificate, create secure, offline backups of the root CA certificate.
6. Remove the root CA certificate, or at least its private key, from all systems.

> **Note**
>
> Make certain that all end-entity certificates are signed with the intermediate CA certificate, and that the process is identical to the previous example. Restore the root CA certificate only if you need to sign another intermediate CA certificate.

Enabling TLS support during setup

Enable TLS support in the server.

To enable TLS support in the server, you should complete one of the following tasks during the setup procedure:

- Provide a key store that contains the certificate to use.
- Make the installer generate a self-signed certificate.

When using the `setup` tool in interactive mode, it prompts you for the information that it needs to configure secure communication, as shown in the following example.

Copyright © 2025 Ping Identity Corporation

```
Do you want to enable the Directory Server services (Available State,
Available or Degraded State, Configuration, Consent, Directory REST API,
Documentation, SCIM2, and Swagger UI) and Administrative Console over
HTTPS?  After setup, you can selectively enable or disable individual
services and applications by configuring the HTTPS Connection Handler
(yes / no) [yes]: yes

On which port should the Directory Server accept connections from HTTPS
clients? [443]: 443

On which port should the Directory Server accept connections from LDAP
clients? [389]: 389

Do you want to enable LDAPS? (yes / no) [yes]: yes
On which port should the Directory Server accept connections from LDAPS
clients? [636]: 636

Do you want to enable StartTLS? (yes / no) [yes]: yes

Certificate server options:

    1)  Generate self-signed certificate (recommended for testing purposes
        only)
    2)  Use an existing certificate located on a Java Keystore (JKS)
    3)  Use an existing certificate located on a PKCS12 keystore
    4)  Use an existing certificate on a PKCS11 token

Enter option [1]: 2

Java Keystore (JKS) path: /ca/ds1-keystore
Keystore PIN: {password}

Truststore options:

    1)  Generate a default JKS truststore
    2)  Use an existing JKS truststore
    3)  Use an existing PKCS12 truststore

Enter option [1]: 2

JKS truststore path: /ca/truststore
Truststore password (can be blank): {password}
```

When using `setup` in non-interactive mode, use the following arguments to configure TLS support.

Argument	Description
`--ldapsPort {port}`	Server enables support for LDAPS (LDAP over TLS) on the specified TCP port.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--httpsPort {port}`	Server enables support for HTTPS for SCIM, the Directory REST API, and the web-based administration console on the specified TCP port.
`--enableStartTLS`	LDAP connection handler enables support for the StartTLS extended operation.
`--generateSelfSignedCertificate`	`setup` generates a self-signed certificate that is presented to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--useJavaKeyStore {path}`	Server uses the specified Java KeyStore (JKS) key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--usePKCS12KeyStore {path}`	Server uses the specified PKCS #12 key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--usePKCS11KeyStore`	Server uses a PKCS #11 key store, like a hardware security module, to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation. The Java Virtual Machine (JVM) must already be configured to access the appropriate key store through PKCS #11.
`--keyStorePassword {password}`	Password that is needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store. The `setup` tool assumes that the private key password matches the key store password.
`--keyStorePasswordFile {path}`	Path to the file that contains the password needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store.
`--certNickname {alias}`	Alias of the private key entry in the specified key store that contains the certificate chain to present to clients during TLS negotiation. This argument is optional but recommended if the key store contains multiple certificates.
`--useJavaTrustStore {path}`	Server uses the specified JKS trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--usePKCS12TrustStore {path}`	Server uses the specified PKCS #12 trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation
`--trustStorePassword {password}`	Password that is needed to interact with the specified JKS or PKCS #11 trust store.
`--trustStorePasswordFile {path}`	Path to the file that contains the password needed to interact with the specified JKS or PKCS #11 trust store.

The following example command sets up the PingDirectory server in non-interactive mode with an existing certificate.

```
$ ./setup \
     --no-prompt \
     --acceptLicense \
     --ldapPort 389 \
     --ldapsPort 636 \
     --httpsPort 443 \
     --enableStartTLS \
     --useJavaKeyStore config/keystore \
     --keyStorePasswordFile config/keystore.pin \
     --certNickname server-cert \
     --useJavaTrustStore config/truststore \
     --trustStorePasswordFile config/truststore.pin \
     --baseDN dc=example,dc=com \
     --rootUserDN "cn=Directory Manager" \
     --rootUserPasswordFile root-pw.txt \
     --maxHeapSize 10g \
     --encryptDataWithPassphraseFromFile encryption-settings-password.txt \
     --instanceName ds1 \
     --location Austin \
     --noPropertiesFile

Enabling TLS support after setup

If the server has been set up without support for TLS, enable TLS support later by completing the following tasks.

Steps

1. Obtain a certificate chain.

Copyright © 2025 Ping Identity Corporation

For more information about obtaining a certificate chain, see Certificate chains. To prepare a Java KeyStore JKS or PKCS #12 key store with an appropriate certificate chain and private key, use the `manage-certificates` tool. We also recommend that you create a trust store that the server can use.

2. Configure the key and trust manager providers.

   For more information, see Configuring key and trust manager providers.

3. Configure connection handlers.

   For more information, see Configuring connection handlers.

Configuring key and trust manager providers

After you have a key store, configure a key manager provider to access it.

The server is preconfigured with key manager providers, `JKS` and `PKCS12`, that you can use with JKS or PKCS #12 key stores, respectively. You can update the appropriate key manager provider in most cases to reference the key store that you plan to use. The following code provides an example.

```
dsconfig set-key-manager-provider-prop \
     --provider-name JKS \
     --set enabled:true \
     --set key-store-file:config/keystore \
     --set key-store-pin-file:config/keystore.pin
```

A similar change configures a trust manager provider to reference the appropriate trust store. The following code provides an example.

```
dsconfig set-trust-manager-provider-prop \
     --provider-name JKS \
     --set enabled:true \
     --set include-jvm-default-issuers:true \
     --set trust-store-file:config/truststore \
     --set trust-store-pin-file:config/truststore.pin
```

> **Note**
>
> If all clients and servers use certificates that are signed by issuers and are included in the JVM's default trust store, you can use the `JVM-Default` trust manager provider to accomplish this task.

Configuring connection handlers

After you configure the key and trust manager providers, update the connection handlers to use the key and trust manager providers.

Steps

- For the LDAP connection handler, use the following command to enable StartTLS with a configuration change. By default, the LDAP connection handler accepts non-secure connections.

  Example:

Copyright © 2025 Ping Identity Corporation

```
dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --set allow-start-tls:true \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert \
  --set ssl-client-auth-policy:optional
```

- If you did not configure secure communication during setup, the LDAPS connection handler is disabled. To configure LDAPS support in this scenario, enable the connection handler and configure most of the same settings. You must set `allow-start-tls` to `false` and `use-ssl` to `true`. See the following code for an example configuration.

  Example:

  ```
  dsconfig set-connection-handler-prop \
    --handler-name "LDAPS Connection Handler" \
    --set enabled:true \
    --set key-manager-provider:JKS \
    --set trust-manager-provider:JKS \
    --set ssl-cert-nickname:server-cert \
    --set ssl-client-auth-policy:optional
  ```

  Example:

  The following example uses a similar configuration change to enable the HTTPS connection handler.

  ```
  dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set enabled:true \
    --set listen-port:443 \
    --set key-manager-provider:JKS \
    --set trust-manager-provider:JKS \
    --set ssl-cert-nickname:server-cert
  ```

Updating the topology registry

After the server connection handlers are updated to enable TLS, update the topology registry to provide information about the new configuration.

The topology registry holds information about server instances that are part of the environment, and it helps to facilitate inter-server communication, such as replication, mirroring portions of the configuration, and the PingDirectory server's automatic backend server-discovery functionality.

The following table details the two types of entries that require updating.

Copyright © 2025 Ping Identity Corporation

Configuration types and their update descriptions

Configuration Type	Update description

Server instance listener configuration	• Provides information that is needed to trust the TLS certificates that instances in the topology present.
	• The server instance listener configuration must include the server certificate, which is defined as the certificate at the head of the chain. This version must be the multi-line, PEM-formatted representation of the certificate. You can use `dsconfig` to import the certificate from a file, as shown in the following example.
	`bin/dsconfig set-server-instance-listener-prop \`
	`--instance-name ds1 \`
	`--listener-name ldap-listener-mirrored-config \`
	`--set server-ldap-port:636 \`
	`--set connection-security:ssl \`
	`--set 'listener-certificate>/ca/ds1-cert.pem'`
	Note
	The less-than operator `>` in the final line indicates that the value is read from a file rather than provided directly. In addition, you might not need to enclose the property name and path within single straight quotes to prevent the shell from interpreting the less-than symbol as an attempt to redirect input.

Server instance configuration	• Provides information about options for communicating with those instances.
	• Update the server instance configuration object to reflect the new methods that are available for communication with the instance. For example, the `preferred-security` property identifies the mechanism by which other instances in the topology attempt to communicate with the instance.
	The following example code sets the LDAPS and HTTPS ports, indicates that StartTLS support is enabled, and instructs other instances to use SSL (LDAPS) when communicating with the instance.
	`dsconfig set-server-instance-prop \`
	`--instance-name ds1 \`
	`--set ldaps-port:636 \`
	`--set https-port:443 \`
	`--set preferred-security:ssl \`
	`--set start-tls-enabled:true`

Troubleshooting TLS-related issues

Use this section for troubleshooting problems that might arise during TLS configuration, including communication and security issues that affect clients as well as the PingDirectory server.

- Log messages

Copyright © 2025 Ping Identity Corporation

- manage-certificates check-certificate-usability
- ldapsearch
- Using low-level TLS debugging

Log messages

The following describes how to use the server's log messages to troubleshoot TLS-related issues.

To troubleshoot TLS-related issues, start by checking the server's access log. If the client can establish a TCP connection to the server, which must occur before TLS negotiation can start, the access log shows a `CONNECT` message with the following information:

- Source and destination address and port for the connection
- Protocol
- Selected client connection policy

The `CONNECT` message does not appear

If the `CONNECT` does not appear, the client might be unable to communicate with the server. The culprit can be a network problem, a firewall that is blocking attempts to communicate, or the client is trying to use an incorrect address or port.

The `CONNECT` message does appear

If the `CONNECT` message appears in the access log, it typically includes a `conn` element that specifies the connection ID. To view additional log messages for the client connection, use the `search-logs` tool. For example, if the connection ID is `12345`, the following command displays the complete set of associated log messages.

```
$ bin/search-logs --logFile logs/access conn=12345
```

If you are using LDAPS

If you are attempting to use LDAPS, one of the following log messages appears next:

- `SECURITY-NEGOTIATION` message – Indicates that the client and server successfully completed the negotiation process and that the issue likely occurred after the TLS session was established. This message also includes details about the negotiation, including the TLS protocol and the selected cipher suite.

Copyright © 2025 Ping Identity Corporation

- `DISCONNECT` message – The issue might involve a failure in the TLS-negotiation process. In such scenarios, the message usually includes a `reason` element that provides additional information about the reason for the disconnect.

  If the failure occurred during TLS negotiation, the usefulness of the `DISCONNECT` message depends in part on whether the failure occurred on the client or the server. For example, if the server decided to abort the negotiation, the message ideally contains the specific reason. If the problem occurred on the client, the log message likely contains only the general category for the failure.

  > **Note**
  >
  > The TLS protocol does not provide a mechanism for conveying detailed error messages. Instead, it offers only a basic alert mechanism with a fixed set of alert types. For example, if a client does not trust the certificate chain that the server presents to it, the server might receive a generic alert like `certificate_unknown`, even if the client knows the precise reason for rejecting the chain. In such instances, you might need to determine whether the client can provide additional details about the issue.

If the access log does not provide useful information

If the access log does not provide useful information, check the server error log. Although the error log does not normally include information about issues that relate to client communication, it provides helpful information in certain circumstances, like when an internal error within the server interferes with communication attempts.

manage-certificates check-certificate-usability

The `manage-certificates` tool offers a `check-certificate-usability` subcommand to examine a specified entry in a key store and to identify potential issues that might interfere with secure communication.

The `check-certificate-usability` tool completes the following tasks:

- Ensures that a specified entry in the key store includes a private key and a complete certificate chain
- Checks whether the certificate at the root of the chain is found in the Java virtual machine's (JVM's) default set of trusted certificates
- Ensures that the current time lies is within the validity window for all certificates in the chain
- Validates the signatures for all certificates in the chain
- Warns if the end-entity certificate is self-signed
- Warns if the end-entity certificate does not contain an extended key usage extension with the `serverAuth` usage
- Warns if the issuer certificates do not have a key usage extension with the `keyCertSign` usage
- Warns if the issuer certificates do not have a basic constraints extension indicating that it can operate as a certification authority

  If the chain violates a path length constraint, the `check-certificate-usability` tool reports an error.
- Ensures that the signature algorithm uses a strong message digest algorithm, like SHA-256

Copyright © 2025 Ping Identity Corporation

The `check-certificate-usability` tool reports an error for weak digest algorithms like MD5 or SHA-1, and reports a warning for unrecognized digest algorithms.

- Ensures that none of the certificates that use an RSA key pair have a key size less than 2048 bits

The following example demonstrates the usage for the `manage-certificates check-certificate-usability` command and its output when no problems are identified.

Copyright © 2025 Ping Identity Corporation

```
$ bin/manage-certificates check-certificate-usability \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert

Successfully retrieved the certificate chain for alias 'server-cert':

ldapsearch

The `ldapsearch` command-line utility is a powerful tool for issuing searches against an LDAP directory server. It also provides a convenient method for troubleshooting a variety of issues, including problems that are relevant to TLS communication.

The following table details arguments that are the most useful for TLS-related communication.

TLS-related communication arguments and their descriptions

Argument	Description
`--hostname {address}`	Address of the server to which the connection is established
`--port {port}`	TCP port of the server to which the connection is established. The standard port for non-secure LDAP, or LDAP to be secured with StartTLS, is `389`, and the standard port for secure LDAPS is `636`. Many deployments use alternate ports, especially non-privileged ports above `1024`.
`--useSSL`	The tool establishes an initially insecure LDAP connection, which is secured later with the StartTLS extended operation.
`--trustStorePath {path}`	Path to the trust store that is used when determining whether to trust the certificate chain that the server presents during TLS negotiation. If neither this argument nor the `--trustAll` argument is provided, the tool prompts you interactively whether to trust server certificates that are not signed by an issuer in the Java virtual machine's (JVM's) default trust store.
`--trustStoreFormat {format}`	Format for the trust store, which is typically `JKS` or `PKCS12`.
`--trustStorePassword {password}`	Password that is required to access the contents of the trust store.
`--trustStorePasswordFile {path}`	Path to the file that contains the password that is required to access the contents of the trust store.
`--trustAll`	The tool blindly trusts all TLS certificate chains that are presented to it. Although this argument can prove useful for troubleshooting purposes, it is not recommended for general use.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--keyStorePath {path}`	**Path to the key store to use if a client certificate chain is presented to the server.** **Note** Use this argument only when one of the following conditions is satisfied: • The server is configured to require clients to present a certificate. • You intend to use the certificate to authenticate through SASL EXTERNAL.
`--keyStoreFormat {format}`	**Format for the key store, which is typically `JKS` or `PKCS12`.**
`--keyStorePassword {password}`	**Password to access the key store.**
`--keyStorePasswordFile {path}`	**Path to the file that contains the password necessary to access the key store.**
`--certNickname {alias}`	**Alias of the private key entry in the key store. Use when obtaining the certificate chain to present to the server.**
`--useSASLExternal`	**The client authenticates with the EXTERNAL SASL mechanism, which typically identifies the client using the certificate chain that is presented during TLS negotiation.**
`--enableSSLDebugging`	**The tool activates the low-level TLS-debugging feature that the JVM provides.**

The following command provides an example of the simplest method for testing TLS communication with the PingDirectory server.

Example

objectClass: ds-root-dse
startupUUID: 8d574122-4584-4522-96d9-0cdcb9d2e339
startTime: 20191113061149Z

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

Trust stores and trust-related arguments

If no trust-related arguments are provided, the tool uses the JVM's default trust store to verify whether to trust the certificate chain, based on the information that it contains. If a trusted authority has signed the server certificate, the negotiation process continues without further interaction.

If the chain cannot be trusted, based on the information in the JVM-default trust store, `ldapsearch` prompts you interactively about whether to trust the certificate. If you accept the chain, the client and server complete the negotiation process, and the client sends the search request to the server. If the search succeeds, the server can communicate over TLS.

Copyright © 2025 Ping Identity Corporation

To test with a trust store instead of being prompted interactively, use the `--trustStorePath` argument that points to the appropriate trust store. If you are using a Java Keystore (JKS) trust store, you might not need to provide the trust store password. If you are using a PKCS #12 trust store, you need to provide the trust store password. The following code provides an example.

Example

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore.p12 \
     --trustStorePasswordFile config/truststore.pin \
     --trustStoreFormat PKCS12 \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

Client certificate chains and key stores

To present a client certificate chain to the server, either because the server's connection handler is configured with an `ssl-client-auth-policy` value of `required` or because you plan to use the certificate to authenticate by way of the SASL EXTERNAL mechanism, provide at least the key store and its corresponding password. You can also specify the alias of the certificate chain to present, which is recommended if your client key store contains multiple certificates. The following code provides an example.

Example

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore.p12 \
     --trustStorePasswordFile config/truststore.pin \
     --trustStoreFormat PKCS12 \
     --keyStorePath client-keystore \
     --keyStorePasswordFile client-keystore.pin \
     --certNickname client-cert \
     --useSASLExternal \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

If you need to further troubleshoot a TLS-related issue

If you encounter a TLS-related issue that you cannot resolve by examining the `ldapsearch` output or the server logs, use the `--enableSSLDebugging` option to enable the JVM's support for low-level debugging of TLS processing. For more information, see Using low-level TLS debugging.

Using low-level TLS debugging

Use tools other than the command-line tools that are provided with the PingDirectory server for performing low-level TLS debugging.

Before you begin

> **Note**
>
> If you need to use low-level debugging options, enable the Java Virtual Machine (JVM)'s support for TLS debugging. Many of the command-line tools that are provided with the PingDirectory server, such as **`ldapsearch`**, offer an `--enableSSLDebugging` argument that simplifies this process.

Steps

1. In the `config/java.properties` file, add the following line to the set of properties for the appropriate tool.

   ```
   -Djavax.net.debug=all
   ```

Copyright © 2025 Ping Identity Corporation

2. For the changes to take effect, run the `bin/dsjavaproperties` command.

Next steps

The next time the tool is run, an output is generated detailing the TLS-related processing that the JVM is performing. You and the Ping Identity support team can use the output to identify the issue.

Domain Name Service (DNS) caching

If needed, two global configuration properties can be used to control the caching of host name-to-numeric IP address (DNS lookup) results returned from the name resolution services of the underlying operating system. Use the `dsconfig` tool to configure these properties.

network-address-cache-ttl

Sets the Java system property `networkaddress.cache.ttl`, and controls the length of time in seconds that a host name-to-IP address mapping can be cached. The default behavior is to keep resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.

network-address-outage-cache-enabled

Caches host name-to-IP address results in the event of a DNS outage. This is set to `true` by default, meaning name resolution results are cached. Unexpected service interruptions may occur during planned or unplanned maintenance, network outages or an infrastructure attack. This cache may allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

To reduce delays due to unnecessary DNS lookups, follow these recommendations:

- Maintain a connection pool in the client app rather than opening new connections for each bind.
- Add appropriate records to DNS, including PTR records.
- Add `options timeout:1` and/or `options single-request` in `/etc/resolv.conf`.
- If IPv6 requests specifically are causing issues, Add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` so that running `bin/dsjavaproperties` and restarting the server will no longer issue IPv6 PTR requests.

IP address reverse name lookups

Ping Identity servers perform some numeric IP address-to-host name lookups, including the following:

- Binding to the Directory: Decoding, examining, or evaluating a DNS bind rule
- Logging: Logging information to certain monitors or writing to the error log
- JMX: Creating a server socket
- Key Management: Generating a truststore
- Replication Server: Creating an SSL socket
- Replication Session Management: Obtaining a session or performing a handshake with a replication server

Copyright © 2025 Ping Identity Corporation

- SASL Authentication: Applying configuration changes
- SMTP Alert Handler: Initializing or sending an alert notification

Address masks configured in Access Control Lists (ACIs), Connection Handlers, Connection Criteria, and Certificate handshake processing might trigger implicit reverse name lookups. For more information about how address masks are configured in the server, review the following information for each server:

- ACI dns: bind rules under *Managing Access Control* (PingDirectory server and PingDirectoryProxy servers)
- `ds-auth-allowed-address`: *Adding Operational Attributes that Restrict Authentication* (PingDirectory server)
- Connection Criteria: *Restricting Server Access Based on Client IP Address* (PingDirectory server and PingDirectoryProxy servers)
- Connection Handlers: *Restrict Server Access Using Connection Handlers* (Configuration Reference Guide for all PingData servers)

dsconfig">

Configure the synchronization environment with `dsconfig`

The `dsconfig` tool can be used to configure any part of PingDataSync, but will likely be used for more fine-grained adjustments. If configuring a Sync Pipe for the first time, use the `bin/create-sync-pipe-config` tool to guide through the necessary Sync Pipes creation steps.

dsconfig interactive">

Configure server groups with `dsconfig` interactive

In a typical deployment, one PingDataSync server and one or more redundant failover servers are configured. Primary and secondary servers must have the same configuration settings to ensure proper operation. To enable this, assign all servers to a server group using the `dsconfig` tool. Any change to one server will automatically be applied to the other servers in the group.

Run the `dsconfig` command and set the global configuration property for server groups to `all-servers`. On the primary PingDataSync server, perform the following steps:

```
$ bin/dsconfig set-global-configuration-prop \
  --set configuration-server-group:all-servers
```

Updates to servers in the group are made using the `--applyChangeToservergroup` option of the `dsconfig` command. To apply the change to one server in the group, use the `--applyChangeTo single-server` option. If additional servers are added to the topology, the `setup` tool will copy the configuration from the primary server to the new server(s).

Start the Global Sync configuration with dsconfig interactive

About this task

Copyright © 2025 Ping Identity Corporation

After the Synchronization topology is configured, perform the following steps to start the Global Sync configuration, which will use only those Sync Pipes that have been started:

Steps

1. On the `dsconfig` main menu, type the number corresponding to the Global Sync Configuration.
2. On the Global Sync Configuration menu, type the number corresponding to view and edit the configuration.
3. On the GlobalSync Configuration Properties menu, type the number corresponding to setting the started property, and then follow the prompts to set the value to `TRUE`.
4. On the GlobalSync Configuration Properties menu, type `f` to save and apply the changes.

Prepare external server communication

About this task

The `prepare-endpoint-server` tool sets up any communication variances that may occur between PingDataSync and the external servers. Typically, directory servers can have different security settings, privileges, and passwords configured on the Sync Source that might reject the import of entries in the Sync Destination.

The `prepare-endpoint-server` tool also creates a Sync User Account and its privileges on all of the external servers (see Sync user account for more detailed information). The `prepare-endpoint-server` tool verifies that the account has the proper privileges to access the `firstChangeNumber` and `lastChangeNumber` attributes in the root DSE entry so that it can access the latest changes. If the Sync User does not have the proper privileges, PingDataSync displays a warning message, which is saved in the `logs/prepare- endpoint-server.log` file.

> **Note**
>
> If the synchronization topology was created using the `create-sync-pipe-config` tool, this command does not need to be run. It is already part of the `create-sync-pipe-config` process.

Perform the following steps to prepare PingDataSync for external server communication:

Steps

1. Use the `prepare-endpoint-server` tool to prepare the directory server instances on the remote host for synchronization as a data source for the subtree, `dc=example,dc=com`. If the user account is not present on the external server, it will be created if a parent entry exists.

```
$ bin/prepare-endpoint-server \
  --hostname sun-ds1.example.com \
  --port 21389 \
  --syncServerBindDN "cn=Sync User,dc=example,dc=com" \
  --syncServerBindPassword secret \
  --baseDN "dc=example,dc=com" \
  --isSource
```

2. When prompted,enter the bind DN and password to create the user account. This step enables the change log database and sets the `changelog-maximum-age` property.

Copyright © 2025 Ping Identity Corporation

3. Repeat steps 1–2 for any other external source servers.
4. For the destination servers, repeat steps 2–3 and include the `--isDestination` option. If destination servers do not have any entries, a "Denied" message will display when creating the `cn=Sync User` entry.

```
$ bin/prepare-endpoint-server \
  --hostname PingIdentity-ds1.example.com \
  --port 33389 \
  --syncServerBindDN "cn=Sync User,cn=Root DNs,cn=config" \
  --syncServerBindPassword sync \
  --baseDN "dc=example,dc=com" \
  --isDestination
```

5. Repeat step 4 for any other destination servers.

HTTP connection handlers

HTTP Connection Handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. They can also be used to host web applications on the server. Each HTTP connection handler must be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this will not prevent the entire PingDirectoryProxy server from starting. The server's `start-server` tool will output any errors to the error log. This allows the server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with a HTTP connection handler include:

listen-address

Specifies the address on which the connection handler will listen for requests from clients. If not specified, then requests will be accepted on all addresses bound to the system.

listen-port

Specifies the port on which the connection handler will listen for requests from clients. Required.

use-ssl

Indicates whether the connection handler will use SSL/TLS to secure communications with clients (whether it uses HTTPS rather than HTTP). If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.

Copyright © 2025 Ping Identity Corporation

http-servlet-extension

Specifies the set of servlet extensions that will be enabled for use with the connection handler. You can have multiple HTTP connection handlers (listening on different address/port combinations) with identical or different sets of servlet extensions. At least one servlet extension must be configured.

http-operation-log-publisher

Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers will be used.

key-manager-provider

Specifies the key manager provider that will be used to obtain the certificate presented to clients if SSL is enabled.

trust-manager-provider

Specifies the trust manager provider that will be used to determine whether to accept any client certificates presented to the server.

num-request-handlers

Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads will be automatically selected based on the number of CPUs available to the JVM.

web-application-extension

Specifies the Web applications to be hosted by the server.

Configure an HTTP connection handler

About this task

A HTTP connection handler has two dependent configuration objects: one or more HTTP servlet extensions and optionally, a HTTP log publisher. The HTTP servlet extension and log publisher must be configured prior to configuring the HTTP connection handler. The log publisher is optional but in most cases, you want to configure one or more logs to troubleshoot any issues with your HTTP connection.

Steps

1. The first step is to configure your HTTP servlet extensions. The following example uses the ExampleHTTPServletExtension in the Server SDK.

```
$ bin/dsconfig create-http-servlet-extension \
  --extension-name "Hello World Servlet" \
  --type third-party \
  --set
"extensionclass:com.unboundid.directory.sdk.examples.ExampleHTTPServletEx
tension" \
  --set "extension-argument:path=/" \
  --set "extension-argument:name=example-servlet"
```

Copyright © 2025 Ping Identity Corporation

2. Next, configure one or more HTTP log publishers. The following example configures two log publishers: one for common access; the other, detailed access. Both log publishers use the default configuration settings for log rotation and retention.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access Logger" \
  --type common-log-file-http-operation \
  --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Detailed Access Logger" \
  --type detailed-http-operation \
  --set enabled:true \
  --set log-file:logs/http-detailed-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

3. Configure the HTTP connection handler by specifying the HTTP servlet extension and log publishers. Note that some configuration properties can be later updated on the fly while others, like listen-port, require that the HTTP Connection Handler be disabled, then re-enabled for the change to take effect.

```
$ bin/dsconfig create-connection-handler \
  --handler-name "Hello World HTTP Connection Handler" \
  --type http \
  --set enabled:true \
  --set listen-port:8443 \
  --set use-ssl:true \
  --set "http-servlet-extension:Hello World Servlet" \
  --set "http-operation-log-publisher:HTTP Common Access Logger" \
  --set "http-operation-log-publisher:HTTP Detailed Access Logger" \
  --set "key-manager-provider:JKS" \
  --set "trust-manager-provider:JKS"
```

4. By default, the HTTP Connection Handler has an advanced monitor entry property, `keep- stats`, that is set to `TRUE` by default. You can monitor the connection handler using the `ldapsearch` tool.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

HTTP correlation IDs

A typical request to a software system is handled by multiple subsystems, many of which might be distinct servers residing on distinct hosts and locations. Tracing the request flow on distributed systems can be challenging, as log messages are scattered across various systems and intermingled with messages for other requests. To make this easier, a correlation ID can be assigned to a request, which is then added to every associated operation as the request flows through the larger system. The correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP(S) Connection Handler.

When a HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID can also be passed to the LDAP subsystem. For the SCIM 1, Delegated Admin, Consent, and Directory REST APIs, the correlation ID will also appear with associated requests in LDAP logs in the `correlationID` key. The correlation ID is also used as the default client request ID value in Intermediate Client Request Controls used by the SCIM 2, Consent, and Directory REST APIs. Values related to the Intermediate Client Request Control appear in the LDAP logs in the `via` key, and are forwarded to downstream LDAP servers when received by the PingDirectoryProxy server. The correlation ID header is also added to requests forwarded by the PingDataGovernance gateway.

For Server SDK extensions that have access to the current HttpServletRequest, the current correlation ID can be retrieved as a string through the `HttpServletRequest's com.pingidentity.pingdata.correlation_id` attribute. For example:

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

Configure HTTP correlation ID support

Correlation ID support is enabled by default for each HTTP Connection Handler.

- To enable correlation ID support for the HTTPS Connection Handler:

```
$ bin/dsconfig set-connection-handler-prop \
                    --handler-name "HTTPS Connection Handler" \
                    --set use-correlation-id-header:true
```

- To disable correlation ID support for the HTTPS Connection Handler:

```
$ bin/dsconfig set-connection-handler-prop \
                    --handler-name "HTTPS Connection Handler" \
                    --set use-correlation-id-header:false
```

Configuring the correlation ID response header

- The server will generate a correlation ID for every HTTP request and send it in the response through the `Correlation-Id` response header. This response header name can be customized. The following example changes the `correlation-id-response-header` property to"X-Request-Id."

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-connection-handler-prop \
                    --handler-name "HTTPS Connection Handler" \
                    --set correlation-id-response-header:X-Request-Id
```

Accepting an incoming correlation ID from the request

- By default, the server generates a new, unique correlation ID for each HTTP request, and ignores any correlation ID that can be set on the request. This can be changed by designating the names of one or more HTTP request headers that contain an existing correlation ID value. This enables the server to integrate with a larger system consisting of every servers using correlation IDs.

```
$ bin/dsconfig set-connection-handler-prop \
                    --handler-name "HTTPS Connection Handler" \
                    --set correlation-id-request-header:X-Request-Id \
                    --set correlation-id-request-header:X-Correlation-Id \
                    --set correlation-id-request-header:Correlation-Id \
                    --set correlation-id-request-header:X-Amzn-Trace-Id
```

HTTP correlation ID example use

In this example, a request to the Directory REST API is made and the correlation ID enables finding HTTP-specific log messages with LDAP-specific log messages. The response to the API call includes a `Correlation-Id` header with the value `a54aee33-c6c6-4467-be25-efd1db7a8b76`.

Configuring the PingDataSync server to use an HTTP proxy server

Some organizations configure their network so that internal systems cannot directly access the Internet, but instead must use an HTTP proxy server to access external services.

The PingDataSync server now supports using an HTTP proxy server in conjunction with the following components:

- The Amazon Key Management Service cipher stream provider
- The Amazon Secrets Manager cipher stream provider
- The Amazon Secrets Manager passphrase provider
- The Amazon Secrets Manager password storage scheme
- The Azure Key Vault cipher stream provider
- The Azure Key Vault passphrase provider

Copyright © 2025 Ping Identity Corporation

- The Azure Key Vault password storage scheme
- The PingOne pass-through authentication plugin
- The PingOne sync source and destination
- The Pwned Passwords password validator
- The SCIMv1 sync destination
- The SCIMv2 sync destination
- The Twilio alert handler
- The Twilio OTP delivery mechanism
- The UNBOUNDID-YUBIKEY-OTP SASL mechanism handler

Setting up the server to use an HTTP proxy server involves two steps, which are described in the following sections.

1. Creating an HTTP proxy external server in the configuration.
2. Configuring the appropriate component(s) to use the HTTP proxy server.

Creating an HTTP proxy external server

An HTTP proxy external server configuration object provides information about a proxy server that should be used. At present, we only support HTTP proxy servers (which can handle both unencrypted HTTP and encrypted HTTPS connections), with or without authentication.

HTTP proxy external server definitions support the following configuration properties:

`server-host-name`

The resolvable name or IP address of the HTTP proxy server to use. This is required.

`server-port`

The port on which the HTTP proxy server is listening for connections. This is required.

`basic-authentication-username`

The username to use if the proxy server requires authentication. This should be omitted if the proxy server does not require authentication.

`basic-authentication-passphrase-provider`

The passphrase provider to use to obtain the password to use if the proxy server requires authentication. This should be omitted if the proxy server does not require authentication.

For example, you can use a configuration change like the following to create an HTTP proxy external server that does not require authentication:

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-external-server \
     --server-name "Example HTTP Proxy Server" \
     --type http-proxy \
     --set server-host-name:proxy.example.com \
     --set server-port:3128
```

Configuring server components to use the HTTP proxy external server

Merely defining an HTTP proxy external server in the configuration does not cause the server to use that proxy server for anything. Instead, you must indicate which components should use that proxy server.

This is necessary because it may only be necessary to use an HTTP proxy server for certain components (for example, it might be necessary when accessing external web services, but not for services on the internal private network).

All of the components that support the use of an HTTP proxy server offer an `http-proxy-external-server` configuration property whose value should be the name of the appropriate HTTP proxy external server definition in the configuration. For example, to update the Pwned Passwords password validator to use the HTTP proxy server defined in the "Example HTTP Proxy Server" configuration object, use a configuration change like the following:

```
dsconfig set-password-validator-prop \
     --validator-name "Pwned Passwords" \
     --set "http-proxy-external-server:Example HTTP Proxy Server"
```

resync tool">

The `resync` tool

The `resync` tool provides bulk synchronization that can be used to verify the synchronization setup. The tool operates on a single Sync Pipe at a time, retrieves entries from the Sync Source in bulk, and compares the source entries with the corresponding destination entries. If destination entries are missing or attributes are changed, they are updated.

The command provides a `--dry-run` option that can be used to test the matches between the Sync Source and Destination, without committing any changes to the target topology. The `resync` tool also provides options to write debugging output to a log.

> **Note**
>
> The `resync` tool should be used for relatively small datasets. For large deployments, export entries from the Sync Source into an LDIF file, run the `bin/translate-ldif` tool to translate and filter the entries into the destination format, and then import the result LDIF file into the Sync Destination.

Use the `resync-help` command for more information and examples. Logging is located in `logs/tools/resync.log` and `logs/tools/resync-errors.log`. If necessary, the logging location can be changed with the `--logFilePath` option.

Test attribute and DN maps

The `resync` tool can be used to test how attribute maps and DN maps are configured by synchronizing a single entry. If the `--logFilePath` and `--logLevel` options are specified, the `resync` tool generates a log file with details.

Copyright © 2025 Ping Identity Corporation

Use the `--dry-run` option and specify a single entry, such as `uid=user.0`. Any logging performed during the operation appears in `logs/tools/resync.log`.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe \
  --sourceSearchFilter "(uid=user.0)" \
  --dry-run \
  --logLevel debug
```

Verify the synchronization configuration

The most common use for the `resync` tool is to test that the Sync Pipe configuration has been set up correctly. For example, the following procedure assumes that the configuration was set up with the Sync Source topology (two replicated Sun Directory servers) with 2003 entries; the Sync Destination topology (two replicated PingDirectory servers) has only the base entry and the `cn=Sync User` entry. Both source and destination topologies have their LDAP Change Logs enabled. Because both topologies are not actively being updated, the `resync` tool can be run with one pass through the entries.

Use `resync` with the `--dry-run` option to check the synchronization configuration. The output displays a timestamp that can be tracked in the logs.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe \
  --numPasses 1 \
  --dry-run
Starting Pass 1
Status after completing all passes[20/Mar/2010:10:20:07 -0500]
---------------------------------
Source entries retrieved 2003
Entries missing 2002
Entries out-of-sync 1
Duration (seconds) 4
Resync completed in 4 s.
0 entries were in-sync, 0 entries were modified, 0 entries were created,
1 entries are still out-of-sync, 2002 entries are still missing, and
0 entries could not be processed due to an error
```

Populate an empty sync destination topology

About this task

The following procedure uses the `resync` tool to populate an empty Sync Destination topology for small datasets. For large deployments, use the `bin/translate-ldif`.

In this example, assume that the Sync Destination topology has only the base entry (`dc=example,dc=com`) and the `cn=Sync User` entry. Perform the following steps to populate an empty Sync Destination:

Steps

1. Run the `resync` command with the log file path and with the log level `debug`. Logging is located in `logs/tools/resync.log` and `logs/tools/resync-errors.log`.

Copyright © 2025 Ping Identity Corporation

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe \
  --numPasses 1 \
  --logLevel debug
```

2. Open the `logs/resync-failed-DNs.log` file in a text editor to locate the error and fix it. An entry cannot be created because the parent entry does not exist.

```
# Entry '(see below)' was dropped because there was a failure at the
resource:
Failed to create entry uid=mlott,ou=People,dc=example,dc=com. Cause:
LDAPException(resultCode=no such object, errorMessage='Entry
uid=user.38,ou=People,dc=example,dc=com cannot be added because its parent
entry ou=People,dc=example,dc=com does not exist in the server',
matchedDN='dc=example,dc=com')
(id=1893859385ResourceOperationFailedException.java:126 Build
revision=4881)
dn: uid=user.38,ou=People,dc=example,dc=com
```

3. Rerun the `resync` command. The command creates the entries in the Sync Destination topology that are present in the Sync Source topology.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe
```

```
...(output from each pass)...
Status after completing all passes[20/Mar/2016:14:23:33 -0500]

Entries created 4
Duration (seconds) 11

Resync completed in 12 s.

156 entries were in-sync, 0 entries were modified, 4 entries were created,
0 entries are still out-of-sync, 0 entries are still missing, and 0
entries could not be processed due to an error
```

> **Note**
>
> If importing a large amount of data into a PingDirectory server, run `export-ldif` and `import-ldif` on the newly populated backend for most efficient disk space use. If needed, run `dsreplication initialize` to propagate the efficient layout to additional replicas.

Set the synchronization rate

About this task

Copyright © 2025 Ping Identity Corporation

The `resync` command has a `--ratePerSecondFile` option that enables a specific synchronization rate. The option can be used to adjust the rate during off-peak hours, or adjust the rate based on measured loads for very long operations.

> **Note**
>
> The `resync` command also has a `--ratePerSecond` option. If this option is not provided, the tool operates at the maximum rate.

Run the `resync` tool first at 100 operations per second, measure the impact on the source servers, then adjust as desired. The file must contain a single positive integer number surrounded by white space. If the file is updated with an invalid number, the rate is not updated.

Steps

1. Create a text file containing the rate. The number must be a positive integer surrounded by white space.

```
$ echo '100 ' >rate.txt
```

2. Run the `resync` command with the `--ratePerSecondFile` option.

```
$ bin/resync --pipe-name "sun-to-ds-sync-pipe" \
  --ratePerSecondPath rate.txt
```

Synchronize a specific list of DNs

About this task

The `resync` command enables synchronizing a specific set of DNs that are read from a file using the `--sourceInputFile` option. This option is useful for large datasets that require faster processing by targeting individual base-level searches for each source DN in the file. If any DN fails (parsing, search, or process errors), the command creates an output file of the skipped entries (`resync-failed-DNs.log`), which can be run again.

The file must contain only a list of DNs in LDIF format with `dn:` or `dn::`. The file can include comment lines. All DNs can be wrapped and are assumed to be wrapped on any lines that begin with a space followed by text. Empty lines are ignored.

Small files can be created manually. For large files, use `ldapsearch` to create an LDIF file, as follows:

Steps

1. Run an `ldapsearch` command using the special OID "1.1" extension, which only returns the DNs in the DIT. For example, on the Sync Source directory server, run the following command:

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com \
  --baseDN dc=example,dc=com \
  --searchScope sub "(objectclass=*)" "1.1" > dn.ldif
```

2. Run the `resync` command with the file.

Copyright © 2025 Ping Identity Corporation

```
$ bin/resync --pipe-name "sun-to-ds-pipe" \
  --sourceInputFile dn.ldif
```

```
Starting pass 1
[20/Mar/2016:10:32:11 -0500]
-----------------------------------
Resync pass 1
Source entries retrieved 1999
Entries created 981
Current pass, entries processed 981
Duration (seconds) 10
Average ops/second 98
Status after completing all passes[20/Mar/2016:10:32:18 -0500]
---------------------------------
Source entries retrieved 2003
Entries created 2003
Duration (seconds) 16
Average ops/second 98
Resync completed in 16 s.
0 entries were in-sync, 0 entries were modified, 2003 entries were
created, 0 entries are still out-of-sync, 0 entries are still missing, and
0 entries could not be processed due to an error
```

3. View the `logs/tools/resync-failed-DNs.log` to determine skipped DNs. Correct the source DNs file, and rerun the `resync` command.

realtime-sync tool">

The `realtime-sync` tool

The `bin/realtime-sync` tool controls starting and stopping synchronization globally or for individual Sync Pipes. The tool also provides features to set a specific starting point for real-time synchronization.

To see the current status of real-time synchronization, view the monitor properties: `num-sync-ops-in-flight`, `num-ops-in-queue`, and `source-unretrieved-changes`. For example, use `ldapsearch` to view a specific Sync Pipe's monitor information:

```
$ bin/ldapsearch --baseDN cn=monitor \
--searchScope sub "(cn=Sync Pipe Monitor: PIPE_NAME)"
```

The Stats Logger can also be used to view status. See the PingDirectory Server Administration Guide for details.

Start real-time synchronization globally

About this task

The `realtime-sync` tool assumes that the synchronization topology is configured correctly.

Perform the following steps to start real time synchronization globally:

Copyright © 2025 Ping Identity Corporation

Steps

1. Run the tool from the `<server-root>/bin` directory. This example assumes that a single Sync Pipe called "dsee-to-ds-sync-pipe" exists.

```
$ bin/realtime-sync start --pipe-name "dsee-to-ds-sync-pipe" \
  --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret
```

2. If more than one Sync Pipe is configured, specify each using the `--pipe-name` option. The following example starts synchronization for a bidirectional synchronization topology.

```
$ bin/realtime-sync start --pipe-name "Sun DS to DS" \
  --pipe-name "DS to Sun DS" \
  --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret
```

Start or Pause synchronization

Pause or start synchronization by using the `start` and `stop` subcommands. If synchronization is stopped and then restarted, changes made at the Sync Source while synchronization was stopped will still be detected and applied. Synchronization for individual Sync Pipes can be started or stopped using the `--pipe-name` argument. If the `--pipe-name` argument is omitted, then synchronization is started or stopped globally.

The following command stops all Sync Pipes:

```
$ bin/realtime-sync stop --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret \
  --no-prompt
```

If a topology has two Sync Pipes, Sync Pipe1 and Sync Pipe2, the following command stops Sync Pipe1.

```
$ bin/realtime-sync stop --pipe-name "Sync Pipe1" \
  --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret --no-prompt
```

Set startpoints

About this task

Startpoints instruct the Sync Pipe to ignore all changes made prior to the current time. Once synchronization is started, only changes made after this command is run will be detected at the Sync Source and applied at the Sync Destination.

Copyright © 2025 Ping Identity Corporation

The `set-startpoint` subcommand is often run during the initial setup prior to starting real-time synchronization. It should be run prior to initializing the data in the Sync Destination.

The `set-startpoint` subcommand can start synchronization at a specific change log number, or back at a state that occurred at a specific time. For example, synchronization can start 10 minutes prior to the current time.

Perform the following steps to set a synchronization startpoint:

Steps

1. If started, stop the synchronization topology globally with the following command:

```
$ bin/realtime-sync stop --pipe-name "Sync Pipe1" \
  --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret \
  --no-prompt
```

2. Set the startpoint for the synchronization topology. Any changes made before setting this command will be ignored.

```
$ bin/realtime-sync set-startpoint --pipe-name "Sync Pipe1" \
  --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret \

  --no-prompt \
  --beginning-of-changelog
```

```
Set StartPoint task 2011072109564107 scheduled to start immediately
[21/Jul/2016:09:56:41 -0500] severity="INFORMATION" msgCount=0
msgID=1889535170
message="The startpoint has been set for Sync Pipe 'Sync Pipe1'.
Synchronization will resume from the last change number in the Sync
Source"
Set StartPoint task 2011072109564107 has been successfully completed
```

Restart synchronization at a specific change log event

About this task

Perform the following steps to restart synchronization at a specific event:

Steps

1. Search for a specific change log event from which to restart the synchronization state. On one of the endpoint servers, run `ldapsearch` to search the change log.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch -p 1389
--bindDN "uid=admin,dc=example,dc=com" \
--bindPassword secret \
--baseDN cn=changelog \
--dontWrap
```

```
"(objectclass=*)"
dn: cn=changelog
objectClass: top
objectClass: untypedObject
cn: changelog
dn: changeNumber=1,cn=changelog
objectClass: changeLogEntry
objectClass: top
targetDN: uid=user.13,ou=People,dc=example,dc=com
changeType: modify

ltZTo6IEFBQUJKZ25OTUM4NFBQotCgA=
changenumber: 2329
```

2. Restart synchronization from change number 2329 using the `realtime-sync` tool. Any event before this change number will not be synchronized to the target endpoint.

```
$ bin/realtime-sync set-startpoint \
  --change-number 2329 \
  --pipe-name "Sync Pipe 1" \
  --bindPassword secret \
  --no-prompt
```

Change the synchronization state by a specific time duration

The following command will start synchronizing data at the state that occurred 2 hours and 30 minutes prior to the current time on External Server 1 for Sync Pipe 1. Any changes made before this time will not be synchronized. Specify days (d), hours (h), minutes (m), seconds (s), or milliseconds (ms).

Copyright © 2025 Ping Identity Corporation

Use `realtime-sync` with the `--startpoint-rewind` option to set the synchronization state and begin synchronizing at the specified time.

```
$ bin/realtime-sync set-startpoint \
  --startpoint-rewind 2h30m \
  --pipe-name "Sync Pipe 1" \
  --bindPassword secret \
  --no-prompt
```

Schedule a real-time sync as a task

About this task

The `realtime-sync` tool features both an offline mode of operation as well as the ability to schedule an operation to run within PingDataSync server's process. To schedule an operation, supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.

Perform the following steps to schedule a synchronization task:

Steps

1. Use the `--start` option with the `realtime-sync` command to schedule a start for the synchronization topology. The following command will set the start time at July 21, 2016 at 12:01:00 AM. The scheduled task can be stopped with the `--stop` subcommand.

   ```
   $ bin/realtime-sync set-startpoint \
     --pipe-name "sun-to-ds-sync-pipe" \
     --port 389 \
     --bindDN "uid=admin,dc=example,dc=com" \
     --bindPassword secret \
     --start 20160721000100 \
     --no-prompt
   ```

   ```
   Set StartPoint task 2009072016103807 scheduled to start Jul 21, 2016
   12:01:00 AM CDT
   ```

2. Run the manage-tasks tool to manage or cancel the task.

   ```
   $ bin/manage-tasks --port 7389 \
     --bindDN "uid=admin,dc=example,dc=com" \
     --bindPassword secret
   ```

Configure the PingDirectory server backend for synchronizing deletes

About this task

Copyright © 2025 Ping Identity Corporation

The PingDirectory server's change log backend's `changelog-deleted-entry-include-attribute` property specifies which attributes should be recorded in the change log entry during a DELETE operation. Normally, PingDataSync cannot correlate a deleted entry to the entry on the destination. If a Sync Class is configured with a filter, such as "`include-filter: objectClass=person`," the `objectClass` attribute must be recorded in the change log entry. Special correlation attributes (other than DN), will also need to be recorded on the change log entry to be properly synchronized at the endpoint server.

On each PingDirectory server backend, use the `dsconfig` command to set the property.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set changelog-deleted-entry-include-attribute:objectClass
```

If the destination endpoint is an Oracle/Sun DSEE (or Sun DS) server, the Sun DSEE server does not store the value of the user deleting the entry, specified in the modifiers name attribute. It only stores the value of the user who last modified the entry while it still existed.

To set up a Sun DSEE destination endpoint to record the user who deleted the entry, use the Ping Identity Server SDK to create a plugin, as follows:

Steps

1. Update the Sun DSEE schema to include a `deleted-by-syncauxiliary` objectclass. It will only be used as a marker objectclass, and not require or allow additional attributes to be present on an entry.
2. Update the Sun DSEE Retro Change Log plugin to include the `deleted-by-sync auxiliary` objectclass as a value for the `deletedEntryAttrs` attribute.
3. Write an `LDAPSyncDestinationPlugin` script that in the `preDelete()` method modifies the entry that is being deleted to include the `deleted-by-sync` objectclass.
4. Update the Sync Class filter that is excluding changes by the Sync User to also include `(!(objectclass=deleted-by-sync))`.

Configure DN maps

Similar to attribute maps, DN maps define mappings when destination DNs differ from source DNs. These differences must be resolved using DN maps in order for synchronization to successfully take place. For example, the Sync Source could have a DN in the following format:

```
uid=jdoe,ou=People,dc=example,dc=com
```

While the Sync Destination could have the standard X.500 DN format.

DN mappings allow the use of wild cards for DN transformations. A single wild card (`*`) matches a single RDN component and can be used any number of times. The double wild card (`**`) matches zero or more RDN components and can be used only once.

> **Note**
>
> If a literal '*' is required in a DN then it must be escaped as `'\2A'`.

Copyright © 2025 Ping Identity Corporation

The wild card values can be used in the to-dn-pattern attribute using {1} to replace their original index position in the pattern, or {attr} to match an attribute value. For example:

```
*,**,dc=com->{1},ou=012,o=example,c=us
```

For example, using the DN, `uid=johndoe,ou=People,dc=example,dc=com`, and mapping to the target DN, `uid=johndoe,ou=012,o=example,c=us`:

- `"*"` matches one RDN component, `uid=johndoe`
- `"**"` matches zero or more RDN components, `ou=People,dc=example`
- `"dc=com"` matches `dc=com` in the DN.

The DN is mapped to the `{1},ou=012,o=example,c=us`. `"{1}"` substitutes the first wildcard element `"uid=johndoe"`, so that the DN is successfully mapped to:

```
uid=johndoe,ou=012,o=example,c=us
```

Regular expressions and attributes from the user entry can also be used in the `to-dn-pattern` attribute. For example, the following expression constructs a value for the `uid` attribute, which is the RDN, out of the initials (first letter of given name and `sn`) and the employee ID (the `eid` attribute) of a user.

```
uid={givenname:/^(.)(.*)/$1/s}{sn:/^(.)(.*)/$1/s}{eid},{2},o=example
```

> **Note**
>
> PingDataSync automatically validates any DN mapping prior to applying the configuration.

Configure a DN map by using dsconfig

About this task

A DN map can be configured using `dsconfig`, either with the interactive DN Map menu, or from the command line.

Perform the following to configure a DN map:

Steps

1. Use `dsconfig` to create a DN map for PingDataSync.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig --no-prompt create-dn-map \
  --map-name nested-to-flattened \
  --set "from-dn-pattern:*,,dc=example,dc=com" \
  --set "to-dn-pattern:uid={givenname:/(.)(.)/\$1/s}{sn:/(.)(.*)/\$1/s}
(eid},{2},o=example" \
  --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret
```

2. After DN mappings are configured, add the new DN map to a new Sync Class or modify an existing Sync Class.

```
$ bin/dsconfig --no-prompt set-sync-class-prop \
  --pipe-name test-sync-pipe \
  --class-name test-sync-class \
  --set dn-map:test-dn-map \
  --port 389 --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret
```

Configure synchronization with JSON attribute values

PingDataSync supports synchronization of attributes that hold JSON objects. The following scenarios are supported:

- Synchronizing a JSON attribute to another JSON attribute - A subset of fields can be synchronized, optionally retaining fields that appear at the destination but not at the source.
- Synchronizing a JSON attribute to a non-JSON attribute - A single field of the JSON value can be extracted with a constructed attribute mapping.
- Synchronizing a non-JSON attribute to a JSON attribute - The source value can be escaped so that it ensures the JSON value is properly formatted.
- Attribute correlation - A JSON field can be used when correlating a destination entry with a source entry.

The following examples show configuration scenarios based on the LDAP `ubidEmailJSON` attribute, which has fields of `value`, `type`, `primary`, and `verified`:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "home",
                "primary" : true,
                "verified" : true}
```

Synchronize ubidEmailJSON fully

If a source JSON attribute value should be synchronized fully to a destination JSON attribute value, no special configuration is required.

Copyright © 2025 Ping Identity Corporation

Synchronize a subset of fields from the source attribute

For example, the following configuration can be used to synchronize the `value` and `type` fields of `ubidEmailJSON` from the source to a destination. To synchronize this source value:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "home",
                "primary" : true}
```

to this value at the destination:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "home"}
```

You can filter JSON field values in the `value-pattern` and `conditional-value-pattern` constructed attribute mapping properties. This enables a given field value to only be mapped for values that match a given filter.

For example, if `ubidEmailJSON` is a JSON attribute and the `value` field is to be extracted only for values where the `type` field is equal to `work`, the value pattern specifying this would be as follows:

```
{ubidEmailJSON.value({{"filterType":"equals","field":"type","value":"work"}})}
```

A JSON Attribute configuration object must be created and associated with the Sync Class. This can be done by either explicitly including the fields to synchronize:

```
$ bin/dsconfig create-json-attribute --pipe-name "A to B" \
  --class-name Users \
  --attribute-name ubidEmailJSON \
  --set include-field:type \
  --set include-field:value
```

Or by excluding the fields that should not be synchronized:

```
$ bin/dsconfig create-json-attribute \
  --pipe-name "A to B" \
  --class-name Users \
  --attribute-name ubidEmailJSON \
  --set exclude-field:preferred \
  --set exclude-field:verified
```

If the destination is prepared to only handle a specific subset of fields, then list the fields to include. However, if only a small, known subset of fields from the source should be excluded, then `exclude-field` could be used. In this example, the destination data for the `ubidEmailJSON` attribute will always be a subset of the full data.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> A Sync Class can be configured to exclude certain attributes from synchronization. Creating a regular attribute mapping will override this setting, and the attribute will be synchronized. Creating a JSON attribute mapping does not override this setting, and the JSON attribute will not be synchronized. A JSON attribute is not a traditional attribute mapping. It only includes information on the destination attribute name. To work around this, the attribute either needs to be mapped from a source attribute, or have its value constructed.

The following scenario illustrates how the destination can include additional fields that are not present at the source.

Retain destination-only fields

To synchronize changes to the source fields while preserving the value of the `verified` field of the `ubidEmailJSON` attribute at the destination, configure the JSON Attribute as follows:

```
$ bin/dsconfig create-json-attribute \
  --pipe-name "A to B" \
  --class-name Users \
  --attribute-name ubidEmailJSON \
  --set id-field:value \
  --set exclude-field:verified
```

The `verified` field is excluded and `value` is chosen to correlate destination values with source values. For example, given that the source and destination `value` fields match, if the source initially contained:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "home"}
```

and the destination contained:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "home",
                "verified" : true},
```

if the source changed to:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "other"}
```

then the destination would change to:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "other",
                "verified" : true}
```

Copyright © 2025 Ping Identity Corporation

However, if the source changed to:

```
ubidEmailJSON: {"value" : "john.smith@example.com",
                "type" : "home"}
```

then the destination would be updated to:

```
ubidEmailJSON: {"value" : "john.smith@example.com",
                "type" : "home"}
```

The `verified` field has been dropped because this logically represents a new JSON object rather than an update of an existing one.

Synchronize a field of a JSON attribute into a non-JSON attribute

If the source stores:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
            "type" : "home"}
```

but the destination stores:

```
mail: jsmith@example.com
```

To synchronize changes between these systems, a constructed attribute mapping must be configured:

```
$ bin/dsconfig create-attribute-mapping \
  --map-name "Attribute Map" \
  --mapping-name mail \
  --type constructed \
  --set "value-pattern:{ubidEmailJSON.value}"
```

The `value-pattern` syntax allows attributes to be referenced by placing them in `\{}`. JSON fields within the attribute can be referenced by using the syntax `\{attribute.field}`. See this property in the Configuration Reference guide, or `dsconfig` tool command help for more information.

After the "Attribute Map" is created, it can be referenced from the Sync Class:

```
$ bin/dsconfig set-sync-class-prop
  --pipe-name "A to B" \
  --class-name Users \
  --set "attribute-map:Attribute Map"
```

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> While LDAP attribute names are not case sensitive, the JSON field names are. By default, errors related to attribute mapping are not logged. To enable error logging, configure the Debug Logger with the following:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true
```

```
$ bin/dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name com.unboundid.directory.sync.mapping \
  --set debug-level:warning
```

Synchronize a non-JSON attribute into a field of a JSON attribute

This scenario provides a reversal of the previous example. The source stores the following information:

```
mail: jsmith@example.com
```

but the destination stores the following information:

```
ubidEmailJSON: {"value" : "jsmith@example.com"}
```

To construct an attribute value that functions as a JSON object, use *JSON attribute mapping* and *JSON attribute mapping field* configuration objects. The following code provides an example:

```
bin/dsconfig create-attribute-mapping --map-name "Attr Map" \
  --mapping-name ubidEmailJSON \
  --type json

bin/dsconfig create-json-attribute-mapping-field --map-name "Attr Map" \
  --mapping-name ubidEmailJSON \
  --field-name "value" \
  --from-attribute mail
```

For more information about these configuration object types, refer to the configuration reference guide.

You can also use a constructed attribute mapping to construct a JSON attribute value as a raw string, as follows:

```
$ bin/dsconfig create-attribute-mapping \
  --map-name "Attr Map" \
  --mapping-name ubidEmailJSON \
  --type constructed \
  --set 'value-pattern:{{"value" : "{mail:jsonEscape}"}}'
```

Copyright © 2025 Ping Identity Corporation

When constructing a value, be aware of the following points:

- Double curly brackets (`{{ }}`) are necessary to represent a single curly bracket (`{ }`) in the output. These brackets are typically used to reference attribute values.
- Use the `:jsonEscape` modifier to escape attribute values that appear within a JSON attribute. This step prevents values that include quotes like '`"John Smith" <jsmith@example.com>`' from producing invalid JSON.

In the following example, a JSON Attribute object must be created because the destination value is likely to be augmented with additional information:

```
$ bin/dsconfig create-json-attribute \
  --pipe-name "A to B" \
  --class-name Users \
  --attribute-name ubidEmailJSON \
  --set id-field:value \
  --set include-field:value
```

Synchronize multiple non-JSON attributes into fields of a JSON attribute

Multiple JSON fields can be defined within a single JSON attribute. For any source attribute that does not exist, the corresponding JSON field is omitted from the JSON attribute. The following code demonstrates the mapping of a standard LDAP schema into the standard PingOne user schema.

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-attribute-map \
  --map-name PingDirectory_to_PingOne_User_Map

...

dsconfig create-attribute-mapping \
  --map-name PingDirectory_to_PingOne_User_Map \
  -mapping-name name \
  --type json

dsconfig create-json-attribute-mapping-field \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name name \
  --field-name formatted \
  --set from-attribute:cn \
  --json-type string

dsconfig create-json-attribute-mapping-field \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name name \
  --field-name given \
  --set from-attribute:givenName \
  --json-type string

dsconfig create-json-attribute-mapping-field \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name name \
  --field-name family \
  --set from-attribute:sn \
  --json-type string
```

Correlating attributes based on JSON fields

When the destination of a Sync Pipe is a PingDirectory server or a PingDirectoryProxy server, source and destination entries can be correlated by referencing a field within a JSON attribute. In the following example, source entries will be matched with destination entries that have the same `value` field within the `ubidEmailJSON` value.

```
$ bin/dsconfig set-sync-class-prop \
  --pipe-name "A to B" \
  --class-name Users \
  --set destination-correlation-attributes:ubidEmailJSON.value
```

This could also be used with the previous example, which does not store `ubidEmailJSON.value` at the source but maps into it before correlating at the destination.

Configure fractional replication

About this task

Copyright © 2025 Ping Identity Corporation

PingDataSync supports fractional replication to any server type. For example, if a replica only performs user authentications, PingDataSync can be configured to propagate only the `uid` and `userpassword` password policy attributes, reducing the database size at the replica and the network traffic needed to keep this servers synchronized.

The following example configures a fractional replication, where the `uid` and `userPassword` attributes of all entries in the source topology are synchronized to the destination topology. Because the `uid` and `userPassword` attributes are present, the `objectclass` attribute must also be synchronized. The example assumes that PingDataSync and the external servers are configured and a Sync Pipe and Sync Class are defined, but real-time synchronization or bulk resync have not been performed.

Perform the following steps to configure fractional replication from the `dsconfig` interactive menu:

Steps

1. On the main menu, type the number corresponding to Sync Classes.
2. On the Sync Class menu, type the number corresponding to viewing and editing an existing Sync Class. Assume that only one Sync Class has been defined.
3. Verify that the Sync Pipe and Sync Class exist.
4. On the SyncClass Properties menu, type the number specifying the source LDAP filter (`include-filter` property) that defines which source entries are to be included in the Sync Class.
5. On the Include-Filter Property menu, type the number corresponding to adding a filter value. For this example, type (`objectclass=person`). When prompted, enter another filter. Press Enter to continue. On the menu, enter 1 to use the value when specifying it.
6. On the SyncClass Properties menu, type the number corresponding to the `auto-mapped-source-attribute` property. Change the value from " `-all-` " to a specific attribute, so that only the specified attribute is automatically mapped from the source topology to the destination topology.
7. On the Auto-Mapped-Source-Attribute Property menu, type the number corresponding to adding the source attributes that will be automatically mapped to the destination attributes of the same name. When prompted, enter each attribute, and then press Enter.

```
Enter another value for the 'auto-mapped-source-attribute' property
[continue]: uid
Enter another value for the 'auto-mapped-source-attribute' property
[continue]: userPassword
Enter another value for the 'auto-mapped-source-attribute' property
[continue]: objectclass
Enter another value for the 'auto-mapped-source-attribute' property
[continue]:
```

8. On the Auto-Mapped-Source-Attribute Property menu, type the number corresponding to removing one or more values. In this example, remove the " `-all-` " value, so that only the `objectclass` , `uid` , and `userPassword` attributes are only synchronized.
9. On the Auto-Mapped-Source-Attribute Property menu, press Enter to accept the values.

Copyright © 2025 Ping Identity Corporation

10. On the Sync Class Properties menu, type the number corresponding to excluding some attributes from the synchronization process. When using the `objectclass=person` filter, the `cn`, `givenName`, and `sn` attributes must be excluded. Enter the option to add one or more attributes, and then add each attribute to exclude on the `excluded-auto-mapped-source-attributes` Property menu. For this example, exclude the `cn`, and `sn` attributes, which are required attributes of the `Person` objectclass. Also exclude the `givenName` attribute,which is an optional attribute of the `inetOrgPerson` objectclass.

```
Enter another value for the 'excluded-auto-mapped-source-attributes'
property
[continue]: givenName
Enter another value for the 'excluded-auto-mapped-source-attributes'
property
[continue]: sn
Enter another value for the 'excluded-auto-mapped-source-attributes'
property
[continue]:
```

11. On the Excluded-Auto-Mapped-Source-Attributes Property menu, press Enter to accept the changes.

> **Note**
>
> If using `entryUUID` as a correlation attribute, some attribute uniqueness errors may occur while using the `resync` tool. Either set the `excluded-auto-mapped-source-attributes` property value to `entryUUID` on the Sync Class configuration menu, or run `resync` with the `--excludeDestinationAttr` entryUUID argument.

12. On the Sync Class Properties menu, review the configuration and accept the changes.

13. On the server instances in the destination topology, turn off schema checking to avoid a schema error that occurs when the required attributes in the `Person` objectclass are not present. Make sure that the global configuration property for the `server-group` is set to `all-servers`. Use the following command to turn off schema checking on all of the servers in the group.

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
  --set check-schema:false \
  --applyChangeTo server-group \
  --port 3389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret
```

14. Run `bin/resync` to load the filtered data from the source endpoint to the target endpoint.

```
$ bin/resync --pipe-name "test-sync-pipe" \
  --numPasses 3
```

15. Run `bin/realtime-sync` to start synchronization.

Copyright © 2025 Ping Identity Corporation

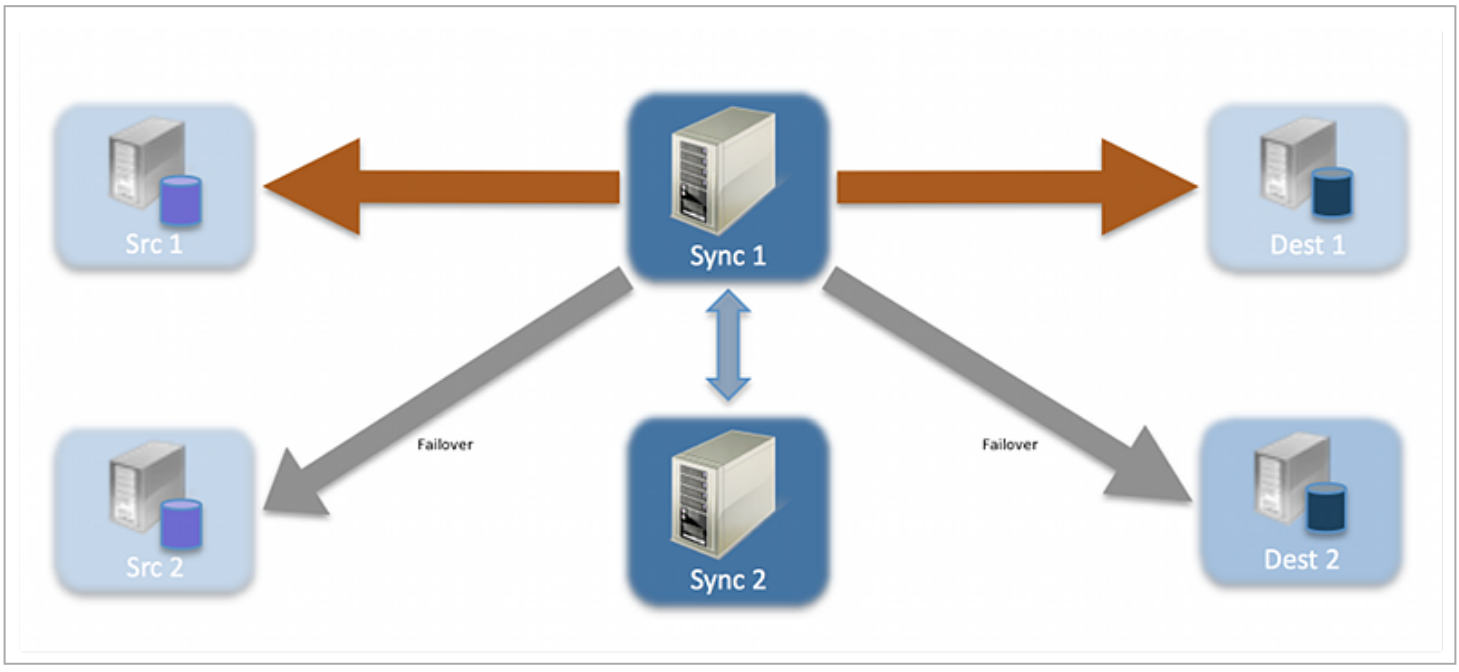
```
$ bin/realtime-sync start --pipe-name "test-sync-pipe" \
  --port 7389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret \
  --no-prompt
```

Configure failover behavior

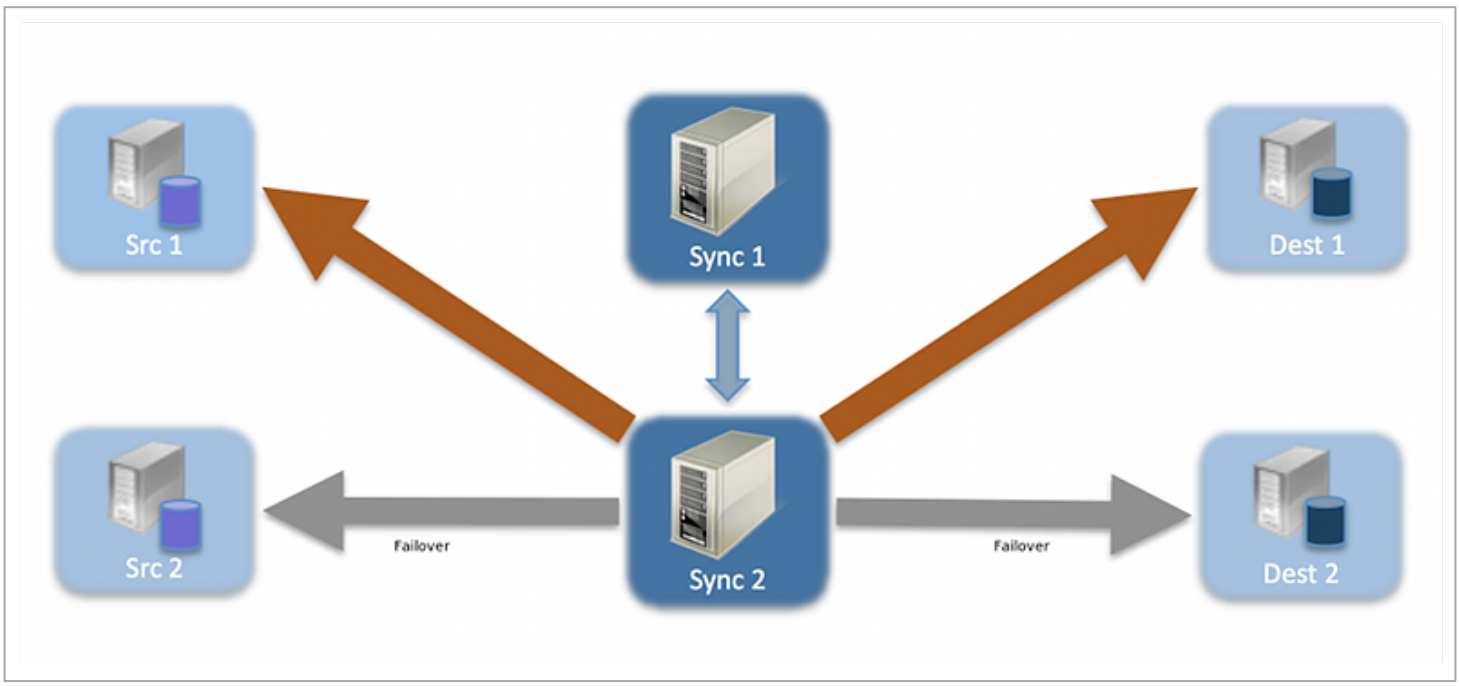
The following illustrates a simplified synchronization topology with a single failover server on the source, destination, and PingDataSync, respectively. The gray lines represent possible failover connections in the event the server is down. The external servers are prioritized so that src1 has higher priority than src2; dest1 has higher priority than dest2.

The main PingDataSync and its redundant failover instance communicate with each other over LDAP and bind using `cn=Intra Sync User,cn=Root DNs,cn=config`. The servers run periodic health checks on each other and share information on all changes that have been processed. Whenever the failover server loses connection to the main server, it assumes that the main server is down and begins processing changes from the last known change. Control reverts back to the main server once it is back online.

Unlike the PingDataSyncs, the external servers and their corresponding failover server(s) do not run periodic health checks. If an external server goes offline, the failover server will receive transactions and remain connected to PingDataSync until the Sync Pipe is restarted, regardless of if the main external server comes back online.



Copyright © 2025 Ping Identity Corporation



Conditions that trigger immediate failover

Immediate failover occurs when PingDataSync receives one of the following error codes from an external server:

- BUSY (51)
- UNAVAILABLE (52)
- SERVER CONNECTION CLOSED (81)
- CONNECT ERROR (91)

If PingDataSync attempts a write operation to a target server that returns one of these error codes, PingDataSync will automatically fail over to the next highest prioritized server instance in the target topology, issue an alert, and then reissue the retry attempt. If the operation is unsuccessful for any reason, the server logs an error.

Failover server preference

PingDataSync supports endpoint failover, which is configurable using the `location` property on the external servers. By default, PingDataSync prefers to connect to and failover to endpoint servers in the same location as itself. If no location settings are configured, PingDataSync will iterate through the configured list of external servers on the Sync Source and Sync Destination when failing over.

PingDataSync does not perform periodic health checks of external servers, and does not failover automatically to a preferred external server. Due to the cost of sync failover, PingDataSync remains connected to a given server until the server stops responding or until the Sync Pipe is restarted. When a failover occurs, PingDataSync returns to the most preferred server, optionally using location settings to identify it, and works its way down the list. The following provides an example configuration of external servers:

Copyright © 2025 Ping Identity Corporation

```
austin1.server.com:1389
london1.server.com:2389
boston1.server.com:3389
austin2.server.com:4389
boston2.server.com:5389
london2.server.com:6389
```

If the austin1 server were to become unavailable, PingDataSync will automatically pick up changes on the next server on the list, london1. If london1 is also down, then the next server, boston1 will be picked up. After PingDataSync iterates through the list, it returns to the top of the list. If PingDataSync is connected to london2 and it goes down, it will fail over to austin1.

To minimize WAN traffic, configure the `location` property for each external server using the `dsconfig` command on PingDataSync. Assume that PingDataSync has its own `location` property (set in the Global Configuration) set to "austin."

```
austin1.server.com:1389 location=austin
london1.server.com:2389 location=london
boston1.server.com:3389 location=boston
austin2.server.com:4389 location=austin
boston2.server.com:5389 location=boston
london2.server.com:6389 location=london
```

With the `location` property set for each server, PingDataSync gets its changes from server austin1. If austin1 goes down, PingDataSync will pick up changes from austin2. If austin2 goes down, the server will iterate through the rest of the list in the order it is configured.

The `location` property has another sub-property, `preferred-failover-location` that specifies a set of alternate locations if no servers in this location are available. If multiple values are provided, servers are tried in the order in which the locations are listed. The `preferred-failover-location` property provides more control over the failover process and allows the failover process to jump to a specified location. Care must be used so that circular failover reference does not take place. Here is an example configuration:

```
austin1.server.com:1389 location=austin preferred-failover-location=boston
london1.server.com:2389 location=london preferred-failover-location=austin
boston1.server.com:3389 location=boston preferred-failover-location=london
austin2.server.com:4389 location=austin preferred-failover-location=boston
boston2.server.com:5389 location=boston preferred-failover-location=austin
london2.server.com:6389 location=london preferred-failover-location=london
```

PingDataSync will respect the `preferred-failover-location` if it cannot find any external servers in the same location as itself, it will look for any external servers in its own `preferred-failover-location`. In this example, when austin1 becomes unavailable, it will fail over to austin2 because they are in the same location. If austin2 is unavailable, it will fail over to boston1, which is in the `preferred-failover-location` of PingDataSync. If boston1 is unavailable, PingDataSync will fail over to boston2, and finally, it will try the london1 and london2 servers.

Copyright © 2025 Ping Identity Corporation

Configuration properties that control failover behavior

There are four important advanced properties to fine tune the failover mechanism:

- `max-operation-attempts` (Sync Pipe)
- `response-timeout` (source and destination endpoints)
- `max-failover-error-code-frequency` (source and destination endpoints)
- `max-backtrack-replication-latency` (source endpoints only)

These properties apply to the following LDAP error codes:

LDAP Error Codes

Error Code	Description
ADMIN_LIMIT_EXCEEDED(11)	Indicates that processing on the requested operation could not continue, because an administrative limit was exceeded.
ALIAS_DEREFERENCING_PROBLEM (36)	Indicates that a problem was encountered while attempting to dereference an alias for a search operation.
CANCELED(118)	Indicates that a cancel request was successful, or that the specified operation was canceled.
CLIENT_SIDE_LOCAL_ERROR(82)	Indicates that a local (client-side) error occurred.
CLIENT_SIDE_ENCODING_ERROR(83)	Indicates that an error occurred while encoding a request.
CLIENT_SIDE_DECODING_ERROR(84)	Indicates that an error occurred while decoding a request.
CLIENT_SIDE_TIMEOUT(85)	Indicates that a client-side timeout occurred.
CLIENT_SIDE_USER_CANCELLED(88)	Indicates that a user canceled a client-side operation.
CLIENT_SIDE_NO_MEMORY(90)	Indicates that the client could not obtain enough memory to perform the requested operation.
CLIENT_SIDE_CLIENT_LOOP(96)	Indicates that a referral loop is detected.
CLIENT_SIDE_REFERRAL_LIMIT_EXCEEDED (97)	Indicates that the referral hop limit was exceeded.
DECODING_ERROR(84)	Indicates that an error occurred while decoding a response.
ENCODING_ERROR(83)	Indicates that an error occurred while encoding a response.
INTERACTIVE_TRANSACTION_ ABORTED (30221001)	Indicates that an interactive transaction was aborted.

Copyright © 2025 Ping Identity Corporation

Error Code	Description
LOCAL_ERROR(82)	Indicates that a local error occurred.
LOOP_DETECT(54)	Indicates that a referral or chaining loop was detected while processing a request.
NO_MEMORY(90)	Indicates that not enough memory could be obtained to perform the requested operation.
OPERATIONS_ERROR(1)	Indicates that an internal error prevented the operation from being processed properly.
OTHER (80)	Indicates that an error occurred that does not fall into any of the other categories.
PROTOCOL_ERROR(2)	Indicates that the client sent a malformed or illegal request to the server.
TIME_LIMIT_EXCEEDED(3)	Indicates that a time limit was exceeded while attempting to process the request.
TIMEOUT(85)	Indicates that a timeout occurred.
UNWILLING_TO_PERFORM(53)	Indicates that the server is unwilling to perform the requested operation.

The max-operation-attempts property

The `max-operation-attempts` property (part of the Sync Pipe configuration) specifies the maximum number of times to retry a synchronization operation that fails for reasons other than the Sync Destination being busy, unavailable, server connection closed, or connect error.

To change the default number of retries, use `dsconfig` in non-interactive mode to change the `max-operation-attempts` value on the Sync Pipe object. The following command changes the number of maximum attempts from five (default) to four.

```
$ bin/dsconfig set-sync-pipe-prop \
  --pipe-name "Test Sync Pipe" \
  --set max-operation-attempts:4
```

Copyright © 2025 Ping Identity Corporation

The response-timeout property

The `response-timeout` property specifies how long PingDataSync should wait for a response from a search request to a source server before failing with LDAP result code 85 (client-side timeout). When a client-side timeout occurs, the Sync Source will retry the request according to the `max-failover-error-code-frequency` property before failing over to a different source server and performing the retry. The total number of retries will not exceed the `max-operation-attempts` property defined in the Sync Pipe configuration. A value of zero indicates that there should be no client-side timeout. The default value is one minute.

Assuming a bidirectional topology, the property can be set with `dsconfig` on the Sync Source and Sync Destination, respectively.

```
$ bin/dsconfig set-sync-source-prop \
  --source-name src \
  --set "response-timeout:8 s"
```

```
$ bin/dsconfig set-sync-destination-prop \
  --destination-name U4389 \
  --set "responsetimeout:9 s"
```

The max-failover-error-code-frequency property

The `max-failover-error-code-frequency` property (part of the Sync Source configuration) specifies the maximum time period that an error code can re-appear until it fails over to another server instance. This property allows the retry logic to be tuned, so that retries can be performed once on the same server before giving up and trying another server. The value can be set to zero if there is no acceptable error code frequency and failover should happen immediately. It can also be set to a very small value (such as 10 ms) if a high frequency of error codes is tolerable. The default value is three minutes.

To change the `max-failover-error-code-frequency` property, use `dsconfig` in non- interactive mode to change the property on the Sync Source object. The following command changes the frequency from three minutes to two minutes.

```
$ bin/dsconfig set-sync-source-prop \
  --source-name source1 \
  --set "max-failover-error-code-frequency:2 m"
```

The max-backtrack-replication-latency property

The `max-backtrack-replication-latency` property (part of the Sync Source configuration) sets the time period that PingDataSync will look for missed changes in the change log due to replication delays. The property should be set to a conservative upper-bound of the maximum replication delay between two servers in the topology. A value of zero implies that there is no limit on the replication latency. The default value is two hours. PingDataSync stops looking in the change log once it finds a change that is older than the maximum replication latency than the last change it processed on the failed server.

For example, after failing over to another server, PingDataSync must look through the new server's change log to find the equivalent place to begin synchronizing changes.

Copyright © 2025 Ping Identity Corporation

Normally, PingDataSync can successfully backtrack with only a few queries of the directory, but in some situations, it might have to look further back through the change log to make sure that no changes were missed. Because the changes can come from a variety of sources (replication, synchronization, and over LDAP), the replicated changes between directory servers are interleaved in each change log. When PingDataSync fails over between servers, it has to backtrack to figure out where synchronization can safely pick up the latest changes.

Backtracking occurs until the following:

- The server determines that there is no previous change log state available for any source servers, so it must start at the beginning of the change log.
- The server finds the last processed replication change sequence number (CSN) from the last time it was connected to that replica, if at all. This process is similar to the `set- startpoint` functionality on the `realtime-sync` tool.
- The server finds the last processed replication CSN from every replica that has produced a change so far, and it determines that each change entry in the next oldest batch of changes has already been processed.
- The server finds a change that is separated by more than a certain duration (specified by the `max-backtrack-replication-latency` property) from the most recently processed change.

The following command changes the maximum backtracking from two hours to three hours.

```
$ bin/dsconfig set-sync-source-prop \
  --source-name source1 \
  --set "max-backtrack-replication-latency:3 h"
```

Configure traffic through a load balancer

If a PingDirectory server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, it will log incoming requests as originating with the intermediate HTTP server instead of the client that actually sent the request. If the actual client's IP address should be recorded to the trace log, enable `X-Forwarded-*` handling in both the intermediate HTTP server and the PingDirectory server. See the product documentation for the device type. For PingDirectory servers:

- Edit the appropriate Connection Handler object (HTTPS or HTTP) and set `use-forwarded-headers` to `true`.
- When `use-forwarded-headers` is set to `true`, the server will use the client IP address and port information in the `X-Forwarded-*` headers instead of the address and port of the entity that's actually sending the request, the load balancer. This client address information will show up in logs where one would normally expect it to show up, such as in the `from` field of the HTTP REQUEST and HTTP RESPONSE messages.

Configure authentication with a SASL external certificate

About this task

By default, PingDataSync authenticates to the PingDirectory server using LDAP simple authentication (with a bind DN and a password). However, PingDataSync can be configured to use SASL EXTERNAL to authenticate to the PingDirectory server with a client certificate.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> This procedure assumes that PingDataSync instances are installed and configured to communicate with the backend PingDirectory server instances using either SSL or StartTLS.

After the servers are configured, perform the following steps to configure SASL EXTERNAL authentication:

Steps

1. **Create a JKS keystore that includes a public and private key pair for a certificate that the PingDataSync instance(s) will use to authenticate to the PingDirectory server instance(s). Run the following command in the instance root of one of the PingDataSync instances. When prompted for a keystore password, enter a strong password to protect the certificate. When prompted for the key password, press ENTER to use the keystore password to protect the private key:**

```
$ keytool -genkeypair \
  -keystore config/sync-user-keystore \
  -storetype JKS \
  -keyalg RSA \
  -keysize 2048 \
  -alias sync-user-cert \
  -dname "cn=Sync User,cn=Root DNs,cn=config" \
  -validity 7300
```

2. **Create a `config/sync-user-keystore.pin` file that contains a single line that is the keystore password provided in the previous step.**

3. **If there are other PingDataSync instances in the topology, copy the `sync-user-keystore` and `sync-user-keystore.pin` files into the config directory for all instances.**

4. **Use the following command to export the public component of the user certificate to a text file:**

```
$ keytool -export \
  -keystore config/sync-user-keystore \
  -alias sync-user-cert \
  -file config/sync-user-cert.txt
```

5. **Copy the `sync-user-cert.txt` file into the `config` directory of all PingDirectory server instances. Import that certificate into each server's primary trust store by running the following command from the server root. When prompted for the keystore password, enter the password contained in the `config/truststore.pin` file. When prompted to trust the certificate, enter `yes`.**

```
$ keytool -import \
  -keystore config/truststore \
  -alias sync-user-cert \
  -file config/sync-user-cert.txt
```

6. **Update the configuration for each PingDataSync instance to create a new key manager provider that will obtain its certificate from the `config/sync-user-keystore` file. Run the following `dsconfig` command from the server root:**

Copyright © 2025 Ping Identity Corporation

```
$ dsconfig create-key-manager-provider \
  --provider-name "Sync User Certificate" \
  --type file-based \
  --set enabled:true \
  --set key-store-file:config/sync-user-keystore \
  --set key-store-type:JKS \
  --set key-store-pin-file:config/sync-user-keystore.pin
```

7. Update the configuration for each LDAP external server in each PingDataSync server instance to use the newly-created key manager provider, and also to use SASL EXTERNAL authentication instead of LDAP simple authentication. Run the following `dsconfig` command:

```
$ dsconfig set-external-server-prop \
  --server-name ds1.example.com:636 \
  --set authentication-method:external \
  --set "key-manager-provider:Sync User Certificate"
```

Next steps

After these changes, PingDataSync should re-establish connections to the LDAP external server and authenticate with SASL EXTERNAL. Verify that PingDataSync is still able to communicate with all backend servers by running the `bin/status` command. All of the servers listed in the "--- LDAP External Servers ---" section should have a status of `Available`. Review the PingDirectory server access log can to make sure that the BIND RESULT log messages used to authenticate the connections from PingDataSync include `authType="SASL", saslMechanism="EXTERNAL", resultCode=0`, and `authDN="cn=Sync User,cn=RootDNs,cn=config"`.

Configure an LDAPv3 Sync Source

Synchronization can be performed with an LDAP V3-compliant source, such as IBM SDS (Tivoli Directory Server), Oracle Unified Directory, DSEE, or OpenDJ, by configuring a Generic LDAP Sync Source. PingDataSync relies on the source server having a `cn=changelog` implementation. If the server does not have a `cn=changelog` implementation, a Server SDK Change Detector extension can be configured to define the change detection criteria that PingDataSync should use.

If multiple Generic LDAP Sync Source instances are defined, the order in which they are added is used as a priority order for failover. If server locations are defined, PingDataSync will always fail over to servers that are in the same location. If there are multiple Sync Sources in the same location as PingDataSync, then PingDataSync will fail over to the first local server in the list and proceed down the list.

During synchronization, when a change is detected by PingDataSync, the changed entry is fetched from the source. Initially, the DN of the entry is used to search for the entry. If that search fails then a second search is performed using the `unique-id-attribute` if it is defined. This is typically an operational attribute that is automatically generated by the server, such as `entryUUID`.

Copyright © 2025 Ping Identity Corporation

Server SDK extensions

Custom server extensions can be created with the Server SDK. Extension bundles are installed from a .zip archive or a file system directory. Use the `manage-extension` tool to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

> **Note**
>
> The `manage-extension` tool must be used with Java extensions packaged using the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation.

The Server SDK enables creating extensions for all PingData servers. Cross-product extensions include:

- Access loggers
- Alert handlers
- Error loggers
- Key Manager providers
- Monitor providers
- Trust Manager providers
- OAuth token handlers
- Manage extension plugins

Synchronize with PingOne

PingDataSync supports PingOne as a synchronization destination and source for newly created or modified accounts with native password changes between directory servers, relational databases, or other PingOne systems.

The following topics include configuration procedures for synchronization between PingOne and the PingDirectory server or other LDAP source servers or targets.

- Prerequisites
- Synchronize changes to a PingOne environment
- Synchronize changes from a PingOne environment
- PingOne synchronization limitations

Prerequisites

Before attempting to synchronize changes to or from a PingOne environment, make certain the prerequisites in this section are satisfied.

- Create a Worker application in PingOne.

Copyright © 2025 Ping Identity Corporation

- Review the PingOne user resource model.

Worker application

A Worker application is an administrator application that can have the same roles as human administrators.

You can use Worker applications to create a userless service app that can perform administrator functions. Role assignments determine the functions that the app can perform.

Required grant type

By default, Worker applications are configured with the required Client Credentials grant type. They can also be configured to support additional grant/response types, similar to the other app types.

The Worker application can also perform administrator functions with the role of its user. To accomplish this task, give the app one or more additional grant types, which are used instead of the role assignments.

Required roles

A role is a collection of permissions that can be assigned to a user. Of the many roles that PingOne includes by default, only the Identity Data Admin role, which manages identities and identity data, is required for the Worker app that you need to create. Permissions center around managing user identities and include functions like creating users, resetting a user's password, and creating, editing, and deleting populations.

Creating a worker application

Creating a worker application creates a sync destination or source for synchronizing changes to and from PingOne.

Before you begin

Before you create a Worker application, have the following information ready:

- The app name and description
- Redirect URLs for authentication (required for interactive applications only)

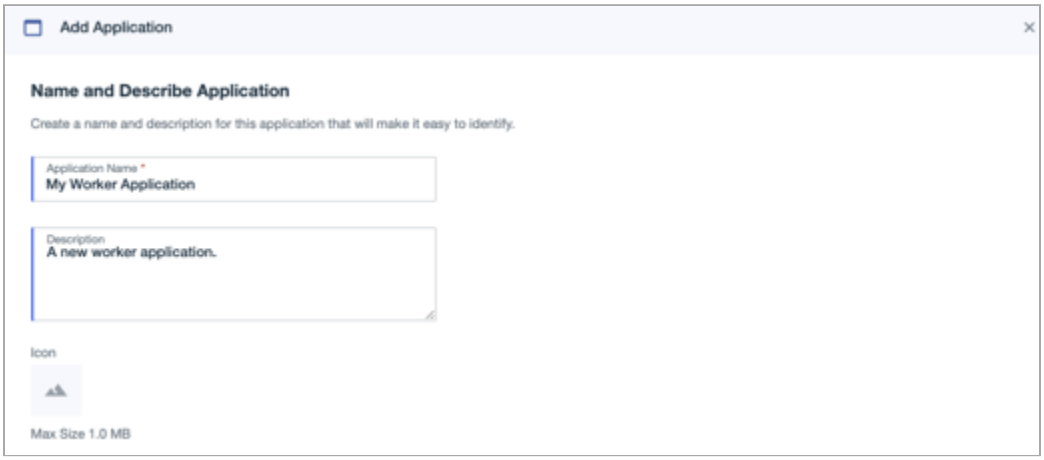
About this task

To create and configure a Worker app in PingOne:

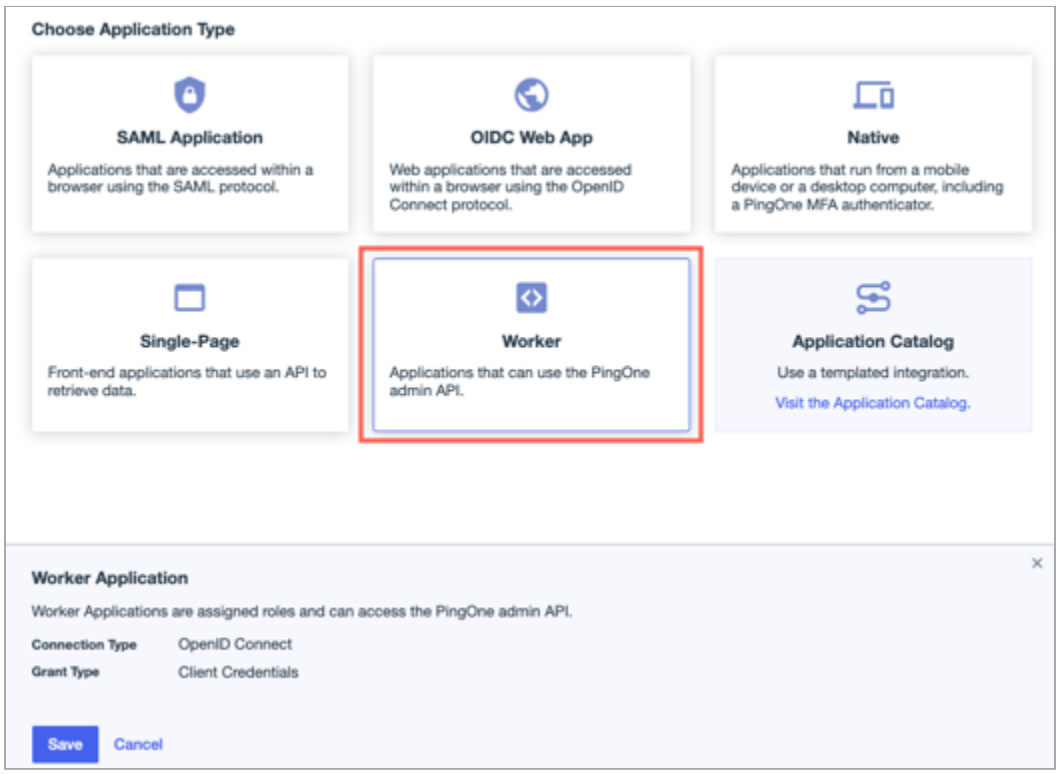
Steps

1. In the PingOne admin portal, go to Connections → Applications.
2. Click the + icon.
3. Create the application profile by entering the following:
    - Application name: A unique identifier for the application.
    - Description (optional): A brief characterization of the application.
    - Icon (optional): A graphic representation of the application. Use a file up to 1MB in JPG, JPEG, GIF, or PNG format.

Copyright © 2025 Ping Identity Corporation



4. In the Choose Application Type section, click Worker.



5. Click Save.

   Result:

   The app is displayed on the Applications page.

6. Make note of the OAuth Client ID, which appears directly below the name of the app.

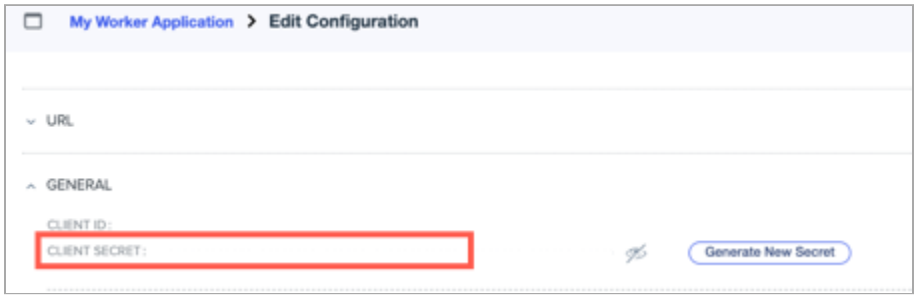
   This value is required when creating a PingOne sync destination or source.

7. Click the Configuration tab, and then click the Pencil icon to edit the configuration:

   1. In the General section, make note of the Client Secret.

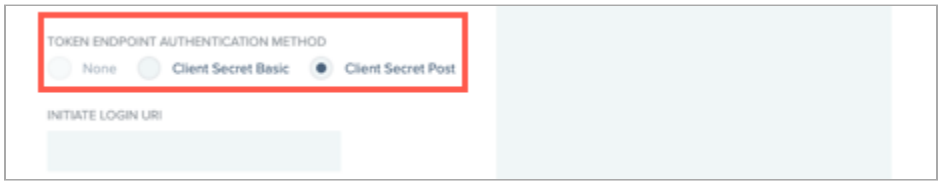
      This value is required when creating a PingOne sync destination or source.

Copyright © 2025 Ping Identity Corporation



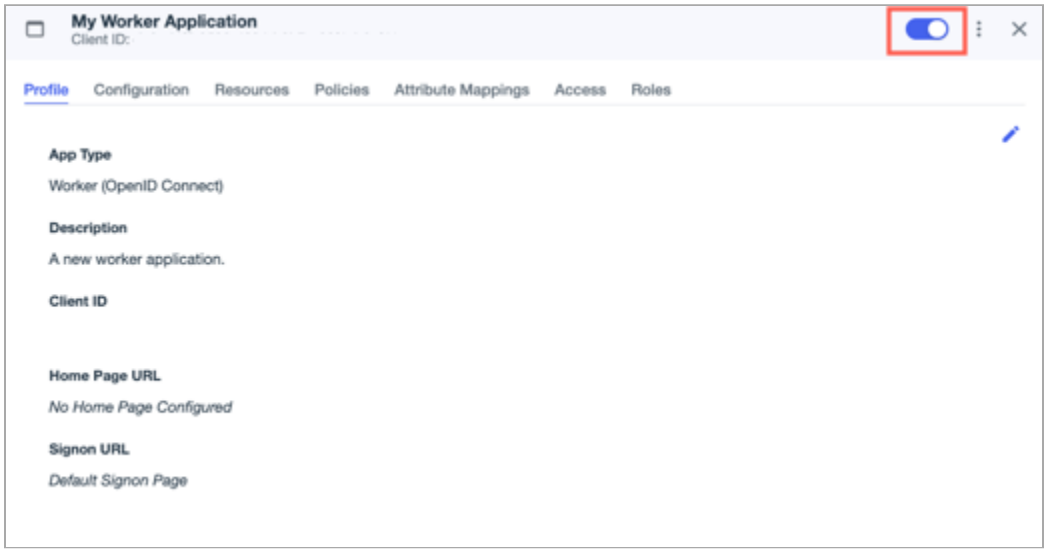
2. For Grant Type, select the Client Credentials check box.

3. For a token endpoint authentication method, click Client Secret Post.



4. Click Save.

8. Click the toggle to enable the application.



9. In the left navigation pane, click Environment → Properties.

10. Make note of the Environment ID.

    This value is required when creating a PingOne sync destination or source.

Copyright © 2025 Ping Identity Corporation

Next steps

Use your Worker application as a sync source or destination for PingOne:

- Synchronize changes to a PingOne environment.
- Synchronize changes from a PingOne environment.

PingOne user resource model

A user resource is a unique identity within PingOne that interacts with the applications and services in the environment to which the user is assigned.

Users are associated with an environment and a population, and the service implements directory functions to create, read, update, delete, and search for user resources. For more information, refer to the .pingidentity.com/pingone/platform/v1/api///[Users data model] or to the PingOne API Guide.

The username field is required with the PingOne user resource model. This field is a string that specifies the user name, which must be unique within an environment. Limited to 128 characters in length, the username must be a well-formed email address or a string of any Unicode letter, mark (like an accent or umlaut), dot, underscore, or hyphen.

Synchronize changes to a PingOne environment

This section describes the configuration that is necessary to synchronize changes to a PingOne environment. PingDataSync supports synchronization of single and multivalued attributes to PingOne. To view an example configuration, see the file located at `<server-root>/resource/reference-ping-one-sync-destination-configuration.dsconfig`.

> **Note**
>
> When configuring a sync pipe in PingDataSync to synchronize users to a PingOne destination, you must include a constructed attribute mapping named `resourceType` with a value-pattern of `user`. To see this attribute mapping in a configuration example, see the file located at `<server-root>/resource/reference-ping-one-sync-destination-configuration.dsconfig`.

Create a PingOne sync destination

Before you create a PingOne sync destination, make certain you have the following information ready:

- Environment ID (*environment-id*)
- OAuth client ID (*oauth-client-id*)
- OAuth client secret (*oauth-client-secret*)

For information about obtaining these values, see "Create a worker application" in Worker application.

The following sample creates a PingOne sync destination.

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-sync-destination  \
  --destination-name PingOne  \
  --type ping-one-customer  \
  --set api-url:https://api.pingone.com/v1 \
  --set auth-url:https://auth.pingone.com/[PING_ONE_ENV_ID]/as/token \
  --set environment-id:[PING_ONE_ENV_ID]  \
  --set oauth-client-id:[PING_ONE_OAUTH_CLIENT_ID]  \
  --set oauth-client-secret:[PING_ONE_OAUTH_CLIENT_SECRET]
```

Configuring JSON attribute mapping

Add the JSON attribute mapping type with sub-objects (the JSON attribute mapping field) that allow you to map individual fields.

About this task

If a source attribute doesn't have a value, the corresponding field is omitted.

> **Note**
>
> Use JSON attribute mappings rather than constructed attribute mappings.

Steps

1. To create an attribute map, run `dsconfig` with the `create-attribute-map` option.

   Example:

   The following example creates an attribute map titled `PingDirectory_to_PingOne_User_Map`.

   ```
   dsconfig create-attribute-map \
       --map-name PingDirectory_to_PingOne_User_Map
   ```

2. To create the attribute mapping, run `dsconfig` with the `create-attribute-mapping` option.

   Example:

   The following example creates the attribute mapping to `PingDirectory_to_PingOne_User_Map`.

   ```
   dsconfig create-attribute-mapping \
       --map-name PingDirectory_to_PingOne_User_Map \
       --mapping-name name \
       --type json
   ```

3. To map JSON attributes, run `dsconfig` with the `create-json-attribute-mapping-field` option.

   Example:

   The following example creates the JSON attribute mapping field `formatted` from the `cn` attribute.

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-json-attribute-mapping-field \
    --map-name PingDirectory_to_PingOne_User_Map \
    --mapping-name name \
    --field-name formatted \
    --set from-attribute:cn \
    --set json-type:string
```

The following example creates the JSON attribute mapping field `given` from the `givenName` attribute.

```
dsconfig create-json-attribute-mapping-field \
    --map-name PingDirectory_to_PingOne_User_Map \
    --mapping-name name \
    --field-name given \
    --set from-attribute:givenName \
    --set json-type:string
```

The following example creates the JSON attribute mapping field `family` from the `sn` attribute.

```
dsconfig create-json-attribute-mapping-field \
    --map-name PingDirectory_to_PingOne_User_Map \
    --mapping-name name \
    --field-name family \
    --set from-attribute:sn \
    --set json-type:string
```

Configuring constructed attribute mappings

> **Note**
>
> It is recommended that you use JSON attribute mappings rather than constructed attribute mappings (see Configuring JSON attribute mapping).

The PingOne User model contains simple JSON attributes like `"title": "Director"` as well as complex JSON objects like `{"name": {"given": "Jane", "family": "Doe"}}`. To ensure accurate processing when you construct attribute mappings that interact with complex objects, construct valid JSON strings and use the command `jsonEscape`, as the following example shows.

```
dsconfig create-attribute-mapping \
   --map-name PingDirectory_to_PingOne_User_Map  \
   --mapping-name name  \
   --type constructed  \
   --set 'value-pattern:{{"given":"{givenname:jsonEscape}","family":"
{sn:jsonEscape}"}}'
```

Some attributes in the User resource are operational and cannot be modified by synchronizing data. For more information, refer to the PingOne API Guide.

Copyright © 2025 Ping Identity Corporation

Correlating entries

The PingOne User Resource model provides an attribute named `externalId`. To ensure that users correlate to the appropriate entry in PingDirectory, map `entryUUID` to this value and configure `externalId` as a destination-correlation-attribute on the Sync class.

Considerations and limitations

There are limitations and other constraints to consider when synchronizing changes to a PingOne environment.

Populations

> **Note**
>
> All PingOne user resources must exist within a population.

The PingOne synchronization destination provides the following methods for managing a user's population:

- If a single population is in use, set the configuration attribute `default-population-id` on the sync destination.
- If multiple populations are in use, use a constructed attribute mapping.

The following syntax provides an example with a constructed attribute mapping:

```
dsconfig create-attribute-mapping \
   --map-name PingDirectory_to_PingOne_User_Map  \
   --mapping-name population  \
   --type constructed  \
   --set 'value-pattern:{{"id":"[DEFAULT_POPULATION_ID]"}}'
```

To set the population, construct a valid JSON object.

Multivalued attributes

If your incoming data is in JSON format, configure your PingOne multivalued attribute as JSON and use a JSON attribute mapping.

If your incoming data is not in JSON format, you can configure your PingOne multivalued attribute as JSON and use a constructed attribute mapping. Otherwise, you must configure your PingOne multivalued attribute as `DECLARED` and use a direct attribute mapping.

> **Important**
>
> Direct attribute mapping does not work with JSON multivalued PingOne attributes even with an attribute with the same name and value in PingDirectory.

Copyright © 2025 Ping Identity Corporation

Synchronize changes from a PingOne environment

This section describes the configuration that is necessary to synchronize changes from a PingOne environment. To view an example configuration, refer to the file `reference-ping-one-sync-source-configuration.dsconfig`, which is located in the folder named `resources`.

Create a PingOne sync source

Before you create a PingOne sync source, make certain you have the following information ready:

- Environment ID (*environment-id*)
- OAuth client ID (*oauth-client-id*)
- OAuth client secret (*oauth-client-secret*)

For information about obtaining these values, see "Create a worker application" in Worker application.

The following sample creates a PingOne sync source.

```
dsconfig create-sync-source \
  --source-name PingOne \
  --type ping-one-customer \
  --set api-url:https://api.pingone.com/v1 \
  --set auth-url:https://auth.pingone.com/[PING_ONE_ENV_ID]/as/token \
  --set environment-id:[PING_ONE_ENV_ID] \
  --set oauth-client-id:[PING_ONE_OAUTH_CLIENT_ID] \
  --set oauth-client-secret:[PING_ONE_OAUTH_CLIENT_SECRET]
```

Configure attribute mapping

The process of synchronizing data uses the concepts and structures associated with LDAP entries. Ping Identity recommends that you conceptualize the PingOne User Resource model as an LDAP entry when configuring an attribute mapping. Additionally, you might need to use JSON pathing when selecting a value for complex JSON attributes within the user.

```
dsconfig create-attribute-mapping \
  --map-name PingOne_to_PingDirectory_User_Map \
  --mapping-name givenname \
  --type constructed \
  --set "value-pattern:{name.given}"
```

Correlating entries

To ensure that users correlate to the appropriate entry in PingDirectory, map the `id` attribute from the user resource to `entryUUID` in PingDirectory.

Copyright © 2025 Ping Identity Corporation

Considerations and limitations

This section describes limitations and other constraints to consider when synchronizing changes from a PingOne environment.

Bidirectional synchronization

If you plan on configuring bidirectional synchronization between PingOne and PingDirectory, make certain that you satisfy the following conditions:

- Use separate worker apps for the source and destination.
- To prevent the unnecessary duplication of changes, add the client ID of the destination worker app to the `actor-id-to-ignore` configuration attribute of the source.
- To ensure that no attribute mappings are mismatched, modify the reference `dsconfig` batch files.

Password synchronization

PingDataSync does not support the synchronizing of passwords from PingOne.

Population management

If your PingOne environment features a large number of populations, or if you want to limit synchronized users to a specific set of populations, provide one or more `population-to-synchronize` configuration attributes to the source. The name or ID of the population can be used.

Synchronization delay

PingDataSync propagates changes throughout PingOne nearly in real time. However, a delay might occur between the time a change occurs in PingOne and the time it becomes available for PingDataSync to synchronize. To help ensure that no changes are missed, a default delay of 5 seconds has been configured within the sync source. For environments of sufficient size or with high rates of change, use the configuration attribute `realtime-sync-polling-offset` on the sync source to increase the delay.

PingOne synchronization limitations

PingOne can return errors when synchronizing with PingDataSync due to a rate limiting mechanism in PingOne. A workaround for this issue has been implemented in PingDataSync.

The PingOne API contains a resource limit mechanism to prevent clients from overwhelming the service and returns HTTP 429 error codes when this limit is reached.

> **Note**
>
> This limit is set to 100 operations per second.

Because PingDataSync sends changes to a destination as quickly as possible, the server might hit this limit, especially if a large number of threads are in use.

Copyright © 2025 Ping Identity Corporation

If the Synchronization server receives HTTP 429 errors from PingOne, it waits briefly and retries any failed operations again. An operation is retried up to 15 times to attempt to synchronize a change. This retry mechanism allows the Sync server to process a change without the operation dropping as a failure after initial HTTP 429 errors.

Synchronize with Active Directory and other directory servers

PingDataSync supports full synchronization for newly created or modified accounts with native password changes between directory server, relational databases, and Microsoft Active Directory (AD) systems.

Considerations

There are three key considerations when synchronizing between AD and PingDirectory:

The `realtime-sync` tool

The `realtime-sync` tool uses the AD DirSync control to detect changes on entries, which requires the control to be searched at the top of the directory information tree (DIT). Because of this, you must point your AD Sync Source to the top of the AD tree for `realtime-sync` to work.

Distinguished name (DN) mapping

The AD Sync Source must be pointed at the top of the DIT, but not every branch under the top of the tree can be easily synchronized.

For example, `cn=Users` is a container organizational unit (OU) that doesn't easily convert into a standard OU. Likewise, `cn=Builtin` is a top-level domain that also contains built-in groups without a purpose in PingDirectory and that don't need to be synchronized.

To avoid synchronizing entries that are native and apply only to AD, point your Sync Classes at specific OUs.

Schema and attribute mapping

The schema between AD and PingDirectory is not a 1:1 relationship, which means that not all attributes can be directly synchronized.

The following attributes are among those that can be directly synchronized:

- `cn`
- `sn`
- `mail`

Other attributes, such as the AD attribute `{{samAccountName}}` aren't defined in PingDirectory by default, and if you don't define schema for the attribute, you can map it to a similar attribute such as the PingDirectory `uid` attribute. You should create attribute mappings for each attribute that you want to synchronize between AD and PingDirectory.

Copyright © 2025 Ping Identity Corporation

Configuration information

For configuration information and procedures for synchronization between PingDirectory server or other Lightweight Directory Access Protocol (LDAP) source servers or targets with Microsoft AD systems, see the following:

- Overview of configuration tasks
- Configuring one way synchronization from Active Directory to PingDirectory
- Mapping AD password policy state attributes to PingDirectory using dsconfig
- Active Directory sync user account
- Preparing external servers
- Configuring sync pipes and sync classes
- Configuring password encryption
- Password sync agent

Overview of configuration tasks

To configure synchronization with Active Directory (AD) systems, the following tasks are performed:

Enable SSL connections

If synchronizing passwords between systems, synchronization with Microsoft Active Directory systems requires that SSL be enabled on the Active Directory domain controller, so that PingDataSync can securely propagate the `cn=Sync User` account password and other user passwords to the target.

Run the create-sync-pipe-config tool

On the PingDataSync server, use the `create-sync-pipe-config` tool to configure the Sync Pipes to communicate with the Active Directory source or target.

Configure outbound password synchronization on an PingDirectory Server Sync Source

After running the `create-sync-pipe-config` tool, determine if outbound password synchronization from an PingDirectory server Sync Source is required. If so, enable the Password Encryption component on all PingDirectory server sources that receive password modifications. The PingDirectory server uses the Password Encryption component, analogous to the Password Sync Agent component, to intercept password modifications and add an encrypted attribute, `ds-changelog-encrypted-password`, to the changelog entry. The component enables passwords to be synchronized securely to the Active Directory system, which uses a different password storage scheme. The encrypted attribute appears in the change log and is synchronized to the other servers, but does not appear in the entries.

Configure outbound password synchronization on an Active Directory Sync Source

After running the `create-sync-pipe-config` tool, determine if outbound password synchronization from an Active Directory Sync Source is required. If so, install the Password Sync Agent (PSA) after configuring PingDataSync.

Copyright © 2025 Ping Identity Corporation

Run the realtime-sync set-startpoint tool

The `realtime-sync set-startpoint` command can take several minutes to run, because it must issue repeated searches of the Active Directory domain controller until it has paged through all the changes and receives a cookie that is up-to-date. NOTE: The Password Sync Agent cannot be pointed at multiple domain clusters.

> **Note**
>
> If the Password Sync Agent is down for any length of time and misses a password change, these changes will not be synced on recovery without either a new password change for the entry or the use of pass-through authentication.

Configuring one way synchronization from Active Directory to PingDirectory

Configure a one-way Sync Pipe with the Active Directory (AD) topology as the sync source and a PingDirectory server topology as the Sync Destination.

About this task

Syncing from AD-LDS to PingDirectory is supported for all features except password syncing.

> **Important**
>
> If you are syncing the `lockoutTime`, `userAccountControl & (ACCOUNTDISABLE == 2)`, or `pwdLastSet` AD attributes, or the AD-LDS `ms-DS-User-Account-Disabled` attribute, see Synchronizing Active Directory with PingDirectory.

> **Note**
>
> The Password Sync Agent cannot be pointed at multiple domain clusters.

Steps

1. **From the `server-root` directory, start PingDataSync.**

```
$ <server-root>/bin/start-server
```

2. **To set up the initial synchronization topology, run the `sync` tool.**

```
$ bin/create-sync-pipe-config
```

3. **In the Create Initial Synchronization Configuration menu, press Enter to continue the configuration.**
4. **In the Synchronization Mode menu, press Enter to accept the default option `1` for `Standard mode`.**
5. **In the Synchronization Direction menu, press Enter to accept the default option `1` for `One way`.**
6. **In the Source Endpoint Type menu, enter option `7` for `Microsoft Active Directory`.**
7. **In the Source Endpoint Name menu, enter a name for the Microsoft AD source server, or press Enter to accept the default value of `Microsoft Active Directory Source`.**

Copyright © 2025 Ping Identity Corporation

8. In the <*Source Server*> Server Security menu, press Enter to accept the default option `1` for `SSL` security.
9. In the <*Source Server*> Servers menu, enter the host name and listener port for Lightweight Directory Access Protocol (LDAP) communication with the source server in the format of `<host name>:<port number>` and press Enter.

   The Data Sync server attempts a connection to the AD source server. After adding the first server, you can add additional servers for the source endpoints that will be prioritized below the first server.
10. When you have finished adding servers, press Enter to continue to the next configuration step.
11. In the Synchronization User Account for <*Source Server*> menu, enter a user account distinguished name (DN) for the source servers, or press Enter to accept the default value.

    The account is used exclusively by the Data Sync Server to communicate with the source external servers.
12. Enter a password for the synchronization user account and press Enter.

    > **Note**
    >
    > The User Account DN password must meet the minimum password requirements for AD domains.
13. In the Destination Endpoint Type menu, press Enter to select the default option `1` for `Ping Identity Directory Server`.
14. In the Destination Endpoint Name menu, enter a name for your destination endpoint, or press Enter to select the default value, `Ping Identity Directory Server Destination`.
15. In the Base DNs for <*Endpoint Server*> menu, enter a base DN where synchronized entries can be found in your endpoint server, or press Enter to accept the default value.

    After your initial entry, you can add additional base DNs by following the prompts.
16. When you have finished entering base DNs for synchronized entries, press Enter to continue the configuration.
17. In the <*Endpoint Server*> Server Security menu, enter the option for the type of security that the Sync Server will use in communication with the endpoint server and press Enter.
18. In the <*Endpoint Server*> Servers menu, enter the host name and port for LDAP communication in the format of `<host name>:<port number>` and press Enter.

    The PingDataSync server attempts a connection to the destination PingDirectory server endpoint. After adding the first server, you can add additional servers for the destination endpoints that will be prioritized below the first server.
19. When you have finished adding servers, press Enter to continue to the next configuration step.
20. In the Synchronization User Account for <*Endpoint Server*> menu, enter a DN for the synchronization user account that will be used in communication with external servers, or press Enter to accept the default value, `[cn=Sync User,cn=Root DNs,cn=config]`.
21. Enter a password for the synchronization user account and press Enter.
22. In the Prepare Server <*Source Server*> menu, press Enter to accept the default option `1` for `Yes` to prepare the source server for synchronization.
23. In the Prepare Server <*Endpoint Server*> menu, press Enter to accept the default option `1` for `Yes` to prepare the endpoint server for synchronization.

Copyright © 2025 Ping Identity Corporation

24. In the Sync Pipe Name menu, enter a name for the Sync Pipe from the source server (AD) to the endpoint server (PingDirectory server), or press Enter to select the default value, `Microsoft_Active_Directory_Source_to_Ping_Identity_Directory_Server_Destination`.
25. In the Pre-configured Sync Class Configuration for Active Directory Sync Source menu, follow the prompts to create the basic sync classes and attribute mappings needed to synchronize user accounts, user passwords, and groups to and from AD.
    1. To synchronize user **`Create`**, **`Modify`**, and **`Delete`** operations from AD, follow the prompts.
    2. Enter the object class for user entries at the endpoint, or press Enter to accept the default value, `inetOrgPerson`.
    3. To configure which password policy state attributes to synchronize, follow the prompts.

       For more information on the AD to PingDirectory password policy state attribute mappings, see Synchronizing Active Directory with PingDirectory.

       > **Note**
       >
       > For the referenced password policy state attributes, AD is treated as the authoritative source because synchronization from PingDirectory to AD is not supported for those attributes.

       > **Important**
       >
       > The password policy in PingDirectory must match the password in AD. For example, the `lockout-failure-count` in PingDirectory must match the account lockout threshold in AD.

    4. To create a DN map for users in the sync pipe, enter `yes` and press Enter. To not create a DN map, press Enter to accept the default option, `no`.
    5. Review the list of basic mappings set up for synchronized user entries and follow the prompts to add any additional attribute mappings. Press Enter to continue.
    6. To synchronize group **`Create`**, **`Modify`**, and **`Delete`** operations from AD, follow the prompts.
26. In the Sync Pipe Sync Class Definitions menu, press Enter to accept the `Microsoft Active Directory Source Users Sync Class`, or to create a new sync class name, enter a value and press Enter.
27. Review the Configuration Summary and press Enter to write the configuration file as displayed.

    Result:

    The server writes the configuration file to a **`dsconfig`** batch file.
28. To apply the configuration changes to the local Data Sync Server, press Enter. To not apply the changes, enter `no` and press Enter.

Synchronizing Active Directory with PingDirectory

When you use the `sync-pipe` tool to configure AD or AD-LDS as a one-way sync with PingDirectory, three AD password policy state attributes require user input to map to a corresponding PingDirectory attribute.

The following table shows these three attributes, the intermediate attribute that is formed between PingDirectory and AD (or AD-LDS), and the extended operation type used by the PingDirectory server to apply the change.

Copyright © 2025 Ping Identity Corporation

AD and AD-LDS attribute	Intermediate attribute	PingDirectory attribute	PasswordPolicyStateOperation opType
`lockoutTime`	`pwdAccountLockedTimeFromAD`	`pwdAccountLockedTime`	`OP_TYPE_SET_AUTH_FAILURE_TIMES`
`userAccountControl & (ACCOUNTDISABLE == 2)` **Note** In AD-LDS, the corresponding attribute is `ms-DS-User-Account-Disabled`.	`ds-pwp-account-disabled-from-ad`	`ds-pwp-account-disabled`	`OP_TYPE_SET_ACCOUNT_DISABLED_STATE`
`pwdLastSet`	`pwdChangedTimeFromAD`	`pwdChangedTime`	`OP_TYPE_SET_PW_CHANGED_TIME`

Note

Intermediate attributes only exist in memory on the PingDataSync server so that they can be consumed for attribute mappings. They don't exist on either the AD server or on the PingDirectory server.

modifies-as-creates

By default, the `modifies-as-creates` sync class property is set to `false`.

Active Directory attributes might not be synchronized as expected when the following is true:

- **You are using the `realtime-sync` tool.**
- **The `modifies-as-creates` sync class property is set to `true`.**
- **A modification is detected on the source endpoint to a missing entry on the destination endpoint.**
- **The modification is to attributes other than the three AD password policy state attributes previously mentioned.**

To avoid this known issue, you can run the `resync` tool instead of the `realtime-sync` tool. Using `resync` will correctly copy all attributes. For more information, see The `resync` tool.

Mapping AD password policy state attributes to PingDirectory using dsconfig

If you have a working sync configuration between PingDirectory and Active Directory (AD) (AD) and want to manage password policy state attributes, use `dsconfig` to map these attributes instead of re-running the `sync` tool.

About this task

Copyright © 2025 Ping Identity Corporation

To map AD password policy state attributes to PingDirectory attributes:

Steps

- Run `dsconfig` with the `create-attribute-mapping` option.

  Example:

  The following example maps the AD attribute `lockoutTime` to the PingDirectory attribute `pwdAccountLockedTime`.

  ```
  dsconfig create-attribute-mapping
          --map-name  "<Microsoft Active Directory Users Attribute Map>"
          --mapping-name pwdAccountLockedTime
          --type direct
          --set from-attribute:pwdAccountLockedTimeFromAD
  ```

  Example:

  The following example maps the AD attribute `userAccountControl & (ACCOUNTDISABLE == 2)` to the PingDirectory attribute `ds-pwp-account-disabled`.

  ```
  dsconfig create-attribute-mapping
          --map-name  "<Microsoft Active Directory Users Attribute Map>"
          --mapping-name ds-pwp-account-disabled
          --type direct
          --set from-attribute:ds-pwp-account-disabled-from-ad
  ```

  Example:

  The following example maps the AD attribute `pwdLastSet` to the PingDirectory attribute `pwdChangedTime`.

  ```
  dsconfig create-attribute-mapping
          --map-name  "<Microsoft Active Directory Users Attribute Map>"
          --mapping-name pwdChangedTime
          --type direct
          --set from-attribute:pwdChangedTimeFromAD
  ```

  > **Note**
  >
  > For more information about synchronizing these AD attributes with PingDirectory, see Synchronizing Active Directory with PingDirectory.

Active Directory sync user account

The Sync User created for Active Directory (AD) is added to the `cn=Administrators` branch and is given most of a root user's permissions. If this account cannot be secured and there is a need to configure the permissions required by the Sync User, the following are required to perform synchronization tasks.

As a Sync Source, these permissions are needed:

- List contents

Copyright © 2025 Ping Identity Corporation

- Read all properties
- Read permissions

Deleted items are a special case. For the PingDataSync server to see deleted entries, the user account must have sufficient access to `cn=Deleted Objects,<domain name>`. Giving access to that distinguished name (DN) requires using the `dsacls` tool, such as:

```
# Take ownership may be required to make the needed changes.
dsacls "CN=Deleted Objects,DC=example,DC=com" /takeOwnership
```

```
# Give the Sync User generic read permission to the domain.
dsacls "CN=Deleted Objects,DC=example,DC=com" /G "example\SyncUser":GR
```

```
# List the permission for the domain.
dsacls "CN=Deleted Objects,DC=example,DC=com"
```

To revoke all permissions from the Sync User, run the following `dsacls` command:

```
dsacls "CN=Deleted Objects,DC=example,DC=com" /R "example\SyncUser"
```

If Active Directory is used as a destination for synchronization, the Sync User account should not be changed.

Preparing external servers

About this task

Perform the following steps to prepare external servers: NOTE: The Password Sync Agent cannot be pointed at multiple domain clusters.

Steps

1. After configuring the source and destination endpoints, PingDataSync prompts to "prepare" each external server. The process requires trusting the certificate presented to the server, and then testing the connection. If this step is not performed, the process can be completed after configuring the Sync Pipes using the prepare-endpoint-server tool.
2. Configuring this server for synchronization requires manager access. Enter the distinguished name (DN) and password of an account capable of managing the external directory server.
3. Enter the maximum age of change log entries. The value is formatted as `[number][time- unit]`, where the time unit format resembles ("8h" for eight hours, "3d" for three days, "1w" for one week). Setting this value caps how long the PingDataSync can be offline. A smaller value limits how many changes are stored and is necessary to limit excessive changelog growth in high-modification environments.
4. To prepare another server in the topology, follow the prompts. The previously entered manager credentials can be reused to access additional servers. Repeat the process for each server configured in the system.

Copyright © 2025 Ping Identity Corporation

Configuring sync pipes and sync classes

About this task

Perform the following steps to configure Sync Pipes and Sync Classes:

Steps

1. On the Sync Pipe Name menu, type a unique name to identify the Sync Pipe, or accept the default.
2. On the Pre-Configured Sync Class Configuration for Active Directory Sync Source menu, enter `yes` to synchronize user CREATE operations, and enter the object class for the user entries at the destination server, or accept the default (user). To synchronize user MODIFY and DELETE operations from Active Directory (AD), enter `yes`.
3. To synchronize passwords from Active Directory, press Enter to accept the default (yes). If synchronizing passwords from Active Directory, install the Ping Identity Password Sync Agent component on each domain controller.
4. To create a distinguished name (DN) map for the user entries in the Sync Pipe, enter the base DN for the user entries at the Microsoft Active Directory Sync Source, then enter the base DN for the user entries at the PingDataSync Destination.
5. A list of basic attribute mappings from the Microsoft Active Directory Source to the PingDirectory Server destination is displayed. More complex attribute mappings involving constructed or DN attribute mappings must be configured with the `dsconfig` tool. The following is a sample mapping.

   ```
   Below is a list of the basic mappings that have been set up for user
   entries synchronized from Microsoft Active Directory ->  {pingdir}
   Server. You can add to or modify this list with any direct attribute
   mappings. To set up more complex mappings (such as constructed or DN
   attribute mappings), use the 'dsconfig' tool.
   1) cn -> cn
   2) sn -> sn
   3) givenName -> givenName
   4) description -> description
   5) sAMAccountName -> uid
   6) unicodePwd -> userPassword
   ```

6. Enter the option to add a new attribute mapping. Enter the source attribute, and then enter the destination attribute. The following example maps the `telephoneNumber` attribute (Active Directory) to the `otherTelephone` attribute (PingDirectory Server).

   ```
   Select an attribute mapping to remove, or choose 'n' to add a new one
   [Press ENTER to continue]: n
   Enter the name of the source attribute: telephoneNumber
   Enter the name of the destination attribute: otherTelephone
   ```

7. If synchronizing group CREATE, MODIFY, and DELETE operations from Active Directory, enter `yes`.
8. Review the basic user group mappings.
9. On the Sync Pipe Sync Class Definitions menu, enter another name for a new Sync Class if required. Repeat steps 2–7 to define this new Sync Class. If no additional Sync Class definitions are required, press Enter to continue.

Copyright © 2025 Ping Identity Corporation

10. Review the Sync Pipe Configuration Summary, and accept the default ("write configuration"), which records the commands in a batch file (`sync-pipe-cfg.txt`). The batch file can be used to set up other topologies. The following summary shows two Sync Pipes and its associated Sync Classes.

```
>>>> Configuration Summary
  Sync Pipe: AD to  {pingdir}  Server
    Source: Microsoft Active Directory
      Type: Microsoft Active Directory
      Access Account: cn=Sync
User,cn=Users,DC=adsync,DC=PingIdentity,DC=com
      Base DN: DC=adsync,DC=PingIdentity,DC=com
      Servers: 10.5.1.149:636
    Destination:  {pingdir}  Server
      Type:  {pingdir}  Server
      Access Account: cn=Sync User,cn=Root DNs,cn=config
      Base DN: dc=example,dc=com
      Servers: localhost:389
    Sync Classes:
      Microsoft Active Directory Users Sync Class
      Base DN: DC=adsync,DC=PingIdentity,DC=com
      Filters: (objectClass=user)
      DN Map: ,CN=Users,DC=adsync,DC=PingIdentity,DC=com ->{1},ou=users,
      dc=example,dc=com
      Synchronized Attributes: Custom set of mappings are defined
      Operations: Creates,Deletes,Modifies
  Sync Pipe:  {pingdir}  Server to AD
    Source:  {pingdir}  Server
      Type:  {pingdir}  Server
      Access Account: cn=Sync User,cn=Root DNs,cn=config
      Base DN: dc=example,dc=com
      Servers: localhost:389
    Destination: Microsoft Active Directory
      Type: Microsoft Active Directory
      Access Account: cn=Sync
User,cn=Users,DC=adsync,DC=PingIdentity,DC=com
      Base DN: DC=adsync,DC=PingIdentity,DC=com
      Servers: 10.5.1.149:636
    Sync Classes:
        {pingdir}  Server Users Sync Class
      Base DN: dc=example,dc=com
      Filters: (objectClass=inetOrgPerson)
      DN Map: ,ou=users,dc=example,dc=com ->{1},CN=Users,DC=adsync,
      DC=PingIdentity,DC=com
      Synchronized Attributes: Custom set of mappings are defined
      Operations: Creates,Deletes,Modifies
```

11. To apply the configuration to the local Ping Data Sync Server instance, type `yes` . The configuration is recorded at `<server-root>/logs/tools/createsync-pipe-config.log` .

Configuring password encryption

About this task

Copyright © 2025 Ping Identity Corporation

This procedure is required if synchronizing passwords from a PingDirectory server to Active Directory (AD), or if synchronizing clear text passwords. These steps are not required if synchronizing from Active Directory to a PingDirectory server, or if not synchronizing passwords. NOTE: The Password Sync Agent cannot be pointed at multiple domain clusters.

> **Note**
>
> If the Password Sync Agent is down for any length of time and misses a password change, these changes will not be synced on recovery without either a new password change for the entry or the use of pass-through authentication.

Steps

1. On the PingDirectory server that will receive the password modifications, enable the Change Log Password Encryption component. The component intercepts password modifications, encrypts the password and adds an encrypted attribute, `ds-changelog- encrypted-password`, to the change log entry. The encryption key can be copied from the output if displayed, or accessed from the `<serverroot>/bin/sync-pipe-cfg.txt` file.

   ```
   $ bin/dsconfig set-plugin-prop --plugin-name "Changelog Password
   Encryption" \
     --set enabled:true \
     --set changelog-password-encryption-key:<key>
   ```

2. On PingDataSync, set the decryption key used to decrypt the user password value in the change log entries. The key allows the user password to be synchronized to other servers that do not use the same password storage scheme.

   ```
   $ bin/dsconfig set-global-sync-configuration-prop \
     --set changelog-password-decryption-key:ej5u9e39pqo68
   ```

Next steps

Test the configuration or populate data in the destination servers using bulk resync mode. See *Using the resync tool on the Identity Sync Server*. Then, use `realtime-sync` to start synchronizing the data. See *Using the realtime-sync tool* for more information. If synchronizing passwords, install the Password Sync Agent (PSA) on all of the domain controllers in the topology.

Password sync agent

> **Note**
>
> The Password Sync Agent cannot be pointed at multiple domain clusters.

> **Note**
>
> If the Password Sync Agent is down for any length of time and misses a password change, these changes will not be synced on recovery without either a new password change for the entry or the use of pass-through authentication.

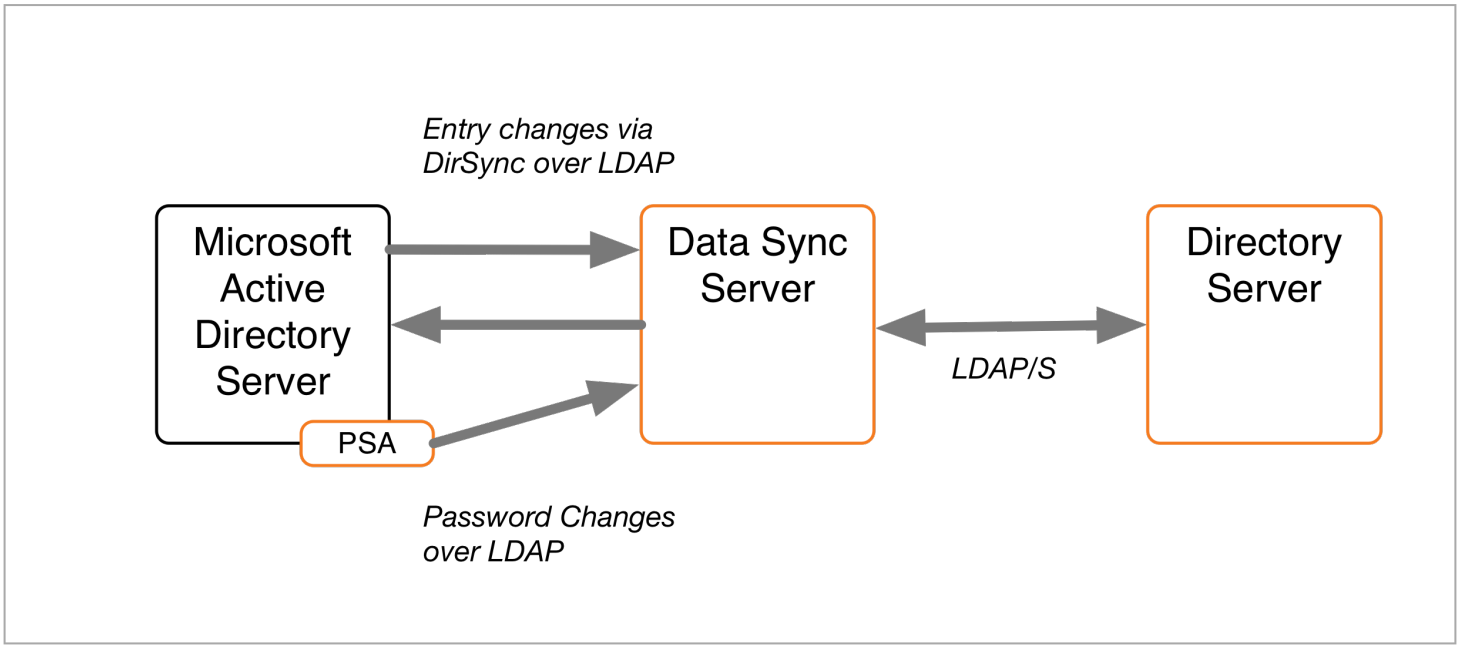
When synchronizing passwords with Active Directory (AD) systems, PingDataSync requires that the Ping Identity Password Sync Agent (PSA) be installed on all domain controllers in the synchronization topology. This component provides real-time outbound password synchronization from Microsoft Active Directory to any supported Sync Destinations.

Copyright © 2025 Ping Identity Corporation

The PSA component provides password synchronization between directories that support differing password storage schemes. The PSA immediately hashes the password with a 160-bit salted secure hash algorithm and erases the memory where the clear-text password was stored. The component only transmits data over a secure (SSL) connection, and follows Microsoft's security guidelines when handling clear-text passwords. The PSA also uses Microsoft Windows password filters, which are part of the local security authority (LSA) process. The password filters enable implementing password policy validation and change notification mechanisms. For more information, see Microsoft's product documentation.

The default password hashing algorithm is SSHA256. To change the algorithm, create a registry key in the Windows registry under `HKLM\SOFTWARE\UnboundID\PasswordSync` called `PASSWORD_HASHING_ALGORITHM`. The options are SSHA, SSHA1, SSHA256, SSHA384, and SSHA512.

> **Note**
>
> For outbound password synchronization from a PingDirectory server to AD, enable the Password Encryption component. See Configuring password encryption for more information.



The PSA supports failover between servers. It caches the hashed password changes in a local database until it can be guaranteed that all PingDataSyncs in the topology have received them. The failover features enable any or all of the PingDataSyncs to be taken offline without losing any password changes from Active Directory.

The PSA is safe to leave running on a domain controller indefinitely. To stop synchronizing passwords, remove the `userPassword` attribute mapping in PingDataSync, or stop the server. The PSA will not allow its local cache of password changes to grow out of control; it automatically cleans out records from its local database as soon as they have been acknowledged. It also purges changes that have been in the database for more than a week.

Before installing the PSA, consider the following:

- The PSA pre-encodes all passwords with a one-way salted SHA-256 hash before uploading them to PingDataSync. Password changes from Active Directory can only be synchronized to destinations which support setting pre-encoded passwords. Currently, pre-encoded password synchronization is limited to PingDirectory, DSEE, Oracle OUD, and OpenDJ. Active Directory explicitly does not allow for the synchronization of pre-encoded passwords.
- Syncing a pre-encoded password to PingDirectory skips password validation.

Copyright © 2025 Ping Identity Corporation

- Unlike the changelog password encryption plugin, the PSA never has access to a decryptable version of the password, so it cannot sync it to any source that doesn't support pre-encoded passwords, such as Active Directory.
- The Active Directory Sync Destination drops any passwords it can't decrypt without logging anything about the dropped change.
- Make sure that the Active Directory domain controller has SSL enabled and running.
- Make sure the PingDataSyncs are configured to accept SSL connections when communicating with the Active Directory host.
- At least one Active Directory Sync Source (ADSyncSource) needs to be configured on PingDataSync and should point to the domain controller(s) on which the PSA will reside.
- At the time of installation, all PingDataSyncs in the sync topology must be online and available.
- The PSA component is for outbound-only password synchronization from the Active Directory Systems. It is not necessary if performing a one-way password synchronization from the PingDirectory Server to the Active Directory server.

Install the password sync agent

About this task

The PingDirectory server distributes the PSA in zip file format with each PingDataSync package. The initial installation of the PSA requires a system restart. Perform the following steps to install the PSA: NOTE: The Password Sync Agent cannot be pointed at multiple domain clusters.

Steps

1. On the domain controller, double-click the `setup.exe` file to start the installation.
2. Select a folder for the PSA binaries, local database, and log files.
3. Enter the host names (or IP addresses) and SSL ports of the PingDataSyncs, such as `sync.host.com:636`. Do not add any prefixes to the host names.
4. Enter the Directory Manager distinguished name (DN) and password. This creates an ADSync user on PingDataSync.
5. Enter a password (secret key) for the ADSync user that will be used by the PSA when connecting to the PingDataSync instances.
6. Click Next to begin the installation. All of the specified PingDataSyncs are contacted, and any failures will roll back the installation. If everything succeeds, a message displays indicating that a restart is required. The PSA will start when the computer restarts, and the LSA process is loaded into memory. The LSA process cannot be restarted at runtime.
7. If synchronizing pre-encoded passwords from Active Directory (AD) to a Ping Identity system, allow pre-encoded passwords in the default password policy.

```
$ bin/dsconfig set-password-policy-prop \
--policy-name "Default Password Policy" \
--set allow-pre-encoded-passwords:true
```

Copyright © 2025 Ping Identity Corporation

Upgrade or uninstall the password agent

PingDataSync provides the `update` tool for upgrades to the server code, including the PSA. The upgrade does not require a restart, because the core password filter is already running under LSA. The upgrade replaces the implementation binaries, which are encapsulated from the password filter DLL.

To uninstall the PSA on the Active Directory (AD) system, use Add/Remove Programs on the Windows Control Panel. The implementation DLL will be unloaded, and the database and log files are deleted. Only the binaries remain.

The core password filter will still be running under the LSA process. It imposes zero overhead on the domain controller, because the implementation DLL has been unloaded. To remove the password filter itself (located at `C:\WINDOWS\System32\ubidPassFilt.dll`), restart the computer. On restart, the password filter and implementation binaries (in the install folder) can be deleted.

> **Note**
>
> The PSA cannot be reinstalled without another reboot.

Manually configure the password sync agent

Configuration settings for the Password Sync Service are stored in the Windows registry in `HKLM\SOFTWARE\UnboundID\PasswordSync`. Configuration values under this registry key can be modified during runtime. The agent automatically reloads and refreshes its settings from the registry. Verify that the agent is working by checking the current log file, located in `<server-root>\logs\password-sync-current.log`.

> **Note**
>
> The Password Sync Agent cannot be pointed at multiple domain clusters.

Synchronize with Relational Databases

PingDataSync supports high-scale, highly-available data synchronization between the directory servers and relational database management systems (RDBMS). Any database with a Java database connectivity (JDBC) 3.0 or later driver can be used.

Use the server SDK

Synchronizing Lightweight Directory Access Protocol (LDAP) data to or from a relational database requires creating a Java database connectivity (JDBC) Sync Source or Destination extension to act as an interface between PingDataSync and the relational database. The Server SDK provides APIs to develop plugins and third-party extensions to the server using Java or Groovy. The Server SDK's documentation is delivered with the Server SDK build in `.zip` format.

The Server SDK contains two abstract classes that correspond to how the database is used:

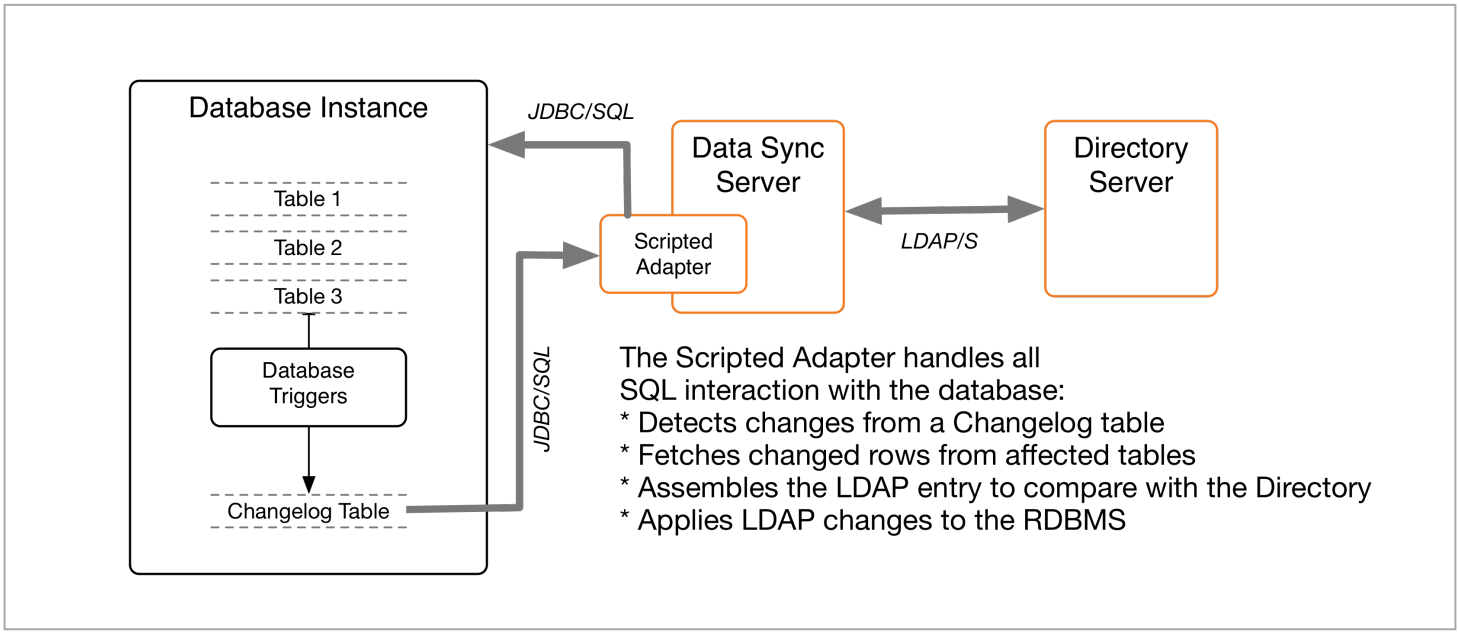
Copyright © 2025 Ping Identity Corporation

```
com.unboundid.directory.sdk.sync.api.JDBCSyncSource

com.unboundid.directory.sdk.sync.api.JDBCSyncDestination
```

The remainder of the SDK contains helper classes and utility functions to facilitate the script implementation. The SDK can use any change tracking mechanism to detect changes in the database. Examples are provided in the `<server-root>/config/jdbc/samples` directory for Oracle Database and Microsoft SQL Server.

PingDataSync uses a scripted adapter layer to convert any database change to an equivalent LDAP entry. The Sync Pipe then processes the data through inclusive (or exclusive) filtering using attribute and DN maps defined in the Sync Classes to update the endpoint servers. For example, a script using Java can be configured by setting the `extension-class` property on a `ThirdPartyJDBCSyncSource` or `ThirdPartyJDBCSyncDestination` configuration object within PingDataSync. The following is a sample architecture.



RDBMS synchronization process

PingDataSync synchronizes data between a directory server and an RDBMS system with a Server SDK extension. PingDataSync provides multiple configuration options, such as advanced filtering (fractional and subtree), attribute and distinguished name (DN) mappings, transformations, correlations, and configurable logging.

To support synchronizing changes, the database must be configured with a change tracking mechanism. An approach involving triggers, (one trigger per table) to record all changes to a change log table, is recommended. The database change log table Ping Identity should record the type of change (INSERT, UPDATE, DELETE), the specific table name, the unique identifier for the changed row, the database entry type, the changed columns (from the source table), the modifier's name, and the changetimestamp.

PingDataSync delegates the physical interaction with the database to a user- defined extension, which has full control of the SQL queries. The extension layer provides flexibility in how the mapping semantics between the Lightweight Directory Access Protocol (LDAP) environment and the relational database environment are defined. The connection management, pooling, retry logic, and other boilerplate code are handled internally by PingDataSync.

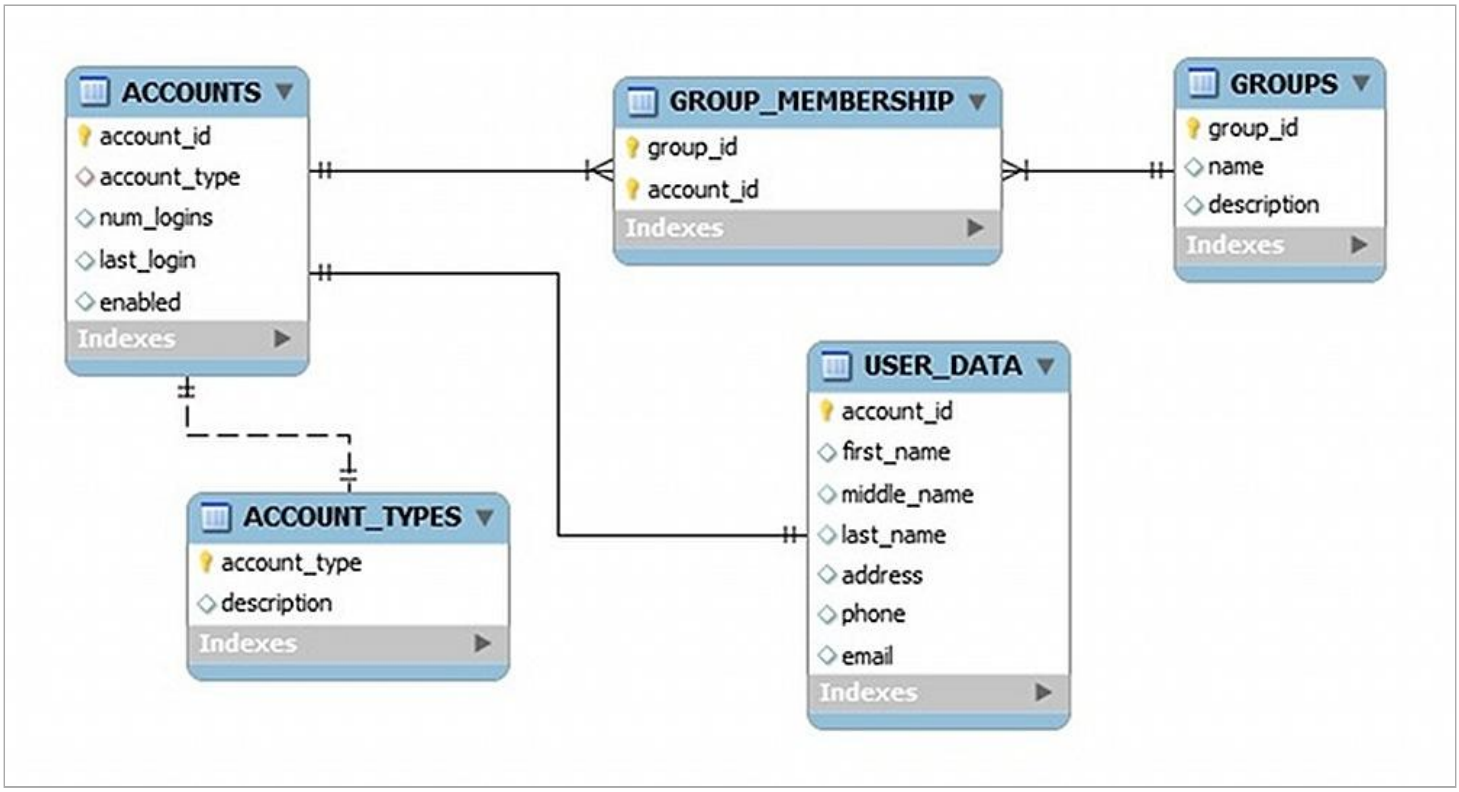
Copyright © 2025 Ping Identity Corporation

The RDBMS Synchronization (DBSync) implementation does not support failover between different physical database servers. Most enterprise databases have a built-in failover layer from which PingDataSync can point to a single virtual address and port and still be highly available. A single RDBMS node can scale to multiple directory server endpoints.

DBSync example

PingDataSync provides a DBSync example between two endpoints consisting of a PingDirectory server source and a RDBMS system, which will be used in this chapter.

The entity-relational diagram for the normalized database schema is available in `<server-root>/config/jdbc/samples/oracle-db/ComplexSchema.jpg`, and is illustrated here:



Five tables are represented with their primary keys in bold. The entity relations and foreign keys are marked by the relationship lines. The illustration shows mapping to a custom object class on the directory server, while the "groups" table maps to a standard Lightweight Directory Access Protocol (LDAP) group entry with `objectclass:groupOfUniqueNames`.

Example directory server entries

The following example assumes that the directory server's schema is configured to handle the mapped attributes. If configuring a database-to-directory Sync Pipe with a newly installed directory server, make sure that the schema has the correct `attributeType` and `objectClass` definitions in place. The definitions can be added in a custom `99-user.ldif` file in the `config/schema` folder of the directory server, if necessary.

The following are the Lightweight Directory Access Protocol (LDAP) entries that are used in the synchronization example:

Copyright © 2025 Ping Identity Corporation

```
dn: accountid=0,ou=People,dc=example,dc=com
objectClass: site-user
firstName: John
lastName: Smith
accountID: 1234
email: jsmith@example.com
phone: +1 556 805 4454
address: 17121 Green Street
numLogins: 4
lastLogin: 20070408182813.196Z
enabled: true

dn: cn=Group 1,ou=Groups,dc=example,dc=com
objectClass: groupOfUniqueNames
description: This is Group 1
uniqueMember: accountID=0,ou=People,dc=example,dc=com
uniqueMember: accountID=1,ou=People,dc=example,dc=com
```

Configure DBSync

About this task

Configuring a DBSync system includes extra tasks to create the extensions and to configure the database. The overall configuration process is as follows:

Steps

1. Download the appropriate Java database connectivity (JDBC) driver to PingDataSync's `/PingDataSync/lib` directory, and restart the server for the driver to load into the runtime.
2. Open the `java.properties` file with a text editor and add the `jdbc.drivers` argument. Save the file. When using custom JDBC endpoints, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file.
3. Run the `dsjavaproperties` command to apply the change. For example, enter the following for start-sync-server:

   ```
   start-sync-server.java-args=-d64 -server -Xmx256m -Xms256m -
   XX:+UseConcMarkSweepGC -
   Djdbc.drivers=foo.bah.Driver:wombat.sql.Driver:com.example.OurDriver ...
   etc.
   ```

4. Create one or more JDBC extensions based on the Server SDK. If configuring for bidirectional synchronization, two scripts are needed: one for the JDBC Sync Source; the other for the JDBC Sync Destination. Place the compiled extensions in the `/lib/extensions` directory.
5. Configure the database change log table and triggers (presented later). The vendor's native change tracking mechanism can be used, but a change log table should also be configured. Each table requires one database trigger to detect the changes and loads them into the change log table.
6. Configure the Sync Pipes, Sync Classes, external servers, distinguished name (DN) and attribute maps for one direction.
7. Run the `resync --dry-run` command to test the configuration settings.

Copyright © 2025 Ping Identity Corporation

8. Run `realtime-sync set-startpoint` to initialize the starting point for synchronization.
9. Run the `resync` command to populate data on the destination endpoint.
10. Start the Sync Pipes using the `realtime-sync start` command.
11. Monitor PingDataSync using the status commands and logs.
12. For bidirectional synchronization, configure another Sync Pipe, and repeat steps 4–8 to test the system.

Create the JDBC extension

The Java database connectivity (JDBC) extension implementation must be written in Java, or the Groovy scripting language. Consult the Server SDK documentation for details on how to build and deploy extensions. The examples in this guide use Java. Java extensions are more strict and will catch programming errors during compile time rather than at runtime. Groovy is more flexible and can accomplish more with less lines of code.

Groovy scripts must reside in the `/lib/groovy-scripted-extensions` directory (Java implementations reside in `/lib/extensions`), which may also contain other plugins built using the Server SDK. If a script declares a package name, it must live under the corresponding folder hierarchy, just like a Java class. For example, to use a script class called `ComplexJDBCSyncSource` whose package is `com.unboundid.examples.oracle`, place it in `/lib/groovy-scripted-extensions/com/unboundid/examples/oracleand` set the `script- class` property on the Sync Source to `com.unboundid.examples.oracle.ComplexJDBCSyncSource`. There are a few reference implementations provided in the `config/jdbc/samples` directory. Use the `manage-extension` tool in the `bin` directory, or `bat` (Windows) to install or update the extension. See the Server SDK extensions section for more information.

When using custom JDBC endpoints, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file. For example:

```
start-server.java-args=<…> -Djdbc.drivers=com.microsoft.sqlserver.jdbc.SQLServerDriver
```

The admin must run `dsjavaproperties` for the update to the `java.properties` file to take effect.

> **Note**
>
> Any changes to an existing script require a manual Sync Pipe restart. Any configuration change automatically restarts the affected Sync Pipe.

The default libraries available on the classpath to the script implementation include:

- Groovy
- Lightweight Directory Access Protocol (LDAP) SDK for Java
- JRE

Logging from within a script can be done with the Server SDK's `ServerContext` abstract class. Some of the `ServerContext` methods are not available when the `resync` tool runs, because it runs outside of the PingDataSync process. Any logging during a `resync` operation is saved to the `logs/tools/resync.log` file.

Copyright © 2025 Ping Identity Corporation

Implement a JDBC sync source

The `JDBCSyncSource` abstract class must be implemented to synchronize data from a relational database. Because PingDataSync is Lightweight Directory Access Protocol (LDAP)-centric, this class enables database content to be converted into LDAP entries. For more detailed information on the class, see the Server SDK Javadoc.

When using custom Java database connectivity (JDBC) sources, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file. For example:

```
start-server.java-args=<…> -Djdbc.drivers=com.microsoft.sqlserver.jdbc.SQLServerDriver
```

The admin must run `dsjavaproperties` for the update to the `java.properties` file to take effect.

The extension imports classes from the Java API, LDAP SDK for Java API, and the Server SDK. Depending on the data, implement the following methods:

- `initializeJDBCSyncSource` – Called when a Sync Pipe first starts, or when the `resync` process starts. Any initialization should be performed here, such as creating internal data structures and setting up variables.
- `finalizeJDBCSyncSource` – Called when a Sync Pipe stops, or when the `resync` process stops. Any clean up should be performed here, and all internal resources should be freed.
- `setStartpoint` – Sets the starting point for synchronization by identifying the starting point in the change log. This method should cause all changes previous to the specified start point to be disregarded and only changes after that point to be returned by the `getNextBatchOfChanges` method. There are several different startpoint types (see SetStartpointOptions in the Server SDK), and this implementation is not required to support them all. If the specified startpoint type is unsupported, this method throws an exception (`IllegalArgumentException`). This method can be called from two different contexts: when the `realtime-syncset-startpoint` command is used (the Sync Pipe is required to be stopped) or immediately after a connection is established to the source server.

  > **Note**
  >
  > The `RESUME_AT_SERIALIZABLE` startpoint type must be supported. This method is used when a Sync Pipe first starts and loads its state from disk.

- `getStartpoint` – Gets the current value of the startpoint for change detection.
- `fetchEntry` – Returns a full source entry (in LDAP form) from the database, corresponding to the `DatabaseChangeRecord` object that is passed. The `resync` command also uses this class to retrieve entries.
- `acknowledgeCompletedOps` – Provides a means for PingDataSync to acknowledge to the database which operations have completed processing.

  > **Note**
  >
  > The internal value for the startpoint should only be updated after a synchronization operation is acknowledged in to this script (through this method). If not, changes could be missed when PingDataSync is restarted.

- `getNextBatchOfChanges` – Retrieves the next set of changes for processing. The method also provides a generic means to limit the size of the result set.
- `listAllEntries` – Used by the `resync` command to get a listing of all entries.

Copyright © 2025 Ping Identity Corporation

- `cleanupChangelog` – In general, we recommend implementing a `cleanupChangelog` method, so that PingDataSync can purge old records from the change log table, based on a configurable age.

See the `config/jdbc/samples` directory for example script implementations and the Server SDK Javadoc for more detailed information on each method.

Implement a JDBC sync destination

The `JDBCSyncDestination` abstract class must be implemented to synchronize data into a relational database. The class enables converting Lightweight Directory Access Protocol (LDAP) content to database content. The extension imports classes from the Java API, LDAP SDK for Java API, and the Server SDK, depending on the database configuration.

When using custom Java database connectivity (JDBC) destinations, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file. For example:

```
start-server.java-args=<…> -Djdbc.drivers=com.microsoft.sqlserver.jdbc.SQLServerDriver
```

The admin must run `dsjavaproperties` for the update to the `java.properties` file to take effect.

Implement the following methods in the script:

- `initializeJDBCSyncDestination` – Called when a Sync Pipe starts, or when the `resync` process starts. Any initialization should be performed here, such as creating internal data structures and setting up variables.
- `finalizeJDBCSyncDestination` – Called when a Sync Pipe stops, or when the `resync` process stops. Any clean up should be performed here, and all internal resources should be freed.
- `createEntry` – Creates a full database entry (or row), corresponding to the LDAP entry that is passed in.
- `modifyEntry` – Modifies a database entry, corresponding to the LDAP entry that is passed in.
- `fetchEntry` – Returns a full destination database entry (in LDAP form), corresponding to the source entry that is passed in.
- `deleteEntry` – Deletes a full entry from the database, corresponding to the LDAP entry that is passed in.

For more detailed information on the abstract class, consult the Server SDK Javadoc.

Configure the database for synchronization

About this task

Configuring the database for synchronization includes defining:

- A database SyncUser account
- The change tracking mechanism
- The database triggers (one per table) for the application

The following procedure uses the example setup script in `/config/jdbc/samples/oracle- db/OracleSyncSetup.sql.` Items in brackets are user-named labels.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Database change tracking necessary if synchronizing FROM the database. If synchronizing TO a database, configure the Sync User account and the correct privileges.

Steps

1. Create an Oracle login (`SyncUser`) for PingDataSync, so that it can access the database server. Grant sufficient privileges to the `SyncUser` for any tables to be synchronized, and change the default password.

```
CREATE USER SyncUser IDENTIFIED BY password
DEFAULT TABLESPACE users TEMPORARY TABLESPACE temp;
GRANT "RESOURCE" TO SyncUser;
GRANT "CONNECT" TO SyncUser;
```

2. Create change log tables on the database as follows:

```
CREATE TABLE ubid_changelog (
  --This is the unique number for the change change_number Number NOT NULL
PRIMARY KEY,
  --This is the type of change (insert, update, delete). NOTE: This should
represent
  --the actual type of change that needs to happen on the destination(for
example a
  --database delete might translate to a LDAPmodify, etc.)
    change_type VARCHAR2(10) NOT NULL,
  --This is the name of the table that was changed table_name VARCHAR(50)
NOT NULL,
  --This is the unique identifier for the row that was changed. It is up
to
  --the trigger code to construct this, but it should follow a DN-like
format
  --(e.g. accountID={accountID}) where at least the primary key(s) are
  --present. If multiple primary keys are required, they should be
delimited
  --with a unique string, such as '%%' (e.g. accountID={accountID}%%
  --groupID={groupID})
    identifier VARCHAR2(100) NOT NULL,
  --This is the database entry type. The allowable values for this must be
  --set on the JDBC Sync Source configuration within the Synchronization
  --Server.
    entry_type VARCHAR2(50) NOT NULL,
  --This is a comma-separated list of columns from the source table that
were updated as part of
  --this change.
    changed_columns VARCHAR2(1000) NULL,
  --This is the name of the database user who made the change
    modifiers_name VARCHAR2(50) NOT NULL,
  --This is the timestamp of the change
    change_time TIMESTAMP(3) NOT NULL, CONSTRAINT chk_change_type
    CHECK (change_type IN ('insert','update','delete'))) ORGANIZATION
INDEX;
```

Copyright © 2025 Ping Identity Corporation

3. Create an Oracle function to get the `SyncUser` name. This is a convenience function for the triggers.

```
CREATE OR REPLACE FUNCTION get_sync_user RETURN VARCHAR2
IS
BEGIN
  RETURN 'SyncUser';
END get_sync_user;
```

4. Create an Oracle sequence object for the change-number column in the change log table.

```
CREATE SEQUENCE ubid_changelog_seq MINVALUE 1 START WITH 1
NOMAXVALUE INCREMENT BY 1 CACHE 100 NOCYCLE;
```

5. Create a database trigger for each table that will participate in synchronization. An example, located in `/config/jdbc/samples/oracle-db/OracleSyncSetup.sql`, shows a trigger for the Accounts table that tracks all changed columns after any INSERT, UPDATE, and DELETE operation. The code generates a list of changed items and then inserts them into the change log table.

Considerations for synchronizing to database destination

When configuring a directory-to-database Sync Pipe, the following are recommended:

Identify the Object Classes

Create a Sync Class per object class, so that they can easily be distinguished and have different mappings and synchronization rules.

For each Sync Class, set the following items in the configuration menus using the `dsconfig` tool.

Set the Include-Filter Property

Make sure the `include-filter` property is set on the Sync Class configuration menu to something that will uniquely identify the source entries, such as `objectClass=customer`.

Create Specific Attribute Mappings

Create an attribute mapping for every Lightweight Directory Access Protocol (LDAP) attribute to be synchronized to a database column, add these to a single attribute map, and set it on the Sync Class. With this configured, the script does not need to know about the schema on the directory side. A constructed attribute mapping that maps a literal value to the `objectClass` attribute can be added to the script to determine the database entry type. For example, `"account" → objectClass` can be added, which would result in the constructed destination LDAP entry always containing an `objectClass` of `"account"`. If needed, a mulit-valued `conditional-value-pattern` property can be used to conditionalize the attribute mapping based on the subtype of the entry or on the value of the attribute. See Conditional Value Mapping for additional information.

Copyright © 2025 Ping Identity Corporation

Create Specific DN Maps (optional)

If necessary, create a distinguished name (DN) map that recognizes the DN's of the source entries and maps them to a desired destination DN. In most cases, the script will use the attributes rather than the DN to figure out which database entry needs to be changed.

Set auto-mapped-source-attribute to "-none-"

Remove the default value of "-all-" from the `auto-mapped-source-attribute` on the Sync Class configuration menu, and replace it with "-none-."

Configure Create-Only Attributes

Any attributes that should be included when created, but never modified (such as `objectclass`) should be specified on the Sync Pipe as a `create-only` attribute. If PingDataSync ever computes a difference in that attribute between the source and destination, it will not try to modify it at the destination. To avoid bidirectional loop-back, set the `ignore-changes-by-[user\|dn]` property on both Sync Sources when configuring for bidirectional synchronization.

Synchronizing DELETE Operations

On PingDirectory Server and Nokia 8661 Directory Server systems, configure the `changelog-deleted-entry-include-attribute` property on the changelog backend menu using the `dsconfig` tool. This property allows for the proper synchronization of DELETE operations. For more information, see Configuring the PingDirectory Server Backend for Synchronizing Deletes .

Attribute-Synchronization-Mode for DBSync

For MODIFY operations, PingDataSync detects any change on the source change log, fetches the source entry, applies mappings, computes the equivalent destination entry, fetches the actual destination entry, and then runs a diff between the two entries to determine the minimal set of changes to synchronize. By default, changes on the destination entry are made only for those attributes that were detected in the original change log entry. This is configurable using the `attribute-synchronization-mode` property, which sets the type of diff operation that is performed between the source and destination entries.

If the source endpoint is a database server, set the `attribute-synchronization-mode` property to `all-attributes` on the Sync Class configuration menu. The diff operation will consider all source attributes. Any that have changed will be updated on the destination, even if the change was not originally detected in the change log. This mode is useful when a list of changed columns in the database might not be available. If both endpoints are directory servers, use the default configuration of `modified-attributes-only` to avoid possible replication conflicts.

Handling MODDN Operations

The concept of renaming an entry (modifyDN) does not have a direct equivalent for relational databases. The `JDBCSyncDestination` API does not handle changes of this type. Instead, the `modifyEntry()` method is called as if it is a normal change. The extension can verify if the entry was renamed by looking at the `SyncOperation` that is passed in (`syncOperation.isModifyDN()`). If true, the `fetchedDestEntry` parameter will have the old DN. The new DN can be obtained by calling `syncOperation.getDestinationEntryAfterChange()` .

Copyright © 2025 Ping Identity Corporation

Configure a directory-to-database sync pipe

The following configures a one-way Sync Pipe with a PingDirectory Server as the Sync Source and an RDBMS (Oracle) system as the Sync Destination with the `create-sync-pipe-config` tool. Sync Pipes can be configured later using `dsconfig`.

Create the sync pipe

The following procedures configure the Sync Pipe, external servers, and Sync Classes. The examples are based on the Complex JDBC sample in the `config/jdbc/samples/oracle-db` directory. The `create-sync-pipe-config` tool can be run with the server offline and the configuration can later be imported.

1. Run the `create-sync-pipe-config` tool.

   ```
   $ bin/create-sync-pipe-config
   ```

2. At the `Initial Synchronization Configuration Tool` prompt, press Enter to continue.
3. On the Synchronization Mode menu, select Standard Mode or Notification Mode.
4. On the Synchronization Directory menu, choose one-way or bidirectional synchronization.

Configure the sync source

1. On the Source Endpoint Type menu, enter the number for the sync source corresponding to the type of source external server.
2. Enter a name for the Source Endpoint.
3. Enter the base distinguished name (DN) for the directory server, which is used as the base for Lightweight Directory Access Protocol (LDAP) searches. For example, enter `dc=example,dc=com`, and then press Enter again to return to the menu. If entering more than one base DN, make sure the DNs do not overlap.
4. On the Server Security menu, select the type of communication that PingDataSync will use with the endpoint servers.
5. Enter the host and port of the source endpoint server. The Sync Source can specify a single server or multiple servers in a replicated topology. The server tests that a connection can be established.
6. Enter the DN of the Sync User account and create a password for this account. The Sync User account enables PingDataSync to access the source endpoint server. By default, the Sync User account is stored as `cn=SyncUser,cn=RootDNs,cn=config`.

Configure the destination endpoint server

1. On the Destination Endpoint Type menu, select the type of datastore on the endpoint server. This example is configuring an Oracle Database.
2. Enter a name for the Destination Endpoint.
3. On the JDBC Endpoint Connection Parameters menu, enter the fully-qualified host name or IP address for the Oracle database server.
4. Enter the listener port for the database server, or press Enter to accept the default (1521).

Copyright © 2025 Ping Identity Corporation

5. Enter a database name such as `dbsync-test`.
6. The server attempts to locate the JDBC driver in the `lib` directory. If the file is found, a success message is displayed.

   ```
   Successfully found and loaded JDBC driver for:
   jdbc:oracle:thin:@//dbsync-w2k8-vm-2:1521/dbsync-test
   ```

   If the server cannot find the JDBC driver, add it later, or quit the `create-sync-pipe-config` tool and add the file to the `lib` directory.
7. Add any additional Java database connectivity (JDBC) connection properties for the database server, or press Enter to accept the default (no). Consult the JDBC driver's vendor documentation for supported properties.
8. Enter a name for the database user account with which PingDataSync will communicate, or press Enter to accept the default (SyncUser). Enter the password for the account.
9. On the Standard Setup menu, enter the number for the language (Java or Groovy) that was used to write the server extension.
10. Enter the fully qualified name of the Server SDK extension class that implements the `JDBCSyncDestination` API.

    ```
    Enter the fully qualified name of the Java class that will implement
    com.unboundid.directory.sdk.sync.api.JDBCSyncDestination:
    com.unboundid.examples.oracle.ComplexJDBCSyncDestination
    ```
11. Configure any user-defined arguments needed by the server extension. These are defined in the extension itself and the values are specified in the server configuration. If there are user-defined arguments, enter `yes`.
12. To prepare the Source Endpoint server, which tests the connection to the server with the Sync User account, press Enter to accept the default (yes). For the Sync User account, it will return "Denied" as the account has not been written yet to the PingDirectory server at this time.

    ```
    Testing connection to server1.example.com:1389  Done
    Testing 'cn=Sync User,cn=Root DNs,cn=config' access     Denied
    ```
13. To configure the Sync User account on the directory server, press Enter to accept the default (yes). Enter the bind DN (`cn=DirectoryManager`) and the bind DN password of the directory server so that you can configure the `cn=Sync User` account. PingDataSync creates the Sync User account, tests the base DN, and enables the change log.

    ```
    Created 'cn=Sync User,cn=Root DNs,cn=config'
    Verifying base DN 'dc=example,dc=com'   Done
    Enabling cn=changelog .....
    ```
14. Enter the maximum age of the change log entries, or press Enter to accept the default.

Copyright © 2025 Ping Identity Corporation

Configure the sync pipe and sync classes

The following procedures define a Sync Pipe and two Sync Classes. The first Sync Class is used to match the `accounts` objects. The second Sync Class matches the `group` objects.

1. Continuing from the previous session, enter a name for the Sync Pipe.
2. When prompted to define one or more Sync Classes, enter `yes`.

Configure the accounts Sync Class

1. Enter a name for the Sync Class. For example, type `accounts_sync_class`.
2. If restricting entries to specific subtrees, enter one or more base distinguished name (DN)s. If not, press Enter to accept the default (no).
3. To set an Lightweight Directory Access Protocol (LDAP) search filter, type `yes` and enter the filter `"(accountid=*)"`. Press Enter again to continue. This property sets the LDAP filters and returns all entries that match the search criteria to be included in the Sync Class. In this example, specify that any entry with an `accountID` attribute be included in the Sync Class. If the entry does not contain any of these values, it will not be synchronized to the target server.
4. Choose to synchronize all attributes, specific attributes, or exclude specific attributes from synchronization, or press Enter to accept the default (all).
5. Specify the operations that will be synchronized for the Sync Class, or press Enter to accept the default.

Configure the groups Sync Class

For this example, configure another Sync Class to handle the `groups` object class. The procedures are similar to that of the configuration steps for the `account_sync_class` Sync Class.

1. On the Sync Class menu, enter a name for a new sync class, such as `groups_sync_class`.
2. To restrict entries to specific subtrees, enter one or more base DNs.
3. Set an LDAP search filter. Type `yes` to set up a filter and enter the filter `"(objectClass=groupOfUniqueNames)"`. This property sets the LDAP filters and returns all entries that match the `groupOfUniqueNames` attribute to be included in the Sync Class. If the entry does not contain any of these values, it will not be synchronized to the target server.
4. Choose to synchronize all attributes, specific attributes, or exclude specific attributes from synchronization, or press Enter to accept the default (all).
5. Specify the operations that will be synchronized for the Sync Class, or press Enter to accept the default.
6. At the prompt to enter the name of another Sync Class, press Enter to continue.
7. On the Default Sync Class Operations menu, press Enter to accept the default. The Default Sync Class determines how all entries that do not match any other Sync Class are handled.
8. Review the configuration, and press Enter to write the configuration to the server.

Use the `dsconfig` tool to make changes to this configuration. See *Configuring PingDataSync* for configuration options and details.

Considerations for synchronizing from a database source

When synchronizing from a database to a directory or RDBMS server, the following are recommended:

Identify Database Entry Types

Identify the database entry types that will be synchronized, and:

- Set the `database-entry-type` property on the Java database connectivity (JDBC) Sync Source (this is required), and make sure the entry types are what the triggers are inserting into the change tracking mechanism.
- Create a Sync Class per entry type, and set different mappings and rules for each one.

For each Sync Class, do the following:

- Make sure the `include-filter` property is set to match the entry type.
- Create a specific attribute mapping for every database column to be synchronized to an LDAP attribute and set it on the Sync Class. If this is done, the script will not have to know about the schema on the directory side.
- Create a distinguished name (DN) map that recognizes the DNs generated by the script and maps them to the correct location at the destination.
- Remove the default value of "-all-" from the `auto-mapped-source-attribute` property on the Sync Class, and replace it with the value `objectClass`. The object class for the fetched source entry is determined by the scripted layer. Values from the database should not be automatically mapped to an attribute with the same name, except the `objectclass` attribute, which should map directly for CREATE operations. If this is not done, an error is generated.
- Change the destination-correlation-attributes property to contain the attributes that uniquely represent the database entries on the directory server destination.

Avoid Bidirectional Loopback

Set the `ignore-changes-by-[user|dn]` property on both Sync Sources when configuring for bidirectional synchronization, to make sure that changes are not looped back by PingDataSync.

See Use the create-sync-pipe tool to configure synchronization for details about creating the Sync Pipe.

Synchronize a specific list of database elements

About this task

The `resync` command enables synchronizing a specific set of database keys that are read from a Java database connectivity (JDBC) Sync Source file using the `--sourceInputFile` option. The contents of the file are passed line-by-line into the `listAllEntries()` method of the `JDBCSyncSource` extension, which is used for the Sync Pipe. The method processes the input and returns `DatabaseChangeRecord` instances based on the input from the file.

Perform the following steps to synchronize a specific list of database elements using the `resync` tool:

Steps

1. Create a file of JDBC Sync Source elements. There is no set format for the file, but it typically contains a list of primary keys or SQL queries. For example, create a file containing a list of primary keys and save it as `sourceSQL.txt`.

Copyright © 2025 Ping Identity Corporation

```
user.0
user.1
user.2
user.3
```

2. Run the `resync` command with the `--sourceInputFile` option to run on individual primary keys in the file.

```
$ bin/resync --pipe-name "dbsync-pipe" \
--sourceInputFile sourceSQL.txt
```

3. If searching for a specific type of database entry, use the `--entryType` option that matches one of the configured entry types in the JDBCSyncSource.

```
$ bin/resync --pipe-name "dbsync-pipe" \
--entryType account \
--sourceInputFile sourceSQL.txt
```

Synchronize with Apache Kafka

Apache Kafka is an open-source streaming platform that communicates state changes in a distributed environment. Changes to a datastore are sent to a *Kafka topic*, which lets customers update other datastores that contain the same information. Although Kafka persists, orders, and transmits changes, it neither detects changes nor applies them to other datastores.

PingDataSync supports Kafka as a sync destination with a Ping Identity sync source, such as PingDirectory server. In this scenario, the Kafka sync destination publishes changes in the PingDirectory server to a Kafka topic, and displays the entry in JSON format both before and after each change. This level of indirection enables other systems and services to react to changes in the PingDirectory server by consuming messages from the topic.

Endpoints that use the Server SDK do not require custom sync destinations.

Restrictions

The following restrictions affect the manner in which a Kafka sync destination is used:

- The sync source must be a Ping Identity sync source.
- The `changelog` backend must be enabled on all instances of the PingDirectory server.
- To ensure the availability of an entry's attributes from before and after a change, the configuration property `changelog-include-key-attribute` must include `'*'`.
- The Sync Pipe must be configured in Notification mode (`synchronization-mode:notification`) because a Kafka sync destination cannot retrieve the current version of a destination entry.

Copyright © 2025 Ping Identity Corporation

Configure a Kafka sync destination

Use the `dsconfig` command or the administration console to synchronize changes to an Apache Kafka environment. You can reuse existing Ping Identity sync sources that were created for other Sync Pipes.

> **Tip**
>
> To configure Kerberos authentication for a Kafka sync destination, supply the `producer-property` attribute with the appropriate values according to the Apache Kafka documentation.

The following objects are required to configure a Kafka sync destination:

- Kafka cluster external server – Defines the procedure for connecting to a Kafka cluster. The Kafka cluster external server can be referenced from multiple Kafka sync destination configuration objects. The only required property is `bootstrap-server`, which identifies some of the Kafka brokers in the environment.

  When `use-ssl` is set to `true`, the following configuration changes are made:

  - A `trust-manager-provider` is configured to validate the Kafka broker's SSL certificate.
  - A `key-manager-provider` is configured to let the Kafka broker authenticate the PingDataSync Kafka producer.

- Kafka sync destination – References the Kafka cluster external server. The Kafka sync destination must specify the name of the topic to use for publishing messages.

  To adjust Kafka messages beyond the mapping, attribute filtering, and other configuration changes that PingDataSync makes, reference one or more of the `KafkaSyncDestinationPlugin` extension points that are implemented by using the Server SDK.

Run the `prepare-endpoint-server` command for the PingDirectory sync source.

SSL configuration

The following table identifies the `trust-manager-provider` and `key-manager-provider` properties of the Kafka cluster external server configuration object, as well as the Kafka configuration properties to which they map.

Configuration Object Type	Configuration Property	Kafka Configuration Property
File-based Trust Manager Provider	`trust-store-file`	`ssl.truststore.location`
File-based Trust Manager Provider	`trust-store-pin`, `trust-store-pin-property`, `trust-store-pin-environment-variable`, or `trust-store-pin-file`	`ssl.truststore.password`
File-based Key Manager Provider	`key-store-file`	`ssl.keystore.location`

Copyright © 2025 Ping Identity Corporation

Configuration Object Type	Configuration Property	Kafka Configuration Property
File-based Key Manager Provider	`key-store-pin`, `key-store-pin-property`, `key-store-pin-environment-variable`, or `key-store-pin-file`	`ssl.keystore.password`
File-based Key Manager Provider	`private-key-pin`, `private-key-pin-property`, `private-key-pin-environment-variable`, or `private-key-pin-file`	`ssl.key.password`

Message format

The distinguished name (DN) of a changed entry represents the default key for published messages. This value can be overridden in either of the following ways:

- With the `message-key-attribute` property of the Kafka sync destination configuration object
- With a `KafkaSyncDestinationPlugin` extension point

The value of the of the message is a JavaScript Object Notation (JSON) object that includes the following fields:

- `type` – Type of change, such as `ADD`, `MODIFY`, `DELETE`, or `RESYNC`.
- `dn` – DN of the changed entry.
- `changeID` – Unique identifier for the change.
- `modifiedAttributes` – List of modified attributes. This field is available only when the type is `MODIFY`.
- `current` – Entry after the change in JSON format. This field is unavailable when the type is `DELETE`.

  The JSON format of a `current` entry is compatible with the PingDirectory Directory REST API.
- `previous` – Entry before the change in JSON format. This field is unavailable if the type is `RESYNC` or `CREATE`.

  The JSON format of a `previous` entry is compatible with the PingDirectory Directory REST API.

Example ADD

The following code provides an example of an addition:

Copyright © 2025 Ping Identity Corporation

```
{
  "type": "ADD",
  "dn" : "uid=jsmith,ou=people,dc=example,dc=com",
  "changeID": "changeNumber=1",
  "current": {
    "objectClass": [
      "top",
      "person",
      "organizationalPerson",
      "iNetOrgPerson"
    ],
    "sn": [
      "Smith"
    ],
    "cn": [
      "John Smith"
    ],
    "telephoneNumber": [
      "+1 123 123 1234"
    ],
    "uid": [
      "jsmith"
    ]
  }
}
```

Example MODIFY

The following code provides an example of a modification:

Copyright © 2025 Ping Identity Corporation

```
{
  "type": "MODIFY",
  "dn" : "uid=jsmith,ou=people,dc=example,dc=com",
  "changeID": "changeNumber=2",
  "modifiedAttributes": [
    "telephoneNumber"
  ],
  "previous": {
    "telephoneNumber": [
      "+1 123 123 1234"
    ],
    "objectClass": [
      "top",
      "person",
      "organizationalPerson",
      "iNetOrgPerson"
    ],
    "sn": [
      "Smith"
    ],
    "cn": [
      "John Smith"
    ],
    "uid": [
      "jsmith"
    ]
  },
  "current": {
    "telephoneNumber": [
      "+1 321 321 3210"
    ],
    "objectClass": [
      "top",
      "person",
      "organizationalPerson",
      "iNetOrgPerson"
    ],
    "sn": [
      "Smith"
    ],
    "cn": [
      "John Smith"
    ],
    "uid": [
      "jsmith"
    ]
  }
}
```

Example DELETE

The following code provides an example of a deletion:

Copyright © 2025 Ping Identity Corporation

```
{
  "type": "DELETE",
  "dn" : "uid=jsmith,ou=people,dc=example,dc=com",
  "changeID": "changeNumber=3",
  "previous": {
    "telephoneNumber": [
      "+1 321 321 3210"
    ],
    "objectClass": [
      "top",
      "person",
      "organizationalPerson",
      "iNetOrgPerson"
    ],
    "sn": [
      "Smith"
    ],
    "cn": [
      "John Smith"
    ],
    "uid": [
      "jsmith"
    ]
  }
}
```

Message customization

After PingDataSync maps the attributes and filters the results, any entries that are changed will utilize the fields of a Kafka message. To restrict the information that is published to a topic, exclude the unwanted attributes from mapping, or include only the attributes that you want to publish.

By using the `KafkaSyncDestinationPlugin` extension point within the Server SDK, you can fully change the message key or value. For more information, including examples, refer to the documentation that is included with the Server SDK packaging.

Synchronize through PingDirectoryProxy servers

Because most data centers deploy directory servers in a proxied environment, PingDataSync can also synchronize data through a proxy server in both load-balanced and entry-balancing deployments. The following proxy endpoints are supported:

- Ping Identity PingDirectoryProxy servers
- Nokia 8661 Directory Proxy Servers

This chapter details a Sync-through-Proxy deployment and provides background information on how it works. Before setting up PingDataSync, review the PingDirectoryProxy Server Administration Guide for information about the PingDirectoryProxy server.

Copyright © 2025 Ping Identity Corporation

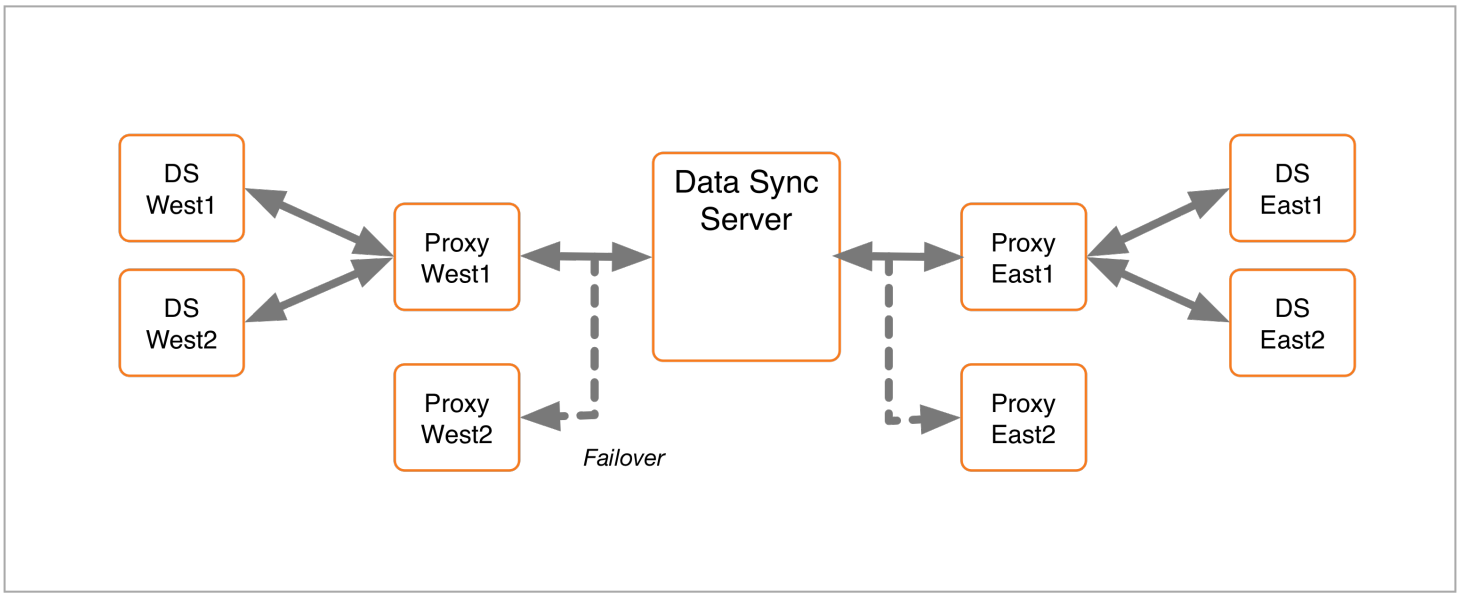
Synchronization through a PingDirectoryProxy server overview

To handle data synchronization through a PingDirectoryProxy server, PingDirectory servers have a `cn=changelog` state management system that supports a token-based API.

In a standard, non-proxied configuration, PingDataSync polls the source server for changes, determines if a change is necessary, and fetches the full entry from the source. Then, it finds the corresponding entry in the destination endpoint using correlation rules and applies the minimal set of changes. The server fetches and compares the full entries to make sure it does not synchronize any stale data from the change log.

In a proxied environment, PingDataSync passes the request through a proxy server to the backend set of directory servers. PingDataSync uses the highest priority proxy server designated in its endpoint server configuration and can use others in the event of a failover.

The following figure illustrates a deployment with two endpoints consisting of a proxy server deployment in front of the backend set of directory servers.



Change log operations

When PingDataSync runs a poll for any changes, it sends a get change log batch extended request to the `cn=changelog` backend. The batch request looks for entries in the change log and asks for the server ID, change number, and replica state for each change.

The PingDirectoryProxy server routes the request to a directory server instance, which then returns a changed entry plus a token identifying the server ID, change number and replica state for each change. The PingDirectoryProxy server then sends a get change log batch response back to PingDataSync with this information. For entry-balancing deployments, the PingDirectoryProxy server must "re-package" the directory server tokens into its own proxy token to identify the specific data set.

Copyright © 2025 Ping Identity Corporation

The first time that PingDataSync issues the batch request, it also issues a get server ID request to identify the specific server ID that is processing the extended request. The PingDirectoryProxy server routes the request to the directory server instance, and then returns a server ID in the response. With the next request, PingDataSync sends a 'route to server' request that specifies the server instance to access again in this batch session. It also issues a server ID request in the event that the particular server is down. This method avoids round-robin server selection and provides more efficient overall change processing.

PingDirectory server and PingDirectoryProxy server tokens

The PingDirectory server maintains a change log database index to determine when to resume sending changes (for ADD, MODIFY, or DELETE operations) in its change log. While a simple stand-alone directory server can track its resume point by the last change number sent, replicated servers or servers deployed in entry balancing environments have a different change number ordering in its change log because updates can come from a variety of sources.

The following figure illustrates two change logs in two replicated directory servers, server A and B. "A" represents the replica identifier for a replicated subtree in Server A, and "B" represents the replica identifier for the same replicated subtree in server B. The replica identifiers with a hyphen ("-") mark any local, non-replicated but different changes. While the two replicas record all of the changes, the two change logs have two different change number orderings because updates come in at different times.

Server A			Server B		
ChangeNumber	**ReplicaIdentifier**	**ReplicationCSN**	**ChangeNumber**	**ReplicaIdentifier**	**ReplicationCSN**
1001	A_{ri}	10	2001	B_{ri}	11
1002	-	-	2002	A_{ri}	10
1003	A_{ri}	15	2003	-	-
1004	B_{ri}	11	2004	B_{ri}	12
1005	B_{ri}	12	2005	A_{ri}	15

To track the change log resume position, the PingDirectory server uses a change log database index to identify the latest change number position corresponding to the highest replication CSN number for a given replica. This information is encapsulated in a directory server token and returned in the get change log batch response to the PingDirectoryProxy server. The token has the following format:

```
Directory Server Token: server ID, changeNumber,replicaState
```

For example, if the PingDirectoryProxy server sends a request for any changed entries, and the directory servers return the change number 1003 from server A and change number 2005 from server B, then each directory server token would contain the following information:

Copyright © 2025 Ping Identity Corporation

```
Directory Server Token A:
  serverID A, changeNumber 1003, replicaState {15(A)}

Directory Server Token B:
  serverID B, changeNumber 2005, replicaState {12(B), 15(A)}
```

Change log tracking in entry balancing deployments

Change log tracking can become more complex in that a shared area of data can exist above the entry-balancing base distinguished name (DN) in addition to each backend set having its own set of changes and tokens.

In the following figure, Server A belongs to an entry-balancing set 1, and server B belonging to an entry-balancing set 2. Shared areas that exist above the entry-balancing base DN are assumed to be replicated to all servers. "SA" represents the replica identifier for that shared area on Server A and "SB" represents the replica identifier for the same area on Server B.

Set 1 - Server A			Set 2 - Server B		
ChangeNumber	ReplicaIdentifier	ReplicationCSN	ChangeNumber	ReplicaIdentifier	ReplicationCSN
1001	SA_{ri}	5	2001	SB_{ri}	10
1002	A_{ri}	10	2002	B_{ri}	20
1003	SB_{ri}	15	2003	SA_{ri}	5

The PingDirectoryProxy server cannot pass a directory server token from the client to the directory server and back again. In an entry-balancing deployment, the PingDirectoryProxy server must maintain its own token mechanism that associates a directory server token (`changeNumber` , `replicaIdentifier` , `replicaState`) to a particular backend set.

```
Proxy Token:
backendSetID 1: ds-token 1 (changeNumber, replicaIdentifier, replicaState)
backendSetID 2: ds-token 2 (changeNumber, replicaIdentifier, replicaState)
```

For example, if the PingDirectoryProxy server returned change 1002 from Server A and change 2002 from Server B, then the Proxy token would contain the following:

```
Proxy Token:
backendSetID 1: ds-token-1 {serverID A, changeNumber 1002, replicaState (5
(SA), 15(A)}
backendSetID 2: ds-token-2 {serverID B, changeNumber 2002, replicaState (10
(SB), 20(B)}
```

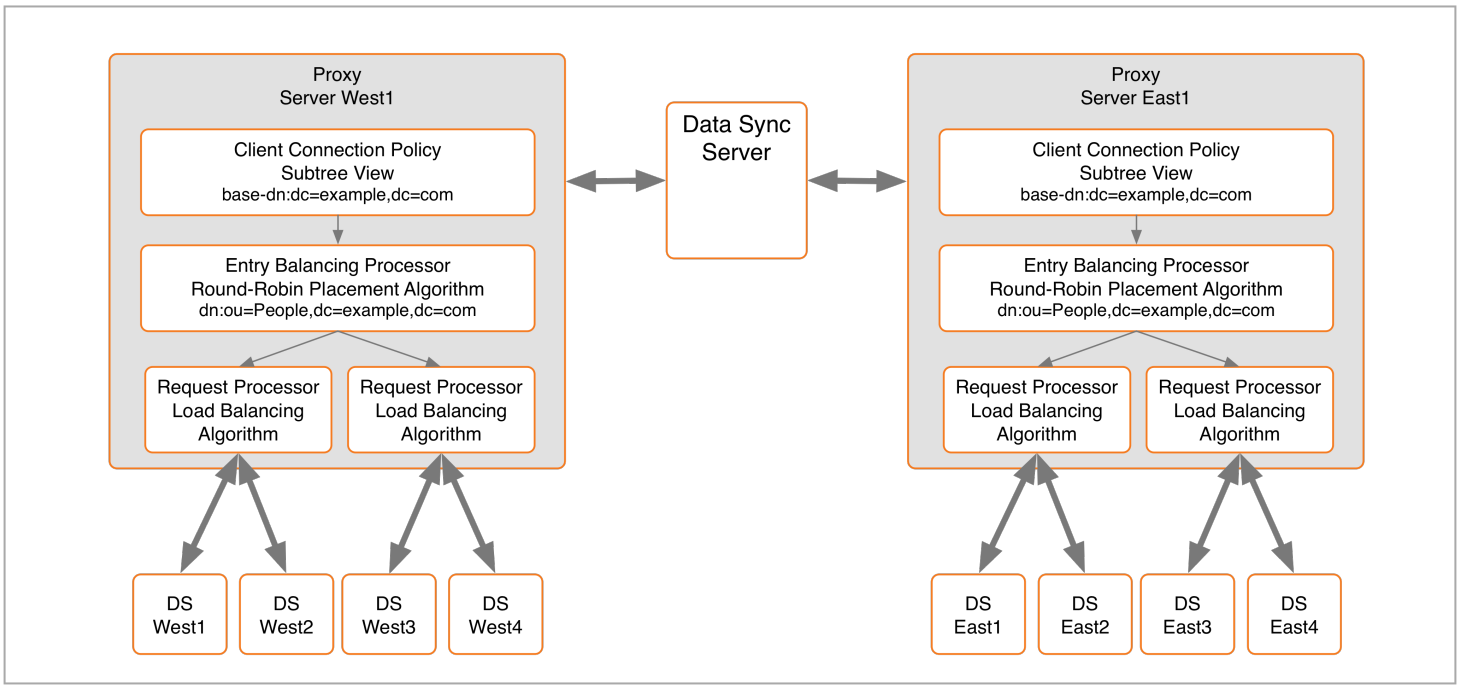
For each change entry returned by a backend, the PingDirectoryProxy server must also decide whether it is a duplicate of a change made to the backend set above the entry-balancing base. If the change is a duplicate, then it is discarded. Otherwise, any new change is returned with a new value of the proxy token.

Copyright © 2025 Ping Identity Corporation

Example configuration

This example configures synchronization through a proxy and uses two endpoints consisting of a PingDirectoryProxy server with a backend set of PingDirectory servers; both sets are replicated.

The PingDirectoryProxy server uses an entry-balancing environment for the distinguished name (DN) `ou=People,dc=example,dc=com` and provides a subtree view for `dc=example,dc=com` in its client connection policy. For this example, communication is over standard Lightweight Directory Access Protocol (LDAP) and failover servers are not installed or designated in PingDataSync.



Configure the source PingDirectory server

About this task

The following procedure configures a backend set of directory servers. The procedure is the same for the source servers and the destination servers in a synchronization topology. For directory server installation and configuration details, see the PingDirectory Server Administration Guide.

Steps

1. On each backend PingDirectory server that will participate in synchronization, enable the change log database, either from the command line or by using a `dsconfig` batch file.

```
$ dsconfig --no-prompt set-backend-prop \
  --backend-name changelog \
  --set enabled:true
```

2. Stop the server if it is running, and import the dataset for the first backend set into the first server in the backend set prior to the import.

Copyright © 2025 Ping Identity Corporation

```
$ bin/stop-server
$ bin/import-ldif --backendID userRoot --ldifFile ../dataset.ldif
$ bin/start-server
```

3. On the first server instance in the first backend set, configure replication between this server and the second server in the same backend set.

```
$ bin/dsreplication enable --host1 ldap-west-01.example.com \
  --port1 389 \
  --bindDN1 "cn=Directory Manager" \
  --bindPassword1 password \
  --replicationPort1 8989 \
  --host2 ldap-west-02.example.com \
  --port2 389 \
  --bindDN2 "cn=Directory Manager" \
  --bindPassword2 password \
  --replicationPort2 9989 \
  --adminUID admin \
  --adminPassword admin \
  --baseDN dc=example,dc=com \
  --no-prompt
```

4. Initialize the second server in the backend set with data from the first server in the backend set. This command can be run from either instance.

```
$ bin/dsreplication initialize \
  --hostSource ldap-west-01.example.com \
  --portSource 389 \
  --hostDestination ldap-west-02.example.com \
  --portDestination 389 \
  --baseDN "dc=example,dc=com" \
  --adminUID admin \
  --adminPassword admin \
  --no-prompt
```

5. Run the following command to check replica status.

```
$ bin/dsreplication status \
  --hostname ldap-west-01.example.com \
  --port 389 \
  --adminPassword admin \
  --no-prompt
```

6. Repeat steps 3 through 6 (import, enable replication, initialize replication, check status) for the second backend set.

Configure a proxy server

About this task

Copyright © 2025 Ping Identity Corporation

The following procedure configures a proxy server, including defining the external servers and configuring the client-connection policy. The procedure is the same for the source servers and the destination servers in a synchronization topology.

For additional changes, use the `dsconfig` tool. For proxy installation and configuration details, see the PingDirectoryProxy Server Administration Guide.

Steps

1. From the PingDirectoryProxy server root directory, run the `prepare-external-server` command to set up the `cn=Proxy User` account for access to the backend directory servers. The server tests the connection and creates the `cn=Proxy User` account.

```
$ bin/prepare-external-server --no-prompt \
  --hostname ldap-west-01.example.com \
  --port 389 --bindDN "cn=Directory Manager" \
  --bindPassword password \
  --proxyBindDN "cn=Proxy User,cn=Root DNs,cn=config" \
  --proxyBindPassword pass \
  --baseDN "dc=example,dc=com"
```

2. Repeat step 1 for any other directory server instances.

3. Run the `dsconfig` command to define the external servers and their types. For this example, round-robin load balancing algorithms are defined, which do not require health checks or locations to be specified.

```
$ bin/dsconfig --no-prompt create-external-server \
  --server-name ldap-west-01 \
  --type "ping-identity-ds" \
  --set "server-host-name:ldap-west-01.example.com" \
  --set "server-port:389" \
  --set "bind-dn:cn=Proxy User" \
  --set "password:password" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-external-server \
  --server-name ldap-west-02 \
  --type "ping-identity-ds" \
  --set "server-host-name:ldap-west-02.example.com" \
  --set "server-port:389" \
  --set "bind-dn:cn=Proxy User" \
  --set "password:password" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig --no-prompt create-external-server \
  --server-name ldap-west-03 \
  --type "ping-identity-ds" \
  --set "server-host-name:ldap-west-03.example.com" \
  --set "server-port:389" \
  --set "bind-dn:cn=Proxy User" \
  --set "password:password" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-external-server
  --server-name ldap-west-04 \
  --type "ping-identity-ds" \
  --set "server-host-name:ldap-west-04.example.com" \
  --set "server-port:389" \
  --set "bind-dn:cn=Proxy User" \
  --set "password:password" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

4. **Create a load-balancing algorithm for each backend set.**

```
$ bin/dsconfig --no-prompt create-load-balancing-algorithm \
  --algorithm-name "test-lba-1" \
  --type "round-robin" --set "enabled:true" \
  --set "backend-server:ldap-west-01" \
  --set "backend-server:ldap-west-02" \
  --set "use-location:false" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-load-balancing-algorithm \
  --algorithm-name "test-lba-2" \
  --type "round-robin" --set "enabled:true" \
  --set "backend-server:ldap-west-03"
  --set "backend-server:ldap-west-04"
  --set "use-location:false" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

5. **Configure the proxying request processors, one for each load-balanced directory server set. A request processor provides the logic to either process the operation directly, forward the request to another server, or hand off the request to another request processor.**

```
$ bin/dsconfig --no-prompt create-request-processor \
  --processor-name "proxying-processor-1" --type "proxying" \
  --set "load-balancing-algorithm:test-lba-1" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig --no-prompt create-request-processor \
  --processor-name "proxying-processor-2" --type "proxying" \
  --set "load-balancing-algorithm:test-lba-2" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

6. Define an entry-balancing request processor. This request processor is used to distribute entries under a common parent entry among multiple backend sets. A backend set is a collection of replicated directory servers that contain identical portions of the data. Multiple proxying request processors are used to process operations.

   Next, define the placement algorithm, which selects the server set to use for new add operations to create new entries. In this example, a round-robin placement algorithm forwards LDAP add requests to backend sets.

```
$ bin/dsconfig --no-prompt create-placement-algorithm \
  --processor-name "entry-balancing-processor" \
  --algorithm-name "round-robin-placement" \
  --set "enabled:true" \
  --type "round-robin" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

7. Define the subtree view that specifies the base distinguished name (DN) for the entire deployment.

```
$ bin/dsconfig --no-prompt create-subtree-view \
  --view-name "test-view" \
  --set "base-dn:dc=example,dc=com" \
  --set "request-processor: entry-balancing-processor" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

8. Finally, define a client connection policy that specifies how the client connects to the proxy server.

```
$ bin/dsconfig --no-prompt set-client-connection-policy-prop \
  --policy-name "default" \
  --add "subtree-view:test-view" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

Configure PingDataSync

About this task

Configure PingDataSync after the PingDirectoryProxy server and its backend set of PingDirectory server instances are configured and fully functional for each endpoint, which are labeled as `ldap-west` and `ldap-east` in this example.

For information about installing and configuring PingDataSync, see Installing PingDataSync.

Copyright © 2025 Ping Identity Corporation

Steps

1. From the PingDataSync root directory, run the `create-sync-pipe-config` tool.

```
$ bin/create-sync-pipe-config
```

2. At the Initial Synchronization Configuration Tool prompt, press Enter to continue.
3. On the Synchronization Mode menu, press Enter to select Standard mode.
4. On the Synchronization Directory menu, choose the option for one-way or bidirectional synchronization.
5. On the First Endpoint Type menu, enter the number for the type of backend data store for the first endpoint. In this example, type the number corresponding to the PingDirectoryProxy server.

```
>>>> First Endpoint Type
Enter the type of datastore for the first endpoint:
1) Ping Identity Directory Server
2) Ping Identity Directory Proxy Server
3) Alcatel-Lucent Directory Server
4) Alcatel-Lucent Proxy Server
5) Sun Directory Server
6) Microsoft Active Directory
7) Microsoft SQL Server
8) Oracle Database
9) Custom JDBC

b) back
q) quit
Enter choice [1]: 2
```

6. Enter a descriptive name for the first endpoint.
7. Enter the base DN where PingDataSync can search for the entries on the first endpoint server.
8. Specify the type of security when communicating with the endpoint server.
9. Enter the host name and port of the endpoint server. PingDataSync tests the connection. Repeat this step if configuring another server for failover.
10. Enter the Sync User account that will be used to access the endpoint server, or press Enter to accept the default `cn=Sync User,cn=Root DNs,cn=config`. Enter a password for the account.
11. The first endpoint deployment is defined using the PingDirectoryProxy server (`ldap-west`). Repeat steps 5-10 to define the second proxy deployment (`ldap-east`) on PingDataSync.
12. Prepare the endpoint servers in the topology. This step confirms that the Sync User account is present on each server and can communicate between PingDataSync and the PingDirectoryProxy servers. In addition to preparing the PingDirectoryProxy server, PingDataSync prepares the backend set of directory servers as the proxy server passes through the authorization to access these servers.
13. Repeat the previous step to prepare the second endpoint server. If other servers have not been prepared, make sure that they are prior to synchronization.

Copyright © 2025 Ping Identity Corporation

14. Define the Sync Pipe from proxy 1 to proxy 2. In this example, accept the default "Ping Identity Proxy 1 to Ping Identity Proxy 2."
15. To customize on a per-entry basis how attributes get synchronized, define one or more Sync Classes. Create a Sync Class for the special cases, and use the default Sync Class for all other mappings.
16. For the default Sync Class Operations, specify the operations that will be synchronized.
17. Review the configuration settings, and write the configuration to PingDataSync in the `sync-pipe-cfg.txt` file.

Test the configuration

About this task

If the `create-sync-pipe-config` tool was not used to create the synchronization configuration, two properties must be verified on each endpoint: `proxy-server` and `use-changelog-batch-request`. The `proxy-server` property should specify the name of the proxy server. The `use-changelog-batch-request` property should be set to `true` on the Sync Source only. The `use-changelog-batch-request` property is not available on the destination endpoint.

The PingDataSync connection parameters (`hostname`, `port`, `bind DN`, and `bind password`) are required.

Steps

1. The following commands check the properties on a Sync Source.

   On the Sync Source:

   ```
   $ bin/dsconfig --no-prompt \
     get-sync-source-prop \
     --source-name "Ping Identity Proxy 1" \
     --property "proxy-server" \
     --property "use-changelog-batch-request"
   ```

   On the Sync Destination:

   ```
   $ bin/dsconfig --no-prompt \
     get-sync-source-prop \
     --source-name "Ping Identity Proxy 2" \
     --property "proxy-server"
   ```

2. From the server root directory, run the `dsconfig` command to set a flag indicating that the endpoints are PingDirectoryProxy servers:

   ```
   $ bin/dsconfig --no-prompt \
     set-sync-source-prop \
     --source-name "Ping Identity Proxy 1" \
     --set proxy-server:ldap-west-01 \
     --set use-changelog-batch-request:true
   ```

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig --no-prompt \
  set-sync-source-prop \
  --source-name "Ping Identity Proxy 2" \
  --set proxy-server:ldap-east-01
```

3. Run the `resync --dry-run` command to test the configuration settings for each Sync Pipe and debug any issues.

```
$ bin/resync --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2"
--dry-run
```

4. Run `realtime-sync set-startpoint` to initialize the starting point for synchronization.

```
$ realtime-sync set-startpoint --end-of-changelog \
  --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2" \
  --port 389 \
  --bindDN "cn=Directory Manager" \
  --bindPassword password
```

> **Note**
>
> For synchronization through proxy deployments, the `--change-number` option cannot be used with the **`realtime-sync set-startpoint`** command, because PingDataSync cannot retrieve specific change numbers from the backend directory servers. Use `--change-sequence-number`, `--end-of-changelog`, or other options available for the tool.

5. Run the `resync` command to populate data on the endpoint destination server if necessary.

```
$ bin/resync --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2"
\
  --numPasses 3
```

6. Start the Sync Pipe using the `realtime-sync start` command.

```
$ bin/realtime-sync start \
  --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2"
```

7. Monitor PingDataSync using the status commands and logs.

Index the LDAP changelog

About this task

Copyright © 2025 Ping Identity Corporation

The PingDirectory server and the Nokia 8661 Directory Server (3.0 or later) both support attribute indexing in the changelog backend to enable get changelog batch requests to filter results that include only changes of specific attributes. For example, in an entry balanced proxy deployment, PingDataSync sends a get changelog batch request to the PingDirectoryProxy server, which will send out individual requests to each backend server.

Each directory server that receives a request must iterate over the whole range of changelog entries, and then match entries based on search criteria for inclusion in the batch. The majority of this processing involves determining whether a changelog entry includes changes to a particular attribute or set of attributes, or not. Changelog indexing can dramatically speed up throughput when targeting specific attributes.

Attribute indexing is configured using the `index-include-attribute` and `index-exclude-attribute` properties on the changelog backend. The properties can accept the specific attribute name or special Lightweight Directory Access Protocol (LDAP) values "*" to specify all user attributes or "+" to specify all operational attributes.

Perform the following steps to configure changelog indexing:

Steps

1. On all source directory servers, enable changelog indexing for the attributes that will be synchronized. Use the index-include-attribute and index-exclude-attribute properties. The following example specifies that all user attributes (index-include- attribute:*) be indexed in the changelog, except the description and location attributes (index-exclude-attribute:description and index-exclude-attribute:location).

   ```
   $ bin/dsconfig set-backend-prop --backend-name changelog \
     --set "index-include-attribute:*" \
     --set "index-exclude-attribute:description \
     --set "index-exclude-attribute:location
   ```

   > **Note**
   >
   > There is little performance and disk consumption penalty when using index-include-attribute:* with a combination of `index-exclude-attribute` properties, instead of explicitly defining each attribute using `index-include-attribute` . The only cautionary note about using `index-include- attribute:*` is to be careful that unnecessary attributes get indexed.

2. On PingDataSync, configure the `auto-map-source-attributes` property to specify the mappings for the attributes that need to be synchronized.

Result

PingDataSync will write a NOTICE message to the error log when the Sync Pipe first starts, indicating whether the server is using changelog indexing or not.

```
[30/Mar/2016:13:21:36.781 -0500] category=SYNC severity=NOTICE
msgID=1894187256 msg="Sync Pipe 'TestPipe' is not using changelog indexing on
the source server"
```

Copyright © 2025 Ping Identity Corporation

Changelog synchronization considerations

If the Sync Source is configured with `use-changelog-batch-request=true`, PingDataSync will use the get changelog batch request to retrieve changes from the Lightweight Directory Access Protocol (LDAP) changelog. This extended request can contain an optional set of selection criteria, which specifies changelog entries for a specific set of attributes.

PingDataSync takes the union of the source attributes from PingDataSync distinguished name (DN) mappings, attribute mappings, and the `auto-mapped-source-attributes` property on the Sync Class to create the selection criteria. However, if it encounters the value "-all-" in the `auto-mapped-source-attributes` property, it cannot make use of selection criteria because the Sync Pipe is interested in all possible source attributes.

When the PingDirectory server receives a get changelog request that contains selection criteria, it returns changelog entries for one or more of the attributes that meet the criteria.

- For ADD and MODIFY changelog entries, the changes must include at least one attribute from the selection criteria.
- For MODDN changelog entries, one of the RDN attributes must match the selection criteria.
- For DELETE changelog entries, one of the `deletedEntryAttrs` much match the selection criteria.

If `auto-mapped` is not set to `all` source attributes, at least one should be configured to show up in the `deletedEntryAttrs` (with the `changelog-deleted-entry-include-attribute` property on the changelog backend).

Another way to do this is to set `use-reversible-form` to `true` on the changelog backend. This includes all attributes in the `deletedEntryAttrs`.

Synchronize in Notification Mode

PingDataSync supports a notification synchronization mode that transmits change notifications on a source endpoint to third-party destination applications.

As with standard mode, notifications can be filtered based on the type of entry that was changed, the specific attributes that were changed, and the type of change (ADD, MODIFY, DELETE). PingDataSync can send a notification to arbitrary endpoints by using a custom server extension.

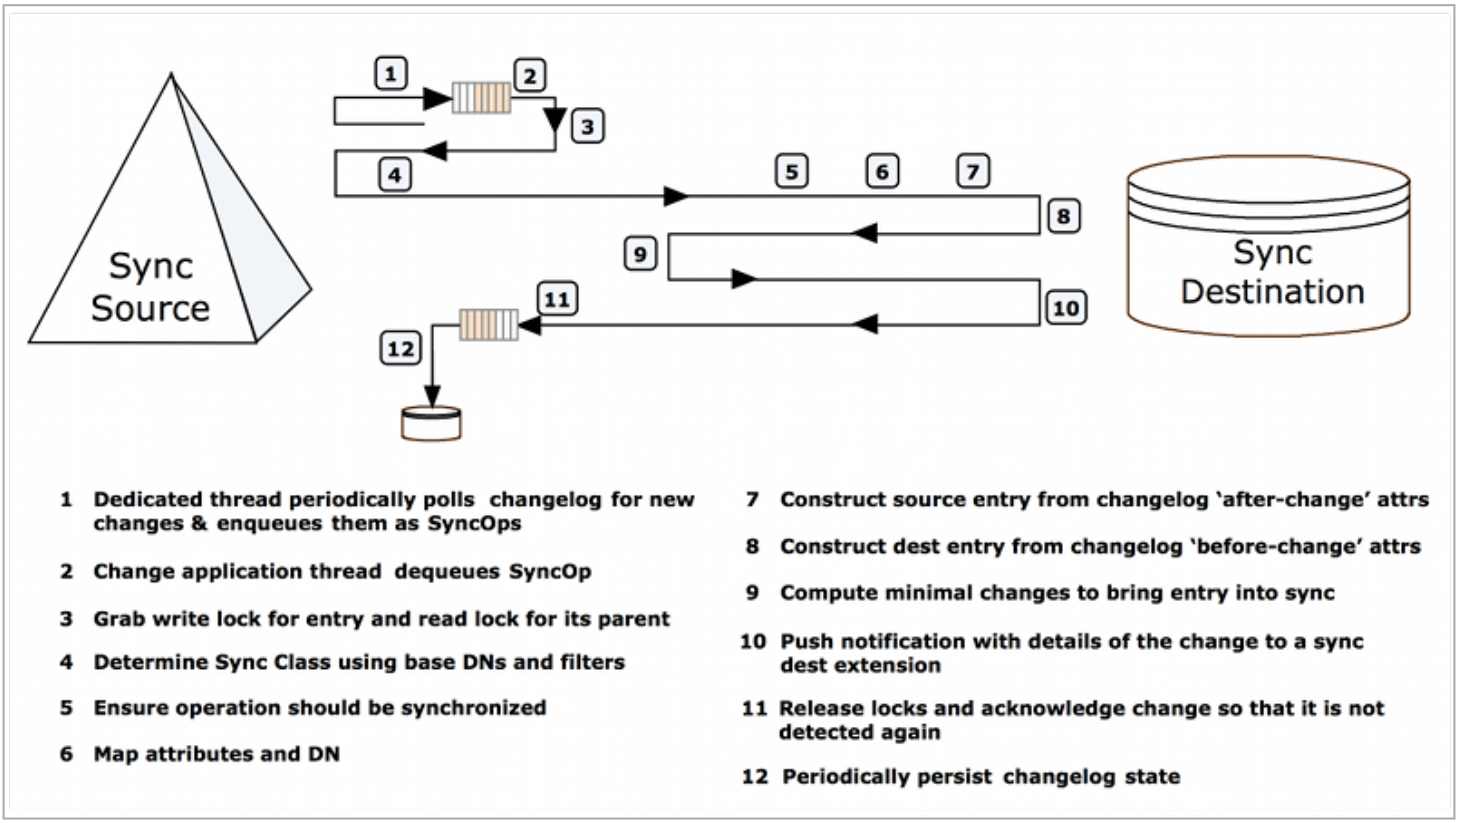
Notification mode overview

PingDataSync supports standard and notification synchronization modes. Notification Mode polls the directory server's Lightweight Directory Access Protocol (LDAP) change log for changes on any entry but skips the fetch and compare phases of processing of Standard Mode. Instead, the Sync Destination is notified of the change regardless of the current state of that entry at the source or destination. PingDataSync accesses state information on the change log to reconstruct the before-and-after values of any modified attribute (for example, for MODIFY change operation types). It passes in the change information to a custom server extension based on the Server SDK.

Third-party libraries can be employed to customize the notification message to an output format required by the client application or service. For example, the server extension can use a third-party XML parsing library to convert the change notifications to a SOAP XML format.

Notification mode can only be used with an PingDirectory Server, Nokia 8661 Directory Server, PingDirectoryProxy server, or Nokia 8661 Directory Proxy Server as the source endpoint.

Copyright © 2025 Ping Identity Corporation



PingDataSync can use notification mode with any type of endpoint; therefore, it is not an absolute requirement to have a custom server extension in your system. For example, it is possible to set up a notification Sync Pipe between two LDAP server endpoints.

Implementation considerations

Before implementing and configuring a Sync Pipe in notification mode, answer the following questions:

- What is the interface to client applications?
- What type of connection logic is required?
- How will the custom server extension handle timeouts and connection failures?
- What are the failover scenarios?
- What data needs to be included in the change log?
- How long do the change log entries need to be available?
- What are the scalability requirements for the system?
- What attributes should be used for correlation?
- What should happen with each type of change?
- What mappings must be implemented?

Copyright © 2025 Ping Identity Corporation

Use the Server SDK and LDAP SDK

To support notification mode, the Server SDK provides a `SyncDestination` extension to synchronize with any client application. The PingDataSync engine processes the notification and makes it available to the extension, which can be written in Java or Groovy. This generic extension type can also be used for standard synchronization mode.

Similar to database synchronization, the custom server extension is stored in the `<server-root>/lib/groovy-scripted-extensions` folder (for Groovy-based extensions) or the jar file in the `<server-root>/lib/extensions` folder (for Java-based extensions) prior to configuring PingDataSync for notification mode. Groovy scripts are compiled and loaded at runtime.

The Server SDK's `SyncOperation` interface represents a single synchronized change from the Sync Source to the Sync Destination. The same `SyncOperation` object exists from the time a change is detected, through when the change is applied at the destination.

The Lightweight Directory Access Protocol (LDAP) SDK's `UnboundIDChangelogEntry` class (in the `com.unboundid.ldap.sdk.unboundidds` package) has high-level methods to work with the `ds-changelog-before-value`, `ds-changelogafter-values`, and `ds-changelog-entry-key-attr-values` attributes. The class is part of the commercial edition of the LDAP SDK for Java and is installed automatically with PingDataSync. For detailed information and examples, see the LDAP SDK Javadoc.

Notification mode architecture

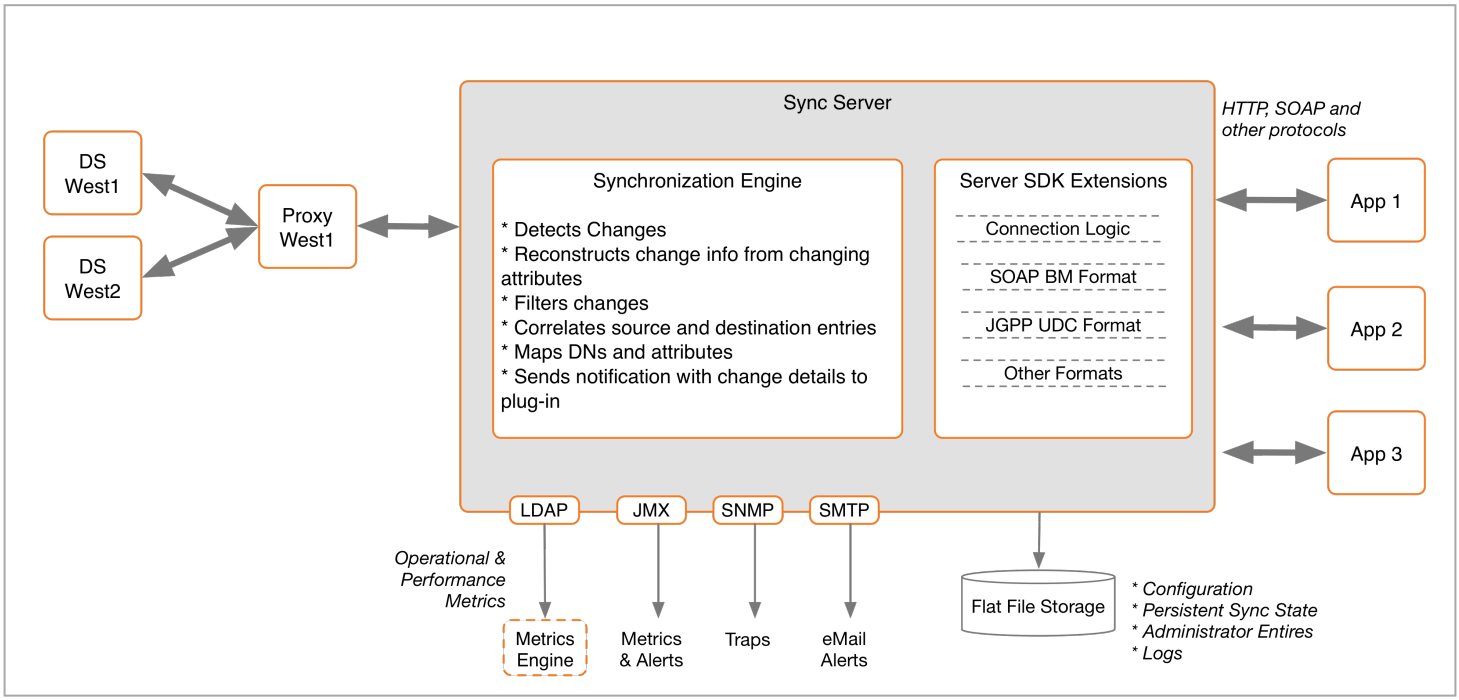
Notification mode, a configuration setting on the Sync Pipe, requires a one-way directional Sync Pipe from a source endpoint topology to a target client application.

PingDataSync detects the changes in the PingDirectory server's Lightweight Directory Access Protocol (LDAP) change log, filters the results specified in the Sync Classes, applies any distinguished name (DN) and attribute mappings, then reconstructs the change information from the change log attributes. A server extension picks up the notification arguments from the `SyncOperation` interface (part of the Server SDK) and converts the data to the desired output format. The server extension establishes the connections and protocol logic to push the notification information to the client applications or services. All of the operations, administration, and management functions available in standard mode, such as monitoring, (LDAP, JMX, SNMP), alerts (JMX, SNMP, SMTP), and logging features are the same for notification mode.

> **Note**
>
> The Server SDK includes documentation and examples on how to create a directory server extension to support notification mode.

For a given entry, PingDataSync sends notifications in the order that the changes occurred in the change log even if a modified attribute has been overwritten by a later change. For example, if an entry's `telephoneNumber` attribute is changed three times, three notifications will be sent in the order they appeared in the change log.

Copyright © 2025 Ping Identity Corporation



Sync source requirements

A separate Sync Pipe is required for each client application that should receive a notification.

The Sync sources must consist of one or more instances of the following directory or proxy servers with PingDataSync:

- Ping Identity PingDirectory Server and PingDirectoryProxy Server 3.0.5 or later
- Nokia 8661 Directory Server
- A Sync destination of any type

You should not configure PingDataSync to interact with backend source servers through a load balancer. You can use PingDirectoryProxy for this configuration instead, assuming you are using PingDirectory Servers as your backends.

> **Note**
>
> Although the PingDirectoryProxy Server and Nokia 8661 Directory Proxy Server can front other vendor's directory servers, such as Active Directory (AD) and Sun DSEE, for processing LDAP operations, PingDataSync cannot synchronize changes from these sources through a proxy server. Synchronizing changes directly from AD and Sun DSEE cannot be done with notification mode.

Failover capabilities

For sync source failovers, configure replication between the PingDirectory servers to ensure data consistency between the servers. A PingDirectoryProxy server can also front the backend PingDirectory server set to redirect traffic, if connection to the primary server fails. A PingDirectoryProxy server must be used for synchronizing changes in an entry-balancing environment. Once the primary PingDirectory server is online, it assumes control with no information loss as its state information is kept across the backend PingDirectory servers.

Copyright © 2025 Ping Identity Corporation

For sync destination failovers, connection retry logic must be implemented in the server extension, which will use the Sync Pipe's advanced property settings to retry failed operations. There is a difference between a connection retry and an operation retry. An extension should not retry operations because PingDataSync does this automatically. However, the server extension is responsible for re-establishing connections to a destination that has gone down, or failing over to an alternate server. The server extension can also be designed to trigger its own error- handling code during a failed operation.

For PingDataSync failovers, the secondary PingDataSyncs will be at or slightly behind the state where the primary server initiated a failover. Both primary and secondary PingDataSyncs track the last failed acknowledgement, so once the primary server fails over to a secondary server, the secondary server will not miss a change.

> **Note**
>
> If failover is a concern between PingDataSyncs, change the `sync-failover-polling-interval` property from 7500 ms to a smaller value. This will result in a quicker failover, but will marginally increase traffic between the two PingDataSyncs. The `sync-failover-connection-timeout` and `sync-failover-response-timeout` properties may also be updated to use different failover timeout durations. Use **`dsconfig`** to access the property on the Global Sync Configuration menu.

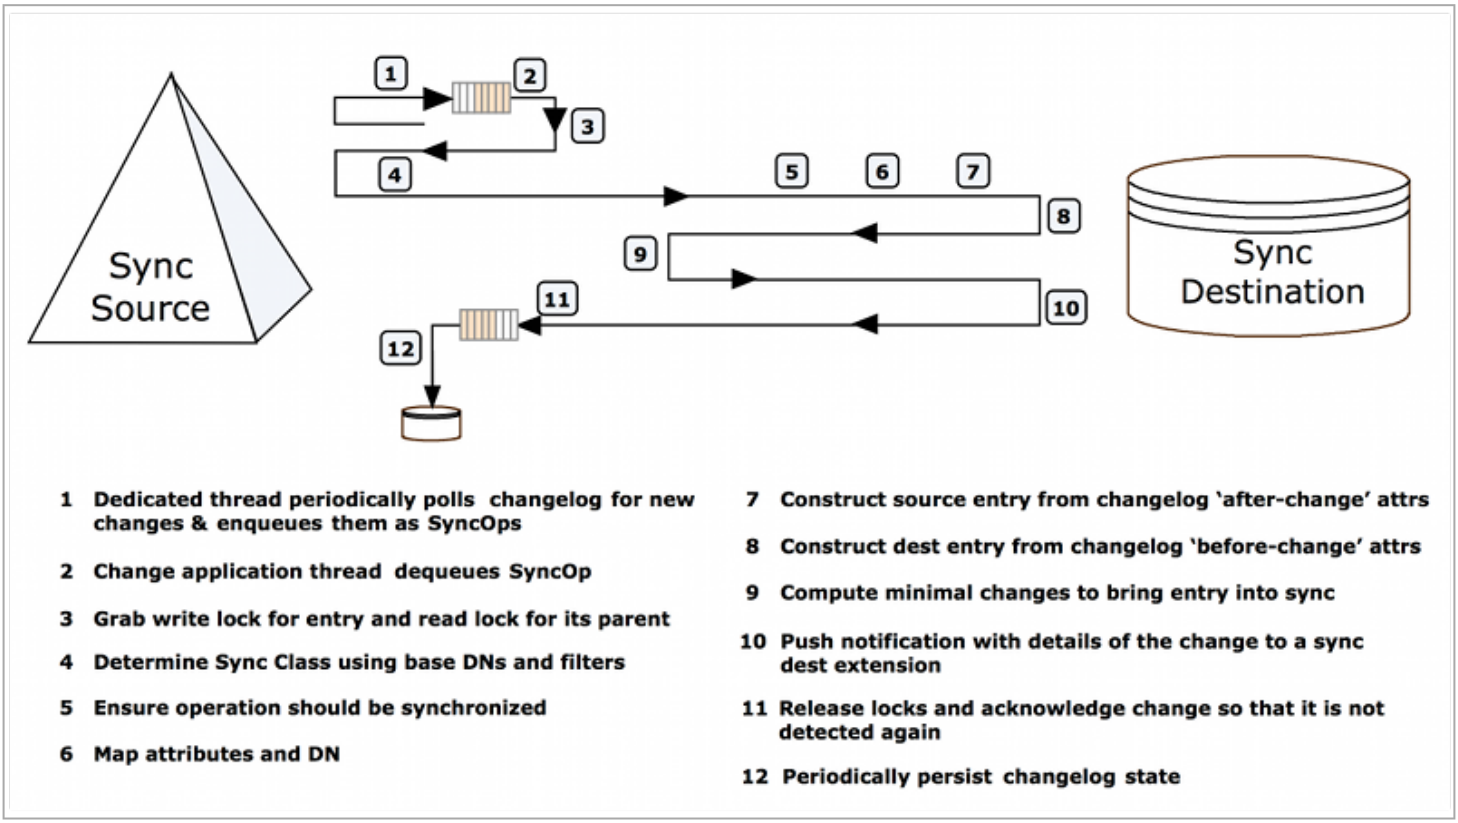
Notification sync pipe change flow

Multi-threaded Sync Pipes allow PingDataSync to process multiple notifications in parallel in the same manner as synchronizing changes in standard mode, which increases throughput and offsets network latency. A single change-detection thread pulls in batches of change log entries and queues them internally. To guarantee consistency, PingDataSync's internal locking mechanisms ensure the following properties:

- Changes to the same entry will be processed in the same order that they appear in the change log.
- Changes to parent entries will be processed before changes to its children.
- Changes to entries with the same RDN value are handled sequentially.

The number of concurrent threads is configurable on the Sync Pipe using the `num-worker-threads` property. In general, single-threading should be avoided.

Copyright © 2025 Ping Identity Corporation



Configure notification mode

PingDataSync supports notification mode with the following components.

Use the create-sync-pipe-config tool

The `create-sync-pipe-config` tool supports the configuration of notification mode. Any pre-existing Sync Sources can be read from the local configuration (in the `config.ldif` file).

LDAP change log features required for notifications

The PingDirectory server and the Nokia 8661 Directory Server require the following advanced global change log properties: `changelog-max-before-after-values` and `changelog-include-key-attribute`.

These properties are enabled and configured during the `create-sync-pipe-config` configuration process on PingDataSync. The properties can also be enabled on the directory servers by using the `dsconfig` advanced properties setting on the Backend Changelog menu.

Copyright © 2025 Ping Identity Corporation

changelog-include-key-attribute

The `changelog-include-key-attribute` property specifies one or more attributes that should always be included in the change log entry. These are attributes needed to correlate entries between the source and destination, such as `uid`, `employeeNumber`, or `mail`. These properties are also needed for evaluating any filters in the Sync Class. For example, if notifications are only sent for user entries, and the Sync Class included the filter `(objectclass=people)`, the `objectclass` attribute must be configured as a `changelog-include-key-attribute` so that the Sync Pipe can evaluate the inclusion criteria when processing the change. In standard mode, values needed in the filter are read from the entry itself after it is fetched instead of from the changelog entry. These attributes are always included in a change log entry, also called a change record, regardless if they have changed or not.

The `changelog-include-key-attribute` property causes the current (after-change) value of the specified attributes to be recorded in the `ds-changelog-entry-key-attr-values` attribute on the change log entry. This applies for all change types. During a delete operation, the values are from the entry before it was deleted. The key values are recorded on every change and override any settings configured in the `changelog-include-attribute`, `changelog-exclude-attribute`, `changelog-deleted-entry-include-attribute`, or `changelog-deleted-entry- exclude-attribute` properties in the directory server changelog (see the Ping Identity PingDirectoryserver Configuration Reference for more information).

Normal Lightweight Directory Access Protocol (LDAP)-to-LDAP synchronization topologies typically use `dn` as a correlation attribute. If `dn` is used as a correlation attribute only, the `changelog-include-key-attribute` property does not need to be set. However, if another attribute is used for correlation, this property must be set during the Sync Pipe configuration.

The LDAP change log attribute, `ds-changelog-entry-key-attr-values`, stores the attribute that is always included in a change log entry on every change for correlation purposes. In addition to regular attributes, virtual and operational attributes can be specified as entry keys.

To view an example, see the Ping Identity PingDirectory server Administration Guide.

changelog-max-before-after-values

The `changelog-max-before-after-values` property specifies the maximum number of "before and after" values (default 200) that should be stored for any changed attribute in the change log. Also, when enabled, it will add the `ds-changelog-before-values` and `ds-changelog-after-values` attributes to any change record that contains changes (for Modify and ModifyDN).

The main purpose of the `changelog-max-before-after-values` property is to ensure that an excessively large number of changes is not stored for multi-valued attributes. In most cases, the directory server's schema defines a multi-valued attribute to be unlimited in an entry. For example, if a group entry whose member attribute references 10000 entries, the desire may be to not have all of the attributes if a new member added.

If either the `ds-changelog-before-values` or the `ds-changelog-after-values` attributes exceed the count set in the `changelog-max-before-after-values` property, the attribute values are no longer stored in a change record but its attribute name and number is stored in the `ds-changelog-attr-exceeded-max-values-count` attribute, which appears in the change record.

In addition to this property, set the `use-reversible-form` property to `TRUE`. This guarantees that sufficient information is stored in the change log for all operation types to be able to replay the operations at the destination. The `create-sync-pipe-config` tool configures these properties when it prepares the servers.

The `changelog-max-before-after-values` property configures the following change log attributes:

- `ds-changelog-before-values` – Captures all "before" values of a changed attribute. It will store up to the specified value in the `changelog-max-before-after-values` property (default 200).

Copyright © 2025 Ping Identity Corporation

- `ds-changelog-after-values` – Captures all "after" values of a changed attribute. It will store up to the specified value in the `changelog-max-before-after-values` property (default 200).
- `ds-changelog-attr-exceeded-max-values-count` – Stores the attribute names and number of before and after values on the change log entry after the maximum number of values (set by the `changelog-max-before-after-values` property) has been exceeded. This is a multi-valued attribute with the following format:

  ```
  attr=attributeName,beforeCount=200,afterCount=201
  ```

  where `attributeName` is the name of the attribute and the `beforeCount` and `afterCount` are the total number of values for that attribute before and after the change, respectively. In either case (before or after the change), if the number of values is exceeding the maximum, those values will not be stored.

LDAP change log for Notification and Standard Mode

Both Notification and Standard mode Sync Pipes can consume the same Lightweight Directory Access Protocol (LDAP) Change Log without affecting the other. Standard mode polls the change record in the change log for any modifications, fetches the full entries on the source and the destination, and then compares them for the specific changes. Notification mode gets the before and after values of a changed attribute to reconstruct an entry, and bypasses the fetch-and-compare phase. Both can consume the same LDAP Change Log with no performance loss or conflicts.

> **Note**
>
> If the configuration obtains the change log through a PingDirectoryProxy server, the contents of the change log will not change as it is being read from the change logs on the directory server backend.

Implementing the server extension

Notification mode relies heavily on the server extension code to process and transmit the change using the required protocol and data formats needed for the client applications.

Create the extension using the Server SDK, which provides the APIs to develop code for any destination endpoint type. The Server SDK's documentation (Javadoc and examples) is delivered with the Server SDK built-in zip format. The SDK provides all of the necessary classes to extend the functionality of PingDataSync without code changes to the core product. Once the server extension is in place, use other third-party libraries to transform the notification to any desired output format.

Consider the following when implementing the extension:

Use the manage-extension tool

Use the manage-extension tool in the `bin` directory or `bat` directory (Windows) to install or update the extension. See Managing Extensions for more information.

Review the Server SDK package

Review Server SDK documentation and examples before building and deploy a Java or Groovy extension.

Copyright © 2025 Ping Identity Corporation

Connection and protocol logic

The Server SDK extension must manage the notification connection and protocol logic to the client applications.

Implementing extensions

Test the create methods, the delete methods, and the modify methods for each entry type. Update the configuration as needed. Finally, package the extensions for deployment. Logging levels can be increased to include more details.

Use the SyncOperation type

The `SyncOperation` class encapsulates everything to do with a given change. Objects of this type are used in all of the synchronization SDK extensions. See the Server SDK Javadoc for the `SyncOperation` class for information on the full set of methods.

Use the EndpointException type

The Sync Destination type offers an exception type called `EndpointException` to extend a standard Java exception and provide custom exceptions. There is also logic to handle Lightweight Directory Access Protocol (LDAP) exceptions, using the LDAP SDK.

About the PostStep result codes

The `EndpointException` class uses PostStep result codes that are returned in the server extension:

- `retry_operation_limited` – Retry a failed attempt up to the limit set by `max_ operation_attempts`.
- `retry_operation_unlimited` – Retry the operation an unlimited number of times until a success, abort, or `retried_operation_limited`.This should only be used when the destination endpoint is unavailable.
- `abort_operation` – Abort the current operation without any additional processing.

Use the ServerContext class for logging

The `ServerContext` class provides several logging methods which can be used to generate log messages and/or alerts from the scripted layer: `logMessage()`, `sendAlert()`, `debugCaught()`, `debugError()`, `debugInfo()`, `debugThrown()`, `debugVerbose()`, and `debugWarning()`. These are described in the Server SDK API Javadocs. Logging related to an individual `SyncOperation` should be done with the `SyncOperation#logInfo` and `SyncOperation#logError` methods.

Diagnosing script errors

When a Groovy extension does not behave as expected, first look in the error log for stack traces. If `classLoader` errors are present, the script could be in the wrong location or may not have the correct package. Groovy checks for errors at runtime. Business logic errors must be systematically found by testing each operation. Make sure logger levels are set high enough to debug.

Configure the Notification sync pipe

The following procedure configures a one-way Sync Pipe with a PingDirectory server as the Sync Source and a generic sync destination. The procedure uses the `create-sync-pipe-config` tool in interactive command-line mode and highlights the differences for configuring a Sync Pipe in notification mode.

Copyright © 2025 Ping Identity Corporation

Considerations for configuring sync classes

When configuring a Sync Class for a Sync Pipe in notification mode, consider the following:

- Exclude any operational attributes from synchronizing to the destination so that its before and after values are not recorded in the change log. For example, the following attributes can be excluded: `creatorsName`, `createTimeStamp`, `ds-entry-unique-id`, `modifiersName`, and `modifyTimeStamp`. Filter the changes at the change log level instead of making the changes in the Sync Class to avoid extra configuration settings with the following:
  - Use the directory server's `changelog-exclude-attribute` property with (`+`) to exclude all operational attributes (`change-log-exclude-attribute:+`).
  - Configure a Sync Class that sets the `excluded-auto-mapped-source-attributes` property to each operational attribute to exclude from the synchronization process.
  - Use the directory server's `changelog-exclude-attribute` property to specify each operational attribute to exclude in the synchronization process. Set the configuration using the `dsconfig` tool on the directory server Change Log Backend menu. For example, `setchangelog-exclude-attribute:modifiersName`.
- Use the `destination-create-only-attribute` advanced property on the Sync Class. This property sets the attributes to include on CREATE operations only.
- Use the `replace-all-attr-values` advanced property on the Sync Class. This property specifies whether to use the ADD and DELETE modification types (reversible), or the REPLACE modification type (non-reversible) for modifications to destination entries. If set to `true`, REPLACE is used.
- If targeting specific attributes that require higher performance throughput, consider implementing change log indexing. See Synchronize through PingDirectoryProxy servers for more information.

Create the sync pipe

About this task

The initial configuration steps show how to set up a single Sync Pipe from a directory server instance to a generic Sync Destination.

Before starting:

- Place any third-party libraries in the `<server-root>/lib/extensions` folder.
- Implement a server extension for any custom endpoints and place it in the appropriate directory.

Steps

1. If necessary, start PingDataSync:

```
$ bin/start-server
```

2. Run the `create-sync-pipe-config` tool.

Copyright © 2025 Ping Identity Corporation

```
$ bin/create-sync-pipe-config
```

3. At the Initial Synchronization Configuration Tool prompt, press Enter to continue.
4. On the Synchronization Mode menu, select the option for notification mode.
5. On the Synchronization Directory menu, enter the option to create a one-way Sync Pipe in notification mode from directory to a generic client application.

Configure the sync source

About this task
Steps

1. On the Source Endpoint Type menu, enter the option for the Sync Source type.
2. Choose a pre-existing Sync Source, or create a new sync source.
3. Enter a name for the Source Endpoint and a name for the Sync Source.
4. Enter the base distinguished name (DN) for the directory server used for Lightweight Directory Access Protocol (LDAP) searches, such as `dc=example,dc=com`, and press Enter to return to the menu. If entering more than one base DN, make sure they do not overlap.
5. On the Server Security menu, select the type of communication that PingDataSync will use with endpoint servers.
6. Enter the host and port of the first Source Endpoint server. The Sync Source can specify a single server or multiple servers in a replicated topology. PingDataSync contacts this first server if it is available, then contacts the next highest priority server if the first server is unavailable. The server tests the connection.
7. On the Sync User Account menu, enter the DN of the sync user account and password, or press Enter to accept the default, `cn=Sync User,cn=Root DNs,cn=config`. This account allows PingDataSync to access the source endpoint server.

Configure the destination endpoint server

About this task
Steps

1. On the Destination Endpoint Type menu, select the type of datastore on the endpoint server. In this example, select the option for Custom.
2. Enter a name for the Destination Endpoint and a name for the Sync Destination.
3. On the Notifications Setup menu, select the language (Java or Groovy) used to write the server extension.
4. Enter the fully qualified name of the Server SDK extension that implements the abstract class. A Java, extension should reside in the `/lib/extensions` directory. A Groovy script should reside in the `/lib/groovy-scripted-extensions` directory.

Copyright © 2025 Ping Identity Corporation

5. Configure any user-defined arguments needed by the server extension. Typically, these are connection arguments, which are defined by the extension itself. The values are then entered here and stored in the server configuration.

6. Configure the maximum number of before and after values for all changed attributes. Notification mode requires this. Set the cap to something well above the maximum number of values that any synchronized attribute will have. If this cap is exceeded, PingDataSync issues an alert. For this example, we accept the default value of 200.

```
Enter a value for the max changelog before/after values,
or -1 for no limit [200]:
```

7. Configure any key attributes in the change log that must be included in every notification. These attributes can be used to find the destination entry corresponding to the source entry, and are present regardless of whether the attributes changed. Later, any attributes used in a Sync Class include-filter must also be configured as key attributes in the Sync Class.

8. In both standard and notification modes, the Sync Pipe processes the changes concurrently with multiple threads. If changes must be applied strictly in order, the number of Sync Pipe worker threads will be reduced to 1. This will limit the maximum throughput of the Sync Pipe.

Next steps

The rest of the configuration steps follow the same process as a standard synchronization mode Sync Pipe. See The Sync User account for more information.

Access control filtering on the sync pipe

PingDataSync provides an advanced Sync Pipe configuration property, `filter-changes-by-user`, which performs access control filtering on a changelog entry for a specific user.

Since the changelog entry contains data from the target entry, the access controls filter out attributes that the user does not have the privileges to see before it is returned. For example, values in the changes, `ds-changelog-before-values`, `ds-changelog-after-values`, `ds-changelog-entry-key-attr-values`, and `deletedEntryAttrs` are filtered out through access control instructions.

> **Note**
>
> This property is only available for notification mode and can be configured using the **`create-sync-pipe-config`** or the **`dsconfig`** tool.

The source server must be a PingDirectory server or Nokia 8661 Directory Server, or a PingDirectoryProxy server or Nokia 8661 Directory Proxy Server that points to a PingDirectory server or Nokia 8661 Directory Server.

Considerations for access control filtering

- The directory server will not return the changelog entry if the user is not allowed to see the target entry.
- The directory server strips out any attributes that the user is not allowed to see.
- If no changes are left in the entry, no changelog entry will be returned.

Copyright © 2025 Ping Identity Corporation

- If only some attributes are stripped out, the changelog entry will be returned.
- Access control filtering on a specific attribute value is not supported. Either all attribute values are returned or none.
- If a sensitive attribute policy is used to filter attributes when a client normally accesses the directory server, this policy will not be taken into consideration during notifications since the Sync User is always connecting using the same method. Configure access controls to filter out attributes, not based on the type of connection made to the server, but based on who is accessing the data. The `filter-changes-by-user` property will be able to evaluate if that person should have access to these attributes.

Configure the sync pipe to filter changes by access control instructions

About this task
Steps

1. Set the filter-changes-by-user property to filter changes based on access controls for a specific user.

```
$ bin/dsconfig set-sync-pipe-prop \
  --pipe-name "Notifications Sync Pipe" \
  --set "filter-changes-by-user:uid=admin,dc=example,dc=com"
```

2. On the source directory server, set the `report-excluded-changelog-attributes` property to include the names of users that have been removed through access control filtering. This will allow PingDataSync to warn about attributes that were supposed to be synchronized but were filtered out. This step is recommended but not required.

```
$ bin/dsconfig set-backend-prop \
--backend-name "changelog" \
  --set "report-excluded-changelog-attributes:attribute-names"
```

> **Note**
>
> PingDataSync only uses the `attribute-names` setting for the PingDirectory server's `report-excluded-changelog-attributes` property. It does not use the `attribute-counts` setting for the property.

Configuring Synchronization with SCIM

PingDataSync provides data synchronization between directory servers or proxy servers and System for Cross-domain Identity Management (SCIM) 1.1 applications over HTTP. Synchronization can be done with custom SCIM applications, or with the PingData PingDirectory server and PingDirectoryProxy server configured as SCIM servers using the SCIM extension.

Synchronize with a SCIM sync destination overview

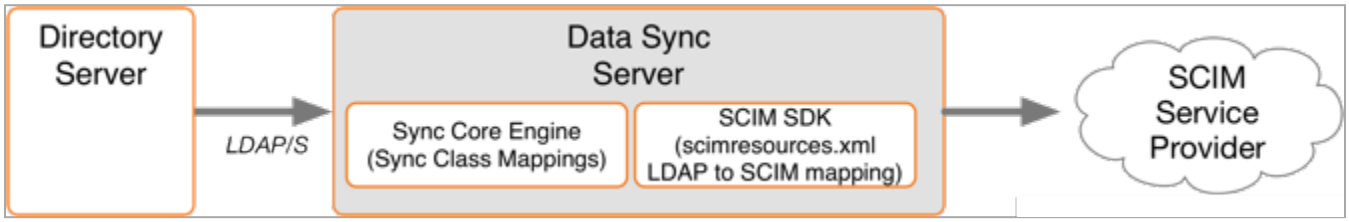
The System for Cross-domain Identity Management (SCIM) 1.1 protocol is designed to make managing user identity in cloud-based applications and services easier. SCIM enables provisioning identities, groups, and passwords to, from, and between clouds. PingDataSync can be configured to synchronize with SCIM service providers.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Both the Ping Identity PingDirectory server and PingDirectoryProxy server can be configured to be SCIM servers using the SCIM HTTP Servlet Extension.

PingDataSync is LDAP-centric and operates on Lightweight Directory Access Protocol (LDAP) attributes. The SCIM sync destination server component acts as a translation layer between a SCIM service provider's schema and an LDAP representation of the entries. While PingDataSync is LDAP-centric and typically at least one endpoint is an LDAP Directory server, this is not a strict requirement. For example, a Java database connectivity (JDBC) to SCIM sync pipe can be configured.

PingDataSync contains sync classes that define how source and destination entries are correlated. The SCIM sync destination contains its own mapping layer, based on `scimresources.xml` that maps LDAP schema to and from SCIM.



> **Note**
>
> PingDataSync can use SCIM only as a sync destination. There is no mechanism in the SCIM protocol for detecting changes, so it cannot be used as a Sync Source.

SCIM destination configuration objects

The `SCIMSyncDestination` object defines a System for Cross-domain Identity Management (SCIM) 1.1 service provider Sync Pipe destination that is accessible over HTTP through the SCIM protocol. It is configured with the following properties:

- `server` – Specifies the names of the SCIM External Servers that are used as the destination of synchronization.
- `resource-mapping-file` – Specifies the path to the `scim-resources.xml` file, a configuration file that defines the SCIM schema and maps it to the Lightweight Directory Access Protocol (LDAP) schema. This file is located in `<server root>/config/scim-resources.xml` by default. This file can be customized to define and expose deployment-specific resources.
- `rename-policy` – Specifies how to handle the rename of a SCIM resource.

The SCIM Sync Destination object is based on the SCIM SDK. Before configuring a SCIM destination, review the following documents on the Simple Cloud web site:

- SCIM Core Schema
- SCIM REST API

Considerations for synchronizing to a SCIM destination

When configuring an Lightweight Directory Access Protocol (LDAP) to System for Cross-domain Identity Management (SCIM) Sync Pipe, consider the following:

Copyright © 2025 Ping Identity Corporation

Use `scim-resources.xml` for attribute and DN mappings

There are two layers of mapping: once at the Sync Class level and again at the SCIM Sync Destination level in the `scim-resources.xml` file. To reduce complexity, do all possible mappings in the `scim-resources.xml` file.

Avoid groups unless the SCIM ID is DN based

Group synchronization is supported if the SCIM ID is based on the distinguished name (DN). If the SCIM ID is not the DN itself, it must be one of the components of the RDN, meaning that the DNs of group members must contain the necessary attribute.

SCIM modifies entries using PUT

The SCIM Sync Destination modifies entries using the full HTTP PUT method. For every modify, SCIM replaces the entire resource with the updated resource. For information about the implications of this on password updates, see Password considerations with SCIM.

Rename a SCIM resource

The System for Cross-domain Identity Management (SCIM) 1.1 protocol does not support changes that require the SCIM resource to be renamed, such as a MODDN operation. Instead, when a change is detected to an attribute value that is used as part of the SCIM ID attribute, PingDataSync handles it in one of the following ways:

- Deletes the specified SCIM resource and then adds the new resource with the new SCIM ID.
- Adds the new resource with the new SCIM ID and then deletes the old resource.
- Skips the rename portion of the change. If renames are expected on the source endpoint, a careful set of destination-correlation attributes should be chosen so that the destination can still be found after it is renamed on the source.

Configure this by setting the `rename-policy` property of the SCIM sync destination.

Password considerations with SCIM

Because the System for Cross-domain Identity Management (SCIM) sync destination modifies entries using a full PUT method, special considerations need to be made for password attributes.

A Ping Identity SCIM server allows password attributes to be omitted from a change when they have not been modified by an operation. This prevents passwords from inadvertently being overwritten during the PUT operation, which does not include the password attribute. Ideally, other SCIM service providers will not wipe a password because a PUT request does not contain it. Check with the SCIM vendor to confirm this behavior before starting a SCIM sync pipe.

Configure synchronization with SCIM

Configure synchronization with System for Cross-domain Identity Management (SCIM) using the `create-sync-pipe-config` utility and the `dsconfig` command. Configuring synchronization between an Lightweight Directory Access Protocol (LDAP) server and a SCIM service provider includes the following:

- Configure one external server for every physical endpoint.

Copyright © 2025 Ping Identity Corporation

- Configure the Sync Source server and designate the external servers that correspond to the source server.
- Configure the Sync Destination server and designate the external servers that correspond to the SCIM sync destination.
- Configure the LDAP to SCIM Sync Pipe.
- Configure the Sync Classes. Each Sync Class represents a type of entry that needs to be synchronized. When specifying a Sync Class for synchronization with a SCIM service provider, avoid including attribute and distinguished name (DN) mappings. Instead use the Sync Class to specify the operations to synchronize and which correlation attributes to use.
- Set the evaluation order for the Sync Classes to define the processing precedence for each class.
- Configure the `scim-resources.xml` file. If possible, change the `<resourceIDMapping>` element(s) to use whatever the SCIM Service Provider uses as the SCIM ID.
- Set Up Communication for each External Server. Run `prepare-endpoint-server` once for every LDAP external server that is part of the Sync Source.
- Use `realtime-sync` to start the Sync Pipe.

Configure the external servers

About this task

Perform the following to configure an external server for each host in the deployment:

Steps

1. Configure a PingDirectory server as an external server, which will later be configured as a Sync Source. On PingDataSync, run the following `dsconfig` command:

```
$ bin/dsconfig create-external-server \
  --server-name source-ds \
  --type ping-identity-ds \
  --set server-host-name:ds1.example.com \
  --set server-port:636 \
  --set "bind-dn:cn=Directory Manager" \
  --set password:secret \
  --set connection-security:ssl \
  --set key-manager-provider:Null \
  --set trust-manager-provider:JKS
```

2. Configure the System for Cross-domain Identity Management (SCIM) server as an external server, which will later be configured as a Sync Destination. The `scim-service-url` property specifies the complete URL used to access the SCIM service provider. The user-name property specifies the account used to connect to the SCIM service provider. By default, the value is `cn=Sync User,cn=Root DNs,cn=config`. Some SCIM service providers may not have the user name in distinguished name (DN) format.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-external-server \
  --server-name scim \
  --type scim \
  --set scim-service-url:https://scim1.example.com:8443 \
  --set "user-name:cn=Sync User,cn=Root DNs,cn=config" \
  --set password:secret \
  --set connection-security:ssl \
  --set hostname-verification-method:strict \
  --set trust-manager-provider:JKS
```

Configure the PingDirectory server sync source

About this task

Configure the Sync source for the synchronization network. More than one external server can be configured to act as the Sync source for failover purposes. If the source is a PingDirectory server, also configure the following items:

- Enable the changelog password encryption plugin on any directory server that will receive password modifications. This plugin intercepts password modifications, encrypts the password, and adds an encrypted attribute to the change log entry.
- Configure the `changelog-deleted-entry-include-attribute` property on the changelog backend, so that PingDataSync can record which attributes were removed during a DELETE operation.

Perform the following steps to configure the Sync source:

Steps

1. Run `dsconfig` to configure the external server as the Sync source. Based on the previous example where the PingDirectory server was configured as `source-ds`, run the following command:

   ```
   $ bin/dsconfig create-sync-source --source-name source \
     --type ping-identity \
     --set base-dn:dc=example,dc=com \
     --set server:source-ds \
     --set use-changelog-batch-request:true
   ```

2. Enable the change log password encryption plugin on any server that receives password modifications. The encryption key can be copied from the output, if displayed, or accessed from the `<server-root>/bin/sync-pipe-cfg.txt` file, if the `create-sync-pipe-config` tool was used to create the sync pipe.

   ```
   $ bin/dsconfig set-plugin-prop \
     --plugin-name "Changelog Password Encryption" \
     --set enabled:true \
     --set changelog-password-encryption-key:<key>
   ```

3. On PingDataSync, set the decryption key used to decrypt the user password value in the change log entries. The key allows the user password to be synchronized to other servers that do not use the same password storage scheme.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-global-sync-configuration-prop \
  --set changelog-password-decryption-key:ej5u9e39pq-68
```

4. Configure the `changelog-deleted-entry-include-attribute` property on the changelog backend.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set changelog-deleted-entry-include-attribute:objectClass
```

Configure the SCIM sync destination

Configure the System for Cross-domain Identity Management (SCIM) sync destination to synchronize data with a SCIM service provider. Run the `dsconfig` command:

```
$ bin/dsconfig create-sync-destination \
  --destination-name scim \
  --type scim \
  --set server:scim
```

Configure the sync pipe, sync classes, and evaluation order

About this task

Configure a Sync Pipe for Lightweight Directory Access Protocol (LDAP) to System for Cross-domain Identity Management (SCIM) synchronization, create Sync classes for the Sync Pipe, and set the evaluation order index for the Sync classes.

> **Note**
>
> The Synchronization mode must be set to Standard. Notification Mode cannot be used with SCIM.

Steps

1. Once the source and destination endpoints are configured, configure the Sync Pipe for LDAP to SCIM synchronization. Run the `dsconfig` command to configure an LDAP-to-SCIM Sync Pipe:

```
$ bin/dsconfig create-sync-pipe \
  --pipe-name ldap-to-scim \
  --set sync-source:source \
  --set sync-destination:scim
```

2. The next set of steps define three Sync Classes. The first Sync Class is used to match user entries in the Sync Source. The second class is used to match group entries. The third class is a DEFAULT class that is used to match all other entries.

   Run the `dsconfig` command to create the first Sync Class and set the Sync Pipe Name and Sync Class name:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-sync-class \
  --pipe-name ldap-to-scim \
  --class-name user
```

3. Use `dsconfig` to set the base distinguished name (DN) and filter for this Sync class. The `include-base-dn` property specifies the base DN in the source, which is `ou=people,dc=example,dc=com` by default. This Sync Class is invoked only for changes at the `ou=people` level. The include-filter property specifies an LDAP filter that tells PingDataSync to include `inetOrgPerson` entries as user entries. The `destination-correlation-attributes` specifies LDAP attributes that allow PingDataSync to find the destination resource on the SCIM server. The value of this property will vary. See Identify a SCIM resource at the destination for details.

```
$ bin/dsconfig set-sync-class-prop \
  --pipe-name ldap-to-scim \
  --class-name user \
  --add include-base-dn:ou=people,dc=example,dc=com \
  --add "include-filter:(objectClass=inetOrgPerson)" \
  --set destination-correlation-attributes:externalId
```

4. Create a second Sync class, which is used to match group entries:

```
$ bin/dsconfig create-sync-class \
  --pipe-name ldap-to-scim \
  --class-name group
```

5. For the second Sync class, set the base DN and the filters to match the group entries.

```
$ bin/dsconfig set-sync-class-prop \
  --pipe-name ldap-to-scim \
  --class-name group \
  --add include-base-dn:ou=groups,dc=example,dc=com \
  --add "include-filter:(|(objectClass=groupOfEntries)\
    (objectClass=groupOfNames)(objectClass=groupOfUniqueNames)\
    (objectClass=groupOfURLs))"
```

6. For the third Sync class, create a DEFAULT Sync class that is used to match all other entries. To synchronize changes from only user and group entries, set `synchronize-creates`, `synchronize-modifies`, and `synchronize-delete` to false.

```
$ bin/dsconfig create-sync-class \
  --pipe-name ldap-to-scim \
  --class-name DEFAULT \
  --set evaluation-order-index:99999 \
  --set synchronize-creates:false \
  --set synchronize-modifies:false \
  --set synchronize-deletes:false
```

Copyright © 2025 Ping Identity Corporation

7. After all of the Sync classes needed by the Sync Pipe are configured, set the evaluation order index for each Sync class. Classes with a lower number are evaluated first. Run `dsconfig` to set the evaluation order index for the Sync class. The actual number depends on the deployment.

```
$ bin/dsconfig set-sync-class-prop \
  --pipe-name ldap-to-scim \
  --class-name user \
  --set evaluation-order-index:100
```

Configure communication with the source server

Configure communication between PingDataSync and the Lightweight Directory Access Protocol (LDAP) source servers with the `prepare-endpoint-server` tool. If user accounts do not exist, this tool creates the appropriate user account and its privileges. Also, because the source is an PingDirectory server, this tool enables the changelog.

> **Note**
>
> The **`prepare-endpoint-server`** tool can only be used on LDAP directory servers. For the SCIM server, manually create a sync user entry.
> Run the **`prepare-endpoint-server`** command to setup communication between PingDataSync and the source server(s). The tool will prompt for the bind distinguished name (DN) and password to create the user account and enable the change log.

```
$ bin/prepare-endpoint-server \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --trustAll \
  --syncServerBindDN "cn=Sync User,cn=Root DNs,cn=config" \
  --syncServerBindPassword "password" \
  --baseDN "dc=example,dc=com" \
  --isSource
```

Start the sync pipe

About this task

The `realtime-sync` tool sets a specific starting point for real-time synchronization, so that changes made before the current time are ignored.

Steps

1. Run the `realtime-sync` tool to set the startpoint for the Sync source.

```
$ bin/realtime-sync set-startpoint \
  --end-of-changelog \
  --pipe-name ldap-to-scim
```

Copyright © 2025 Ping Identity Corporation

2. When ready to start synchronization, run the following command:

```
$ bin/realtime-sync start \
  --pipe-name ldap-to-scim \
  --no-prompt
```

Map LDAP schema to SCIM resource schema

The resources configuration file is used to define the System for Cross-domain Identity Management (SCIM) resource schema and its mapping to Lightweight Directory Access Protocol (LDAP) schema. The default configuration of the `scim-resources.xml` file provides definitions for standard SCIM Users and Groups resources, and mappings to standard LDAP `inetOrgPerson` and `groupOfUniqueNames` object classes. It is installed with the PingDirectory server. This file can be customized by adding extension attributes to the Users and Groups resources, or by adding new extension resources. The resources file is composed of a single `<resources>` element, containing one or more `<resource>` elements.

The default configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. In all cases, this must be changed to match the attribute that the destination SCIM service provider is using for its SCIM resource ID. For example, if the destination uses the value of the `uid` attribute, modify the `scim-resources.xml` file to change the `resourceIDMapping` as follows:

```
<resourceIDMapping ldapAttribute="uid"/>
```

Ideally, this would be an attribute that exists on the source LDAP entry. If not, PingDataSync can construct it using a Constructed Attribute Mapping. For example, the SCIM service provider used the first and last initials of the user, concatenated with the employee ID (given by the `eid` attribute)as the SCIM resource ID. In this case, an attribute mapping would be constructed as follows:

```
$ dsconfig create-attribute-mapping \
  --map-name MyAttrMap \
  --mapping-name scimID \
  --type constructed \
  --set 'value-pattern:{givenname:/^(.)(.*)/$1/s}{sn:/^(.)(.*)/$1/s}{eid}'
```

This creates an attribute called `scimID` on the mapped entry when processed by the Sync engine. For example, if the user's name was John Smith, with employee ID 12345, then the `scimID` would be `js12345`. Once this is done, configure the `scim-resources.xml` file as follows:

```
<resourceIDMapping ldapAttribute="scimID" />
```

This will cause it to pull out the constructed `scimID` value from the entry and use that at the SCIM resource ID when making requests to the service provider.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Constructed attribute mappings support multivalued source attributes for conditional (using the `conditional-value-pattern` property) and non-conditional (using the `value-pattern` property) value patterns. Only one of the source attributes that contribute to a given value pattern can be multivalued.

For any given SCIM resource endpoint, only one `<LDAPAdd>` template can be defined, and only one `<LDAPSearch>` element can be referenced. If entries of the same object class can be located under different subtrees or base distinguished name (DN)s of the PingDirectory server, then a distinct SCIM resource must be defined for each unique entry location in the Directory Information Tree. If using the SCIM HTTP Servlet Extension for the PingDirectory server, this can be implemented in many ways, such as:

- Create multiple SCIM servlets, each with a unique `resources.xml` configuration, and each running under a unique HTTP connection handler.
- Create multiple SCIM servlets, each with a unique `resources.xml` configuration, each running under a single, shared HTTP connection handler, but each with a unique context path.

LDAP attributes are allowed to contain characters that are invalid in XML (because not all valid UTF-8 characters are valid XML characters). Make sure that any attributes that contain binary data are declared using `dataType=binary` in the `scim-resources.xml` file. When using the Identity Access API, make sure that the underlying LDAP schema uses the Binary or Octet String attribute syntax for attributes that contain binary data. This instructs the server to base64-encode the data before returning it to clients.

If attributes that are not declared as binary in the schema and contain binary data (or just data that is invalid in XML), the server will check for this before returning them to the client. If the client has set the content-type to XML, then the server can choose to base64-encode any values that include invalid XML characters. When this is done, a special attribute is added to the XML element to alert the client that the value is base64-encoded. For example:

```
<scim:value base64Encoded="true">AAABPB0EBZc=</scim:value>
```

The remainder of this section describes the mapping elements available in the `scimresources.xml` file.

<resource> element

A `resource` element has the following XML attributes:

- `schema`: a required attribute specifying the System for Cross-domain Identity Management (SCIM) schema URN for the resource. Standard SCIM resources already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom resources using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the resource used to access it through the SCIM REST API.
- `mapping`: a custom Java class that provides the logic for the resource mapper. This class must extend the `com.unboundid.scim.ldap.ResourceMapper` class.

A `resource` element contains the following XML elements in sequence:

- `description`: a required element describing the resource.
- `endpoint`: a required element specifying the endpoint to access the resource using the SCIM REST API.

Copyright © 2025 Ping Identity Corporation

- `LDAPSearchRef`: a mandatory element that points to an `LDAPSearch` element. The `LDAPSearch` element allows a SCIM query for the resource to be handled by an Lightweight Directory Access Protocol (LDAP) service and also specifies how the SCIM resource ID is mapped to the LDAP server.
- `LDAPAdd`: an optional element specifying information to allow a new SCIM resource to be added through an LDAP service. If the element is not provided then new resources cannot be created through the SCIM service.
- `attribute`: one or more elements specifying the SCIM attributes for the resource.

<attribute> element

An `attribute` element has the following XML attributes:

- `schema`: a required attribute specifying the schema URN for the System for Cross-domain Identity Management (SCIM) attribute. If omitted, the schema URN is assumed to be the same as that of the enclosing resource, so this only needs to be provided for SCIM extension attributes. Standard SCIM attributes already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom SCIM attributes using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the SCIM attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- `required`: an optional attribute indicating whether the SCIM attribute is required to be present in the resource. The default value is `false`.

An `attribute` element contains the following XML elements in sequence:

- `description`: a required element describing the attribute. Then just one of the following elements:
- `simple`: specifies a simple, singular SCIM attribute.
- `complex`: specifies a complex, singular SCIM attribute.
- `simpleMultiValued`: specifies a simple, multi-valued SCIM attribute.
- `complexMultiValued`: specifies a complex, multi-valued SCIM attribute.

<simple> element

A `simple` element has the following XML attributes:

- `dataType`: a required attribute specifying the simple data type for the System for Cross-domain Identity Management (SCIM) attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `decimal`, `integer`, and `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case- ignore match. The default value is `false`.

Copyright © 2025 Ping Identity Corporation

A `simple` element contains the following XML element in sequence:

- `mapping`: an optional element specifying a mapping between the SCIM attribute and an Lightweight Directory Access Protocol (LDAP) attribute. If this element is omitted, the SCIM attribute has no mapping and the SCIM service ignores any values provided for the SCIM attribute.

<complex> element

The `complex` element does not have any XML attributes. It contains the following XML element:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex System for Cross-domain Identity Management (SCIM) attribute, and an optional mapping to Lightweight Directory Access Protocol (LDAP). The standard type, primary, and display sub-attributes do not need to be specified.

<simpleMultiValued> element

A `simpleMultiValued` element has the following XML attributes:

- `childName`: a required attribute specifying the name of the tag that is used to encode values of the System for Cross-domain Identity Management (SCIM) attribute in XML in the REST API protocol. For example, the tag for the standard emails SCIM attribute is email.
- `dataType`: a required attribute specifying the simple data type for the plural SCIM attribute (i.e. the data type for the value sub-attribute). The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, and `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case- ignore match. The default value is `false`.

A `simpleMultiValued` element contains the following XML elements in sequence:

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to Lightweight Directory Access Protocol (LDAP).
- `mapping`: an optional element specifying a default mapping between the SCIM attribute and an LDAP attribute.

<complexMultiValued> element

A `complexMultiValued` element has the following XML attributes:

- `tag`: a required attribute specifying the name of the tag that is used to encode values of the System for Cross-domain Identity Management (SCIM) attribute in XML in the REST API protocol. For example, the tag for the standard `addresses` SCIM attribute is `address`.

A `complexMultiValued` element contains the following XML elements in sequence:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

`canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to Lightweight Directory Access Protocol (LDAP).

Copyright © 2025 Ping Identity Corporation

<subAttribute> element

A `subAttribute` element has the following XML attributes:

- `name` : a required element specifying the name of the sub-attribute.
- `readOnly` : an optional attribute indicating whether the System for Cross-domain Identity Management (SCIM) sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false` .
- `required` : an optional attribute indicating whether the SCIM sub-attribute is required to be present in the SCIM attribute. The default value is `false` .
- `dataType` : a required attribute specifying the simple data type for the SCIM sub-attribute. The following values are permitted: `binary` , `boolean` , `dateTime` , `integer` , and `string` .
- caseExact:an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case- ignore match. The default value is `false` .

A `subAttribute` element contains the following XML elements in sequence:

- `description` : a required element describing the sub-attribute.
- `mapping` : an optional element specifying a mapping between the SCIM sub-attribute and an Lightweight Directory Access Protocol (LDAP) attribute. This element is not applicable within the `complexMultiValued` element.

<canonicalValue> element

A `canonicalValue` element has the following XML attributes:

- `name` : specifies the value of the type sub-attribute. For example, work is the value for emails, phone numbers and addresses intended for business purposes.

A `canonicalValue` element contains the following XML element in sequence:

- `subMapping` : an optional element specifying mappings for one or more of the sub-attributes. Any sub-attributes that have no mappings will be ignored by the mapping service.

<mapping> element

A `mapping` element has the following XML attributes:

- `ldapAttribute` : a required element specifying the name of the Lightweight Directory Access Protocol (LDAP) attribute to which the System for Cross-domain Identity Management (SCIM) attribute or sub-attribute map.
- `transform` : an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP, and LDAP to SCIM. The available transformations are described in Map LDAP schema to SCIM resource schema.

Copyright © 2025 Ping Identity Corporation

<subMapping> element

A `subMapping` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute that is mapped.
- `ldapAttribute`: a required element specifying the name of the Lightweight Directory Access Protocol (LDAP) attribute to which the System for Cross-domain Identity Management (SCIM) sub-attribute maps.
- `transform`: an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described later. Available transformations are described in Map LDAP schema to SCIM resource schema.

<LDAPSearch> element

A `LDAPSearch` element has the following XML attributes:

- `baseDN`: a required element specifying the Lightweight Directory Access Protocol (LDAP) search base distinguished name (DN) to be used when querying for the System for Cross-domain Identity Management (SCIM) resource.
- `filter`: a required element specifying an LDAP filter that matches entries representing the SCIM resource. This filter is typically an equality filter on the LDAP object class.
- `resourceIDMapping`: an optional element specifying a mapping from the SCIM resource ID to an LDAP attribute. When the element is omitted, the resource ID maps to the LDAP entry DN.

> **Note**
>
> The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them with an `ID` attribute.

<resourceIDMapping> element

A `resourceIDMapping` element has the following XML attributes:

- `ldapAttribute`: a required element specifying the name of the Lightweight Directory Access Protocol (LDAP) attribute to which the System for Cross-domain Identity Management (SCIM) resource ID maps.
- `createdBy`: a required element specifying the source of the resource ID value when a new resource is created by the SCIM consumer using a POST operation. Allowable values for this element include `<scim-consumer>`, meaning that a value must be present in the initial resource content provided by the SCIM consumer, or directory, (as would be the case if the mapped LDAP attribute is `entryUUID`).

If the LDAP attribute value is not listed as destination correlation attribute, this setting is not used by PingDataSync.

The following example illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

Copyright © 2025 Ping Identity Corporation

```
<LDAPSearch id="userSearchParams">
  <baseDN>ou=people,dc=example,dc=com</baseDN>
  <filter>(objectClass=inetOrgPerson)</filter>
  <resourceIDMapping ldapAttribute="entryUUID" createdBy="directory"/>
</LDAPSearch>
```

<LDAPAdd> element

A `LDAPAdd` element has the following XML attributes:

- `DNTemplate`: a required element specifying a template that is used to construct the distinguished name (DN) of an entry representing a System for Cross-domain Identity Management (SCIM) resource when it is created. The template may reference values of the entry after it has been mapped using `{ldapAttr}`, where `ldapAttr` is the name of an Lightweight Directory Access Protocol (LDAP) attribute.
- `fixedAttribute`: zero or more elements specifying fixed LDAP values to be inserted into the entry after it has been mapped from the SCIM resource.

<fixedAttribute> element

A `fixedAttribute` element has the following XML attributes:

- `ldapAttribute`: a required attribute specifying the name of the Lightweight Directory Access Protocol (LDAP) attribute for the fixed values.
- `onConflict`: an optional attribute specifying the behavior when the LDAP entry already contains the specified LDAP attribute. The default value `merge` indicates that the fixed values should be merged with the existing values. The value `overwrite` indicates that the existing values are to be overwritten by the fixed values. The value `preserve` indicates that no changes should be made.

A `fixedAttribute` element contains the following XML element:

- `fixedValue`: one or more elements specifying the fixed LDAP values.

Identify a SCIM resource at the destination

When a System for Cross-domain Identity Management (SCIM) Sync Destination needs to synchronize a change to a SCIM resource on the destination SCIM server, it must first fetch the destination resource. If the destination resource ID is known, the resource will be retrieved by its ID. If not, a search is performed using the mapped destination correlation attributes. Configuring this requires coordination between the Sync Class and the `scim-resources.xml` mapping file.

The `scim-resources.xml` mapping file treats the value of the `<resourceIDMapping>` element's `ldapAttribute` attribute as the SCIM ID of the source entry. If this value is also listed as a value of the Sync Class's `destination-correlation-attributes` property, then the value of this Lightweight Directory Access Protocol (LDAP) attribute is used as the SCIM ID of the destination resource.

Copyright © 2025 Ping Identity Corporation

If no value of `destination-correlation-attributes` matches the `<resourceIDMapping>` element's `ldapAttribute` attribute, the SCIM ID of the destination resource is considered unknown. In this case, the SCIM Sync Destination treats the values of `destination- correlation-attributes` as search terms, using them to construct a filter for finding the destination resource. Each value of `destination-correlation-attributes` will be mapped to a corresponding SCIM attribute name, and equality matches will be used in the resulting filter.

If the `ldapAttribute` value is not listed as a destination correlation attribute, this setting is not used by PingDataSync.

The following table illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

Identifying a SCIM resource

Method for retrieving SCIM resource	Condition	Example condition	Example request
Retrieve resource directly	Used if a `destination-correlation-attribute` value matches the `<resourceIDMapping>ldapAttribute` value.	`destination-correlation-attribute=mail,uid;<resourceIDMapping ldapAttribute="mail" createdBy= "directory"/>`	`GET scim/Users/ person@example.com`
Retrieve resource using search	Used if no `destination-correlation-attribute` value matches the `<resourceIDMapping>ldapAttribute` value.	`destination-correlation-attribute=mail,uid;<resourceIDMapping ldapAttribute="entryUUID" createdBy = "directory"/>`	`GET /scim/Users? filter=emails+eq+"person@example.com" and+userName+eq"person"`

The unique ID of a destination SCIM resource will most likely be unknown, and the search method will need to be used. However, not all SCIM service providers support the use of filters. Therefore, not all SCIM service providers may be usable as SCIM Sync Destinations.

Configuring synchronization to a SCIM 2.0 server

The PingDataSync server now supports System for Cross-domain Identity Management (SCIM) 2.0 servers as a sync destination, which means that it is possible to push changes (including creates, modifies, and deletes) read from another source to a server using the SCIM 2.0 protocol described in RFC 7644.

> **Note**
>
> It is currently not possible to use a SCIM 2.0 server as a source, enabling changes made in that server to synchronize to other types of destinations.

Copyright © 2025 Ping Identity Corporation

The `create-sync-pipe-config` tool does not provide support for creating a sync pipe with a SCIM 2.0 sync destination, so you will need to create the necessary configuration manually using a tool like `dsconfig` or the administrative console. This involves the following steps:

1. Creating a sync source to allow the PingDataSync server to pull the changes to be synchronized. See Configure the sync source.
2. Optionally configuring a changelog password decryption key in the PingDataSync server if the source is a PingDirectory server instance. See Configure the changelog password decryption key in the PingDataSync server (optional).
3. Configuring a SCIM 2.0 external server with the details necessary to connect and authenticate to the destination server. See Configure the SCIM 2.0 external server.
4. Configuring a set of SCIM 2.0 attribute mappings to describe how the PingDataSync server should map attributes from the internal LDAP representation of entries obtained from the sync source into a form that can be sent to the SCIM 2.0 server. See Configure SCIM 2.0 attribute mappings.
5. Configuring one or more SCIM 2.0 endpoint mappings to provide information about the endpoints to which changes will be synchronized in the SCIM 2.0 server, including the attribute mappings for attributes associated with each endpoint. See Configure SCIM 2.0 endpoint mappings.
6. Configuring a SCIM 2.0 sync destination, which references the SCIM 2.0 external server and endpoint mappings created in earlier steps, and provides additional configuration options. See Configure the SCIM 2.0 sync destination.
7. Configuring a sync pipe to associate the appropriate sync source with the SCIM 2.0 sync destination. See Configure a sync pipe.
8. Configuring one or more sync classes for that sync pipe to indicate how the PingDataSync server should treat various types of entries read from the source when pushing changes to the destination. See Configure sync classes.
9. Optionally using the `realtime-sync set-startpoint` command to set the startpoint at the end of the changelog if the source is a PingDirectory server instance. See Set the changelog startpoint for the sync source (optional).
10. Using the `resync` tool to perform an initial bulk synchronization of the content in the sync source into the SCIM 2.0 sync destination. See Perform an initial bulk synchronization with the `resync` tool.
11. Using the `realtime-sync start` command to start synchronizing changes from the source into the SCIM 2.0 sync destination. See Start real-time synchronization.

Configure the sync source

The sync source describes the service from which entries and changes are read so that they can be synchronized to the sync destination.

The process for configuring a sync source varies based on the type of service that you use, such as, an LDAP server or a relational database, so you should consult the appropriate documentation for the specific type of sync source that you want to use.

Copyright © 2025 Ping Identity Corporation

Currently, the `create-sync-pipe-config` tool does not offer support for the System for Cross-domain Identity Management (SCIM) 2.0 sync destination, so you might need to configure the sync source manually with a tool like `dsconfig` or the administration console. However, if you plan to synchronize from the desired source to another type of destination, and if that destination is one that is supported by the `create-sync-pipe-config` tool, then you can reuse the sync source created for that pipe.

If the sync source server is a PingDirectory server, then you can use the `prepare-endpoint-server` tool to make necessary changes to allow the PingDataSync server to interact with that directory server instance. This includes creating the account that the PingDataSync server uses to authenticate to the PingDirectory server and enabling the changelog to allow the PingDataSync server to retrieve information about changes processed in the PingDirectory server.

Running `prepare-endpoint-server --help` shows you the complete usage for the tool, but the following example demonstrates a sample usage:

```
bin/prepare-endpoint-server \
     --hostname ds-source.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore \
     --syncServerBindDN "cn=Sync User,cn=Root DNs,cn=config" \
     --syncServerBindPasswordFile sync-user-password.txt \
     --baseDN dc=example,dc=com \
     --isSource
```

In addition, if the source server is a PingDirectory server instance, then you should enable the Changelog Password Encryption plugin in that server to indicate that it should store an encrypted representation of clear-text passwords in the changelog along with their encoded form. See Configuring password encryption.

Doing this allows the PingDataSync server to retrieve those clear-text passwords so that they can be synchronized to the SCIM 2.0 sync destination. You can do this with a change like the following:

```
dsconfig set-plugin-prop \
     --plugin-name "Changelog Password Encryption" \
     --set enabled:true \
     --set changelog-password-encryption-key:<this-is-the-key-you-want-to-use>
```

Configure the changelog password decryption key in the PingDataSync server (optional)

If the sync source is a PingDirectory server instance that has the Changelog Password Encryption plugin enabled, then you need to configure the PingDataSync server with the same key so that it can decrypt those passwords.

You can do this with a change like the following:

```
dsconfig set-global-sync-configuration-prop \
     --set changelog-password-decryption-key:<this-is-the-key-you-want-to-use>
```

Copyright © 2025 Ping Identity Corporation

Configure the SCIM 2.0 external server

The System for Cross-domain Identity Management (SCIM) 2.0 external server configuration object provides the information that the PingDataSync server needs to connect and authenticate to the SCIM 2.0 service.

First, you must create an HTTP authentication method that allows the PingDataSync server to authenticate to the SCIM 2.0 server to authorize requests. In most cases, this authentication is an OAuth 2.0 bearer token, and you will likely want to obtain that token using the client credentials grant type. This allows you to provide a client ID and client secret to the OAuth authorization server to obtain a bearer token.

In this case, the client secret is sensitive information, so the PingDataSync server uses a passphrase provider to access it, which allows it to be obtained from a variety of sources, like an optionally encrypted file, Amazon Secrets Manager, Azure Key Vault, a CyberArk Conjur instance, or a HashiCorp Vault instance. For example:

```
dsconfig create-passphrase-provider \
     --provider-name "SCIMv2 Client Secret" \
     --type file-based \
     --set enabled:true \
     --set password-file:config/scimv2-client-secret.txt

dsconfig create-http-authorization-method \
     --method-name "SCIMv2 Authorization Method" \
     --type client-credentials-bearer-token \
     --set enabled:true \
     --set oauth-server-token-endpoint-url:https://oauth.example.com/as/token \
     --set hostname-verification-method:strict \
     --set oauth-client-id:this-is-the-client-id \
     --set "oauth-client-secret-passphrase-provider:SCIMv2 Client Secret" \
     --set request-method:get \
     --set credentials-submission-method:basic-authorization \
     --set "maximum-token-lifetime:1 h"
```

The SCIM 2.0 external server configuration offers the following properties:

`scim-service-url`

The base URL to the SCIM 2.0 service to be used. This should not include any endpoint name because that will be appended through the endpoint mapping. This is required.

`key-manager-provider`

A key manager provider to use during SSL negotiation with the SCIM 2.0 server. This is optional, and it will likely only be used if the PingDataSync server needs to supply a client certificate to the SCIM 2.0 server.

`ssl-cert-nickname`

The nickname (alias) of the client certificate to present to the SCIM 2.0 server. This is only needed if a `key-manager-provider` is specified and only if the associated key store has multiple certificates that could be used.

Copyright © 2025 Ping Identity Corporation

`trust-manager-provider`

A trust manager provider to use to determine whether to trust the certificate chain presented by the SCIM 2.0 server during Secure Sockets Layer (SSL) negotiation. This is optional, and if you don't specify it, then the PingDataSync server will rely primarily on the Java Virtual Machine (JVM)'s default set of trusted issuers. If the SCIM 2.0 server is using a certificate signed by one of those trusted issuers, then you can leave this property unset.

`hostname-verification-method`
