

PingDirectory

Contents

PingDirectory.....	20
Release Notes.....	21
PingDirectory suite of products 9.0.0.6 (August 2023).....	21
PingDirectory suite of products 9.0.0.5 (April 2023).....	21
PingDirectory suite of products 9.0.0.4 (January 2023).....	22
PingDirectory suite of products 9.0.0.2 (July 2022).....	22
PingDirectory suite of products 9.0.0.1 (March 2022).....	23
PingDirectory suite of products 9.0.0.0 (December 2021).....	23
Previous Releases.....	30
PingDirectory Server Administration Guide.....	30
Introduction to PingDirectory Server.....	30
Server features.....	30
Administration framework.....	32
Server tools location.....	33
Installing the PingDirectory Server.....	33
Prepare your environment.....	33
Getting the installation packages.....	42
Deploying the administrative console.....	43
Signing on to the Administrative Console.....	45
Configuring the administrative console.....	46
Directory Server folder layout.....	50
make-ldif template format.....	51
Server installation modes.....	63
Before you begin.....	63
Ping license keys.....	64
Setting up the PingDirectory server in interactive mode.....	65
Installing the Directory Server in non-interactive mode.....	68
Installing a lightweight server.....	69
Uninstalling the Server.....	70
Uninstalling the server in interactive mode.....	71
Uninstalling the server in non-interactive mode.....	71
Uninstalling selected components in non-interactive mode.....	72
Upgrading the Server.....	72
Upgrade overview and considerations.....	72
Upgrading servers in a topology.....	75
Upgrading the Directory Server.....	78
Reverting an update.....	78
Getting Started with Directory Server.....	79
Multiple backends.....	80
Importing data.....	81
Running the server.....	82
Stopping the Directory Server.....	85
Scheduling a server shutdown.....	85
Restarting the server.....	85
Running the server as a Microsoft Windows service.....	86

Running the status tool.....	87
Tuning the Server.....	88
About minimizing disk access.....	88
Memory allocation and database cache.....	89
Database preloading.....	93
Databases on storage area networks, network-attached storage, or running in virtualized environments.....	95
Database cleaner.....	96
Compacting common parent DNs.....	96
Setting the import thread count.....	97
JVM properties for server and command-line tools.....	97
Tuning for disk-bound deployments.....	98
Uncached attributes and entries.....	99
JVM garbage collection using CMS.....	102
Configuring the Server.....	105
About the configuration tools.....	105
About the dsconfig configuration tool.....	105
Using dsconfig in interactive command-line mode.....	105
Using dsconfig in non-interactive mode.....	109
Getting the equivalent dsconfig non-interactive mode command.....	111
Using dsconfig batch mode.....	111
Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth tokens.....	113
About recurring tasks and task chains.....	114
Using exec tasks.....	117
Topology configuration.....	118
Servers and certificates.....	120
Using the Configuration API.....	169
Working with the Directory REST API.....	183
Configuring the Server using the Administrative Console.....	185
Generating a summary of configuration components.....	188
Administrator account classes.....	188
Using separate administrator accounts.....	189
Unpredictable identifiers for server administrators.....	191
Secure communication for server administrators.....	191
Managing root user accounts.....	191
Default root privileges.....	192
Configuring administrator accounts.....	194
Configuring a global administrator.....	198
Configuring server groups.....	199
Client connection policy configuration.....	201
Securing the Server with lockdown mode.....	213
Configuring maximum shutdown time.....	214
About working with referrals.....	214
Configuring a read-only server.....	217
Configuring HTTP access for the Directory Server.....	218
DNS caching.....	230
IP address reverse name lookups.....	231
Configuring traffic through a load balancer.....	231
Working with the Referential Integrity plugin.....	233
Working with the Unique Attribute plugin.....	233
Working with the Purge Expired Data plugin.....	235
Configuring uniqueness across attribute sets.....	237
Working with the Last Access Time plugin.....	241
Working with pass-through authentication.....	241
Troubleshooting server performance issues.....	250

Configuring the Directory Server for Oracle compatibility.....	254
Supporting unindexed search requests.....	255
Syncing passwords to PingOne.....	255
Single sign-on with the PingDirectory Server administrative console.....	256
Configuring Soft Deletes.....	265
About soft deletes.....	266
General tips on soft deletes.....	266
Configuring soft deletes on the Server.....	268
Searching for soft deletes.....	271
Undeleting a soft-deleted entry using the same RDN.....	273
Undeleting a soft-deleted entry using a new RDN.....	274
Modifying a soft-deleted entry.....	275
Hard deleting a soft-deleted entry.....	276
Configuring soft deletes by connection criteria.....	277
Configuring soft deletes by request criteria.....	278
Configuring soft-delete automatic purging.....	279
Soft and hard delete processes.....	280
Soft delete controls and tool options.....	282
Monitoring soft deletes.....	283
Disabling soft deletes as a global configuration.....	287
Importing and exporting data.....	288
Importing data.....	288
Running an offline import.....	289
Running an online LDIF import.....	291
Adding entries to an existing Directory Server.....	293
Filtering data import.....	293
Exporting data.....	294
Encrypting LDIF exports and signing LDIF files.....	295
Filtering data exports.....	297
Scrambling data files.....	298
Backing Up and Restoring Data.....	299
About backing up and restoring data.....	299
Retaining backups.....	300
Moving or restoring a user database.....	306
Comparing the data in two Directory Servers.....	307
Reverting or replaying changes.....	310
Working with Groups.....	312
Overview of groups.....	312
About the isMemberOf and isDirectMemberOf virtual attribute.....	313
Using static groups.....	315
Using dynamic groups.....	321
Using virtual static groups.....	326
Creating nested groups.....	330
Maintaining referential integrity with static groups.....	332
Monitoring the group membership cache.....	334
Using the entry cache to improve the performance of large static groups.....	334
Tuning the index entry limit for large groups.....	336
Summary of commands to search for group membership.....	337
Migrating Oracle groups.....	338
Working with Indexes.....	341
Overview of indexes.....	341
General tips on indexes.....	341
Index types.....	343
System indexes.....	344
Managing local DB indexes.....	345
Composite indexes.....	348

JSON indexes.....	350
Working with local DB VLV indexes.....	351
Working with filtered indexes.....	354
Tuning indexes.....	355
Managing Entries.....	360
Searching entries.....	360
Working with the matching entry count control.....	366
Adding entries.....	367
Deleting entries using ldapdelete.....	371
Deleting entries using ldapmodify.....	371
Modifying entries using ldapmodify.....	372
Working with the parallel-update tool.....	378
Working with the watch-entry Tool.....	380
Working with LDAP transactions.....	380
Working with Virtual Attributes.....	382
Viewing the list of default virtual attributes.....	382
Viewing the list of default virtual attributes using dsconfig non-interactive mode.....	384
Viewing virtual attribute properties.....	384
Enabling a virtual attribute.....	385
Creating user-defined virtual attributes.....	386
Creating mirror virtual attributes.....	389
Editing a virtual attribute.....	390
Deleting a virtual attribute.....	391
Working with Composed Attributes.....	391
Virtual attribute limitations.....	391
Overview of composed attributes.....	392
Composed attribute plugin configuration properties.....	393
Populate composed attribute values task.....	400
Composed attribute dependency considerations.....	401
Schema validation considerations.....	401
Replication considerations.....	402
Synchronization Server considerations.....	402
Directory Proxy Server considerations.....	403
Troubleshooting considerations.....	403
Security considerations.....	403
Limitations of composed attributes relative to virtual attributes.....	403
Encrypting Sensitive Data.....	404
About encrypting and protecting sensitive data.....	404
About backing up and restoring the encryption-settings definitions.....	412
Configuring sensitive attributes.....	418
Configuring global sensitive attributes.....	422
Excluding a global sensitive attribute on a client connection policy.....	422
Working with the LDAP Changelog.....	423
Overview of the LDAP changelog.....	424
Viewing the LDAP changelog properties.....	429
Enabling the LDAP changelog.....	429
Changing the LDAP changelog database location.....	430
Viewing the LDAP changelog parameters in the Root DSE.....	432
Viewing the LDAP changelog using ldapsearch.....	433
Indexing the LDAP changelog.....	435
Tracking virtual attribute changes in the LDAP changelog.....	436
Managing Access Control.....	437
Overview of access control.....	437
Access token validators.....	449
Working with targets.....	456
Examples of common access control rules.....	461

Validating ACIs before migrating data.....	463
Migrating ACIs from Oracle to the Server.....	465
Working with privileges.....	468
Working with proxied authorization.....	473
Working with parameterized ACIs.....	482
\$attr.attrName macro.....	483
Managing the Schema.....	483
About the schema.....	483
About the Schema Editor.....	483
Default Directory Server schema files.....	484
Extending the Directory Server schema.....	485
About managing attribute types.....	487
Creating a new attribute over LDAP.....	492
Managing object classes.....	493
Managing an object class over LDAP.....	497
Creating a new object class using the Schema Editor.....	499
Extending the schema using a custom schema file.....	499
About managing matching rules.....	502
About managing attribute syntaxes.....	510
Using the Schema Editor utilities.....	516
Modifying a schema definition.....	516
Deleting a schema definition.....	517
Managing schema checking.....	517
Managing matching rule uses.....	519
Managing DIT content rules.....	520
Managing name forms.....	521
Managing DIT structure rules.....	522
About managing JSON attribute values.....	523
Configuring JSON attribute constraints.....	524
Managing password policies.....	530
Viewing password policies.....	530
About the password policy properties.....	532
Access log.....	534
Modifying an existing password policy.....	538
Creating new password policies.....	538
Deleting a password policy.....	541
Modifying a user's password.....	541
Enabling YubiKey authentication.....	544
Enabling social sign-on.....	544
Managing user accounts.....	545
Disabling password policy evaluation.....	548
About managing password validators.....	549
Managing Replication.....	556
Overview of replication.....	556
Replication versus synchronization.....	557
Replication terminology.....	558
Replication architecture.....	561
Replication deployment planning.....	562
Enabling replication.....	565
Deploying a basic replication topology.....	568
Example deployment with non-interactive dsreplication.....	573
Configuring assured replication.....	576
Managing the topology.....	584
Advanced configuration.....	587
Modifying the replication purge delay.....	588
Configuring a single listener-address for the replication server.....	589

Monitoring replication.....	590
Replication best practices.....	591
Replication conflicts.....	593
Troubleshooting replication.....	597
Replication reference.....	601
Advanced topics reference.....	625
Managing Logging.....	634
Default Directory Server logs.....	634
Types of log publishers.....	635
Managing access and error log publishers.....	639
Managing file-based access log publishers.....	640
Generating access log summaries.....	644
About log compression.....	646
About log signing.....	646
About encrypting log files.....	647
Creating new log publishers.....	649
Configuring log rotation.....	650
Configuring log rotation listeners.....	651
Configuring log retention.....	652
Configuring filtered logging.....	653
Managing Admin Alert Access Logs.....	654
Managing the Syslog-Based Access Log Publishers.....	655
Managing the File-Based Audit Log Publishers.....	659
Managing the JDBC Access Log Publishers.....	660
Managing the File-Based Error Log Publisher.....	665
Managing the Syslog-Based Error Log Publisher.....	666
Creating File-Based Debug Log Publishers.....	667
Managing Monitoring.....	668
The monitor backend.....	668
Monitoring disk space usage.....	670
Monitoring with the PingDataMetrics Server.....	671
About the collection of system monitoring data.....	671
Monitoring key performance indicators by application.....	672
Configuring the external Servers.....	672
Preparing the servers monitored by the PingDataMetrics Server.....	672
Configuring the Processing Time Histogram plugin.....	673
Setting the connection criteria to collect SLA statistics by application.....	673
Proxy considerations for tracked applications.....	674
Monitoring using SNMP.....	674
SNMP implementation.....	674
Configuring SNMP.....	675
MIBS.....	678
Monitoring with the Administrative Console.....	678
Accessing the Processing Time Histogram.....	679
Monitoring with JMX.....	679
Running JConsole.....	680
Monitoring the Directory Server using JConsole.....	681
Monitoring using the LDAP SDK.....	682
Monitoring over LDAP.....	683
Profiling server performance using the Stats Logger.....	683
Enabling and configuring the StatsD monitoring endpoint.....	685
Adding custom logged statistics to a Periodic Stats Logger.....	687
Updating the Global Configuration.....	689
Monitoring PingDirectory metrics with Splunk.....	690
Sending PingDirectory metrics with StatsD.....	690
Using the Directory Server app for Splunk.....	692

Managing Notifications and Alerts.....	692
Account status notifications.....	692
Administrative alert handlers.....	697
Configuring the JMX connection handler and alert handler.....	697
Configuring the SMTP alert handler.....	698
Configuring the SNMP subagent alert handler.....	699
Email account status notification handler.....	699
Working with the Alerts Backend.....	715
Working with alarms, alerts, and gauges.....	716
Testing alerts and alarms.....	718
Managing SCIM Servlet Extensions.....	721
SCIM 1.1 and 2.0 servlet extensions management.....	721
Managing Server SDK Extensions.....	757
About the Server SDK.....	757
Available types of extensions.....	757
DevOps and infrastructure-as-code.....	758
Limitations when automating PingDirectory Server deployments.....	758
Server profiles.....	758
Topology-management tools.....	764
Deployment automation.....	765
Troubleshooting the PingDirectory Server.....	770
Directory Server gauges.....	771
Working with the collect-support-data tool.....	777
Directory Server Troubleshooting information.....	780
About the monitor entries.....	785
Directory Server troubleshooting tools.....	785
Troubleshooting resources for Java applications.....	788
Command-Line Tools.....	806
Available command-line tools.....	806
Saving options in a file.....	827
Sample dsconfig batch files.....	829
Running task-based tools.....	830

PingDirectoryProxy Server Administration Guide..... 831

Introduction to the PingDirectoryProxy Server.....	831
Overview of the PingDirectoryProxy features.....	831
Overview of the Directory Server components and terminology.....	832
Server component architecture.....	839
Directory Server configuration overview.....	842
Installing the PingDirectoryProxy Server.....	843
Before you begin.....	843
Preparing the operating system.....	846
Getting the installation packages.....	852
Signing on to the Administrative Console.....	853
Ping license keys.....	853
Installing the Directory Proxy Server.....	854
Directory Server folder layout.....	860
Uninstalling the Server.....	861
Uninstalling the server in interactive mode.....	861
Uninstalling the server in non-interactive mode.....	862
Uninstalling selected components in non-interactive mode.....	863
Upgrading the PingDirectoryProxy Server.....	863
Upgrade overview and considerations.....	864
Upgrading servers in a topology.....	864
Upgrading the Directory Proxy Server.....	865

Reverting an update.....	866
Getting Started with Directory Server.....	868
Running the server.....	868
Stopping the Directory Server.....	871
Scheduling a server shutdown.....	871
Restarting the server.....	871
Running the server as a Microsoft Windows service.....	872
Configuring the Directory Proxy Server.....	873
About the configuration tools.....	873
Using the create-initial-proxy-config tool.....	873
Configuring a standard Directory Proxy Server deployment.....	874
About the dsconfig configuration tool.....	877
Using dsconfig in interactive command-line mode.....	877
Changing the dsconfig object menu.....	878
Using dsconfig in non-interactive mode.....	879
Using dsconfig batch mode.....	880
Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth tokens.....	881
Topology configuration.....	883
Using the Configuration API.....	885
Working with the Directory REST API.....	899
Configuring server groups.....	901
Generating a summary of configuration components.....	903
Configuring server groups.....	904
DNS caching.....	906
IP address reverse name lookups.....	906
Configuring traffic through a load balancer using dsconfig	907
Managing root user accounts.....	908
Default root privileges.....	908
Configuring locations.....	910
Configuring batched transactions.....	914
Configuring server health checks.....	915
Configuring LDAP external servers.....	918
Servers and certificates.....	924
Configuring load balancing.....	973
Configuring HTTP connection handlers.....	984
Configuring proxy transformations.....	990
Configuring request processors.....	992
Configuring server affinity.....	994
Configuring subtree views.....	995
Client connection policy configuration.....	996
Configuring globally unique attributes.....	1002
Configuring the Global Referential Integrity plugin.....	1004
Configuring an Active Directory Server back-end.....	1005
Setting up SSO to PingDirectory from PingOne.....	1006
Managing Access Control.....	1010
Overview of access control.....	1010
Access token validators.....	1022
Working with targets.....	1029
Examples of common access control rules.....	1034
Validating ACIs before migrating data.....	1036
Migrating ACIs from Oracle to the Server.....	1038
Working with privileges.....	1042
Deploying a Standard Directory Proxy Server.....	1047
Introduction.....	1047
Automatic server discovery.....	1048

Creating a standard multi-location deployment.....	1060
Expanding the deployment.....	1068
Merging two data sets using proxy transformations.....	1074
Deploying an Entry-Balancing Directory Proxy Server.....	1083
Deploying an entry-balancing proxy configuration.....	1083
Rebalancing your entries.....	1095
Managing the global indexes in entry-balancing configurations.....	1098
Working with alternate authorization identities.....	1105
Managing Entry-Balancing Replication.....	1108
Overview of replication in an entry-balancing environment.....	1108
Replication prerequisites in an entry-balancing deployment.....	1109
About the --restricted argument of the dsreplication command-line Tool.....	1110
Checking the status of replication in an entry-balancing deployment.....	1111
Example of configuring entry-balancing replication.....	1111
Managing the Directory Proxy Server.....	1117
Managing logs.....	1117
Types of log publishers.....	1122
Creating new log publishers.....	1122
About log compression.....	1124
About log signing.....	1124
About encrypting log files.....	1124
Configuring log rotation.....	1127
Configuring log rotation listeners.....	1127
Configuring log retention.....	1128
Setting resource limits.....	1129
Monitoring the Directory Proxy Server.....	1131
Working with alarms, alerts, and gauges.....	1134
Administrative alert handlers.....	1138
Working with virtual attributes.....	1140
Managing Monitoring.....	1141
The monitor backend.....	1141
Monitoring disk space usage.....	1143
Monitoring with the PingDataMetrics Server.....	1144
Monitoring using SNMP.....	1147
Monitoring with the Administrative Console.....	1151
Accessing the Processing Time Histogram.....	1152
Monitoring with JMX.....	1152
Monitoring using the LDAP SDK.....	1155
Monitoring over LDAP.....	1156
Profiling server performance using the Stats Logger.....	1156
Enabling and configuring the StatsD monitoring endpoint.....	1160
DevOps and Infrastructure as Code.....	1162
Server profiles.....	1162
Troubleshooting the PingDirectoryProxy Server.....	1168
Garbage Collection Diagnostic Information.....	1168
Working with the Troubleshooting Tools.....	1169
Directory Server troubleshooting tools.....	1170
Troubleshooting resources for Java applications.....	1175
SCIM 1.1 and 2.0 servlet extensions management.....	1191
Overview of SCIM 1.1 fundamentals.....	1191
Creating your own SCIM 1.1 application.....	1193
Configuring SCIM 1.1.....	1193
Configuring advanced SCIM 1.1 extension features.....	1198
Configuring the Identity Access API.....	1204
Monitoring the SCIM servlet extension.....	1206
Managing the SCIM 2.0 Servlet Extension.....	1209

Managing Server SDK Extensions.....	1224
About the Server SDK.....	1224
Available types of extensions.....	1225
Command-Line Tools.....	1225
Available command-line tools.....	1226
Saving Options in a File.....	1242
Sample dsconfig batch files.....	1244
Running task-based tools.....	1244
Consent Solution Guide.....	1246
Introduction to the Consent Service and Consent API.....	1246
Consent Service overview.....	1246
Consent API overview.....	1247
How consents are collected.....	1247
How consents are enforced.....	1247
How applications use the Consent API.....	1248
Configuring the Consent Service.....	1248
Configuration overview.....	1248
Example configuration scenarios.....	1249
Setting up with the configuration scripts.....	1249
Setting up in a replicated PingDirectory Server environment.....	1250
Configuration reference.....	1251
Authorization.....	1259
Managing Consents.....	1261
Overview of consent management.....	1261
Consent definitions and localizations.....	1261
Perform an audit on consents.....	1262
Logging.....	1267
Correlating user and consent data.....	1268
Troubleshooting the Consent Service.....	1269
Delegated Admin Application Guide.....	1270
Delegated Admin overview.....	1270
Introduction to Delegated Admin.....	1270
Features.....	1270
Installing Delegated Admin.....	1271
Installation locations.....	1271
Prerequisites.....	1272
Supported browsers.....	1272
Obtaining the installation files.....	1272
Before you install.....	1272
Installing the application.....	1273
Next steps.....	1277
Upgrading Delegated Admin.....	1277
Upgrade considerations.....	1277
Upgrade PingDirectory Server.....	1278
Upgrade the application.....	1281
Configuring Delegated Admin.....	1283
Configuration overview.....	1283
Authentication configuration.....	1283
Configuring delegated administrator rights on PingDirectory Server.....	1284
Parameterized Delegated Administrator Rights.....	1287
Configuring user self-service.....	1287
Configuring attributes and attribute search on PingDirectory Server.....	1289

Users and groups.....	1293
Generic resource types.....	1301
Working with correlated REST resources.....	1302
Setting up a DN reference attribute.....	1304
Differentiating resource types within the same subtree.....	1307
Configuring a resource's summary display in the Delegated Admin GUI.....	1307
Customizing UI form fields.....	1308
Setting up email invitations for a new user.....	1310
Enabling the referential integrity plugin.....	1313
Enabling log tracing.....	1313
Specify a custom hostname and port for your Directory Server.....	1314
Changing the application logo.....	1314
Configure the session timeout.....	1315
Verifying the installation.....	1315
Reporting.....	1315
Compatibility matrix.....	1316
Configuring PingFederate Server.....	1316
Configuring PingFederate as the identity provider.....	1317
Configuring the OAuth server.....	1318
Configuring PingDirectory Server as the token validator (create OAuth client for PingDirectory).....	1320
Configuring Delegated Admin as a new client (create OAuth client for Delegated Admin). 1321	
Setting Cross-Origin Resource Sharing (CORS) settings.....	1322
Configuring PingFederate as a new client (create OAuth client for PingFederate).....	1322
Optional configuration tasks.....	1323

PingDataSync Server Administration Guide.....1323

Introduction to the PingDataSync Server.....	1323
Overview of PingDataSync.....	1323
Data synchronization process.....	1324
Synchronization modes.....	1326
PingDataSync operations.....	1326
Configuration components.....	1328
Sync flow examples.....	1329
Sample synchronization.....	1333
Installing the PingDataSync Server.....	1334
System requirements.....	1335
Upgrade overview and considerations.....	1338
Install the JDK.....	1338
Optimize the Linux operating system.....	1338
Ping license keys.....	1341
Installing PingDataSync.....	1342
Signing on to the Administrative Console.....	1343
Server folders and files.....	1344
Start and stop the server.....	1345
Run the server as a Microsoft Windows service.....	1346
Uninstall the server.....	1347
Update servers in a topology.....	1347
Revert an update.....	1349
Install a failover server.....	1350
Administrative accounts.....	1352
Configuring PingDataSync.....	1352
Configuration checklist.....	1353
Sync user account.....	1355
Configure PingDataSync in Standard mode.....	1355

Use the Configuration API.....	1360
Configuration with the dsconfig tool.....	1373
Topology configuration.....	1375
Servers and certificates.....	1377
Domain Name Service (DNS) caching.....	1426
IP address reverse name lookups.....	1426
Configure the synchronization environment with dsconfig.....	1427
Prepare external server communication.....	1428
HTTP connection handlers.....	1428
Resync tool.....	1434
Realtime-sync tool.....	1438
Configure the PingDirectory Server backend for synchronizing deletes.....	1441
Configure DN maps.....	1442
Configure synchronization with JSON attribute values.....	1443
Configure fractional replication.....	1448
Configure failover behavior.....	1450
Configure traffic through a load balancer.....	1455
Configure authentication with a SASL external certificate.....	1455
Configure an LDAPv3 Sync Source.....	1456
Server SDK extensions.....	1457
Synchronize with PingOne.....	1457
Prerequisites.....	1457
Setting up SSO to PingDirectory from PingOne.....	1460
Synchronize changes to a PingOne environment.....	1465
Synchronize changes from a PingOne environment.....	1467
PingOne synchronization limitations.....	1469
Synchronize with Active Directory and other directory servers.....	1469
Overview of configuration tasks.....	1469
Configuring one way synchronization from Active Directory to PingDirectory.....	1470
Mapping AD password policy state attributes to PingDirectory using dsconfig.....	1473
Active Directory sync user account.....	1474
Preparing external servers.....	1475
Configuring sync pipes and sync classes.....	1475
Configuring password encryption.....	1477
Password sync agent.....	1478
Synchronize with Relational Databases.....	1481
Use the server SDK.....	1481
RDBMS synchronization process.....	1481
DBSync example.....	1482
Configure DBSync.....	1483
Create the JDBC extension.....	1483
Configure the database for synchronization.....	1486
Considerations for synchronizing to database destination.....	1487
Configure a directory-to-database sync pipe.....	1488
Considerations for synchronizing from a database source.....	1491
Synchronize a specific list of database elements.....	1491
Synchronize with Apache Kafka.....	1492
Restrictions.....	1492
Configure a Kafka sync destination.....	1492
Message format.....	1493
Synchronize through PingDirectoryProxy servers.....	1496
Synchronization through a Proxy Server overview.....	1496
Example configuration.....	1498
Configure the source PingDirectory Server.....	1499
Configure a proxy server.....	1500
Configure PingDataSync.....	1502

Test the configuration.....	1503
Index the LDAP changelog.....	1505

Release Notes

Unless otherwise noted, all of the following enhancements, known issues, and resolved issues apply to PingDirectory Server, PingDataSync Server, PingDirectoryProxy, and PingDataMetrics Server.

PingDirectory suite of products 9.0.0.6 (August 2023)

Fixed an issue where the server rejected certain operations PingDirectory DS-45767 **Fixed**
Fixed an issue in which the server would always reject an operation with a request control that the client did not have permission to use, regardless of the control's criticality. It will continue to reject the operation if the disallowed control has a criticality of true, but if the criticality is false, the server will continue processing the operation as if that control had not been requested.

Fixed a security issue PingDirectory DS-47632 **Security**
Fixed a security issue that could potentially affect customers using Delegated Admin. Customers are advised to apply a maintenance patch or upgrade to the latest supported version of the PingDirectory Server. The Delegated Admin application is unaffected and does not require updating. Additional details are provided in SECADV039.

PingDirectory suite of products 9.0.0.5 (April 2023)

Fixed an issue causing missing operational attributes PingDataSync DS-46695 **Fixed**
Fixed an issue that caused missing IntraSync User operational attributes after running the `manage-profile replace-profile` subcommand.

Fixed an issue with changing passwords PingDirectory DS-46882 **Fixed**
Fixed an issue where attempting to change a password that's within the `minAge` now responds with an `UNABLE_TO_PERFORM` code rather than `INVALID_CREDENTIALS`.

PingDirectory suite of products 9.0.0.4 (January 2023)

Fixed an issue preventing the server from refreshing monitor data DS-41468 **Fixed**

Fixed an issue that prevented the server from refreshing the monitor data used to detect and warn about an upcoming certificate expiration. This could cause the server to continue to warn about an expiring certificate even after that certificate had been replaced.

Fixed an issue with the dsreplication tool PingDirectory DS-45044 **Fixed**

Fixed an issue with the dsreplication tool where baseDNs and restricted baseDNs were improperly handled as case sensitive.

Fixed an issue with the encode-password tool PingDirectory DS-45546 **Fixed**

Fixed an issue that caused the encode-password tool to fail when the AES256 password storage scheme is enabled.

Fixed an issue with resource limits PingDirectory DS-45638 **Fixed**

Fixed an issue where resource limits for the topology admin user created during replication enable were not set.

Fixed an issue causing configurations not to load correctly PingDirectoryProxy DS-45798 **Fixed**

In the PingDirectoryProxy server, "manage-profile replace-profile" sometimes failed with an error similar to the following: The tool was unable to merge configuration from the existing server into the new server: LDAPException(resultCode=80 (other) ... This fix ensures that the configuration is loaded prior to the merge that the error message refers to.

Fixed an issue causing replication enablement to fail PingDirectory DS-45960 **Fixed**

Fixed an issue that caused replication enablement to fail if there is at least one topology-wide administrator with no password.

Fixed an issue with changes to Password Policy State attributes PingDataSync DS-46121 **Fixed**

Fixed an issue where changes to certain Password Policy State attributes would not be applied to the correct entry when using a Ping Identity Sync Destination under very specific circumstances.

Fixed an issue preventing users from changing their passwords PingDirectoryPingDir DS-46395 **Fixed**

Fixed an issue in which the server could prevent users from changing their own passwords with the password modify extended operation if their account was in a "must change password" state and the request passed through the PingDirectoryProxy server.

Improved maximum-attributes-per-add-request and maximum-modifications-per-modify-request PingDirectoryProxy

Updated the PingDirectoryProxy server to expose the maximum-attributes-per-add-request and maximum-modifications-per-modify-request properties in the global configuration. These properties were previously only visible in the PingDirectory server configuration, but they also apply to requests that pass through the PingDirectoryProxy server.

The replication server now continues to handle incoming replication connections DS-46382 **Improved**

The replication server now continues to handle incoming replication connections even when there is an unexpected exception.

PingDirectory suite of products 9.0.0.2 (July 2022)

Updated Kafka version DS-45462 **Security**

Updated PingDirectory products to use Kafka v2.8.1.

Updated the server to create the esTokenizer.ping file if it does not exist PingDirectory DS-45449 **Fixed**

Updated the server to create the esTokenizer.ping file if it does not exist for a backend containing encrypted data. This file might be needed to open the database environment for a backend containing encrypted indexes, but it would not have been automatically created when upgrading from a pre-7.0 server to a later version with support for encrypted indexes.

Updated the active operations monitor provider PingDirectory, PingDirectoryProxy DS-45485 **Improved**

Updated the active operations monitor provider to improve the string representations of active operations and persistent searches. The timestamps now have a precision of milliseconds rather than seconds, and the strings can now be parsed using the access log API in the LDAP SDK for Java.

Fixed Directory REST API with mismatched syntax DS-45725 DS-45725 DS-45725 **Fixed**

Fixed an issue where the Directory Rest API returns an HTTP 500 error response when trying to retrieve a SCIM entry whose corresponding LDAP entry contains a valid Generalized Time Syntax attribute value not matching the specific format `YYYYMMDDhhmmssZ`.

Fixed a SCIM POST request error response issue PingDirectory DS-45863 **Fixed**

Resolved an issue where SCIM POST requests that violated a unique attribute constraint received an error response with status 400 (Bad Request) instead of 409 (Conflict).

Fixed a performance issue with large numbers of virtual static groups PingDirectory DS-46017, SF#:0076120 **Fixed**

Resolved an issue with slow response time on PingDirectory servers configured with a large number (10,000 or more) of virtual static groups.

Fixed a SCIM POST request error response issue PingDirectory DS-45647, SF#:00750326 **Fixed**

Resolved an issue where SCIM POST requests that violated a unique attribute constraint got an internal error instead of the expected SCIM error response.

Fixed a PingDataSync to PingOne sync performance issue PingDataSync DS-46119, SF#:00760293 **Fixed**

Fixed an issue encountered when using PingDataSync with a PingOne Sync Destination that caused sync to slow down significantly after 5 minutes and generate extraneous requests to the sync destination.

PingDirectory suite of products 9.0.0.1 (March 2022)

Issue with syncing multi-valued JSON attributes to a PingOne destination PingDataSync **Issue**

For multi-valued JSON attributes, you should not use JSON attribute mappings when synchronizing data to a PingOne destination. When synchronizing JSON data, you can use a direct attribute mapping if the data at the source server is JSON. If the data at the source server should be assembled into JSON form, you can define a constructed attribute mapping.

Added support for synchronizing data to custom attributes defined in PingOne destinations PingDataSync

Added support for synchronizing data to custom attributes defined in PingOne destinations. This includes multi-valued attributes and JSON attributes in the PingOne environment.

When defining attribute mappings for a PingOne destination, you can use direct attribute mappings for string to string or JSON to JSON synchronizations. If a string attribute at the source server should be stored as JSON in the PingOne environment, you should define a constructed attribute mapping in PingDataSync.

PingDirectory suite of products 9.0.0.0 (December 2021)

New entry-balancing options PingDirectory **Improved**

Entry-balancing is a PingDirectoryProxy Server configuration that allows the entries within a portion of the directory information tree (DIT) to reside on multiple external servers. The entry counter, hash distinguished name (DN) and round-robin placement algorithms can now be configured to exclude backend sets for `add` operations allowing for greater control over the use of multiple servers for entry balancing.

You can interact with entries within the data store including LDAP and several REST APIs PingDirectory

PingDirectory provides a number of interfaces for interacting with entries within the data store including LDAP and several REST APIs. In this release, the Directory REST API can now return any tagging options that are defined for an attribute. These tagging options are treated as subtypes of the same attribute while not explicitly declared in the schema.

CyberArk Conjur and Azure Key Vaults support added PingDirectory **Improved**

In an earlier release, PingDirectory added support for a passphrase provider API to secure administrative passphrases, pins or passwords. This release adds both CyberArk Conjur and Azure Key Vaults to the list of available passphrase and cipher stream providers. Cipher stream providers are used to protect the keys stored in the encryption settings database

OAuth tokens can be used with the File Servlet PingDirectory **Improved**

Because administrators now have the ability to single sign-on (SSO) to the PingDirectory administrative console, the File Servlet used to download files from a server instance can now also use OAuth tokens for authentication along with the basic HTTP authentication method, such as username and password.

Apply your own branding to console elements. PingDirectory, PingDirectoryProxy, PingDataSync **Fixed**

The administrative console is one tool you can use to configure and manage PingDirectory servers. In this release, you can now apply your own branding to console elements such as background colors, images and logos, and certain text elements. Sign on, sign out, and configuration pages are included in possible configuration areas. For more information, see the `README.txt` file in the console `.war` file shipped with PingDirectory.

New `--performLocalCleanup` option added to the `remove-defunct-server` command PingDirectory

To improve the defunct server topology cleanup process when your topology is unhealthy, such as during a network outage or disaster recovery, a new option to the `remove-defunct-server` command cleans up stale replication metadata before the server is added back into the topology. This new argument, `--performLocalCleanup`, allows administrators to easily take a server out of a topology for maintenance or troubleshooting and return the server back to the topology later. For more information on `remove-defunct-server` and its options, run `bin/remove-defunct-server --help`.

Added support for a pluggable pass-through authentication plugin PingDirectory **Improved**

Earlier PingDirectory Server versions support pass-through authentication to remote LDAP servers or to PingOne, which can be useful when migrating data into the Directory Server from another service, or when the Directory Server needs to coexist with another service that is an authoritative source for user passwords. This release adds support for a pluggable pass-through authentication plugin, which makes it possible to pass through simple bind requests to an arbitrary external service using a pass-through authentication handler to manage interaction with that service, and the Server SDK has been updated to allow creating custom pass-through authentication handlers. As with existing pass-through authentication support, this functionality is only available for LDAP simple binds, and it does not support SASL authentication. For more information on this plugin, see [Working with pass-through authentication](#) on page 241

Added new options to the `dsreplication` command to make replication faster PingDirectory **Improved**

In multi-server deployments, replication is used to maintain consistency of data and schema between the servers. With larger deployments, attempting to initialize replication for multiple servers can take longer. New options to the `dsreplication` command can now speed up this process by initializing replication on multiple servers in parallel. The number of servers can either be the entire set of servers in the deployment, or a subset of servers based on location, or instance name or a specific number. For more information on `dsreplication` subcommands, see [Summary of the dsreplication Subcommands](#) on page 601.

Added a new password storage scheme to provide enhanced security PingDirectory **Improved**

Typically, the passwords for administrative users have been stored directly in PingDirectory based on the configured password storage scheme. To provide enhanced security for those administrative accounts that need it, a new password storage scheme has been added that allows for the password to be stored in an external vault. Currently, Amazon AWS Secrets Manager, Azure Key Vault, CyberArk Conjur, and HashiCorp Vault are supported.

The `config-audit` logs track the originating account information for individual changes PingDirectory

To better manage the configuration of multiple servers in large topologies, PingDirectory uses the `config-audit` log file to allow administrators to easily determine, replay or undo configuration changes made to servers. Previously, when modifying topology or cluster configuration, the original requesting account information was not logged. Now, to assist administrators and improve server auditing, the `config-audit` logs will track the originating account information that made individual changes. For circumstances where more protection is required, there is a new property that will redact any sensitive attributes that might be written to the log file (instead of the default obfuscation behavior). This includes instances where administrative users change their passwords and affects any other condition where the sensitive attribute might be displayed for informational purposes such as alerts.

PingDataSync can now include Active Directory account state information PingDataSync **Improved**

Many customers use PingDataSync Server to either migrate from Active Directory or use Active Directory in conjunction with PingDirectory to manage user accounts. Administrators can now configure PingDataSync to include account state information set in Active Directory specifically lockout time, the last time the password was set and whether or not the account is disabled. This information can now be properly set within PingDirectory based on the information set in the account in Active Directory.

Entry balancing and global index PingDirectoryProxy

Issue

If the DirectoryProxy Server is configured to use entry balancing and cannot use the global index to determine which backend sets should be used to process an operation, it broadcasts the request to all

backend sets, and it will examine the results obtained from each of the backend sets to determine which is the best one to return to the client.

In previous releases, the server always preferred a success result over a non-success result, but if the operation failed in all backend sets, then the DirectoryProxy Server could have selected a result from a backend server in which the target entry didn't exist (for example, with a `noSuchObject` result code) rather than from one in which the entry did exist but the operation failed for some other reason. The 9.0.0.0-EA release addresses this by examining the result codes for all broadcast operations and prioritizing failure results indicating that the target entry exists in the associated backend set over those that do not.

There are still known cases, however, in which the DirectoryProxy Server might select a less appropriate result to return to the client. For example, if a `bind` operation fails, the backend server is likely to return an `invalidCredentials` result regardless of whether the target user entry exists in that backend set. If the `bind` attempt fails in one backend set because the target user exists but their account is in a state that doesn't allow it to authenticate (for example, if their password is expired or their account is locked), then the `bind` response from that server might include response controls that would be useful to return to the client, but the 9.0.0.0-EA release might not choose that response as the one to return to the client. This will be addressed in the 9.0.0.0 GA release later this year.

Fixed `dsrepltool` Topology, `cn=config` replication PingDirectory DataSync

When a server is removed with the `dsreplication disable` or `remove-defunct-server` tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

Fixed keys servers password storage PingDirectory

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

Note:

Because this change only applies to the most recent version of `remove-defunct-server` and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past `dsreplication` and `remove-defunct-server` could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

Fixed Directory REST API PingDirectory

DS-37117 Fixed

Fixed an issue where the Directory REST API encountered internal server errors while processing entries whose attributes have LDAP tagging options.

Added LDAP pass-through authentication handler PingDirectory

DS-38498, DS-38621 Fixed

An LDAP pass-through authentication handler has also been provided, which allows the new plugin to be used as an alternative to the existing LDAP-specific pass-through authentication plugin. The new implementation provides additional functionality not available in the previous plugin, including the ability to indicate whether pass-through authentication should be allowed for accounts that are locked or have expired passwords and the ability to set timeouts that will be used when interacting with external LDAP servers. It also has improved default settings and offers better diagnostic information about its processing.

Added authentication password stores PingDirectory PingDirectory PingDataMeta PingDataSync

Added support for password storage schemes that allow users to authenticate with passwords stored in the Amazon AWS Secrets Manager service, the Microsoft Azure Key Vault service, a CyberArk Conjur instance, or a HashiCorp Vault instance.

The `dsrepltool` `initialize` command PingDirectory

To enhance initialization performance, the `dsreplication initialize-all` command now initializes multiple target servers in parallel when the `--parallel` option is used (subject to the `--parallelLimit`

DS-47766

option). The `--sameLocationOnly` and `--destinationInstanceName` options can be used to limit the destinations that are initialized.

Added

Added a global configuration property to indicate that the values of sensitive configuration properties should be redacted when constructing the `dsconfig` representation for a configuration change, which could be included in the server's configuration audit log or administrative alerts whenever a configuration change is applied. By default, the values of configuration properties that are defined as sensitive will be obscured rather than redacted, which allows the change to be replayed without revealing the actual value of the property. However, it is now possible to redact such values rather than obscuring them, which provides stronger protection against exposing those values, but could interfere with the ability to replay the configuration audit log if it contains changes involving sensitive properties.

Added sorting functionality to the Name and Category columns of the monitor table in the administrative console. PingDirectory Proxy DS-4296

Added sorting functionality to the **Name** and **Category** columns of the monitor table in the administrative console.

Added replica-partial-backlog attribute to replication summary monitor PingDirectory DS-4296 **Fixed**

To help with replication backlog analysis, the replication summary monitor now includes a `replica-partial-backlog` attribute that shows how each origin replica contributes partial backlog with the `per-origin-replication-backlog` property. The `replica-partial-backlog` attribute also shows the change numbers used for the calculation.

Updated the server to record the original requester distinguished name (DN) and IP address in access log and config audit log messages for mirrored configuration changes. PingDirectory Proxy DS-4358 **Fixed**

Updated the server to record the original requester distinguished name (DN) and IP address in access log and config audit log messages for mirrored configuration changes.

Fixed issues related to server handling of controls in search requests PingDirectory Proxy DS-4358 **Fixed**

Fixed a couple of issues in which the server might not properly handle other controls included in a search request containing a join request control. For search operations passing through the Directory Proxy Server, other response controls could have been inadvertently stripped from search result entries when adding the join result control. Further, if a search request included a join request control in conjunction with one or more other controls, the request control immediately following the join request control might not have been properly handled.

Added support for obtaining secrets from CyberArk PingDirectory Proxy DS-4367 **Fixed**

The Conjur cipher stream provider can use a retrieved secret to generate the encryption key used to protect the contents of the encryption settings database. The Conjur passphrase provider can be used in other cases in which the server might need a clear-text secret, including as a PIN needed to access a certificate key store or as credentials for authenticating to an external service. The server can authenticate to Conjur using a username and a password or an API key.

Added support for obtaining secrets from Azure Key Vault PingDirectory Proxy DS-4400 **Fixed**

The Azure Key Vault cipher stream provider can use a retrieved secret to generate the encryption key used to protect the contents of the encryption settings database. The Azure Key Vault passphrase provider can be used in other cases in which the server might need a clear-text secret, including as a PIN needed to access a certificate key store or as credentials for authenticating to an external service.

limits

These can be used to avoid potential denial of service attacks. Both limits are set to 1000 by default, which is likely to be adequate for all legitimate use cases, and neither property affects the number of values that can be provided for an attribute.

Fixed proxied authorization issue PingDirectory DS-4408 **Fixed**

Addressed an issue where proxied authorization would fail in rare cases for usernames with 57 or 58 characters and DNs with 108 or 109 characters.

Fixed manage-profile replace-profile did not correctly handle keystore files with a .bcfks extension while in FIPS-140-2-compliant mode. PingDirectory Proxy DS-4425 **Fixed**

Fixed an issue where `manage-profile` `replace-profile` did not correctly handle keystore files with a `.bcfks` extension while in FIPS-140-2-compliant mode.

Fixed View API Commands link appeared to be disabled in the administrative console. PingDirectory Proxy PingDataMetrics DS-4425 **Fixed**

Resolved an issue where the **View API Commands** link appeared to be disabled in the administrative console.

Fixed silent replication failure PingDirectory DS-4445 **Fixed**

Fixed an issue where non-DN modifications associated with a `moddn` change would silently fail to replicate.

Added new --performLocalCleanup argument to remove-defunct-server PingDirectory DS-4445 **Fixed**

Added a new argument, `--performLocalCleanup`, to `remove-defunct-server` that simplifies the replication artifact cleanup process. To clean up replication artifacts on earlier releases of the Directory Server, run `remove-defunct-server` with no bind arguments while the server is offline.

Added PKCS #11 cipher stream provider PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Added a PKCS #11 cipher stream provider that can require access to a certificate in a PKCS #11 token to unlock the server's encryption settings database. Only certificates with RSA key pairs can be used because Java virtual machines (JVMs) do not currently provide adequate key wrapping support for elliptic curve key pairs.

Server instances can now be safely mirrored to older servers in mixed-version topologies PingDirectory

Server instances, which are within a mirrored subtree, can now be safely mirrored to older servers in mixed version topologies. This is done by adding the following to server instances: `objectclass: extensibleObject`.

Fixed dsreplication disable PingDirectory, PingDataSync

When a server is removed with the `dsreplication disable` or `remove-defunct-server` tools, its secret keys are now distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, prior to this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

Note:

Because this change only applies to the most recent version of `remove-defunct-server` and `dsreplication disable`, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past `dsreplication` and `remove-defunct-server` could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it does not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

Added PingData Administrative Console configuration capability PingDirectory, PingDataMetrics, PingDataSync

The PingData Administrative Console can now be configured to supply PINs to its trust stores through the `oidc-trust-store-pin-passphrase-provider` and `trust-store-pin-passphrase-provider` settings. This means trust store types that require passphrases (ex: PKCS12 or BCFKS) are now properly supported.

Fixed PingData Administrative Console file retrieval PingDirectory, PingDataMetrics, PingDataSync

The PingData Administrative Console can now retrieve files created from `collect-support-data` or `server-profile` tasks when using single sign-on (SSO) to authenticate with the managed server.

Updated the file servlet PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync DS-44602 Fixed

Updated the file servlet to add support for token-based authentication using an OAuth 2.0 access token or an OpenID Connect ID token. The servlet previously only supported basic authentication.

Improved argument handling PingDirectory, PingDataMetrics, PingDataSync

The tool will only use relative paths that exist below the server root, and it previously silently ignored absolute paths or relative paths that referenced files outside of the server root. It will now exit with an error if the `includePath` argument is used to provide an absolute path or a path outside the server root. It will accept but warn about paths that reference files that do not exist.

Fixed dsreplication default password policy PingDirectory, PingDirectoryProxy

Fixed an issue that caused an internal root account (used for processing certain types of internal operations) to be subject to the server's default password policy. With some password policy configurations, if a DirectoryProxy Server attempted to perform an internal operation that targeted data in a backend Directory Server, that operation could have been incorrectly rejected.

Fixed symmetric keys issue PingDirectory

DS-44648 Fixed

Addressed an issue where symmetric keys were not being sanitized in the `config-audit.log`.

Updated the export-ldif tool PingDirectory

DS-44669 Fixed

Updated the `export-ldif` tool to always base64 encode values with any ASCII control characters. The LDIF specification in RFC 2849 only requires base64 encoding for the NUL, LF, and CR control characters,

and those are the only control characters that were previously base64 encoded. However, the specification also permits base64 encoding for any type of character, and always base64 encoding all control characters is safer and reduces the chance for errors when working with values containing such characters.

Made various improvements to the `ldap-diff` tool PingDirectory, PingDirectoryProxy, PingData, PingDataMetric, PingDataSync

- Added the ability to perform a byte-for-byte comparison of attribute values rather than using schema-based logical equivalence.
- Added the ability to use a properties file to obtain default values for command-line arguments.
- Improved the ability to use different TLS-related settings for the source and target servers.
- Improved support for SASL authentication.

Updated the `migrate-ldap-schema` tool PingDirectory DS-44758 **Fixed**

Updated the `migrate-ldap-schema` tool to provide more flexibility for TLS negotiation, support for SASL authentication, support for using a properties file, and better validation for migrated attribute type and object class definitions.

Fixed `remove-defunct-server` issue PingDirectory, PingDirectoryProxy, PingData, PingDataSync

Fixed an issue in which `remove-defunct-server` would remove attributes from `config.ldif` if they were identical apart from case.

Improved performance for modify operations PingDirectory DS-44884 **Fixed**

Improved performance for modify operations that need to insert an entry ID into the middle of a very large composite index ID set.

Addressed a connection error in `remove-defunct-server` PingDirectory DS-44892 **Fixed**

Addressed a connection error in `remove-defunct-server` when the tool tried to migrate secret keys on a single-instance topology (i.e., a server that is not part of a replication topology). The tool now only moves secret keys if the server is part of a topology.

Fixed an error when backing up an encrypted backend PingDirectory DS-44904 **Fixed**

Fixed a race condition that could sporadically cause an error when backing up an encrypted backend.

Addressed an issue where simple binds on entries PingDirectory DS-44931 **Fixed**

Addressed an issue where simple binds on entries without passwords would not update the relevant password policy attributes, such as `ds-pwp-auth-failure`.

Updated the crypto manager configuration PingDirectory, PingDataSync

Updated the crypto manager configuration to add properties for controlling the set of TLS protocols and cipher suites that will be used for outbound connections, as well as properties for controlling whether to enable TLS cipher suites that rely on the SHA-1 digest algorithm or the RSA key exchange algorithm.

Fixed an issue where the server might not use appropriate resource limit values PingDirectory, PingDirectoryProxy

Fixed an issue in which the server might not use appropriate resource limit values for accounts that bind with pass-through authentication. In such cases, the server might apply size limit, time limit, idle time limit, and other constraints from the global configuration instead of alternative values for those limits set in the user entry.

Fixed server hang issues PingDirectory DS-45032 **Fixed**

- Addressed an issue that caused `remove-defunct-server` to hang.
- Addressed an issue that caused `remove-defunct-server` to hang when performing replication artifact cleanup in non-interactive mode.

For `initilaze-all dsreplication` subcommand avoid closing connections to remote servers PingDirectory

For the `initilaze-all dsreplication` subcommand avoid closing connections to remote servers multiple times in order to apply the new generation ID.

Added support for Eclipse Foundation JDKs PingDirectory, PingDirectoryProxy, PingData, PingDataSync

Added support for the use of Java Development Kits (JDKs) obtained through Eclipse Foundation.

Fixed an issue where explicit `createTimestamp` values are replicated to peer servers PingDirectory

Fixed an issue where explicit `createTimestamp` values are replicated to peer servers using a default timestamp format rather than the non-default format value stored on the first server.

Updated the `initilaze-all ds` tool PingDirectory

This might allow the virtual attribute to provide values from another entry even if the requester would not otherwise have permission to access those values.

Fixed a PingDirectory Server performance issue involving high CPU usage PingDirectory DS-45115 **Fixed**

Fixed a Ping Directory Server performance issue involving high CPU usage when writing LDAP data to certain clients using TLSv1.3 connection security.

Removed Rediscovery Endpoint argument PingDirectory PingDataMetrics PingDataSync

In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.

Fixed a composed attribute plugin issue PingDirectory DS-45153 **Fixed**

Fixed an issue that prevented the composed attribute plugin from working for operations that are part of a multi-update request.

Fixed issue where server with newly initialized database could go into lockdown PingDirectory

Fixed an issue where a server with a newly initialized database (through `dsreplication initialize`) could go into lockdown mode and report that the server might have missed one or more updates. This generally occurred only if the initialized server was restarted right after initialization completed.

Changed default administrative console tab PingDirectory PingDirectoryProxy PingDataMetrics PingDataSync

Changed the default tab in the administrative console to **Modify** when updating an existing server resource with new changes

Added support for new extended operations PingDirectory PingDirectoryProxy PingDataMetrics PingDataSync

Added support for new extended operations to help manage the server's listener and inter-server certificates. Updated the `replace-certificate` tool to add support for replacing and purging certificates in a remote instance, and to allow skipping validation for the new certificate chain.

Added support for BellSoft JDKs PingDirectory PingDirectoryProxy PingDataMetrics PingDataSync

Added support for the use of JDKs obtained through BellSoft.

Improved performance of server encryption PingDirectory DS-45203 **Fixed**

Resolved a performance issue that could cause servers installed using a server encryption option to spend several minutes waiting in the `Initializing Crypto Manager` phase during server startup.

Added scroll bar to administrative console's Server list PingDirectory PingDirectoryProxy PingDataMetrics PingDataSync

Added a scroll bar to the administrative console's **Server** list to ensure all servers are accessible regardless of screen size.

Updated the entry counter, hash DN, and round robin placement algorithms PingDirectory DS-44878 **Fixed**

Updated the entry counter, hash DN, and round robin placement algorithms to make it possible to exclude specified backend sets from consideration when adding new entries to an entry-balanced topology.

Improved server logic PingDirectoryProxy DS-44798 **Fixed**

Improved the logic the server uses to select the best result to return to the client when an operation fails in an entry-balanced topology after the request was broadcast to all backend sets. In some cases, the server could have incorrectly returned a result from a backend set in which the target entry did not exist instead of a more appropriate result from the backend set that did contain the entry.

Fixed dashboard icon issue PingDataMetrics DS-44224 **Fixed**

Addressed an issue where icons on the dashboards were not properly displayed.

Synchronize from Active Directory attribute `pwdAccountLockedTime` PingDataSync

Because `pwdAccountLockedTime` cannot be written to directly, an extended operation is used. This synchronization depends on a direct attribute mapping that maps from `pwdAccountLockedTimeFromAD` to `pwdAccountLockedTime`.

Added attribute mapping from `ds-pwp-account-disabled` from Active Directory PingDataSync

Synchronize from Active Directory `userAccountControl` bit indicating that the account is disabled (bit #2) (or `msDS-UserAccountDisabled` on AD-LDS) to PingDirectory attribute `ds-pwp-account-disable`. Because `ds-pwp-account-disabled` cannot be written to directly, an extended operation is used. This synchronization depends on a direct attribute mapping that maps from `ds-pwp-account-disabled-from-ad` to `ds-pwp-account-disabled`.

Added direct attribute mapping from `pwdLastSet` to `pwdChangedTime` PingDataSync

Synchronize from Active Directory attribute `pwdLastSet` with the password changed time to PingDirectory attribute `pwdChangedTime`. Because `pwdChangedTime` can not be written to directly an extended operation is used. This synchronization depends on a direct attribute mapping that maps from `pwdChangedTimeFromAD` to `pwdChangedTime`.

Fixed PingDataSync server not synchronizing multiple attributes PingDataSync

Fixed an issue where the PingDataSync server failed to synchronize certain modifications involving multiple attributes with the same base name but with different option tags, and any of these attributes

having more values in the source entry than the `replace-all-attr-values-limit` for the `Sync` class.

Fixed issue where PingDataSync was not syncing entries to PingOne environments DS-45138 **Fixed**

Addressed an issue where PingDataSync was not syncing entries to PingOne environments due to rate-limiting responses from PingOne.

Fixed a `max-rate-per-second` configuration setting PingDataSync

DS-45138 **Fixed**

Addressed an issue where the `max-rate-per-second` configuration setting was not being applied to the `resync` tool.

Previous Releases

For information about enhancements and issues resolved in previous major and minor releases of PingData products, follow the links below to their release notes:

- [7.3](#)

PingDirectory Server Administration Guide

The PingDirectory server is a high-performance, extensible [MISSING glossAcronymn or glossSurfaceform for gLDAP] directory that provides seamless data management over a distributed system while meeting the constant performance demands for today's markets.

Introduction to PingDirectory Server

PingDirectory Server is a high-performance, extensible directory and platform, written completely in Java.

The PingDirectory Server centralizes consumer and user identity management information, subscriber data management, application configurations, and user credentials into a network, enterprise, or virtualized database environment. It provides seamless data management over a distributed system based on a standardized solution that meets the constant performance demands for today's markets. The PingDirectory Server simplifies administration, reduces costs, and secures information in systems that scale for large numbers of users.

The following topics provide an overview of the PingDirectory Server's features and components:

- [Server features](#) on page 30
- [Administration framework](#) on page 32
- [Server tools location](#) on page 33

Server features

The PingDirectory Server provides an extensive feature-rich set of tools to meet a variety of production needs.

Full LDAP version 3 implementation

The PingDirectory Server fully supports LDAPv3, which supports the Request For Comments (RFCs) specified in the protocol. The Directory Server provides a feature-rich solution that supports the core LDAPv3 protocol in addition to server-specific controls and extended operations.

High availability

The PingDirectory Server supports N-way multi-primary replication that eliminates single points of failure and ensures high availability for a networked topology. The PingDirectory Server allows you to store data across multiple machines and disk partitions for fast replication. The PingDirectory Server supports replication in entry-balancing proxy server deployments.

Administration tools

The PingDirectory Server provides a full set of command-line tools, an administrative console, and a Java-based setup tool to configure, monitor, and manage any part of the server.

The PingDirectory Server has a task-based subsystem that provides automated scheduling of basic functions, such as:

- Backups
- Restores
- Imports
- Exports
- Restarts
- Shutdowns

The set of utilities includes a troubleshooting support tool that aggregates system metrics into a `.zip` file, which administrators can send to your authorized support provider for analysis.

Self-service account manager application

The Self Service Account Manager project, hosted at <https://github.com/pingidentity/ssam>, is a customizable web application allowing users to perform their own account registration, profile updates, and password changes. The project is for testing and development purposes only and is not a supported application.

Delegated admin application

A Javascript-based web application can be installed for business users to manage identities stored in the PingDirectory Server. The application provides delegated administration of identities for:

- Help desk or customer service representatives initiating a password reset and unlock
- An employee in HR updating an address stored within another employee profile
- An application administrator updating identity attributes or group membership to allow application single sign-on (SSO) access.

Security mechanisms

The PingDirectory Server provides extensive security mechanisms to protect data and prevent unauthorized access. Access control list (ACL) instructions are available down to the attribute value level and can be stored within each entry.

The PingDirectory Server allows connections over SSL through an encrypted communication tunnel. Clients can also use the StartTLS extended operation over standard, non-encrypted ports. Other security features include:

- A privilege subsystem for fine-grained granting of rights
- A password policy subsystem that allows configurable password validators and storage schemes
- SASL authentication mechanisms to secure data integrity, such as:
 - PLAIN
 - ANONYMOUS
 - EXTERNAL
 - CRAM-MD5
 - Digest-MD
 - GSSAPI

The PingDirectory Server supports various providers and mappers for certificate-based authentication in addition to the ability to encrypt specific entries or sensitive attributes. For more information, see the PingDirectory Server Security Guide.

Monitoring and notifications

The PingDirectory Server supports monitoring entries using:

- PingDataMetrics Server
- JConsole
- SNMP
- The Administrative Console

Administrators can track the response times for LDAP operations using a monitoring histogram as well as record performance statistics down to sub-second granularity. The PingDirectory Server supports configurable notifications, auditing, and logging subsystems with filtered logging capabilities.

Powerful LDAP SDK

The PingDirectory Server is based on a feature-rich LDAP SDK for Java, designed by Ping Identity. The LDAP SDK is a Java API standard that overcomes the limitations of the Java Naming and Directory Interface (JNDI) model. For example, JNDI does not address the use of LDAP controls and extended operations. The LDAP SDK for Java provides support for controls and extended operations to leverage Ping Identity's extensible architecture for their applications.

 **Note:**

For more information on the LDAP SDK for Java, see <http://www.LDAP.com>.

System for Cross-domain Identity Management (SCIM) extension

The PingDirectory Server provides a SCIM servlet extension to facilitate moving users to, from, and between cloud-based software as a service (SaaS) applications in a secure and fast manner.

Server SDK

Ping Identity provides the Server SDK, which is a library of Java packages, classes, and build tools to help in-house or third-party developers create client extensions for:

- PingDirectory
- PingDirectoryProxy
- PingDataSync Server

The servers have a highly extensible and scalable architecture with multiple plugin points for your customization needs. The Server SDK provides APIs to alter the behavior of each server's components without affecting its code base.

Administration framework

The PingDirectory Server provides an administration and configuration framework capable of managing stand-alone servers, server groups, and highly-available deployments that include multiple redundant server instances.

Administrators can configure changes locally or remotely:

- On a single server
- On all servers in a server group

Each server configuration is stored as a flat file (LDIF) that can be accessed under the `cn=config` branch of the directory information tree (DIT). Administrators can tune the configuration and perform maintenance

functions over LDAP using a suite of command-line tools or an administrative console (for configuration and monitoring). The PingDirectory Server provides plugins to extend the functionality of its components.

Server tools location

The PingDirectory Server stores a full set of command-line tools for maintaining your system in the `PingDirectory/bin` directory for UNIX or Linux machines and the `PingDirectory\bat` directory for Microsoft Windows machines.

Ping Identity distributes the PingDirectory Server, administrative console, and LDAP SDK for Java in `.zip` format. After extracting the file, you can access the `setup` utility in the server root directory, located at `PingDirectory`.

Before installing the PingDirectory Server, see [Prepare your environment](#) on page 33 for important information on setting up your machines. See [Installing the PingDirectory Server](#) on page 33 for information on installing a server instance using the `setup` utility. You can run this utility in either interactive command-line or non-interactive command-line. For information on modifying the configuration of a server instance or a group of servers using the command-line tools and the administrative console, see [Configuring the Server](#) on page 105.

Installing the PingDirectory Server

After you prepare your hardware and software system, you can set up the server using PingDirectory Server's installation modes.

To install the server, see the following topics:

- [Prepare your environment](#) on page 33
- [Getting the installation packages](#) on page 42
- [Signing on to the Administrative Console](#) on page 45
- [Directory Server folder layout](#) on page 50
- [make-ldif template format](#) on page 51
- [Push-replace DS GUI installation mode](#)
- [Server installation modes](#) on page 63
- [Before you begin](#) on page 63
- [Ping license keys](#) on page 64
- [Setting up the PingDirectory server in interactive mode](#) on page 65
- [Installing the Directory Server in non-interactive mode](#) on page 68
- [Installing a lightweight server](#) on page 69

Prepare your environment

PingDirectory Server offers a highly portable and scalable architecture that runs on multiple platforms and operating systems.

The Directory Server is specifically optimized for operating systems used in environments that process a large number of entries.

For information on setting up your server machines for optimal processing efficiency, see the following topics:

- [Before You Begin](#)
- [Preparing the Operating System \(Linux\)](#)
- [Running as a Non-Root User \(Linux\)](#)

Before you begin

The Directory Server requires certain software packages for the proper operation of the server.

For optimal performance, PingDirectory Server requires Java for 64-bit architectures. To view the minimum required Java version, access the Customer Support Center portal or contact your authorized support provider for the latest supported software versions.

Tip:

Implement a Network Time Protocol (NTP) system so that multi-server environments are synchronized and timestamps are accurate.

System requirements

The PingDirectory server requires certain software packages to operate properly.

Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software are suspected of causing issues.

The following system requirements are qualified and certified to be compatible with the PingDirectory server.

Running PingDirectory on Amazon Web Services (AWS)

To take advantage of snapshots for backing up any important files, install the PingDirectory server on an Elastic Block Store (EBS) file system. You should also move any databases, logs, and other files to a high-performance file system that is separate from the rest of the server image and create an S3 bucket for storing backups, schema, and other artifacts.

The following guidelines and considerations can help you avoid environmental constraint issues:

- PingDirectory does not support the Elastic File System (EFS) for database persistence.
- For the lowest cost, use t3.medium or t3a.medium and up.
- For the best performance, use m5dn, c5dn, or r5dn instance types (size xlarge and up) and the local SSD for PingDirectory database persistence.
- The A1 and M6g instance types, Ampere and Graviton, are not qualified by Ping at this time.
- Using network load balancers (NLBs) can lead to severed connections, which could cause issues that are difficult to diagnose.

Platforms

The following operating systems support PingDirectory Server, PingDirectoryProxy Server, PingDataSync Server, and PingDataMetrics Server's installation and deployment:

- Amazon Linux 2
- Canonical Ubuntu 18.04 LTS and 20.04 LTS
- CentOS 7.7 and 8.1
- Microsoft Windows Server 2016 and 2019
- Oracle Linux 7.9, 8.2, and 8.4
- Red Hat Enterprise Linux ES 7.7, 7.9, 8.1, 8.2, and 8.4
- SUSE Linux Enterprise 12 SP5 and 15 SP1

Attention:

The PingDirectory suite of products has been tested with the default configurations of all operating system components. Customized implementations or installed third-party plugins from your organization might affect the deployment of this product.

Docker

To deploy PingDirectory server using Docker, you must have a supported version of Docker.

The following versions of Docker are supported:

- Docker 20.10.9

For more information, see the [pingidentity/pingdirectory Docker image](#) and the [Ping Identity DevOps documentation](#).

Note:

Only the Directory Server software is licensed under Ping Identity's end user license agreement, and any other software components contained within the image are licensed solely under the terms of the applicable open source/third-party license.

Ping Identity accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

Java Runtime Environment

You must have one of the following versions of the Java Development Kit installed prior to installing the server:

- Amazon Corretto 8 and 11
- OpenJDK 8 64-bit and 11
- Oracle JDK 8 64-bit and 11 LTS 64-bit

Note:

The [Ping Identity Java Support Policy](#) applies to your [MISSING glossAcronymn or glossSurfaceform for gJRE].

Browsers

The following are the browsers supported by the PingDirectory Server administrative console:

- Chrome
- Firefox
- Edge

Installing Java

Even if your system already has Java installed, you might want to create a separate Java installation for use by the PingDirectory Server so that updates to the system-wide Java installation do not impact the Directory Server.

About this task

PingDirectory Server requires Java. For optimized performance, use Java for 64-bit architectures. View the minimum required Java version on your Customer Support Center portal, or contact your authorized support provider for the latest software versions supported.

Note:

A separate Java installation requires that you download the Java Development Kit (JDK) instead of the Java Runtime Environment (JRE) for the 64-bit version.

Steps

1. Go to the [Oracle download site](#).
2. Click JDK Download.
3. On the download page, select the download file for your operating system and accept the license agreement to start the download.

Preparing the operating system (Linux)

Several operating system customizations can improve the performance of PingDirectory Server on Linux systems.

These customizations include:

- [Increasing the file descriptor limit on Linux systems](#)
- [Setting the file system flushes](#) on page 38
- [Editing OS-level environment variables](#)
- [Downloading some useful monitoring tools for Redhat Linux systems](#)

Configuring the file descriptor limits

Operating system default file descriptor limits restrict the number of PingDirectory Server connections. Change the descriptor limits to allow more connections.

About this task

The Directory Server allows for an unlimited number of connections by default, but the file descriptor limit on the operating system restrict the number of connections. Many Linux distributions have a default file descriptor limit of 1024 per process, which might be too low for the server if it needs to handle a large number of concurrent connections.

If the operating system relies on `systemd`, see the Linux operating system documentation for instructions on setting the file descriptor limit.

After you set the operating system limit, you can configure the number of file descriptors that the server will use either by using a `NUM_FILE_DESCRIPTOR` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as `NUM_FILE_DESCRIPTOR=12345`. If these are not set, the operating system uses the default of 65535 descriptors. This is an optional change you can make if you want to ensure that the server shuts down safely prior to reaching the file descriptor limit.

Steps

1. Display the current `fs.file-max` limit of the system.

```
sysctl fs.file-max
```

The `fs.file-max` limit is the maximum server-wide file limit you can set without tuning the kernel parameters in the `proc` file system.

2. Edit the `/etc/sysctl.conf` file.

If there is a line that sets the value of the `fs.file-max` property, make sure that its value is set to at least 1.5 times the per-process limit.

If there is no line that sets a value for this property, add the following to the end of the file:

```
fs.file-max = 100000
```

Note:

100000 is just an example here. Specify a value of at least 1.5 times the per-process limit.

3. Display the current hard limit of the system.

```
ulimit -aH
```

The `open files (-n)` value is the maximum number of open files per process limit.

The value should be set to at least 65535.

4. Edit the `/etc/security/limits.conf` file.

If the file has lines that set the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines before `#End of file`, making certain to insert a tab between the columns.

```
* soft nofile 65535
* hard nofile 65535
```

Note:

The number of open file descriptors is limited by the physical memory available to the host. You can determine this limit with the following command.

```
cat /proc/sys/fs/file-max
```

If the `file-max` value is significantly higher than the 65535 limit, consider increasing the file descriptor limit to between 10% and 15% of the system-wide file descriptor limit. For example, if the `file-max` value is 810752, you could set the file descriptor limit to 100000. If the `file-max` value is lower than 65535, the host is likely not sized appropriately.

5. Reboot your system, and then use the `ulimit` command to verify that the file descriptor limit is set to 65535.

```
# ulimit -n
```

Result

Note:

For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits.

```
/etc/security/limits.d/20-nproc.conf
```

Add or edit the following lines if they do not already exist:

```
* soft nproc 65536
* soft nofile 65536
* hard nproc 65536
* hard nofile 65536
root soft nproc unlimited
```

Tuning the file system

Administrators can tune ext3 and ext4 file systems by setting the file system flushes and noatime to improve server performance.

Newer ext4 systems use delayed allocation to improve performance. This delays block allocation until it writes data to disk. Delayed allocation improves performance and reduces fragmentation by using the actual file size to improve block allocation.

This feature might increase the risk of data loss in cases where a system loses power before all of the data has been written to disk. This can occur if a program is replacing the contents of a file without forcing a write to the disk with `fsync`. To reduce this risk, make sure the default `auto_da_alloc` option is enabled on ext4 file systems.

The following changes can be made in the `/etc/fstab` file.

Setting the file system flushes

Improve Directory Server performance by reducing the span between file system flushes.

About this task

By default, Linux servers running the ext3 file system flush the data to disk every five seconds.

Steps

1. If the Directory Server is running on a Linux server using the ext3 file system, consider editing the mount options for that file system to include the following command.

```
commit=1
```

This variable changes the flush frequency from five seconds to one second.

2. You should also set the flush frequency in the `/etc/fstab` file.

Changing the mount command alone does not survive across reboots.

Setting noatime on ext3 and ext4 Systems

If your Linux server uses an ext3 or ext4 file system, set `noatime` to improve performance by turning off any `atime` updates during read access.

About this task

Additionally, set the flush frequency to the `/etc/fstab` file. Performing the change through the `mount` command alone does not survive across reboots.

Steps

- Run the `mount` command for the relevant system. Choose from:

- ext3 system:

```
# mount -t ext3 -o noatime /dev/fs1
```

- ext4 system:

```
# mount -t ext4 -o noatime /dev/fs1
```

Setting the maximum user processes

To address memory problems when running multiple servers, increase the default maximum user process limit.

About this task

Some Linux distributions, such as Redhat Enterprise Linux Server and CentOS 6.0 or later, set the default maximum number of user processes to 1024. This is considerably lower than the same parameter on older distributions. The default value of 1024 leads to some Java virtual machine memory errors when running multiple servers on a machine because each Linux thread counts as a user process.

At startup, the Directory Server and its tools automatically attempt to raise the maximum user processes limit to 16,383 if the value reported by `ulimit` is less than that. If, for any reason, the server is unable to automatically set the maximum processes limit to 16,383, it displays an error message.

There are several ways to set the maximum user process limit.

Steps

- Set the limit in `/etc/security/limits.conf`.

Replace the (*) with the name of the user under which the software will run.

Example:

```
* soft nproc 65535
* hard nproc 65535
```

- Set the `NUM_USER_PROCESSES` environment variable to 16383.
- In the `config/num-user-processes` file, set the `NUM_USER_PROCESSES` to 16383.

About editing OS-level environment variables

Certain environment variables might affect the Directory Server in unexpected ways. This is particularly true for environment variables that are used by the underlying operating system to control how it uses non-default libraries.

For this reason, the Directory Server explicitly overrides the values of key environment variables like `<PATH>`, `<LD_LIBRARY_PATH>`, and `<LD_PRELOAD>` to ensure that environment settings used to start the server do not inadvertently impact its behavior.

If you need to edit any of these environment variables, set the values of those variables by manually editing the `<set_environment_vars>` function of the `lib/_script-util.sh` script.

You must stop (`bin/stop-server`) and re-start (`bin/start-server`) the server for the change to take effect.

Installing sysstat and pstack (Red Hat)

If you plan to run PingDirectory on a Red Hat Linux system, install a couple of packages, `sysstat` and `pstack`, that are disabled by default, but are useful for troubleshooting.

About this task

The troubleshooting tool `collect-support-data` uses the `iostat`, `mpstat`, and `pstack` utilities to collect monitoring, performance, and stack trace information on the server's processes.

Steps

- To install `sysstat` on your Red Hat system, run the following command.

```
$ sudo yum install sysstat gdb dstat -y
```

Installing dstat (SUSE Linux)

dstat is a system monitoring tool that can help you troubleshoot PingDirectory servers on SUSE distributions.

About this task

The **collect-support-data** tool uses the **dstat** utility for system monitoring. **dstat** can be obtained from the OpenSUSE project website. The following process shows how to install the **dstat** utility on SUSE Enterprise Linux 11 SP2:

Steps

1. Sign on as the root user.
2. Add the appropriate repository using the **zypper** tool.
3. Install the **dstat** utility.

```
$ zypper install dstat
```

Disabling file system swapping

Because file system swapping can interfere with PingDirectory, disable performance tuning tools like **tuned**.

About this task

Steps

1. Sign on as the root user.
2. Add the line `vm.swappiness = 0` to the file `/etc/sysctl.conf`.
3. Restart the system to apply the change.
4. Optional: If you need to tune performance after disabling file system swapping, do the following:
 - a. Clone the existing performance profile.
 - b. Run **tuned**.
 - c. Add the line `vm.swappiness = 0` to the file `/usr/lib/tuned/profile-name/tuned.conf`.
 - d. To select the updated profile, run **tuned-adm profile customized_profile**.
 - e. Restart the system to apply the changes.

Omitting vm.overcommit_memory

An improperly configured value for the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file might cause the **setup** or **start-server** tool to fail.

About this task

For Linux systems, the `vm.overcommit_memory` property sets the kernel policy for memory allocations. The default value of 0 indicates that the kernel determines the amount of free memory to grant a `malloc` call from an application. If the property is set to a value other than zero, the operating system might grab too much memory, reducing the amount of available memory for the **setup** or **start-server** tools.

Steps

Omit the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file to ensure that enough memory is available for these tools.

Managing system entropy

Linux uses entropy to calculate random data that is used by the system in cryptographic operations.

About this task

Some environments with low entropy might have intermittent performance issues with SSL-based communication. This is more typical on virtual machines but can occur in physical instances as well.

Steps

- Monitor the `kernel.random.entropy_avail` in `sysctl` value for best results.

Setting file system event monitoring (inotify)

An event monitoring tool such as `inotify` can be configured for notifying processes about file system events, including file creation, deletion, and updates.

About this task

Linux limits the number of `inotify` watches a user can receive.

Steps

- To increase the limit, edit `etc/sysctl.conf` to add the following line.

```
fs.inotify.max_user_watches = 524288
```

- Run the following command.

```
$ sudo sysctl -w fs.inotify.max_user_watches=524288
```

Tuning the I/O scheduler

Using the correct I/O scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load.

About this task

Important:

For file systems running on an SSD or in a virtualized environment, use the recommended `noop` scheduler. For all other systems, use the `deadline` scheduler.

The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

Steps

1. To determine which scheduler is configured on your system, run the following command.

```
$ cat /sys/block/<block-device>/queue/scheduler
```

2. To change the scheduler on a running system, run the following command.

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

3. To apply the change, restart the system.

Running as a non-root user (Linux)

You have two options to run as a non-root user but still allow connections on a privileged port.

Use a load balancer or directory proxy server

Many environments can run the server on a non-privileged port but be hidden by a hardware load balancer or LDAP directory proxy server.

Use `netfilter`

Use the `netfilter` mechanism, exposed through the `iptables` command, to automatically redirect any requests from a privileged port to the unprivileged port on which the server is listening.

Enabling the server to listen on privileged ports (Linux)

For your convenience, enable the server to listen on privileged ports while running as a non-root user.

About this task

Linux systems have a mechanism called capabilities that is used to grant specific commands the ability to do things that are normally only allowed for a root account:

- The `setcap` command assigns capabilities to an application.
- The `cap_net_bind_service` capability enables a service to bind a socket to privileged ports (port numbers less than 1024).

Steps

1. If Java is installed in `/ds/java` (and the Java command to run the server is `/ds/java/bin/java`), you can grant the `cap_net_bind_service` capability to the Java binary with the following command.

```
$ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
```

2. Create the file `/etc/ld.so.conf.d/libjli.conf` with the path to the directory that contains the `libjli.so` file.

The java binary needs an additional shared library (`libjli.so`) as part of the Java installation. Because this process imposes stricter limits on where the operating system looks for shared libraries to load for commands that have capabilities assigned, it is also necessary to tell the operating system where to look for this library.

Example: For example, if the Java installation is in `/ds/java`, the contents of that file should be:

```
/ds/java/lib/amd64/jli
```

3. To apply the changes, run the following command.

```
$ sudo ldconfig -v
```

Getting the installation packages

Obtain the latest `.zip` release bundle from Ping Identity and extract it to a folder of your choice to begin the installation process.

About this task

The release bundle contains the Directory Server code, tools, and package documentation.

Complete the following steps to unpack the build distribution.

Steps

1. Download the latest `.zip` distribution of the Directory Server software.
2. Extract the compressed `.zip` archive file to a directory of your choice.

Example:

```
$ unzip PingDirectory-<version>.zip
```

Result:

You can set up the Directory Server.

Deploying the administrative console

Although the default configuration for PingDirectory Server features an embedded administrative console, you can run the administrative console as a standalone instance.

To administer multiple servers from a single console instance, you can use Docker or a Java application server like Tomcat or Jetty to run the administrative console as a standalone instance. Running the console as a standalone instance also allows you to make changes to the console without restarting the directory server's HTTPS connection handlers.

For more information, see the following:

- [Using Docker to run a standalone administrative console](#) on page 43
- [Setting up the administrative console on a Tomcat environment](#) on page 44

Using Docker to run a standalone administrative console

Use the administrative console Docker image to run the console as a standalone instance and connect it to a running PingDirectory container.

About this task

The PingData administrative console is available as a standalone Docker image on [Docker Hub](#).

To see a `docker-compose` example that deploys a PingDirectory container with a corresponding console, see the [PingDirectory getting started demo](#).

Note:

The [Ping Identity Helm charts](#) also include support for the PingData administrative console, which you should use when deploying the console in Kubernetes.

Steps

- To connect with a PingDirectory server that is deployed in Docker, run the administrative console image in a local Docker deployment.

The network you use must match the network used by the PingDirectory Server's container.

Example:

The following example deploys the standalone console image in a local Docker deployment with the console listening on port 8443 using the `pingnet` network.

```
docker run \
  --name pingdataconsole \
  --publish 8443:8443 \
  --network pingnet \
  --detach \
```

```
pingidentity/pingdataconsole:edge
```

Important:

You can change the first port in the `--publish` line based on what port you want to use on your local machine, but don't change the second port. To access the console outside of Docker on port 9443, for example, use `9443:8443`.

- To access the console, go to `https://<hostname>:<port>/console/login` and enter the following credentials.

Field	Credential
Server	<code><PingDirectory container name>:<LDAPS port></code> <div style="border: 1px solid black; padding: 5px; margin-top: 5px;"> Note: The name of the server you enter on the sign-on page must match the name of the PingDirectory container you are trying to connect to along with the LDAPS port of that container. For example, use <code>pingdirectory:1636</code> to connect to a standalone PingDirectory Docker container on the same network. </div>
Username	administrator
Password	2FederateM0re

Docker server profiles

To customize the console's configuration, include an `application.yaml.subst` file in the server profile in the `instance/webapps/console/WEB-INF/classes/` directory.

Note:

The `.subst` extension indicates that environment variable values, such as `${Ping_Identity_Password}`, are replaced before the `application.yaml` file is used by the console.

The `Server_Profile_URL` and `Server_Profile_Path` environment variables are used to specify the server profile you want to deploy with. To see an example server profile used to configure single sign-on (SSO) for the administrative console, see the [pingdataconsole-ss0 server profiles](#).

Setting up the administrative console on a Tomcat environment

Use a Java application server to set up the administrative console as a standalone instance.

Before you begin

To set up a standalone console, you need the `admin-console.war` file from the PingDirectory Server's `resource/admin-console.zip` archive.

About this task

You can use the `.war` file with Java application servers, such as Tomcat or Jetty. The following example uses Tomcat as the server environment.

Note:

Because Tomcat server version 10 has a defect with Spring Boot applications, use Tomcat 9 instead.

Steps

1. Download the Tomcat 9 `.zip` file from the [Apache Tomcat downloads page](#).
2. Extract the `.zip` archive files.
3. To set up the Tomcat server, follow the instructions in the `RUNNING.txt` file from the extracted directory.
4. Copy the `admin-console.war` file into the `webapps` folder in the Tomcat root directory.
5. To start the Tomcat server, run the `startup.sh` or `startup.bat` file from the `bin` folder of the Tomcat root directory.

Result:

Tomcat automatically extracts the console from the compressed `.war` file into an exploded application directory and starts running the console.

6. To access the console, use the `admin-console` path from the Tomcat server path.

By default, the path to access the console is `localhost:8080/admin-console`.

Signing on to the Administrative Console

After the server is installed, sign on to the Administrative Console at `https://<host>:<port>/console/login` to verify the configuration and manage the server. The root user DN or the common name of a root user DN is required to log into the Administrative Console. For example, if the DN created when the server was installed is `cn=Directory Manager,directory manager` can be used to log into the Administrative Console.

If the Administrative Console needs to run in an external container, such as Tomcat, a separate package can be installed according to that container's documentation. Contact Ping Identity Customer Support for the package location and instructions.

Note:

The session timeout for the console is 24 hours by default. When this duration is exceeded, all inactive users are logged off automatically.

To set a different timeout value, configure the `server.sessionTimeout` application parameter, which specifies the timeout duration in seconds. You can set the value as an init parameter either in the console or on the command line, as shown below.

- Console

Select **Web Application Extensions # Console** and then use the **Init Parameter** field.

- Command line

The following example uses a value of 1800 seconds (30 minutes).

```
dsconfig set-web-application-extension-prop --no-prompt \
--extension-name Console \
--add init-parameter:server.sessionTimeout=1800
```

For the change to take effect, restart the HTTP(S) Connection Handler or the server itself.

Configuring the administrative console

After you have deployed the PingDirectory administrative console, you can configure it.

For more information, see the following:

- [Configuring PingDirectory Server to disable the embedded administrative console](#) on page 46
- [The administrative console's application.yml configuration file](#) on page 47
- [Selecting servers to manage in the administrative console](#) on page 49

Configuring PingDirectory Server to disable the embedded administrative console

To decouple the embedded console from your PingDirectory Server instance, use `dsconfig` or the administrative console.

About this task

Note:

The Docker images on Docker Hub have the embedded console disabled by default. For more information on deploying the administrative console and the Directory Server with Docker, see [Using Docker to run a standalone administrative console](#) on page 43.

To configure a PingDirectory server that doesn't have an embedded console running:

Steps

1. Use `dsconfig` or the administrative console.

Choose from:

- To use `dsconfig`, run `dsconfig set-connection-handler-prop`.

```
dsconfig set-connection-handler-prop \
  --handler-name "<HTTPS Connection Handler>" \
  --reset web-application-extension
```

Note:

Replace `<HTTPS Connection Handler>` with the name of the connection handler hosting the administrative console.

- To use the administrative console, open the console:
 - a. From the **Configuration** page, go to **Connection Handlers**.
 - b. In the **Connection Handlers** list, select the HTTP or HTTPS connection handler that is hosting the administrative console.
 - c. Go to **Web Application Extension** and click the arrows to move **Console** from the **Selected** column on the right to the **Available** column on the left.

2. To finalize your changes, restart the HTTPS connection handler using `dsconfig`.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "<HTTPS Connection Handler>" \
  --set enabled:false

dsconfig set-connection-handler-prop \
```

```
--handler-name "<HTTPS Connection Handler>" \
--set enabled:true
```

The administrative console's application.yml configuration file

You can configure the standalone PingDirectory Server administrative console by modifying the `/WEB-INF/classes/application.yml` file.

The following table describes the different configuration settings listed in the default `application.yml` file included with the administrative console and what they do.

Setting	Description
<code>spring.*</code>	See the Spring API docs for information about these properties. You should not modify them.
<code>management.server.base-path</code>	Controls the prefix of the Spring Boot Actuator endpoints of the console application. You should not modify this setting.
<code>logging.level.*</code>	Controls the severity level of messages logged about these packages.
<code>log.console</code>	If this is set to <code>true</code> , the console logs messages to a file.
<code>log.file</code>	If logging is enabled, this specifies the file that the console will log to.
<code>PingData.SSO.OIDC.enabled</code>	If this is set to <code>true</code> , the console attempts to use OpenID Connect (OIDC) single sign-on (SSO) to bind to the managed server. If <code>false</code> , the console asks for a username and password.
<code>PingData.SSO.OIDC.issuer-uri</code>	The issuer URI to the OIDC provider.
<code>PingData.SSO.OIDC.client-id</code>	The client ID used with the OIDC provider.
<code>PingData.SSO.OIDC.client-secret</code>	The client secret used with the OIDC provider.
<code>PingData.SSO.OIDC.trust-store-file</code>	The file path to the trust store used when communicating with the OIDC provider.
<code>PingData.SSO.OIDC.trust-store-type</code>	The type of trust store specified by <code>PingData.SSO.OIDC.trust-store-file</code> .
<code>PingData.SSO.OIDC.trust-store-pin</code>	Specifies the password used with the trust store specified by <code>PingData.SSO.OIDC.trust-store-file</code> .
<code>PingData.SSO.OIDC.trust-store-pin-environment-variable</code>	Specifies the environment variable containing the password used with the trust store specified by <code>PingData.SSO.OIDC.trust-store-file</code> .

Setting	Description
<code>PingData.SSO.OIDC.strict-hostname-verification</code>	If this is set to <code>true</code> , the console requires a matching host name on the OIDC provider certificate.
<code>PingData.SSO.OIDC.trust-all</code>	If this is set to <code>true</code> , the console accepts any OIDC provider certificate.
<code>PingData.SSO.OIDC.username-attributes</code>	The LDAP attribute containing the username of the user the console is logging in as when using SSO.
<code>login.hide-server</code>	If this is set to <code>true</code> , the 'server' field is hidden on the sign on page.
<code>ldap.server</code>	Auto-populates the 'server' field on the sign on page. If <code>login.hide-server=true</code> , this value determines which directory server the console tries to bind to.
<code>ldap.init-user</code>	Auto-populates the <code>user</code> field on the sign-on page.
<code>ldap.init-password</code>	Auto-populates the <code>password</code> field on the sign-on page.
<code>ldap.trust-store-file</code>	The file path to the trust store used when binding to the directory server.
<code>ldap.trust-store-type</code>	Specifies the type of trust store specified by <code>trust-store-file</code> .
<code>ldap.trust-store-pin</code>	Specifies the password used with the trust store specified by <code>trust-store-file</code> .
<code>ldap.trust-store-pin-environment-variable</code>	Specifies the environment variable containing the password used with the trust store specified by <code>trust-store-file</code> .
<code>ldap.file-servlet-name</code>	Specifies the name of the file servlet on the managed directory server to use when fetching generated <code>collect-support-data</code> (CSD) or server profiles.
<code>ldap.csd-task-enabled</code>	If this is set to <code>true</code> , the console has a button that has the managed directory server run a <code>collect-support-data</code> task.
<code>ldap.csd-destination-folder</code>	The file path to the folder where the managed directory server stores generated CSD files after running the <code>collect-support-data</code> task.

Setting	Description
<code>ldap.profile-destination-folder</code>	<p>The file path to the folder where the managed directory server stores generated server profiles after running the <code>generate-server-profile</code> task.</p> <p> Important: Do not change this property.</p>
<code>branding.custom-folder</code>	<p>The file path to the folder that holds custom <code>branding.properties</code>, <code>branding.css</code>, and <code>favicon.ico</code> files.</p> <p>If empty, default Ping Identity branding is used instead.</p>
<code>configuration.complexity</code>	<p>Determines the maximum complexity level for shown configuration objects.</p> <p>The possible values are <code>basic</code>, <code>standard</code>, <code>advanced</code>, and <code>expert</code>.</p>

Note:

After modifying the `application.yml` file, you must restart the console for your changes to take effect.

Selecting servers to manage in the administrative console

You can use a single console to manage multiple servers.

About this task

To select which server you want to manage, use one of the following four methods:

Steps

- To use the `application.yml` file to select a server for the administrative console to manage:
 - a. Set the `ldap.server` property to the address of the LDAP server to bind to.
 - b. Restart the console using the following command.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "<HTTPS Connection Handler>" \
  --set enabled:false

dsconfig set-connection-handler-prop \
  --handler-name "<HTTPS Connection Handler>" \
  --set enabled:true
```

- To switch between managed servers in a single topology while signed on to the administrative console, in the **Servers** list, select the server you want to manage.

[Configuration Guide](#)

- To select a server when single sign-on (SSO) is not enabled and the `login.hide-server` property in `application.yml` is `false`:
 - If you are signed on to the console, sign off of your current session.
 - Change the **Server** field value on the console sign-on page to the address of the LDAP server you want to manage.

- To select a server when SSO is enabled:

- Enter the console URL with the `ldap-hostname` and `ldaps-port` query parameters specified when accessing the console.

```
https://<hostname>:<port>/console/login?ldap-hostname=<ldap.host>&ldaps-port=<ldaps-port>
```

Example:

In the following example URL, `<hostname>` is `localhost`, `<port>` is `443`, `ldap-hostname` is `ldap.host`, and the `ldaps-port` is `636`.

```
https://localhost:443/console/login?ldap-hostname=ldap.host&ldaps-port=636
```

Directory Server folder layout

After extracting the Directory Server distribution file, you see the following folders and command-line utilities.

Layout of the Directory Server Folders

Directories/Files/Tools	Description
<code>License.txt</code>	Licensing agreement for the Directory Server.
<code>README</code>	<code>README</code> file that describes the steps to set up and start the Directory Server.
<code>bak</code>	Stores the physical backup files used with the backup command-line tool.
<code>bat</code>	Stores Windows-based command-line tools for the Directory Server.
<code>bin</code>	Stores UNIX/Linux-based command-line tools for the Directory Server.
<code>classes</code>	Stores any external classes for server extensions.
<code>collector</code>	Used by the server to make monitored statistics available to PingDataMetrics Server.
<code>config</code>	Stores the configuration files for the backends (admin, config) as well as the directories for messages, schema, tools, and updates
<code>db</code>	Stores the Oracle Berkeley Java Edition database files for the Directory Server.

Directories/Files/Tools	Description
docs	Provides the product documentation.
import-tmp	Stores temporary imported items.
ldif	Stores any LDIF files that you might have created or imported.
legal-notice	Stores any legal notices for dependent software used with the Directory Server.
lib	Stores any scripts, jar, and library files needed for the server and its extensions.
locks	Stores any lock files in the backends.
logs	Stores log files for the Directory Server.
metrics	Stores the metrics that can be gathered for this server and surfaced in PingDataMetrics Server.
resource	Stores the MIB files for SNMP and can include ldif files, make-ldif templates, schema files, dsconfig batch files, and other items for configuring or managing the server.
revert-update	The revert-update tool for UNIX/Linux systems.
revert-update.bat	The revert-update tool for Windows systems.
setup	The setup tool for UNIX/Linux systems.
setup.bat	The setup tool for Windows systems.
scim-data-tmp	Used to create temporary files containing System for Cross-domain Identity Management (SCIM) request data.
uninstall	The uninstall tool for UNIX/Linux systems.
uninstall.bat	The uninstall tool for Windows systems.
update	The update tool for UNIX/Linux systems.
update.bat	The update tool for Windows systems.
Velocity	Stores any customized Velocity templates and other artifacts (CSS, Javascript, images), or Velocity applications hosted by the server.

make-ldif template format

The `make-ldif` template demonstrates the use of all supported tags.

`make-ldif` template

**Note:**

Because this file contains elements that are not defined in the schema, do not import it into a directory.

```
# Copyright 2012-2020 Ping Identity Corporation
# All Rights Reserved.
#
# This file provides a make-ldif template whose primary purpose is to
# demonstrate the use of all variations of all supported tags. It is not
# intended to result in an LDIF file that should be imported into a
# directory,
# since it includes elements that aren't defined in the schema.
# Nevertheless,
# this file may be useful to individuals looking to create their own
# make-ldif templates or to customize an existing template.

# Any global replacement tokens defined at the top of the template file will
# be replaced with their corresponding value later in the template anywhere
# the token name appears in square brackets.
define basedn=dc=example,dc=com

# A branch is a special kind of entry with a fixed, non-dynamically
# generated
# DN (although the DN may be based partially or entirely on a global
# replacement token). Some kinds of tags may be used in branch definitions
# (as
# indicated below through the "allowed-in-branch" attribute. Also, the
# "subordinateTemplate" element specifies the type and number of entries to
# create immediately below each branch.

# The template definitions come after the branch definitions, and define
# entries that will be dynamically generated, including their DNs. Entries
# generated from a template may be either created directly below a branch,
# or
# they may be created below other template-generated entries (i.e., a
# template
# may include a "subordinateTemplate" element indicating that one or more
# entries of a different type should appear below each of the initial
# template
# entries. In this template file, each template below will demonstrate the
# use of exactly one tag, and exactly one variation of that tag (so tags
# with
# multiple variations may be illustrated through multiple templates).

template: attribute-value-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: attribute value tag with name
syntax: open-curly-brace attribute-name close-curly-brace
example: {cn}
allowed-in-branch: true
description: This tag will be replaced with the first value of the indicated
attribute. The specified attribute must have already been assigned at
least one value earlier in the template.

template: attribute-value-tag-with-name-and-max-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: attribute value tag with name and max length
syntax: open-curly-brace attribute-name colon max-length close-curly-brace
example: {cn:5}
allowed-in-branch: true
description: This tag will be replaced with at most the specified number
of characters from the beginning of the first value of the indicated
attribute. The specified attribute must have already been assigned at
least one value earlier in the template.

template: dn-tag-full
rdnAttr: cn
objectClass: top

```

```

objectClass: make-ldif-example
cn: dn tag with full dn
syntax: less-than "dn" greater-than
example: <dn>
allowed-in-branch: true
description: This tag will be replaced with the full DN of the entry
  currently being generated. All RDN attributes must be assigned values
  earlier in the template.

template: dn-tag-partial
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: dn tag with partial dn
syntax: less-than "dn" colon num-components greater-than
example: <dn:1>
allowed-in-branch: true
description: This tag will be replaced with at most the specified number of
  components from the entry currently being generated, as counted from left
  to right (e.g., a value of 1 will cause only the RDN to be used, a value
  of 2 will cause both the current entry's RDN and the parent entry's RDN to
  be used, etc.). All RDN attributes must be assigned values earlier in the
  template.

template: escaped-characters
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: An example of escaping special characters
syntax: backslash-character character-to-escape
example: \{ "this" : "is JSON" \}
allowed-in-branch: true
description: The following characters need to be escaped with a backslash in
  order to be taken literally by make-ldif: \{ \} \< \> \[ \]

template: file-tag-path
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: file tag with path
syntax: less-than "file" colon file-path greater-than
example: <file:cities>
allowed-in-branch: true
description: This tag will be replaced with a randomly-selected line from
  the specified file. The file may be specified using a full path, but if no
  path information is provided, then it will be assumed to be in the config/
  MakeLDIF directory below the server root.

template: file-tag-path-sequential
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: file tag with path and sequential
syntax: less-than "file" colon file-path colon "sequential" greater-than
example: <file:cities:sequential>
allowed-in-branch: true
description: Each subsequent use of this tag will be replaced with the next
  line from the specified file. Once all lines of the file have been used,
  then subsequent uses will start over from the beginning of the file.

template: first-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example

```

```

cn: first tag
syntax: less-than "first" greater-than
example: <first>
allowed-in-branch: false
description: This tag will be replaced with a first name value (taken
  from the first.names file). The algorithm that the make-ldif tool uses
  guarantees that the combination of the first and last name values will
  always be unique, no matter how many entries are generated (although it may
  need to append a number to the last name value in LDIF files with extremely
  large numbers of values).

template: guid-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: GUID tag
syntax: less-than "guid" greater-than
example: <guid>
allowed-in-branch: true
description: This tag will be replaced with a randomly-generated globally-
  unique identifier (GUID), also known as a universally-unique identifier
  (UUID).

template: ifabsent-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifabsent tag with name
syntax: less-than "ifabsent" colon attribute-name greater-than
example: <ifabsent:cn>This value will only appear if the resulting entry
  doesn't have a cn attribute.
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
  always be replaced with the empty string. However, it may cause any in
  which this tag is used to be completely suppressed from the resulting entry
  if the specified attribute already exists in the generated entry. This is
  primarily useful for attributes whose inclusion in generated entries is not
  guaranteed (e.g., randomly determined via the presence tag).

template: ifabsent-tag-with-name-and-value
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifabsent tag with name
syntax: less-than "ifabsent" colon attribute-name colon attribute-value
  greater-than
example: <ifabsent:cn:value>This value will only appear if the resulting
  entry doesn't have a cn attribute with a value of "value".
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
  always be replaced with the empty string. However, it may cause any in
  which this tag is used to be completely suppressed from the resulting entry
  if the specified attribute value already exists in the generated entry.
  This is primarily useful for attributes whose inclusion in generated
  entries is not guaranteed (e.g., randomly determined via the presence tag).

template: ifpresent-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifpresent tag with name
syntax: less-than "ifpresent" colon attribute-name greater-than
example: <ifpresent:cn>This value will only appear if the resulting entry
  includes a cn attribute.

```

```

allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
always be replaced with the empty string. However, it may cause any in
which this tag is used to be completely suppressed from the resulting entry
if the specified attribute is missing from the generated entry. This is
primarily useful for attributes whose inclusion in generated entries is not
guaranteed (e.g., randomly determined via the presence tag).

```

```

template: ifpresent-tag-with-name-and-value
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifpresent tag with name
syntax: less-than "ifpresent" colon attribute-name colon attribute-value
greater-than
example: <ifpresent:cn:value>This value will only appear if the resulting
entry includes a cn attribute with a value of "value".
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
always be replaced with the empty string. However, it may cause any in
which this tag is used to be completely suppressed from the resulting entry
if the specified attribute value is missing from the generated entry. This
is primarily useful for attributes whose inclusion in generated entries is
not guaranteed (e.g., randomly determined via the presence tag).

```

```

template: last-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: last tag
syntax: less-than "last" greater-than
example: <last>
allowed-in-branch: false
description: This tag will be replaced with a last name value (taken
from the last.names file). The algorithm that the make-ldif tool uses
guarantees that the combination of the first and last name values will
always be unique, no matter how many entries are generated (although it may
need to append a number to the last name value in LDIF files with extremely
large numbers of values).

```

```

template: list-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: list tag
syntax: less-than "list" colon value1 colon value2 ... colon valueN greater-
than
example: <list:first:second:third>
allowed-in-branch: true
description: This tag will be replaced with one of the values in the given
list. The value will be selected at random, with each possibility having
the same chance of being selected.

```

```

template: list-tag-with-weights
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: list tag with weights
syntax: less-than "list" colon value1 semicolon weight1 colon value2
semicolon weight2 ... colon valueN semicolon weightN greater-than
example: <list:first;50:second;30:third;20>
allowed-in-branch: true
description: This tag will be replaced with one of the values in the given
list. The value will be selected at random, with the relative weight for

```

each value used to determine its likelihood of being selected. The weight values do not need to add up to 100, but if they do add up to 100 then the weights will be treated as percentages.

```

template: local-value-line
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: local value definition line
syntax: local name=tags
local streetAddress=<random:numeric:5> <file:streets> Street
local locality=<file:cities>
local region=<file:states>
local postalCode=<random:numeric:5>
examplePostalAddressJSON: \{"formatted": "{streetAddress}, {locality},
  {region}, {postalCode},
  US", "streetAddress": "{streetAddress}", "locality": "{locality}", "region": "{region}", "postalCode": "{postalCode}"\}
allowed-in-branch: true
description: This line will define a local value that can be accessed using
  \{name\} just like attribute accesses. The local is evaluated strictly on
  each template entry creation.

template: multiple-tag-with-fixed-number-of-values
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: multiple tag with fixed number of values
syntax: less-than "multiple" colon num-values greater-than
example: <multiple:5><random:alpha:10>
allowed-in-branch: true
description: This tag will cause make-ldif to attempt to generate the
  specified number of different values for this attribute. Any line
  including this tag must have a value that includes some variable content so
  that all of the values will be different.

template: multiple-tag-with-range-of-values
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: multiple tag with range of values
syntax: less-than "multiple" colon min-values colon max-values greater-than
example: <multiple:1:5><random:alpha:10>
allowed-in-branch: true
description: This tag will cause make-ldif to attempt to generate a number
  of different values for this attribute, with the number of values to
  generate selected at random between the specified minimum and maximum
  bounds. Any line including this tag must have a value that includes some
  variable content so that all of the values will be different.

template: multiple-tag-with-number-of-values-determined-from-attribute
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: multiple tag with fixed number of values
syntax: less-than "multiple" colon open-curly-brace attribute-name close-
  curly-brace greater-than
random-integer: <random:numeric:1:5>
example: <multiple:{random-integer}><random:alpha:10>
allowed-in-branch: true
description: This tag will cause make-ldif to attempt to generate a number
  of different values for this attribute, with the number of values to
  generate determined from another attribute already defined in the entry
  (which may itself be dynamically-generated). Any line including this tag

```

must have a value that includes some variable content so that all of the values will be different.

```
template: parentdn-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: parentdn tag
syntax: less-than "parentdn" greater-than
example: <parentdn>
allowed-in-branch: false
description: This tag will be replaced with the full DN of the entry
  immediately superior to the entry being generated.
```

```
template: presence-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: presence tag
syntax: less-than "presence" colon percent greater-than
example: <presence:50>There is a 50% chance that this value will appear in
  the generated entry.
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and
  will always be replaced with the empty string. However, it may be used
  to control whether the entire attribute value will appear in the resulting
  entry.
```

```
template: rdn-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: rdn tag
syntax: less-than "rdn" greater-than
example: <rdn>
allowed-in-branch: true
description: This tag will be replaced with the RDN of the entry being
  generated. All RDN attributes must be assigned values earlier in the
  template.
```

```
template: random-tag-alpha-fixed-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag alpha fixed length
syntax: less-than "random" colon "alpha" colon length greater-than
example: <random:alpha:5>
allowed-in-branch: true
description: This tag will be replaced with a string containing the
  specified number of randomly-selected lowercase alphabetic characters.
```

```
template: random-tag-alpha-variable-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag alpha variable length
syntax: less-than "random" colon "alpha" colon min-length colon max-length
  greater-than
example: <random:alpha:5:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing a number
  of randomly-selected lowercase alphabetic characters. The length of the
  string will be selected at random between the specified minimum and maximum
  length.
```

```
template: random-tag-numeric-fixed-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag numeric fixed length
syntax: less-than "random" colon "numeric" colon length greater-than
example: <random:numeric:5>
allowed-in-branch: true
description: This tag will be replaced with a string containing the
  specified number of randomly-selected numeric digits.

template: random-tag-numeric-range
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag numeric range
syntax: less-than "random" colon "numeric" colon lower-bound colon upper-
bound greater-than
example: <random:numeric:1:10>
allowed-in-branch: true
description: This tag will be replaced with a numeric value selected at
  random between the specified lower and upper bounds.

template: random-tag-numeric-range-custom-format
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag numeric range custom format
syntax: less-than "random" colon "numeric" colon lower-bound colon upper-
bound colon format greater-than
example: <random:numeric:1:1000:0000>
allowed-in-branch: true
description: This tag will be replaced with a numeric value selected at
  random between the specified lower and upper bounds. It will use the
  specified format string (as used by the java.text.DecimalFormat class) to
  format the value.

template: random-tag-alphanumeric-fixed-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag alphanumeric fixed length
syntax: less-than "random" colon "alphanumeric" colon length greater-than
example: <random:alphanumeric:5>
allowed-in-branch: true
description: This tag will be replaced with a string containing the
  specified number of randomly-selected lowercase alphabetic characters and
  numeric digits.

template: random-tag-alphanumeric-variable-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag alphanumeric variable length
syntax: less-than "random" colon "alphanumeric" colon min-length colon max-
length greater-than
example: <random:alphanumeric:5:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing a number
  of randomly-selected lowercase alphabetic characters and numeric digits.
  The length of the string will be selected at random between the specified
  minimum and maximum length.
```

```
template: random-tag-chars-fixed-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag chars fixed length
syntax: less-than "random" colon "chars" colon characters colon length
greater-than
example: <random:chars:abcdef:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing the
specified number of characters selected at random from the provided
character set.

template: random-tag-chars-variable-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag chars variable length
syntax: less-than "random" colon "chars" colon characters colon min-length
colon max-length greater-than
example: <random:chars:abcdef:5:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing a number of
characters selected at random from the provided character set. The length
of the string will be selected at random between the specified minimum and
maximum length.

template: random-tag-hex-fixed-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag hex fixed length
syntax: less-than "random" colon "hex" colon length greater-than
example: <random:hex:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing the
specified number of randomly-selected hexadecimal digits.

template: random-tag-hex-variable-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag hex variable length
syntax: less-than "random" colon "hex" colon min-length colon max-length
greater-than
example: <random:hex:5:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing a number
of randomly-selected hexadecimal digits. The length of the string will be
selected at random between the specified minimum and maximum length.

template: random-tag-base64-fixed-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag base64 fixed length
syntax: less-than "random" colon "base64" colon length greater-than
example: <random:base64:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing the
specified number of randomly-selected characters from the base64 character
set.

template: random-tag-base64-variable-length
```

```

rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag base64 variable length
syntax: less-than "random" colon "base64" colon min-length colon max-length
greater-than
example: <random:base64:5:10>
allowed-in-branch: true
description: This tag will be replaced with a string containing a number of
randomly-selected characters from the base64 character set. The length of
the string will be selected at random between the specified minimum and
maximum length.

template: random-tag-month
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag month
syntax: less-than "random" colon "month" greater-than
example: <random:month>
allowed-in-branch: true
description: This tag will be replaced with a string containing the name of
a randomly-selected month of the year. The American English name of the
month will be used, with the first letter capitalized.

template: random-tag-month-with-max-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag month with max length
syntax: less-than "random" colon "month" colon max-length greater-than
example: <random:month:3>
allowed-in-branch: true
description: This tag will be replaced with a string containing at most
the specified number of characters from the beginning of the name of a
randomly-selected month of the year. The American English name of the
month will be used, with the first letter capitalized.

template: random-tag-telephone
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag telephone
syntax: less-than "random" colon "telephone" greater-than
example: <random:telephone>
allowed-in-branch: true
description: This tag will be replaced with a string containing a randomly-
generated telephone number, using the international representation of a
U.S. telephone number in the format "+1 xxx xxx xxxx" (in which each x
represents a randomly-selected numeric digit).

template: random-tag-timestamp
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag timestamp
syntax: less-than "random" colon "timestamp" greater-than
example: <random:timestamp>
allowed-in-branch: true
description: This tag will be replaced with a string containing a
generalized time representation of a randomly-selected time within the last
ten years.

template: random-tag-timestamp-range

```

```

rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: random tag timestamp range
syntax: less-than "random" colon "timestamp" colon min-timestamp colon max-
timestamp greater-than
example: <random:timestamp:20000101000000.000Z:20091231235959.999Z>
allowed-in-branch: true
description: This tag will be replaced with a string containing a
generalized time representation of a randomly-selected time within the
specified time range (in which the minimum and maximum values should also
be specified using the generalized time format).

template: sequential-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: sequential tag
syntax: less-than "sequential" greater-than
example: <sequential>
allowed-in-branch: true
description: This tag will be replaced with a sequentially-incrementing
value such that each subsequent entry will have a value that is greater
than the one in the entry before it. The first value generated will be
zero.

template: sequential-tag-with-starting-point
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: sequential tag with starting point
syntax: less-than "sequential" colon initial-value greater-than
example: <sequential:1>
allowed-in-branch: true
description: This tag will be replaced with a sequentially-incrementing
value such that each subsequent entry will have a value that is greater
than the one in the entry before it. The first value generated will be the
specified initial value.

template: sequential-tag-with-starting-point-and-reset-below-new-parent
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: sequential tag with starting point and reset below new parent
syntax: less-than "sequential" colon initial-value colon "true" greater-than
example: <sequential:1:true>
allowed-in-branch: true
description: This tag will be replaced with a sequentially-incrementing
value such that each subsequent entry will have a value that is greater
than the one in the entry before it. The first value generated will be the
specified initial value. If this template is used below multiple parents,
then the counter will be reset to the initial value for the first entry
below each new parent.

template: underscore-dn-tag-full
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: underscore dn tag with full dn
syntax: less-than "_dn" greater-than
example: <_dn>
allowed-in-branch: true

```

```

description: This tag will be replaced with the full DN of the entry
  currently being generated, except with commas replaced with underscores.
  All RDN attributes must be assigned values earlier in the template.

template: underscore-dn-tag-partial
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: underscore dn tag with partial dn
syntax: less-than "_dn" colon num-components greater-than
example: <_dn:1>
allowed-in-branch: true
description: This tag will be replaced with at most the specified number of
  componenets from the entry currently being generated, as counted from left
  to right (e.g., a value of 1 will cause only the RDN to be used, a value
  of 2 will cause both the current entry's RDN and the parent entry's RDN
  to be used, etc.), except with commas replaced with underscores. All RDN
  attributes must be assigned values earlier in the template.

template: underscore-parentdn-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: underscore-parentdn tag
syntax: less-than "_parentdn" greater-than
example: <_parentdn>
allowed-in-branch: false
description: This tag will be replaced with the full DN of the entry
  immediately superior to the entry being generated, except with commas
  replaced with underscores.

```

Server installation modes

One of the strengths of the PingDirectory Server is the ease with which you can install a server instance using the **setup** tool. The **setup** tool allows you to quickly install and configure a stand-alone Directory Server instance.

To install a server instance, run the **setup** tool in one of the following modes: interactive command-line, or non-interactive command-line mode.

- **Interactive Command-Line Mode.** Interactive command-line mode prompts for information during the installation process. To run the installation in this mode, use the **setup** command without any options.
- **Non-Interactive Command-Line Mode.** Non-interactive command-line mode is designed for setup scripts to automate installations or for command-line usage. To run the installation in this mode, **setup** must be run with the `--no-prompt` option as well as the other arguments required to define the appropriate initial configuration.

All installation and configuration steps should be performed while logged on to the system as the user or role under which the Directory Server will run.

Before you begin

After you have unzipped the Directory Server ZIP file, you may want to carry out the following functions depending on your deployment requirements:

- **Custom Schema Elements.** If your deployment uses custom schema elements in a custom schema file (for example, `98-schema.ldif`), you may do one of the following:
 - Copy your custom schema file to the `config/schema` directory before running `setup`.
 - Copy your custom schema file to the `config/schema` directory after `setup` and re-start the server. If replication is enabled, the restart will result in the schema replicating to other servers in the replication topology.
 - Use the **Schema Editor** after `setup`. If replication is enabled, schema definitions added through the **Schema Editor** will replicate to all servers in the replication topology without the need for a server restart.
- **Certificates.** If you are setting up a new machine instance, copy your keystore and truststore files to the `<server-root>/config` directory prior to running `setup`. The keystore and truststore passwords can be placed, in clear text, in corresponding `keystore.pin` and `truststore.pin` files in `<server-root>/config`.
- **Encryption Passphrase.** Encryption for directory data, backups, LDIF exports, and log files can be enabled during `setup` by providing or generating an encryption key with a passphrase.
- **Locations.** Location names are used to define a grouping of PingDirectory Server products based on physical proximity. For example, a location is most often associated with a single datacenter location. During the installation, assign a location to each server for optimal inter-server behavior. The location assigned to a server within Global Configuration can be referenced by components within the server as well as processes external to the server to satisfy "local" versus "remote" decisions used in replication, load balancing, and failover.
- **Validate ACIs.** Many directory servers allow for less restrictive application of its access control instructions (ACIs), so that they accept invalid ACIs. For example, if a Sun/Oracle server encounters an access control rule that it cannot parse, then it will simply ignore it without any warning, and the server may not offer the intended access protection. Rather than unexpectedly exposing sensitive data, PingDirectory Server rejects any ACIs that it cannot interpret, which ensures data access is properly limited as intended, but it can cause problems when migrating data with existing access control rules to a PingDirectory Server. If you are migrating from a Sun/Oracle deployment to a PingDirectory Server, PingDirectory Server provides a `validate-acis` tool in the `bin` directory (UNIX or Linux systems) or `bat` directory (Windows systems) that identifies any ACI syntax problems before migrating data. For more information, see [Validating ACIs Before Migrating Data](#).

Important:

Each server deployment requires an execution of `setup`. Duplicating a `server-root` is not supported. The installation of the server doesn't write or require any data outside of the `server-root` directory.

After you run the `setup` tool, do not copy the `server-root` to another location or system to duplicate the installation because this isn't a supported method of deployment. If a host or file system change is needed, you can move the `server-root` to another host or disk location.

Ping license keys

License keys are required to install, update, and renew all Ping products.

How to obtain a license

To obtain a license key, contact your account representative or use the [Ping Identity licensing portal](#).

When do you need a license

A license is required for setting up a new single server instance and can be used site-wide for all servers in an environment. Additionally, you must obtain a new license when updating a server to a new major version, such as when upgrading from 7.3 to 8.0. When cloning a server instance with a valid license, you do not need a new license.

 **Note:**

The update process displays a prompt for a new license.

How to specify a license

- Specify a license at setup

You have these options:

- Use the `--licenseKeyFile <path-to-license>` option with `setup`.
- Copy the license file to the server root directory and then run the `setup` tool. The tool discovers the license file.

- Specify a license after setup

Use the Administrative Console or `dsconfig` (in the Topology section, select License).

 **Note:**

Placing the new license file in the server root directory does not work in this case.

How to view the license status

To view the details of a license, including its expiration, you have these options:

- The server's `status` tool
- The Administrative Console's **Status** page (On the **Monitors** tab, search for License.)

License expiration

The server provides a notification as the expiration date approaches.

Before a license expires, obtain a new one and install it by using `dsconfig` or the Administrative Console.

 **Note:**

An expiring license causes alerts and alarms but does not affect the functionality of the product.

Setting up the PingDirectory server in interactive mode

The `setup` tool also provides an interactive text-based command-line interface to set up PingDirectory server instance.

About this task

Complete the following steps to install the PingDirectory server in interactive mode.

Steps

1. Extract the distribution `.zip` archive, review [Before you begin](#) on page 63, and then go to the server root directory.

Example:

```
$ ./setup
```

If the `JAVA_HOME` environment variable is set to an older version of Java, explicitly specify the path to the Java Development Kit (JDK) installation during the setup process. Either set the

<*JAVA_HOME*> environment variable with the JDK path or execute the `setup` command in a modified Java environment using the `env` command.

Example:

```
$ env JAVA_HOME=/ds/java ./setup
```

2. Read the Ping Identity End-User License Agreement, and type `yes` to continue.
3. Enter the fully qualified host name or IP address of the local host, or press Enter to accept the default.
4. Enter the distinguished name (DN) for the initial root user, or press Enter to accept the default (`cn=Directory Manager`).
5. Enter and confirm the root user password.
6. Press Enter to enable the Ping Identity services (Configuration, Consent, Delegated Admin, Documentation, and Directory REST API) and Administrative Console over HTTPS.

After setup, you can enable or disable individual services and applications by configuring the HTTPS Connection Handler.

7. Enter the port on which the PingDirectory server will accept connections from HTTPS clients, or press Enter to accept the default.
8. Select the unencrypted LDAP connection setting option for this server or press Enter to accept the default (option 3).

Choose from:

- Do not accept unencrypted LDAP connections

 **Note:**

If you select this option, skip to step 12.

- Accept unencrypted LDAP connections, but require StartTLS to secure all communication on those connections
 - Accept unencrypted LDAP connections, but optionally allow StartTLS to secure communication on those connections
 - Accept unencrypted LDAP connections and do not enable support for StartTLS
9. Enter the port on which the PingDirectory server will accept connections from LDAP clients, or press Enter to accept the default.
 10. Select the desired setting for enabling LDAPS, or press Enter to accept the default (yes).

 **Note:**

If you do not enable LDAPS, skip to step 12.

11. Enter the port on which the PingDirectory server will accept connections from LDAPS clients, or press Enter to accept the default.
12. Select the certificate option for this server:
Choose from:
 - Generate a self-signed certificate for testing purposes only.
 - Enter the keystore path and keystore PIN to use an existing certificate using a Java Keystore, .
 - Enter the keystore path and the keystore PIN to use an existing certificate using use a PKCS#12 keystore.
 - Enter only the keystore PIN to use the PKCS#11 token.

13. Choose the desired encryption for the directory data, backups, and log files from the choices provided: Choose from:
- Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments. Use the same encryption passphrase when setting up each server in the topology.
 - Encrypt data with a key generated from a passphrase read from a file.
 - Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
 - Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
 - Do not encrypt server data.

14. Type the base DN for the data, or accept the default base DN of `dc=example,dc=com`.

15. To choose an option to generate and import sample data, type the desired number of entries, or press Enter to accept the default number (10000).

This option is used for quick evaluation of the PingDirectory server. See [Importing data](#) on page 81 if you want to use other options to initialize the server.

16. Choose the option to tune the amount of memory that will be consumed by the PingDirectory server and its tools.

17. Press Enter to prime or preload the database cache at startup prior to accepting client connections.

Priming the cache can increase the startup time for the PingDirectory server but provides optimum performance after startup has completed. This option is best used for strict throughput or response time performance requirements, or if other replicas in a replication topology can accept traffic while this PingDirectory server instance is starting. Priming the cache may also allow the server to collect information at startup that may be helpful in tuning garbage collection in the Java virtual machine (JVM). See [JVM Garbage Collection Using CMS](#).

18. Enter a location name for this server.

19. Enter a unique instance name for this server.

You cannot change the name after you set it.

20. Press Enter to accept the default (yes) to start the PingDirectory server after the configuration has completed.

To configure additional settings or import data, enter `no` to keep the server in shutdown mode.

21. Select the desired option for populating the `config/tools.properties` file during setup, or press Enter to select the default (option 1).

Choose from:

- Do not populate the `tools.properties` file
- Populate the `tools.properties` file with properties needed to connect to the server
- Populate the `tools.properties` file with properties needed to connect to the server, and also include the initial root user DN as the default bind DN
- Populate the `tools.properties` file with properties needed to connect to the server, and also include the DN and password for the initial root user DN as the default bind DN and password

This fourth option, which is not recommended for production environments, populates the `tools.properties` file with properties needed to connect to the server, includes the DN for the initial root user as the default bind DN, and writes the password for that user to a `tools.pin` file for use as the default bind password.

22. In the **Setup Summary** window, review your configuration details, and then select your setup option, or press Enter to select the default (option 1):

Choose from:

- Set up the server with the parameters you have given
- Provide the setup parameters again
- Cancel the setup

Result

If you select option 1, your PingDirectory is configured and initialized.

Installing the Directory Server in non-interactive mode

Run the `setup` command in non-interactive mode to automate the installation process using a script or to run the command directly from the command line.

Non-interactive mode is useful when setting up production or QA servers with specific configuration requirements.

The non-interactive command-line mode requires that all mandatory options be present for each command call. If there are missing or incorrect arguments, the `setup` tool fails and aborts the process. You must also use a `--no-prompt` option to suppress interactive output, except for errors, when running in non-interactive mode. Additionally, you must also use the `--acceptLicense` option and specify the port using the `--ldapPort` or `--ldapsPort` option. If neither option is specified, an error message is displayed. To view the license, run the `bin/review-license` command.

To automatically tune the Java virtual machine (JVM) to use maximum memory, use the `--maxHeapSize {memory}` option. To preload the database at startup, use the `--primeDB` option.

To configure a deployment using a truststore, see [Installing the Directory Server in Non-Interactive Mode with a Truststore](#).

To see a description of the available command-line options for the `setup` tool, use `setup --help`.

Installing the Directory Server in non-interactive mode

Install a Directory Server in a production or QA environment with no security enabled.

Steps

- Extract the distribution `.zip` file, review “Before You Begin”, and then run `setup` with the `--no-prompt` option for non-interactive mode from the `<server-root>` directory.

The following command uses the default root user distinguished name (DN) (`cn=Directory Manager`) with the specified `--rootUserPassword` option. You must include the `--acceptLicense` option or the setup generates an error message. The `--instancename` option specifies the name for the server instance and should be unique across all instances in the topology. The `--location` option specifies the name of the location in which the instance will be installed. You should generally configure your topology with a separate location for each data center to allow inter-server communication to prioritize servers in the same location over those in remote locations.

Example:

```
$ ./setup --no-prompt --rootUserPassword "password" \
  --baseDN "dc=example,dc=com" --acceptLicense --ldapPort 389 \
  --instancename Instance1 --location Location1
```

Installing the Directory Server in non-interactive mode with a truststore

About this task

You can set up the Directory Server using an existing truststore for secure communication. This section assumes that you have an existing keystore and truststore with trusted certificates.

Steps

- Unzip the distribution ZIP file, review [Before You Begin](#), and then, from the server root directory, run `setup` with the `--no-prompt` option for non-interactive mode. The following example enables security using both SSL and StartTLS. It also specifies a JKS keystore and truststore that define the server certificate and trusted CA. The `userRoot` database contents will remain empty and the base DN entry will not be created.

Example:

```
$ ./setup --no-prompt --rootUserPassword "password" \
--baseDN "dc=example,dc=com" --ldapPort 389 --enableStartTLS \
--ldapsPort 636 --useJavaKeystore config/keystore.jks \
--keyStorePasswordFile config/keystore.pin \
--certNickName server-cert --useJavaTrustStore config/truststore.jks \
--acceptLicense --instancename Instance1 --location Location1
```

The password to the private key with the keystore is expected to be the same as the password to the keystore. If this is not the case, the private key password can be defined with the Administrative Console or the `dsconfig` tool by editing the Trust Manager Provider standard configuration object.

Installing a lightweight server

Users who want to demo or test a lightweight version of the Directory Server on a memory-restricted machine can do so by removing all unused or unneeded configuration objects.

All configuration entries, whether enabled or not, take up some amount of memory to hold the definition and listeners that are notified of changes to those objects.

The configuration framework does not allow you to remove objects that are referenced, and in some cases if you have one configuration object referencing another but really do not need it, then you must first remove the reference to it. If you try to remove a configuration object that is referenced, both `dsconfig` and the administrative console should prevent you from removing it and tell you what still references it.

Depending on your test configuration, some example configuration changes that can be made are as follows:

Reduce the number of worker threads

Each thread has a stack associated with it, and that consumes memory. If you're running a bare-bones server, then you probably do not have enough load to require a lot of worker threads.

```
$ bin/dsconfig set-work-queue-prop \
--set num-worker-threads:8 \
--set num-administrative-session-worker-threads:4 \
--set max-work-queue-capacity:100
```

Reduce the percentage of JVM memory used for the JE database cache

When you have a memory-constrained environment, you want to ensure that as much of the memory that is there is available for use during processing and not tied up caching database contents.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set db-cache-percent:5
```

Disable the Dictionary Password Validator

The Dictionary Password Validator takes a lot of memory to hold its dictionary. Disabling it frees up some memory. You can delete the other password validators if not needed, such as Attribute Value, Character Set, Length-based, Repeated Characters, Similarity-based, or Unique Characters Password Validator.

```
$ bin/dsconfig delete-password-validator --validator-name Dictionary
```

Remove non-essential schema files

Although not recommended for production deployments, some candidates that you can remove are the following: 03-rfc2713.ldif, 03-rfc2714.ldif, 03-rfc2739.ldif, 03-rfc2926.ldif, 03-rfc2985.ldif, 03-rfc3712.ldif, 03-uddiv3.ldif.

There are other items that can be removed, depending on your desired configuration. Contact your authorized support provider for assistance.

Uninstalling the Server

The Directory Server provides an `uninstall` command-line utility for quick removal of the code base.

To uninstall a server instance, run the `setup` tool in interactive command-line, or non-interactive command-line mode.

Interactive command-line mode

Interactive command-line mode is a text-based interface that prompts the user for input. To use this mode, run the `bin/uninstall` command without any options.

Non-interactive command-line mode

Non-interactive command-line mode suppresses progress information from being written to standard output during processing, except for fatal errors. To run this mode, use the `bin/uninstall` command with the `--no-prompt` option.

Note:

For standalone installations with a single Directory Server instance, you can also manually remove the Directory Server by stopping the server and recursively deleting the directory and subdirectories, as in the following example.

```
$ rm -rf /ds/PingDirectory
```

Uninstalling the server in interactive mode

Interactive mode uses a text-based, command-line interface to help you remove your instance.

About this task

If `uninstall` cannot remove all of the Directory Server files, the `uninstall` tool generates a message with a list of the files and directories that must be manually deleted. The `uninstall` command must be run as either the root user or the same user (or role) that installed the Directory Server.

Steps

1. From the server root directory, run the `uninstall` command.

Example:

```
$ ./uninstall
```

2. Select the components to be removed.

Choose from:

- Remove all components - If you want to remove all components, press **Enter** to accept the default (remove all).
- Select the components to be removed - If you do not want to remove all components, enter the option to specify the removal of only specific components.

For each type of server component, press **Enter** to remove it or enter `no` to keep it.

3. If the Directory Server is part of a replication topology, enter `yes` to provide your authentication credentials (Global Administrator ID and password). If you are uninstalling a standalone server, continue to step 7.
4. Enter the Global Administrator ID and password to remove the references to this server in other replicated servers, and then enter or verify the host name or IP address for the server that you are uninstalling.
5. Select how you want to trust the server certificate if you have set up SSL or StartTLS. Press **Enter** to accept the default.

Example:

```
How do you want to trust the server certificate for the Directory Server
on server.example.com:389?

1) Automatically trust
2) Use a trust store
3) Manually validate

Enter choice [3]:
```

6. View the logs for any remaining files and manually remove any remaining files or directories.

If your Directory Server is running, the server shuts down before continuing the uninstall process. The uninstall action processes the removal requests before completing.

Uninstalling the server in non-interactive mode

The `uninstall` utility provides a non-interactive method to enter the command with the `--no-prompt` option.

About this task

Another useful argument is the `--forceOnError` option that continues the uninstall process when an error is encountered. If an option is incorrectly entered or if a required option is omitted and the `--forceOnError` option is not used, the command fails and aborts.

Steps

1. From the server root directory, run **uninstall** tool with the `--remove-all` option to remove all of the Directory Server's libraries.

The optional `--quiet` option suppresses output information.

Example:

The following command assumes that the Directory Server is standalone and not part of a replication topology.

```
$ ./uninstall --remove-all --no-prompt --quiet --forceOnError
```

2. If any files or directories remain, manually remove them.

Uninstalling selected components in non-interactive mode

Steps

1. From the server root directory, run **uninstall** with the `--backup-files` option to remove the Directory Server's backup files.

Example:

```
$ ./uninstall --backup-files --no-prompt --quiet --forceOnError
```

2. To view the other options available to remove specific components, use the `--help` or `-H` option.

Upgrading the Server

This section presents multiple update scenarios and their implications to consider when upgrading your server code.

Ping Identity issues software release builds periodically with new features, enhancements, and fixes for improved server performance. Use the Directory Server's update utility to upgrade the current server code version.

Upgrade overview and considerations

The following content provides a brief description of the upgrade process and considerations that might affect your upgrade decisions.

Overview

For the upgrade process, you must download and extract a new version of the Directory Server `.zip` file on the server that will be updated. In addition, you must run the **update** utility with the `--serverRoot` or `-R` option value from the new root server pointing to the installation that will be upgraded.

Considerations

Consider the following when planning for and upgrading replicating servers:

- The upgrading process affects only the server being upgraded. The process does not alter the configuration of other servers.
- The **update** tool verifies that the Java version installed meets the new server requirements. Before running the tool, install the Java version that is supported by the new server.
- For precautionary measures, backup the user data `userRoot` before an upgrade. Restoring from a backup might be necessary if all other servers in the replication topology have been upgraded and a database or encoding change in the new server version prevents the database from being used with

the older server version. The `update` and `revert-update` utilities issue a warning when this is the case.

- Temporarily raise the replication purge delay for all servers in the topology to cover the expected downtime for maintenance. This results in a temporary increase in disk usage for the replicationChanges database stored in `<server-root>/changelogDb`.
- Replication does not need to be disabled on a server before an upgrade.
- Make sure upgraded servers are working as expected before upgrading the last server in the topology.
- After all replicating servers are upgraded, enable new features.

Tip:

For additional considerations, see the [Planning your upgrade guide](#).

Upgrade considerations introduced in PingDirectory 9.0.0.0

Important:

If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

When cleaning replication history from a Directory Server, you must now use `remove-defunct-server`'s new argument, `--performLocalCleanup`. If you have existing automation around disaster recovery, the old method of running `remove-defunct-server` without bind credentials no longer does this replication cleanup step. For PingDirectory versions 9.0.0.0 and later, update any existing automation to use the `--performLocalCleanup` flag.

Upgrade considerations introduced in PingDirectory 8.x

Keep in mind the following upgrade considerations introduced in PingDirectory 8.x versions.

Important:

If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

Upgrade considerations introduced in 8.3.0.0

- [RFC 8996](#) was released, officially deprecating the TLSv1 and TLSv.1.1 protocols and explicitly stating that these must not be used. Per this specification, only TLSv1.2 and TLSv1.3 are considered acceptable for use. Therefore, for this release, TLSv1 and TLSv.1.1 are disabled by default. Disabling support for TLSv1 and TLSv.1.1 does not prevent these protocols from being used, it only disables them by default. Support for these legacy protocols can be re-enabled in the configuration if necessary. Also, support for TLS cipher suites that use the SHA-1 message digest is being

deprecated, as SHA-1 is no longer considered secure. We are also deprecating support for TLS cipher suites that use RSA key exchange because these do not provide forward secrecy.

- Changes to entries made by the clients using the SCIMv2 API will now have the actual user ID, making the request stored in the access and audit logs. By default, the server will continue to use the "SCIM2 Servlet" user as the authorization identity for all SCIM2 requests, and the DN of this user will be recorded in the access log and in the `creatorsName` and `modifiersName` attributes. If you want to change this behavior, change the value of the `map-access-tokens-to-local-users` property from `disabled` to either `optional` or `required`. This will cause the server to map the token to a local user, and if the mapping is successful, the mapped user's DN will be used as the authorization identity for the operations.

Upgrade considerations introduced in 8.2.0.0

- This upgrade moves to Jetty 9.4. As a result, the HTTPS Connection Handler no longer supports TLS_RSA ciphers by default. If you use any legacy HTTPS clients that still require TLS_RSA ciphers, modify the `ssl-cipher-suite` property of the HTTPS Connection Handler to include them.

Upgrade considerations introduced in 8.1.0.0

- If you have upgraded a server that is in a cluster (that has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you can create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- The `bypass-pw-policy` privilege was intended to provide a way for administrators to bypass certain password restrictions that would normally be imposed when managing passwords for other users. A user with this privilege could use it to bypass password validation for their own entry. The `bypass-pw-policy` privilege now only applies when changing another user's password (that is, an administrative password reset), and only in the following scenarios:
 - A user with this privilege will be permitted to set pre-encoded passwords.
 - A user with this privilege will be permitted to set passwords that would otherwise be rejected by one or more password validators.
 - A user with this privilege will be permitted to set passwords that match the current password or that are in the password history.

The privilege will only apply when changing the password for another user, and it will have no effect for a self password change. Further, a user with this privilege will no longer be exempted from any other restrictions in their own password policy. Before upgrading, you should search for users that have the `bypass-pw-policy` privilege and check for compatibility issues. You can use the existing password validators and a custom password policy to enforce passwords for administrative users.

- Missing changes will now be detected when the backend is reverted and there are insufficient changes in the changelog database. When in this particular missing-changes state the local replica will not accept changes from the local replication server.
- Fixed an issue in which the server could incorrectly evaluate a matched values request control containing an extensible match filter that specified both an attribute type and a matching rule. The server incorrectly used the attribute type's equality matching rule instead of the matching rule specified in the filter.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve

backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the `encryption-settings export` and `encryption-settings import` commands) and then making it the preferred definition (with `encryption-settings set-preferred`) in all instances.

- Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.

Upgrading servers in a topology

An update to the current PingDirectory Server release includes the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts.

Before you begin

Before you can update and migrate the admin backend, the following conditions must be satisfied:

- Run the update tool and provide LDAP authentication options to the peer servers of the server being updated. The `update` tool connects to the peer servers of the server being updated to obtain the necessary information to populate the topology registry.
- On every server in the topology, configure the encryption protocol requested, either plain, TLS, StartTLS, or SASL, for an LDAP connection.
- Ensure the LDAP credentials are present on every server in the topology.
- Ensure the users related to the LDAP credentials have permissions to read from the admin backend and the config backend of every server in the topology. For example, you can use a root DN user that has `inherit-default-privileges` set to true, such as the `cn=Directory Manager` user, that exists on every server.
- The instance name is set on every server and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server is uniquely identified by its instance name. After the name is set, it cannot be changed.

Tip:

If needed, use the following command to set the instance name of a server prior to the update.

```
$ bin/dsconfig set-global-configuration-prop \
  --set instance-name:uniqueName
```

Important:

This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than a 7.x to a 7.x version and is not applicable to any updates to a server version of 8.x or later.

About this task

Upgrade to a server that uses a topology registry to store network configuration, administrator user accounts, and keys information, as well as migrate the information from the previous server version. The following requirements must be met:

- When the first server is being updated, all other servers in the topology are online.
- When updating additional servers, all topology information was obtained from one of the servers that has already been updated.

- The users related to the provided LDAP credentials have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server and is unique across all servers in the topology.

Steps

1. To make clustered configuration changes in a mixed-version cluster, choose one of the following options:

Choose from:

- Update each server to the same version.
- Temporarily split up the cluster by changing the `cluster-name` property on the server instance configuration objects.

Note:

Changes to clustered configurations are not allowed in mixed-version clusters. This applies to configuration in the `cn=Cluster,cn=config` subtree and only applies to servers with matching cluster names.

2. Make clustered configuration changes again to mirror these changes across the topology.

Result:

When all of these conditions are met, the cluster-wide configuration is synchronized on all servers in the topology.

Note:

Older versions have some topology configuration under the `cn=cluster,cn=config` JSON attribute and field constraints. These items do not support mirrored cluster-wide configuration data. In an update, avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree primary. If additional configuration steps are needed, see step 4.

3. To synchronize the cluster-wide configuration data across all servers in the topology, run the `config-diff` tool on each pair of servers to determine the differences, and use `dsconfig` to update each instance using the `config-diff` output.

Example:

```
$ bin/config-diff --sourceHost hostName \  
  --sourcePort port \  
  --sourceBindDN bindDN \  
  --sourceBindPassword password \  
  --targetHost hostName \  
  --targetPort port \  
  --targetBindDN bindDN \  
  --targetBindPassword password
```

Restoring a mixed topology to a clean state

Perform the following steps to restore a mixed-version 6.2 - 7.x topology with replication problems to a clean state with all servers at the same level and with replication functioning normally.

About this task

Note:

This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than 7.x to a 7.x version and is not applicable to any updates to server version 8.x or later.

If you are upgrading a Directory Server version prior to 7.3 to 7.3 or later and at least one server was previously removed from the topology, you might receive an error message similar to one of the following:

```
[09/Dec/2019:18:37:56.927 -0700] instanceName="[INSTANCE_NAME]" \
  threadID=438 category=REPLICATION severity=NOTICE msgID=118947975
msg="The \
  replication total backlog count is 163364"
```

Or:

```
[09/Dec/2019:17:15:10.108 -0700] category=REPLICATION \
  severity=SEVERE_ERROR msgID=14942295 msg="While clearing the database 997
\
  o=mycompany, the following error happened: (JE 7.5.12) Attempted to
remove \
  non-existent database 997 o=mycompany DatabaseNotFoundException: (JE
7.5.12) \
  Attempted to remove non-existent database 997 o=pingone (DbTree.java:922
\
  DbTree.java:1183 DbTree.java:1235 Environment.java:1001

DirectoryThread.java:352 \
  (7.3.0.4-20191127203417.000Z-83a75e2a) "
```

Steps

1. To export a safe copy of the data, run **bin/export-ldif** on the primary server.
2. Start the down-level primary server and stop the upgraded replica server.
3. Run **bin/remove-defunct-server** on the upgraded replica server and do the following when prompted:
 - a. Select the replica server itself.
 - b. Supply the credentials for the primary server when prompted.
 - c. Select **[c]** to continue.
 - d. Enter the path to the local `changelogDB` when prompted.
4. Leave the upgraded replica server stopped and stop the down-level primary server.
5. Run **bin/dsreplication** on the primary server and do the following:
 - a. Select **2) Manage the topology (add and remove servers)**.
 - b. Select **4) Cleanup Server**.
 - c. Select **[c]** to continue.
 - d. Enter the path to the local `changelogDB` when prompted.
6. Start the down-level primary server and the upgraded replica server.
7. Run **bin/status** on both servers and verify that status of **Replication: disabled** in **Data Sources**.
8. Upgrade the replica server to version 7.3.0.5 or later, which contains fixes for issues 00668265 and DS-40955.
9. Upgrade the primary server to the same level as the replica server.
10. To re-enable replication between the primary and replica server, run the **bin/dsreplication** tool.

11. Re-initialize the replica server data from the primary server.
12. Run `bin/status` on both servers to verify that replication is enabled in **Data Sources** and that both servers show the same number of entries.

Upgrading the Directory Server

Perform an upgrade to the Directory Server with the following steps.

Steps

1. Download and extract the new version of the Directory Server in a location outside the existing server's installation.

For these steps, assume the existing server installation is located in `/prod/PingDirectory` and the new server version is extracted in the `/home/stage/PingDirectory` location.

2. Run the `update` tool provided with the new server package to update the existing Directory Server.

Note:

The update tool might prompt for confirmation of the server configuration changes if it detects customization and display the following code.

```
$ /home/staging/PingDirectory/update --serverRoot /prod/PingDirectory
```

Reverting an update

After PingDirectory Server has been updated, you can revert to the last version or one level back using the `revert-update` tool.

About this task

The `revert-update` tool accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the `revert-update` tool multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing PingDirectory Server, you can run the `revert-update` command to revert to its previous state, then run the `revert-update` command again to return to its original state. The following steps detail reverting from 7.x to a version prior to 7.0.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server displays warnings about "offline configuration changes," but they are not critical and do not appear on subsequent start ups.

To revert to the most recent server version:

Steps

- Use `revert-update` in the server root directory to revert back to the most recent version of the server.

Example:

```
$ PingDirectory-old/revert-update
```

Next steps

Reverting from the 7.0 version or later to a version earlier than 7.0 using the `revert-update` command might require extra steps. This is also the case when updating or reverting from a version earlier than 6.2.0.2 to a 6.2.0.2 version or later. These steps are listed when the `update` and `revert-update` tool

are run as well. Depending on your installation and configuration, you might need to perform one or more of the following tasks:

- When updating or reverting from 6.2.0.2 or later to a version earlier than 6.2.0.2, indexes might need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and rebuild the indexes using the **rebuild-index** tool. The command for recreating an index is in the `Undo` portion of the `logs/config-audit.log` file. To later revert to an older version, delete and recreate those composite indexes again after the revert process completes.
- When updating to 7.x for the first time, instance names must be set for each server in the topology if they were not previously set. This is done with the following **dsconfig** command.

```
$ bin/dsconfig --bindDN "cn=Directory Manager" \
  --bindPassword secret \
  --no-prompt set-global-configuration-prop \
  --set instance-name:<name>
```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the **admin** backend. As long as new servers are not added to the topology after this update, you can use the **revert-update** command to return to the previous version. However, if new servers are added, then the restored **admin** backend of this server does not contain information about the new servers, and the local server cannot communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.
- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a version earlier than 7.x, any servers in the topology using the topology portion of the configuration rather than the **admin** backend must know that the reverted server was downgraded to the **admin** backend. To do this, run the following **dsconfig** command on one of the servers that has not been reverted.

```
$ bin/dsconfig set-server-instance-prop \
  --instance-name <Reverted server instance name> \
  --set server-version:<Version to which server is reverted>
```

- If the topology does not have a primary server when this command is run, the **revert-update** will not succeed. In this case, you must make one of the remaining updated servers in the topology the primary with the following command. This enables the chosen instance to run the **revert-update** command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
  --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions, such as 6.x or earlier. To later revert to an older version, you must export the data to LDIF before performing the reversion. Then, re-import the data after the revert process completes. In addition, you must delete the `changelogDb/` and `db/changelog/` directories in the reverted server root after the revert process completes.

Getting Started with Directory Server

After you have set up your Directory Server instance, you can configure any specific server settings, import your user database, or run initial performance tests to optimize your server's throughput.

 **Note:**

The URL is based on the host name and HTTPS port specified during installation, such as `https://hostname.com:443/console`.

Apply Server Configurations

Apply your server configuration changes individually or using a `dsconfig` batch file. The batch file defines the Directory Server configuration tool, `dsconfig`, commands necessary to configure your server instance. For more information on using batch files, see [Using dsconfig in Batch Mode](#).

If you are migrating from a Sun Java System 5.x, 6.x, 7.x directory server, you can use the `bin/migrate-sun-ds-config` command to migrate your configuration settings to this new server instance.

Import Data

Import user data using the `import-ldif` tool. The import serves as an initial test of the schema settings.

```
$ bin/import-ldif --backendID userRoot --ldifFile ../user-data.ldif
```

Install and Configure the Delegated Admin Application

Install a Javascript-based web application for business users to manage identities stored in the Directory Server. The application provides delegated administration of identities for help desk or customer service representatives initiating a password reset and unlock, an employee in HR updating an address stored within another employee profile, or an application administrator updating identity attributes or group membership to allow application single sign-on (SSO) access.

Run Performance Tests

The Directory Server provides two tools for functional performance testing using in-house LDAP clients that access the server directly: `searchrate` to test search performance and `modrate` to test modification performance.

```
$ bin/searchrate --baseDN "dc=example,dc=com" --scope sub \
  --filter "(uid=user.[0-1999])" --attribute givenName --attribute sn \
  --attribute mail --numThreads 10

$ bin/modrate --entryDN "uid=user.[0-1999],ou=People,dc=example,dc=com" \
  --attribute description --valueLength 12 --numThreads 10
```

Multiple backends

You can create multiple local database backends, each containing one or more different base distinguished names (DNs).

There should be at most one replicating domain on each local database backend. The replication domain should not span multiple local database backends.

The typical entry-balancing configuration involves two local database backends:

- One backend serves the global domain data that resides above the entry-balancing point.
- One backend is defined with the entry-balancing point as the base DN, such as `ou=people,dc=example,dc=com`.

With multiple local database backends configured, you can manage the data existing with each backend independently. Separate index settings are applied to each local database backend.

When creating multiple database backends, consider the following:

- No two backends can have the same base DN.
- If any base DN for a given backend is subordinate to a base DN on another backend, then all base DNs on that backend must be subordinate to the base DN of the other backend.
- The total of all `db-cache-percent` values should be no more than 65-70% in most cases and should never exceed 100%.

Importing data

After installing the database, such as userRoot, import data into the database.

Steps

- To add a server to a replicating set:
 - a. Perform a `dsreplication enable` operation.
 - b. Import the database through the `dsreplication initialize` operation.
- To add a server to a non-replicating set or to add the first server of a future replicating set, import the data with the `bin/import-ldif` tool.

For more information about the `bin/import-ldif` tool, see [Importing and exporting data](#) on page 288.

Generating sample data

PingDirectory Server provides LDIF templates to generate sample entries for initializing your server. You can generate the sample data with the `make-ldif` utility together with template files that come bundled with the `.zip` build, or you can use template files that you create yourself.

About this task

The templates create sequential entries for testing PingDirectory Server with a range of dataset sizes. The Directory Server templates are located in the `config/MakeLDIF`.

The sample data templates generate a dataset with basic access control privileges that grants anonymous read access to anyone, grants users the ability to modify their own accounts, and grants the admin account full privileges. The templates also include the `uid=admin` and `ou=People` entries.

Steps

- To generate randomized sample data, use the `--randomSeed` option with the `make-ldif` command.
Example:

```
$ bin/make-ldif --templateFile config/MakeLDIF/example-10k.template \
  --ldifFile /path/to/data.ldif --randomSeed 0
```

Note:

If the `--randomSeed` option is used with the same seed value, the template always generates the same `.ldif` file.

Result: The command generates 10,000 sample entries and writes them to an output file, `data.ldif`. The random seed generator is set to 0.

- To bypass the `make-ldif` command, use the `--templateFile` option with the `import-ldif` tool.

Importing data on the Directory Server using offline import

Steps

1. Create a `.ldif` file that contains entries or locate an existing file.
The `import-ldif` tool requires a `.ldif` file, which conforms to standard LDIF syntax without change records. The `changeType` attribute is not allowed in the input LDIF. For information on adding entries to , see [Managing Entries](#).
2. Stop the Directory Server.
3. To import data from an LDIF file to the Directory Server, use the `import-ldif` command.

Tip:

For assistance with the list of options, run `import-ldif --help`.

In the following example, the data is imported from the `data.ldif` file to the `userRoot` backend. Entries rejected due to schema violation are written with the rejection reason to the `rejects.ldif` file. Skipped entries, written to `skipped.ldif`, occur if an entry cannot be placed under a branch node in the directory information tree (DIT) or if exclusion filters, such as `--excludeBranch`, `--excludeAttribute`, or `--excludeFilter` are used. The `--overwrite` option instructs `import-ldif` to overwrite existing skipped and rejected files. The `--overwriteExistingEntries` option indicates that any existing data in the backend should be overwritten, and the `--stripTrailingSpaces` option strips trailing spaces on attributes that would otherwise result in an LDIF parsing error.

Example:

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif --
rejectFile
  rejects.ldif --skipFile skipped.ldif --overwrite --
overwriteExistingEntries --stripTrailingSpaces
```

4. Restart the Directory Server.

Running the server

Run the server as a background or foreground process.

Steps

1. To start the Directory Server, run the `bin/start-server` command on UNIX or Linux systems.
An analogous command is in the `bat` folder on Microsoft Windows systems.

Note:

The `bin/start-server` command starts the Directory Server as a background process when no options are specified.

2. Optional: To run the Directory Server as a foreground process, use the `bin/start-server` command with the `--nodetach` option.

Starting the Directory Server

Start the directory server using the terminal.

Steps

- To start the server, on the terminal run `bin/start-server`.

Example:

```
$ bin/start-server
```

Running the server as a foreground process

Use the terminal to run the PingDirectory service as a foreground process.

Steps

1. To launch the Directory Server as a foreground process, open the terminal and enter `bin/start-server` with the `--nodetach` option.

Example:

```
$ bin/start-server --nodetach
```

2. To stop the Directory Server:

Choose from:

- Press **CTRL+C** in the terminal window where the server is running.
- Run the `bin/stop-server` command from another terminal window.

Starting the server at boot time

By default, PingDirectory Server does not start automatically when the system is booted. Instead, you must manually start it with the `bin/start-server` command.

About this task

To configure the Directory Server to start automatically when the system boots, use the `create-systemd-script` utility to create a script, or create the script manually.

Steps

1. Create the service unit configuration file in a temporary location, where "ds" is the user running PingDirectory.

Example:

```
$ bin/create-systemd-script \
  --outputFile /tmp/ping-directory.service \
  --userName ds
```

2. As a root user, copy the `ping-directory.service` configuration file into the `/etc/systemd/system` directory.
3. To read the new configuration file, reload `systemd`.

Example:

```
$ systemctl daemon-reload
```

4. To start the PingDirectory, run the `start` command.

Example:

```
$ systemctl start ping-directory.service
```

- To configure the PingDirectory to start automatically when the system boots, run the `enable` command.

Example:

```
$ systemctl enable ping-directory.service
```

- Log out as root.

To perform this task on an RC system, create the startup script with `bin/create-rc-script` and move it to the `/etc/init.d` directory.

Note:

Create symlinks to this script from the `/etc/rc3.d` directory (starting with an “S” to ensure that the server is started) and `/etc/rc0.d` directory (starting with a “K” to ensure that the server is stopped).

Signing on to the Administrative Console

After the server is installed, access the administrative console, `https://hostname:HTTPport/console/login`, to verify the configuration and manage the server.

To sign on to the administrative console, use the initial root user DN specified during setup (by default `cn=Directory Manager`).

You can use the `dsconfig` command or the administrative console to create additional root DN users in `cn=Root DNs`, `cn=config`. These new users require the fully qualified DN as the username, such as `cn=new-admin,cn=Root DNs,cn=config`. To use a simple username (without the `cn=` prefix) for signing on to the administrative console, the root DN user must have the `alternate-bind-dn` attribute configured with an alternate name, such as "admin."

The default link to the administrative console is `https://hostname:HTTPport/console/login`.

If you need to run the administrative console in an external container, such as Tomcat, you can install a separate package (`/server-root/resource/admin-console.zip`) according to that container's documentation.

Note:

The default session timeout for the console is 24 hours. When this duration is exceeded, all inactive users are signed off automatically.

To set a different timeout value, configure the `server.sessionTimeout` application parameter, which specifies the timeout duration in seconds. You can set the value as an init parameter either in the console or on the command line, as shown below.

For changes to take effect, restart the HTTP(S) Connection Handler or the server.

Console

- Go to **Web Application Extensions # Console**.
- Use the **Init Parameter** field.

Command line

- The following example uses a value of 1800 seconds (30 minutes).

```
dsconfig set-web-application-extension-prop --no-prompt \
--extension-name Console \
--add init-parameter:server.sessionTimeout=1800
```

Stopping the Directory Server

The Directory Server provides a simple shutdown script, `bin/stop-server`, to stop the server. Run it manually from the command line or within a script.

About this task

If the Directory Server has been configured to use a large amount of memory, then it might take several seconds for the operating system to fully release the memory and make it available again. If you try to start the server too quickly after shutting it down, then the server might fail because the system does not yet have enough free memory. On UNIX systems, run the `vmstat` command and watch the values in the "free" column increase until all memory held by the Directory Server is released back to the system.

You can also set a configuration option that specifies the maximum shutdown time a process might take.

Steps

- Use the `bin/stop-server` tool to shut down the server.

Example:

```
$ bin/stop-server
```

Scheduling a server shutdown

Schedule a server shutdown.

Steps

- To schedule a server shutdown, use the `bin/stop-server` tool with the `--stopTime YYYYMMDDhhmmss` option .

The Directory Server schedules the shutdown and sends a notification to the `server.out` log file. The following example sets up a shutdown task that is scheduled to be processed on June 6, 2012 at 8:45 A.M. CDT. The server uses the UTC time format if the provided timestamp includes a trailing "Z", for example, `20120606134500Z`. The command also uses the `--stopReason` option that writes the reason for the shut down to the logs.

Example:

```
$ bin/stop-server --stopTime 20120606134500Z --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --stopReason "Scheduled offline maintenance"
```

Restarting the server

Restart the Directory Server.

About this task

Running the command is equivalent to shutting down the server, exiting the Java Virtual Machine (JVM) session, and then starting up again.

Steps

- Go to the server root directory, and run the `bin/stop-server` command with the `-R` or `--restart` options.

Example:

```
$ bin/stop-server --restart
```

Running the server as a Microsoft Windows service

The server can run as a Windows service on Windows Server 2012 R2 and Windows Server 2016. This enables signing-out of a machine without stopping the server.

Registering the server as a Windows service

Register the server as a Windows service using the Windows command prompt.

About this task

Perform the following steps to register the server as a service:

Steps

1. Stop the server with `bin/stop-server`.
You cannot register a server while it is running.
2. To register the server as a service, from a Windows command prompt, run `bat/register-windows-service.bat`.
3. After registration, start the server from the Windows Services Control Panel or with the `bat/start-server.bat` command.

Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

Running multiple service instances

Only one instance of a particular service can run at one time.

About this task

Services are distinguished by the `wrapper.name` property in the `<server-root>/config/wrapper-product.conf` file.

Steps

1. To run additional service instances, change the `wrapper.name` property on each additional instance.
2. Add or change descriptions of the service in the `wrapper-product.conf` file.

Deregistering and uninstalling services

To uninstall a service, you must first deregister it.

About this task

While a server is registered as a service, it cannot run as a non-service process or be uninstalled.

Steps

1. To remove the service from the Windows registry, use the `bat/deregister-windows-service.bat` file.
2. To uninstall the server, run the `uninstall.bat` script.

Configuring log files for services

About this task

The log files are stored in `<server-root>/logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or the file reaches its maximum size. Only the last three log files are retained.

Steps

These configurations can be changed in the `<server-root>/config/wrapper.conf` file.

Running the status tool

The Directory Server provides a `status` tool that outputs the current state of the server as well as other information, such as server version, java runtime environment statistics, operation processing times, work queue, and administrative alerts.

About this task

The `status` tool is located in the `bin` directory for UNIX and Linux or the `bat` directory for Windows.

Steps

1. Run the `status` command on the command line.

The following code displays an example of the current Directory Server status and limits the number of viewable alerts in the last 48 hours. It provides the current state of each connection handler, data sources, JE environment statistics, processing times by operation type, and the current state of the work queue.

Example:

```
$ bin/status --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret

      --- Server Status ---

Info     : 28/Mar/2012 10:44:22 -0500 : The Directory Server has started
        : successfully
Info     : 28/Mar/2012 10:44:18 -0500 : The Directory Server is starting

Shown are alerts of type [Info,Warning,Error,Fatal] from the past 48
hours Use the
--maxAlerts and/or --severity options to filter this list

```

Note:

By default, the `status` command displays the alerts generated in the last 48 hours. To change this default setting, see step 2.

2. To limit the number of viewable alerts from the default 48 hours, use the `--maxAlerts` option.

Tuning the Server

PingDirectory Server's installation process automatically determines the optimal Java Virtual Machine (JVM) settings based on calculations of the machine running setup.

The default configuration and JVM settings are suitable for most deployments, but it is not uncommon in high-performance environments to make slight changes to the Directory Server's JVM settings as well as performance and resource-related configuration changes with the `dsconfig` tool. For these high-performance environments, tuning can achieve optimum throughput performance and disk space usage for PingDirectory Server and its tools.

About minimizing disk access

Minimizing disk access is critical to the directory server performance.

Defining a Java Virtual Machine (JVM) heap size that can contain the entire contents of the database cache in memory minimizes read operations from disk and achieves optimal performance. The database on-disk is comprised of transaction log files, which are only appended to. After an initial database import, the size on-disk will grow by a factor of at least 25% as inactive records accumulate in the transaction logs.

During normal operation, the on-disk size of the database transaction logs does not represent the memory needed to cache the database.

Consider minimizing the size of the database based on the known characteristics of your data. Doing so reduces hard disk requirements and the memory requirements for the database cache. An example of this is the Directory Server automatically compacting common parent distinguished names (DN).

Finally, consider the write load on your server and its effect on the database. Write operations will always require an associated write-to-disk, but an environment that sustains a high load of write operations might consider tuning the background database cleaner to minimize the size of the database on disk.

Memory allocation and database cache

Memory allocation and database cache comprise the basic components of the Directory Server footprint and logic behind the automated tuning of the `setup` tool.

The Directory Server's optimal performance is dependent on:

- The proper allocation of memory to the Java Virtual Machine (JVM) heap
- The number of processor cores in the system
- The correct combination of JVM options for optimized garbage collection

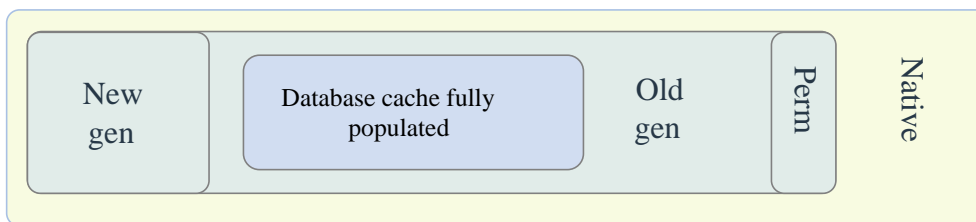

The `setup` tool for Directory Server automatically assigns the JVM options and determines the memory allocation based on the total amount of memory on the system; however, in most production deployments, additional tuning might be required to meet the performance objectives for your system.

Often directory server performance tuning can be accomplished by adjusting a few settings. Tuning these settings, which include both JVM and configuration options, require an understanding of the JVM heap structure and the expected database usage.

Directory Server process memory

The Directory Server consists mainly of a Java Virtual Machine (JVM) heap and a marginal amount of memory allocated by the JVM's execution of native code.

While we frequently refer to the JVM Heap as the maximum memory consumed by the Directory Server, the actual process size is slightly larger than the `Xmx` value because of accumulation of small chunks of native code that Java requires for things, such as SSL sockets.

Within the JVM Heap, the principal memory components are the new and old generations. The new generation is a smaller area of memory where all data is initially allocated and is cleaned of garbage often. Any data that is present long enough is promoted to the old generation for the longer term. The old generation is where the database cache eventually resides. The old generation size is computed from the leftover heap after defining the `MaxHeapSize` and new generation sizes. It is not explicitly stated in the JVM options. A typical set of generation definitions for the JVM is as follows, where `mx` and `ms` values represent the heap size.

```
-Xmx16g -Xms16g -XX:MaxNewSize=2g -XX-NewSize=2g
```

Note:

The `mx` and `ms` values should always be the same, and the `MaxNewSize` and `NewSize` values should be the same. This helps avoid negative changes in performance.

The `MaxNewSize` and `NewSize` values should never need to exceed 2g. The `setup` and `dsjavaproperties` tools set `MaxNewSize` and `NewSize` values based on the results of extensive performance testing and should not need to be changed.

Determining heap and database cache size

Define proper memory allocation of the directory server components using the Directory Server `setup` command.

About this task

To define the proper memory allocation of the directory server components:

Steps

1. Run the Directory Server `setup` command.

Note:

This must be done on hardware that represents the target production platform, especially with regard to process and memory, and the largest heap size that the `setup` tool allows.

2. To define schema and production database settings for the database import, use the `import-ldif` tool.

Note:

After running `import-ldif`, the database is at its most optimized state on-disk with no inactive records. Over time, the on-disk representation of the database grows up to 25-50% as inactive records accumulate before being removed by the server's cleaner thread.

3. After the database is imported, start the server and make any needed configuration changes.
Example: Set the `prime-method` to `preload` on the `userRoot` backend configuration.
4. Restart the Directory Server and watch for a successful preload message.
Choose from:
 - If preloading completes, proceed to step 6.
 - If preloading does not complete, proceed to step 5.
5. If preloading does not complete, troubleshoot with the following steps:
 - a. In the `config/java.properties` file, in the `start-server.java-args` entry, edit the entry to use larger values for `-Xmx` and `-Xms` arguments.
 - b. Run the following command.

```
bin/dsjavaproperties
```
 - c. Restart the server and proceed to step 6.

- After preload completes, run the `status` command to review the database cache utilization.

**Note:**

A fully loaded database needs at least 10-20% cache headroom available for future growth, as in the following example.

Example:

```

--- JE Environment ---
ID      : Cache Full : Cache   : On-Disk : Alert
-----:-----:-----:-----:-----
userRoot : 30%       : 1.1 gb : 868.6mb : None

```

- Optional: To see the state of the database cache in more detail, run an `ldapsearch` on the backend monitor.

**Note:**

In addition to the user configured backends, there might be backends for replication and changelog. The heap is shared among all backends. For information on how the heap amount allocated to each backend is calculated, see [Automatic DB cache percentages](#) on page 91.

Automatic DB cache percentages

Adjust the allocation of the DB cache percentage when setting up the server.

About this task

The setup process automatically tunes the percentage of the `db-cache-percent` property for the `userRoot` backend based on the maximum configured Java Virtual Machine (JVM) heap size. This is only done for the `userRoot` backend during setup. Other backends created by the user are allocated 10%. Change the allocation if needed. When setting up the server:

Steps

- Install the server with the necessary memory.

**Note:**

The server autotunes the size of the cache.

- Set the autotuned cache size to the limit for the combined cache sizes of all of the backends.
- Divide the server cache based on the expected size of the data in each backend.

Automatic memory allocation

If the Memory Tuning feature is enabled during setup, the `setup` algorithm determines the maximum Java Virtual Machine (JVM) heap size based on the total amount of available system memory. Otherwise, the server allocates a maximum JVM heap of 384 MB.

About this task

Directory Server also allows you to specify the maximum heap size during the setup process. For more information, see [JVM Properties for Server and Command-Line Tools](#).

Steps

- To enable Memory Tuning during the setup process:
Choose from:
 - Select the feature in interactive command-line mode.
 - Add the `--jvmTuningParameter` option using the `setup` tool in non-interactive command-line mode.
 - Regenerate the Java properties file with `bin/dsjavaproperties` and the `--jvmTuningParameter` options.

Note:

If Memory Tuning is selected, the server allocates the maximum JVM heap depending on the total system memory. The following table displays the automatically allocated maximum JVM heap memory based on available system memory.

Allocated Max JVM Memory if Tuning is Enabled

Available Memory	Allocated JVM Memory
16 GB or more using a 64-bit JVM	The maximum JVM heap size is set to 70% of total system memory. If the maximum JVM heap size is less than or equal to 128GB of memory, which should be the case for systems with up to 160 GB of memory, then the initial heap size is set to equal the maximum heap size.
6 GB#16 GB using a 64-bit JVM	Total system memory - 4 GB
4 GB–6 GB using a 64-bit JVM	2 GB
2 GB–4 GB	512 MB
1 GB–2 GB	384 MB

Automatic memory allocation for the command-line tools

At setup, the Directory Server automatically allocates memory to each command-line utility based on the maximum Java Virtual Machine (JVM) heap size.

The server sets each command-line utility in the `config/java.properties` file with `-Xmx/Xms` values, depending on the expected memory needs of the tools.

Because some tools can be invoked as a server task while the server is online, there are two definitions of the tool in the `config/java.properties` file:

`.Online`

Typically requires minimal memory because the task is performed within the Directory Server's JVM.

`.Offline`

Can require the same amount of memory needed by the Directory Server. Examples include `import-ldif.offline` and `rebuild-index.offline`.

With large databases, some tools, such as `ldap-diff` and `verify-index`, might need more than the minimal memory. The following table lists the tools that are expected to have more than the minimal memory needs along with the rules for defining the default heap size.

Default Memory Allocation to the Command-Line Tools

Command-Line Tools	Allocated JVM Memory
start-server, import-ldif (offline), rebuild-index (offline)	MaxHeapSize
backup (offline), dbtest export-ldif (offline), ldap-diff, restore (offline), scramble-ldif, summarize-access-log, verify-index	If Max System Memory is: <ul style="list-style-type: none"> ▪ Greater than or equal to 16 GB: set heap to 3 GB ▪ Greater than or equal to 8 GB: set heap to 1 GB ▪ Greater than or equal to 4 GB: set heap to 512 MB ▪ Under 4 GB: set heap to 256 MB

Database preloading

The ability to maintain the database contents in the database cache within the Java Virtual Machine (JVM) memory is key to the Directory Server performance.

With a properly sized database cache, a priming method of preload directs the server to load the database contents into memory at server startup before accepting the first client connection. The time needed to preload the database is proportional to the database size. To avoid priming, you can start the server with the `start-server --skipPrime` command. If the priming method is `none`, or the `--skipPrime` option is specified at startup, the database cache slowly builds as entries are accessed. This can take several days to reach optimal performance.

The preload priming method is suitable for nearly all Directory Server deployments. If the size of the database precludes storing the whole database in memory, there are priming alternatives for optimizing server performance. This type of deployment is considered disk-bound since the disk is accessed when processing most operations. See the section Disk-Bound Deployments for more information. The remaining priming options are applicable to these environments.

The Directory Server database `prime-method` property configures how the caches get primed, what gets primed, such as data, internal nodes, system indexes, and where it gets primed, for example a database cache, file system cache, or both. The `prime-method` property is a multi-valued option that enables preloading the internal nodes into the database cache before the server starts and then primes the values in the background by cursoring across the database. For more details, see the PingDirectory Server Configuration Reference.

The following is a summary of the priming methods:

Preload All Data

Prime the contents of the backend into the database cache.

Preload Internal Nodes Only

Prime only internal database structure information into the database cache, but do not prime any actual data. This corresponds to the `cache-keys-only` cache-mode.

Cursor Across Indexes

Use the `cursor-across-indexes` property to iterate through backend contents. This is similar to and might be slower than using the preload mechanism, but it enables priming to happen in the background after the server has started. This is used when shorter start up times are desired, and the slower performance of an uncached database is acceptable until the database is primed.

Configuring database preloading

Use the `dsconfig` tool to set the database priming method.

If multiple prime methods are used, the order in which they are specified in the configuration is the order in which they are performed. Changing the preloading option requires restarting the Directory Server. The following procedures shows how to configure database preloading.

Configuring database preloading

Configure database preloading.

Steps

1. To load the database contents from disk into memory when the server starts up, set the prime method to preload.

This eliminates the need for the server to gradually prime the database cache using client traffic and ensures that the server has optimal performance when it starts to receive client connections.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set prime-method:preload
```

2. To apply the changes, restart the Directory Server.
 - a. Run `bin/stop-server`.
 - b. Run `bin/start-server`.

Configuring multiple preloading methods

Configure multiple preloading methods.

Steps

1. To achieve the benefits of preloading without delaying server startup, set `prime-method` to `preload-internal-nodes-only`, which caches all of the keys within the database, but not the values.

The database values themselves can be cached in the background once the server has been started with the `cursor-across-indexes` option.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --add prime-method:preload-internal-nodes-only \
  --add prime-method:cursor-across-indexes \
  --set background-prime:true
```

2. To apply the changes, restart the Directory Server.
 - a. Run `bin/stop-server`.
 - b. Run `bin/start-server`.

Configuring system index preloading

Configure system index preloading.

About this task

Some environments have many indexes configured though only a few are used for performance-sensitive traffic.

Steps

1. To reduce server start up time, preload only the necessary indexes into the database at startup.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --set prime-method:preload \
  --set prime-all-indexes:false \
  --set system-index-to-prime:dn2id \
  --set system-index-to-prime:id2entry
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name mail \
  --set prime-index:true
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name uid \
  --set prime-index:true
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name entryUUID \
  --set prime-index:true
```

2. To apply the changes, restart the Directory Server.
 - a. Run `bin/stop-server`.
 - b. Run `bin/start-server`.

Databases on storage area networks, network-attached storage, or running in virtualized environments

There are several considerations when using network-based storage or storage abstracted by virtualization that are not issues when databases are stored on local disks.

A data durability problem occurs when remote storage or the virtualization environment experiences service interruptions, ranging from connectivity loss to total failure from power loss. Data corruption can occur when the storage layer accepts data for writing that is not made durable before a crash occurs. In these cases, a database property can be set that reduces the likelihood of data loss and data corruption. The database property `database-on-virtualized-or-network-storage` can be set on a per-backend environment basis to request all database writes to be written durably to the underlying storage.

There is a performance penalty when enabling this property and, in most cases, is not recommended except where network storage is unreliable. For network file systems, the benefits of faster recovery and less likelihood of data loss from unplanned events might outweigh the penalty. The exact overhead of enabling `database-on-virtualized-or-network-storage` depends on the characteristics of the database, the host file system, storage array configuration, and network and virtualization input and output parameters. The write overhead penalty might be substantial for SAN environments. Incremental and full backup strategies should be used instead if performance is unacceptable.

To enable `database-on-virtualized-or-network-storage` for each applicable backend, use the following command as an example, which references the configuration for the userRoot backend.

```
$ bin/dsconfig set-global-configuration-prop \
  --set database-on-virtualized-or-network-storage:true
```

This should be set to `false` if the database is on a local disk.

Database cleaner

Production environments that have a high volume of write operations might require cleaner thread tuning to control the on-disk database size as log files with inactive nodes wait to be cleaned and deleted.

The Directory Server stores its Oracle Berkeley DB Java Edition (JE) database files on-disk in the `db` directory. Each JE database log file is labeled `nnnnnnnnn.jdb`, where `nnnnnnnnn` is an 8-digit hexadecimal number that starts at 00000000 and is increased by 1 for each file written to disk. JE only appends data to the end of each file and does not overwrite any existing data. JE uses one or more cleaner threads that run in the background to compact the number of JE database (`db`) files.

The cleaner threads begin by scanning the records in each `db` file, starting with the file that contains the smallest number of active records. Next, the cleaner threads append any active records to the most recent database file. If a record is no longer active due to modifications or deletions, the cleaner threads leave it untouched. After the `db` file no longer has active records, the cleaner threads can either delete the file or rename the discarded file.

Note:

Because of this approach to cleaning, the database size on-disk can temporarily increase when cleaning is being performed and files are waiting to be removed.

The local DB backend configuration object has two properties that control database cleaning: `db-cleaner-min-utilization` and `db-num-cleaner-threads`. The `db-cleaner-min-utilization` property determines, by percentage, when to begin cleaning out inactive records from the database files. By default, the property is set to 75, which indicates that database cleaning ensures that at least 75% of the total log file space is devoted to live data.

Note:

This property only affects the on-disk representation of the database and not the in-memory database cache—only live data is ever cached in memory.

The `db-num-cleaner-threads` property determines how many threads are configured for `db` cleaning. The default single cleaner thread is normally sufficient. However, environments with a high volume of write traffic might need to increase this value to ensure that database cleaning can keep up.

If the number of database files grow beyond your expected guidelines or if the Directory Server is experiencing an increased number of update requests, you can increase the number of cleaner threads using the `dsconfig` tool by going to **Backend # Select Advanced Properties # db-num-cleaner-threads**.

Compacting common parent DNs

PingDirectory Server compacts entry distinguished names (DNs) by tokenizing common parent DNs.

About this task

Tokenizing the common parent DNs allows you to increase space usage efficiency when encoding entries for storage.

By default, PingDirectory generates tokens for the following:

- Base DNs for the backend, such as `dc=example,dc=com`
- Any `compact-common-parent-dn` values defined in the server configuration
- `ou=People,<base dn>`
- `ou=Groups,<base dn>`

The tokens are generated in this order. You can also define additional common base DNs to be tokenized.

Steps

- Use the following configuration to tokenize two branches: `ou=people,dc=example,dc=com` and `ou=customers,dc=example,dc=com`.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --add "compact-common-parent-dn:ou=people,dc=example,dc=com" \
  --add "compact-common-parent-dn:ou=customers,dc=example,dc=com"
```

Setting the import thread count

For most systems, the default setting of 16 threads is sufficient and provides good import performance. On some systems, increasing the import thread count can lead to improved import performance while selecting a value that is too large can actually cause import performance to degrade.

About this task

If minimizing LDIF import time is crucial to your deployment, you must determine the optimal number of import threads for your system, which is dependent on both the underlying system and the data set being imported.

Steps

- Use the `dsconfig` command to set the number of import threads.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set import-
thread-count:24
```

JVM properties for server and command-line tools

The Directory Server and tools refer to the `config/java.properties` file for Java Virtual Machine (JVM) options that include important memory settings.

The `java.properties` file sets the default Java arguments for the Directory Server and each command-line utility includes the default `<JAVA_HOME>` path.

The `java.properties` is generated at server setup time and defines memory-related JVM settings based on the user-provided value for max heap size if you selected the aggressive memory tuning option at setup. Most of the JVM options specified for both server and tools do not need customization after setup. The exception is the `-Xmx/Xms` options, which specify the maximum and initial JVM heap size. See the section on [Memory Allocation and Database Cache](#) for advice on tailoring the `-Xmx/Xms` values.

Other than altering the heap size of the server process (`start-server`) or command-line tools, the most common change required to `java.properties` is when you want to update the JVM version. A single edit applies the new JVM to all server and tool use.

Applying changes using `dsjavaproperties`

To apply the changes to the `config/java.properties` file, edit the file manually, and then run the `bin/dsjavaproperties` utility.

The `dsjavaproperties` tool uses the information contained in the `config/java.properties` file to generate a `lib/set-java-home` script, or `lib\set-java-home.bat` on Microsoft Windows systems, which is used by the Directory Server and all of its supporting tools to identify the Java environment and its JVM settings. During the process, `dsjavaproperties` calculates an MD5 digest of the contents of the `config/java.properties` file and stores the digest in the generated `set-java-home` script.

The `dsjavaproperties` utility also performs some minimal validation whenever the property references a valid Java installation by verifying that `$(java-home)/bin/java` exists and is executable.

If you make any changes to the `config/java.properties` file but forget to run `bin/dsjavaproperties`, the Directory Server compares the MD5 digest with the version stored in `set-java-home` and sends a message to standard error if the digests differ.

```
WARNING -- File /ds/PingDirectory
         /config/java.properties has been edited without
         running dsjavaproperties to apply the changes
```

Updating the Java version in the properties file

To change the version of Java that is used by the server and tools, edit the `config/java.properties` file and apply the change by invoking `bin/dsjavaproperties` with no command line options.

About this task

You must restart the server for the change to take affect.

Steps

- Inside `config/java.properties`, alter the value of `default.java-home` to point to the Java correct Java Runtime Environment (JRE).

Any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration.

Example:

```
$ bin/dsjavaproperties
```

Regenerating the Java properties file

The `dsjavaproperties` command provides an `--initialize` option that allows you to regenerate the Java properties file specifically if you set up the Directory Server using standard memory usage but opt for aggressive memory tuning after setup.

About this task

Rather than reconfigure the Java properties file by re-running `setup` or manually editing the `java.properties` file, you can regenerate the properties file for aggressive memory tuning. Any existing file is renamed with a `.old` suffix.

Steps

- Run the `dsjavaproperties` command to regenerate the java properties file for aggressive memory tuning.

Example:

```
$ bin/dsjavaproperties --initialize --jvmTuningParameter AGGRESSIVE
```

Tuning for disk-bound deployments

Configure the server for a disk-bound configuration.

About this task

For best performance, configure the Directory Server to fully cache the DIT in the backend database cache. Directory Server configuration assumes this scenario. For databases too large to fit in memory, other options are available:

- Configure the server for a disk-bound data set. When the database is stored on an SSD, this configuration yields server performance that is comparable to a fully-cached scenario.

- Use uncached attributes or entries as described in the following section.
- Use a Directory Proxy Server in an entry-balancing deployment, which allows all data to be cached in a partitioned environment.

Steps

1. When installing the server, choose the **Aggressive** option for JVM memory configuration and to preload the data when the server starts.
2. Set the `default-cache-mode` of the `userRoot` backend to `cache-keys-only`.
3. Set operating system `vm.swappiness` to 0 to protect the Directory Server JVM process from an overly aggressive file system cache.
4. When the data set is imported with the above settings, verify in the `import-ldif` output that the cached portions of the data set fit comfortably within the database cache.

Uncached attributes and entries

Although achieving optimal Directory Server performance requires that the entire data set be fully cached, there can be deployments in which fully caching the data set is not possible due to hardware or financial constraints, or in which acceptable performance can be achieved by only caching a portion of the data.

The Directory Server already provides support for controlling caching on a per-database basis, such as to cache only certain indexes and system databases, but these features might not provide sufficient control over how memory is used, particularly with regard to which entries are included in the cache, and they do not provide any degree of control over caching only a portion of attributes.

To better address the needs of environments that require partial caching, the Directory Server provides two new options: the ability to exclude certain entries from the cache, and the ability to exclude certain attributes from the cache. The Directory Server uses an `uncached-id2entry` database container, which is similar to the `id2entry` database that maps an entry's unique identifier and its encoded representation. The `uncached-id2entry` database contains either complete or partial representations of entries that are intended to receive less memory for caching. For example, if an entry has a large attribute and the system has hardware constraints on memory, then you can configure the system to not cache this particular attribute or entry. This functionality is only available for the local DB backend, which uses the Berkeley DB Java Edition database.

The `uncached-id2entry` database can be included in the set of databases to prime, but if priming is to be performed, it only includes internal nodes and not leaf nodes. For example, the internal nodes of the `uncached-id2entry` database are included in the preload if the `prime-all-indexes` option is set to "true," or if the `system-index-to-prime-internal-nodes-only` option has a value of `uncached-id2entry`.

Backup and Restore

There are no special considerations for backup and restore with regard to uncached entries and attributes. Backup successfully saves your database contents, including uncached entries and attributes. Because of the way the server deals with changes to uncached entry and uncached attribute configuration, there is no problem with restoring a backup that was taken with a different uncached entry configuration than is currently in place for the server. Any entries encoded in a manner that is inconsistent with the current uncached entry or uncached attribute configuration are properly re-encoded whenever they are updated, or whenever the re-encode entries task is invoked.

Replication

Replication does not propagate information about which portions of entries might have been cached or uncached, nor does it require that different replicas have the same uncached attribute or uncached entry configuration.

LDIF Import and Export

When LDIF content is imported into the server, the `uncached` attribute and `uncached` entry configuration is used to determine on a per-entry basis whether some or all of the content for that entry should be written into the `uncached-id2entry` database. The determination is based on the current configuration and is completely independent of and unaware of the configuration that might have been in place when the LDIF data was initially exported. Neither the LDIF import nor export tools provide any options that specifically target only cached or only uncached content, but these tools do provide the ability to include or exclude entries using search filters or to include or exclude specific attributes.

Server Access Log

Server access log messages can include `uncachedDataAccessed=true` in the result message for any operation in which it was necessary to access uncached data in the course of processing the associated request. For add, delete, modify, or modify DN result messages, `uncachedDataAccessed=true` indicates that at least a portion of the new or updated entry was written into the `uncached-id2entry` database or that at least a portion of the updated entry was formerly contained in the `uncached-id2entry` database. For compare result messages, it indicates that at least a portion of the target entry was contained in the `uncached-id2entry` database and that data from the uncached portion of the entry was required to evaluate the assertion. For search result messages, it indicates that one or more of the entries evaluated as potential matches contained uncached data and that data from the uncached portion of at least one entry was needed in determining what data should be returned to the client.

Uncached Entry and Attribute Properties

The Directory Server provides three new advanced properties on the local DB backend to control the caching mode for the `uncached-id2entry` database:

`uncached-id2entry-cache-mode`

Specifies the cache mode that is used when accessing the records in the `uncached-id2entry` database. If the system has enough memory available to fully cache the internal nodes for this database, then `cache-keys-only` is recommended. Otherwise it is better to select `no-caching` to minimize the amount of memory required for interacting with the `uncached-id2entry` database. For more information, see the PingDirectory Server Configuration Reference.

`uncached-attribute-criteria`

Specifies the criteria used to identify attributes that are written into the `uncached-id2entry` database, rather than the `id2entry` database. This property is only used for entries in which the associated `uncached-entry-criteria` does not indicate that the entire entry should be uncached. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all attributes are written into the `id2entry` database.

`uncached-entry-criteria`

Specifies the criteria used to identify entries that are written into the `uncached-id2entry` database, rather than the `id2entry` database. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all entries are written into the `id2entry` database.

Configuring uncached attributes and entries

Configure uncached attributes and entries.

About this task

The following procedure assumes that the `uncached-id2entry-cache-mode` property is set to the default value, `cache-keys-only`. For more information on the `uncached-id2entry` cache modes, see the PingDirectory Server Configuration Reference.

Steps

1. Run `dsconfig` to uncache entries that match the criteria.

Example:

```
$ bin/dsconfig create-uncached-entry-criteria \
  --criteria-name "Fully Uncached l=austin" --type filter-based \
  --set enabled:true --set "filter:(l=austin)"
```

The filter uncaches all entries that have its location set to "austin", such as `l=austin`.

2. Run `dsconfig` to uncache attributes that match the criteria.

The `--type simple` option indicates that the simple uncached attribute criteria be used to specify the attribute-type that should be uncached. For those entries that are fully stored in the `uncached-id2entry` database container, the uncached attribute is ignored.

Example:

In this example, the attribute-type criteria that should be uncached is `jpegPhoto`.

```
$ bin/dsconfig create-uncached-attribute-criteria \
  --criteria-name "Uncached jpegPhoto" --type simple \
  --set enabled:true --set attribute-type:jpegPhoto
```

3. Set the uncached properties for the `userRoot` backend.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set "uncached-entry-criteria:Fully Uncached l=austin" \
  --set "uncached-attribute-criteria:Uncached jpegPhoto"
```

4. Run the `re-encode-entries` tool to initiate a task that causes a local DB `userRoot` backend to re-encode all or a specified subset of the entries that it contains.

The tool does not alter the entries themselves but provides a useful mechanism for applying significant changes to the way that entries are stored in the backend.

Example:

The following example initiates a task that re-encodes all fully-cached entries in the `userRoot` backend, rate-limited to no more than 100 entries per second.

```
$ bin/re-encode-entries --hostname directory.example.com --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --backendID userRoot --skipFullyUncachedEntries \
  --skipPartiallyUncachedEntries --ratePerSecond 100
```

JVM garbage collection using CMS

To ensure reliable server performance with Java, the Directory Server depends on Java's Concurrent Mark and Sweep process (CMS) for background garbage collection.

Out of several garbage collection options, CMS is the ideal choice for consistent system availability. For the most part, the CMS collector runs as one or more background threads within the Java virtual machine (JVM), freeing up space in JVM Heap from an area called the old generation. One of the criteria used by CMS to determine when to start background garbage collection is a parameter called **CMSInitiatingOccupancyFraction**. This percentage value, which applies to the Old Generation, is recommended for the JVM to initiate CMS when data occupancy in Old Generation reaches the threshold.

Ideally, the database cache takes less than 70% of the space available in the Old Generation, and the **CMSInitiatingOccupancyFraction** value of 80 leaves plenty of headroom to prevent the JVM from running out of space in Old Generation because of an inability for CMS to keep up. Because CMS takes processing resources away from the Directory Server, do not set the **CMSInitiatingOccupancyFraction** at or below the expected database cache size, which would result in the constant running of CMS in the background. For a description of determining Old Generation size, see the section on [Memory Footprint and Database Cache](#).

When the CMS collection process cannot keep pace with memory demands in the Old Generation, the JVM resorts to pausing all application processing to allow a full garbage collection. This event, called a "stop-the-world pause", does not break existing TCP connections or alter the execution of the Directory Server requests. The goal in tuning CMS is to prevent the occurrence of these pauses. When one does occur, the Directory Server generates an alert after the pause and records the pause time in the error log.

Because determining an ideal **CMSInitiatingOccupancyFraction** can be difficult, we warn if the Directory Server detects a garbage collection pause by generating a recommended value for the occupancy threshold based on the current amount of memory being consumed by the backend caches. Unfortunately, an administrator cannot determine the ideal occupancy threshold value in advance. To warn of any impending garbage collection pauses, the Directory Server calculates a recommended value for the **CMSInitiatingOccupancyFraction** property and exposes it in the JVM Memory Usage monitor entry in the following attribute:

```
recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

Also, when you start the server, an administrative alert indicates the current state of the **CMSInitiatingOccupancyFraction** and its recommended value.

```
$ bin/start-server [20/April/2012:10:35:25 -0500] category=CORE
  severity=NOTICE msgID=458886
msg="PingDirectory Server
      8.1.0.0 (build 20120418135933Z, R6226) starting up"

... (more output) ...

[20/April/2012:10:35:53 -0500] category=UBID_EXTENSIONS severity=NOTICE
msgID=1880555580 msg="Memory-intensive Directory Server
components are configured to consume 71750382 bytes of memory:
['userRoot local DB backend' currently consumes 26991632 bytes and
can grow to a maximum of 64323584 bytes, 'changelog cn=changelog backend'
currently consumes 232204 bytes and can grow to a maximum of 2426798 bytes,
'Replication Changelog Database' currently consumes 376661 bytes and can
grow to a maximum of 5000000 bytes]. The configured value of
CMSInitiatingOccupancyFraction is 36 which is less than the minimum
recommended value (43) for the server's current configuration. Having
this value too low can cause the Concurrent Mark and Sweep garbage
collector to run too often, which can cause a degradation of throughput
and response time. Consider increasing the CMSInitiatingOccupancyFraction
value to at least the minimum value, preferably setting it to the
recommended value of 43 by editing the config/java.properties file,
```

```
running dsjavaproperties, and restarting the Directory Server.
If the server later detects that this setting actually leads to a
performance degradation, a separate warning message will be logged.
If this server has not yet been fully loaded with data, then you
can disregard this message"
```

```
[20/April/2012:10:35:53 -0500] category=CORE severity=NOTICE msgID=458887
msg="The Directory Server has started successfully"
```

The Directory Server only makes a recommendation if all of the backends are preloaded and the **CMSInitiatingOccupancyFraction** JVM property is explicitly set, which is done automatically. For example, if you installed the Directory Server and specified that the database be preloaded (or "primed") at startup, then the Directory Server can make a good recommendation for the Directory Server when a pause occurs. If the backend database cache is not full and has not been preloaded, then the recommended value might be an inaccurately low value.

Note:

The generated value for the Directory Server property could change over time with each Directory Server build, Java release, or changes in data set. If the current value is close to the recommended value, then you do not need to change the property unless the server experiences a JVM pause.

If the Directory Server experiences a JVM garbage collection pause, you can retrieve the recommended value from the server, reset the Directory Server property, run **dsjavaproperties**, and restart the server.

Determining the CMSInitiatingOccupancyFraction

Use the terminal to determine the **CMSInitiatingOccupancyFraction** value.

Steps

1. Retrieve the `prime-method` property for the backend.

Example:

```
$ bin/dsconfig get-backend-prop --backend-name userRoot \
  --property prime-method
```

Note:

If you set the `Preload Database at startup` option during the installation, then skip to step 3.

2. If the `prime-method` property was not configured, run **bin/dsconfig** to set the property to `PRELOAD`, and then restart the Directory Server to preload the database cache.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --set prime-method:preload

$ bin/stop-server
```

```
$ bin/start-server
```

Result: At startup, you see an administrative message if the current **CMSInitiatingOccupancyFraction** property is below the recommended value.

Note:

You can get the recommended value from this message and change it in the `config/java.properties` file in step 5.

3. If you were unable to see the recommended **CMSInitiatingOccupancyFraction** property at startup presented in the previous step, pre-tune the value of the **CMSInitiatingOccupancyFraction** property to ensure that all of the data is imported into the server and preloading is enabled in the backend.
 - a. Retrieve the recommended **CMSInitiatingOccupancyFraction** value by issuing the following search.

Example:

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectclass=ds-memory-usage-monitor-entry)" \
  cms-initiating-occupancy-fraction \
  recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

Note:

If the `recommended-cms-initiating-occupancy-fraction-for-current-data-set` is not present, then make sure that the server has been restarted since enabling preload for the backends.

Result:

```
dn: cn=JVM Memory Usage,cn=monitor
cms-initiating-occupancy-fraction:80
recommended-cms-initiating-occupancy-fraction-for-current-data-set:55
```

4. Open the `config/java.properties` file using a text editor and manually edit the **CMSInitiatingOccupancyFraction** (or any other property) to its recommended value in the `start-server.java-args` property.
5. Save the file.

The following arguments are recommended for a Sun 5440 server. Contact your authorized support provider for specific assistance.

Example:

```
start-server.java-args=-d64 -server -Xmx20g -Xms20g -XX:MaxNewSize=1g
-XX:NewSize=1g -XX:ParallelGCThreads=16 -XX:+UseConcMarkSweepGC
-XX:+CMSConcurrentMTEnabled -XX:+CMSParallelRemarkEnabled
-XX:+CMSParallelSurvivorRemarkEnabled -XX:ParallelCMSThreads=8
-XX:CMSMaxAbortablePrecleanTime=3600000
-XX:+CMSScavengeBeforeRemark -XX:RefDiscoveryPolicy=1
-XX:CMSInitiatingOccupancyFraction=55 -XX:+UseParNewGC
-XX:+UseBiasedLocking -XX:+UseLargePages
-XX:+HeapDumpOnOutOfMemoryError
```

The `-XX:ParallelGCThreads` should be limited to 16 (default) or to 8 for smaller systems. The `-XX:ParallelCMSThreads` should be limited to 8.

- To apply the changes, run the `bin/dsjavaproperties` command.

Example:

```
$ bin/dsjavaproperties
```

- Restart the Directory Server.

Configuring the Server

Configure the server to meet the performance, hardware, operating system, and memory requirements for your production environment.

The out-of-the-box, initial configuration settings for the PingDirectory Server provide an excellent starting point for most general-purpose Directory Server applications. However, additional tuning might be necessary to meet the needs of your production environment.

The Directory Server stores its configuration settings in an LDIF file, `config/config.ldif`. Rather than editing the file directly, the Directory Server provides command-line options and an administrative console to configure the server. The Directory Server also includes tools to create server groups to apply configuration changes to multiple servers at one time

About the configuration tools

Use the administrative console or the `dsconfig` command-line tool to modify the PingDirectory Server.

You can access and modify the PingDirectory Server configuration in the following ways:

- Use the Administrative Console. The PingDirectory Server provides an administrative console for graphical server management and monitoring. The console provides equivalent functionality to the `dsconfig` command for viewing or editing configurations. All configuration changes using this tool are recorded in `logs/config-audit.log`, which also has the equivalent reversion commands that let you back out of a configuration.
- Use the `dsconfig` command-line tool. The `dsconfig` tool is a text-based menu-driven interface to the underlying configuration. The tool runs the configuration using three operational modes: interactive command-line mode, non-interactive command-line mode, and batch mode. All configuration changes made using this tool are recorded in `logs/config-audit.log`.

About the dsconfig configuration tool

The `dsconfig` tool is the text-based management tool used to configure the underlying Directory Server configuration.

The `dsconfig` tool has three operational modes: interactive mode, non-interactive mode, and batch mode.

The `dsconfig` tool offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, you should keep the server running when you access the configuration for the server to give the user feedback about the validity of the configuration.

Using dsconfig in interactive command-line mode

In interactive mode, the `dsconfig` tool offers a filtering mechanism that only displays the most common configuration elements.

About this task

The user can specify that more expert level objects and configuration properties be shown using the menu system.

Running `dsconfig` in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the PingDirectory Server.

Steps

1. To start `dsconfig` in interactive command-line mode, invoke the `dsconfig` script without any arguments.

Result: You are prompted for connection and authentication information to the Directory Server, and then a menu displays the available operation types.

2. To accept the default values, press **Enter**.

Note:

In some cases, a default value is provided in square brackets. For example, `[389]` indicates that the default value for that field is port 389.

3. To skip the connection and authentication prompts, provide the connection and authentication information using the command-line options of `dsconfig`.

Configuring the Server using `dsconfig` interactive mode

Configure the PingDirectory Server using the `dsconfig` command-line tool in interactive mode.

Steps

1. Launch the `dsconfig` tool in interactive command-line mode.

Example:

```
$ bin/dsconfig
```

2. Enter the LDAP connection parameters.
Choose from:

- Enter the Directory Server host name or IP address.
- Press **Enter** to accept the default.

3. Enter the number corresponding to the type of LDAP connection that you are using on the Directory Server, or press **Enter** to accept the default.

The numbers for the LDAP connection type are 1 for LDAP, 2 for SSL, and 3 for StartTLS. The default entry is 1.

4. Enter the LDAP listener port number, or accept the default port.

The default port is the port number of the server local to the tool.

5. Enter the user bind DN and the bind DN password.

The default is `cn=Directory Manager`.

6. On the **Directory Server Configuration Console** main menu, enter a number corresponding to the configuration that you want to change.

Note:

The number might change between releases or within the same release, depending on the options selected, such as in cases where more expert level objects and properties are displayed.

7. In this example, select the number for Backend.

8. Set the `db-cache-percent` to 40%.

The optimal cache percentage depends on your system performance objectives and must be tuned as determined through analysis. In many cases, the default value chosen by the `setup` utility is sufficient.

9. On the **Backend management** menu, enter the number corresponding to view and edit an existing backend.

10. Select the backend to work with or press **Enter** to accept the default.

In this example, using the basic object menu, only one backend that can be viewed in the directory, `userRoot`.

11. From the **Local DB Backend** properties menu, type the number corresponding to the `db-cache-percent` property.
12. Enter the option to change the value, and then type the value for the `db-cache-percent` property.
In this example, type `40` for 40 %.
13. To apply the changes, enter `f`.

Note:

Before you apply the change, the `dsconfig` interactive command-line mode provides an option to view the equivalent non-interactive command based on your menu selections. This is useful in building `dsconfig` script files for configuring servers in non-interactive or batch mode. If you want to view the equivalent `dsconfig` non-interactive command, type `d`. For more information, see [Getting the Equivalent dsconfig Non-Interactive Mode Command](#).

14. In the **Backend management** menu, to quit the `dsconfig` tool, enter `q`.

Viewing dsconfig advanced properties

Configure `dsconfig` interactive mode to hide or display additional advanced properties.

About this task

Note:

For most configuration settings, some properties are more likely to be modified than others.

Steps

1. Repeat steps 1–9 in [Configuring the Server using dsconfig interactive mode](#) on page 106.
2. To display the advanced properties, from the **Local DB Backend properties** menu, enter `a`.
Result: This toggles any hidden properties.

Changing the dsconfig object menu

The purpose of object levels is to present only those properties that an administrator will likely use.

About this task

Because some configuration objects are more likely to be modified than others, the PingDirectory Server provides four different object menus that hide or expose configuration objects to the user. The `object` type is a convenience feature designed to improve menu readability.

The following object menus are available:

Basic

Only includes the components that are configured most frequently.

Standard

Includes all components in the Basic menu plus other components that might occasionally need to be altered in many environments.

Advanced

Includes all components in the Basic and Standard menus plus other components that might require configuration under special circumstances or that might be harmful if configured incorrectly.

Expert

Includes all components in the Basic, Standard, and Advanced menus plus other components that almost never require configuration, or that could seriously impact the functionality of the server if not properly configured.

To change the `dsconfig` object menu:

Steps

1. Using `dsconfig`, repeat steps 1–6 in [To Install the Directory Server in Interactive Mode](#).
2. On the **PingDirectory Server configuration** main menu, enter the letter `o` to change the object level.
Basic objects are displayed by default.
3. Enter a number corresponding to an object level of your choice.
Choose from:
 - Enter 1 for Basic.
 - Enter 2 for Standard.
 - Enter 3 for Advanced.
 - Enter 4 for Expert.
4. Review the menu at the new object level.

Additional configuration options for the Directory Server components are displayed.

dsconfig interactive administrative alerts

The `dsconfig` tool and the administrative console provide a feature that displays notifications for certain operations that require further administrative action to complete the process.

If you change a certain backend configuration property, the admin action appears in two places during a `dsconfig` interactive session:

- When configuring the property
- Before you apply the change

For example, if you change the `db-directory` property on the `userRoot` backend, such as specifying the path to the file system path that holds the Oracle Berkeley DB Java Edition backend files, an admin action reminder displays during one of the steps.

The admin action alert also appears as a final confirmation step. The alert allows you to continue and apply the change or back out of the configuration if the resulting action cannot be conducted at the present time. For example, after you type the letter `f` to apply the `db-directory` property change, the admin alert message appears:

```
Enter choice [b]: f One or more configuration property changes require
administrative action or confirmation/notification. Those properties
include: * db-directory: Modification requires that the Directory Server be
stopped, the database directory manually relocated, and then the Directory
Server restarted. While the Directory Server is stopped, the directory
and files pertaining to this backend in the old database directory must
be manually moved or copied to the new location. Continue? Choose 'no' to
return to the previous step (yes / no) [yes]:
```

```
Enter choice [b]: f One or more configuration property changes require
administrative action or confirmation/notification. Those properties include:
* db-directory: Modification requires that the Directory Server be stopped,
the database directory manually relocated, and then the Directory Server
restarted. While the Directory Server is stopped, the directory and files
```

pertaining to this backend in the old database directory must be manually moved or copied to the new location. Continue? Choose 'no' to return to the previous step (yes / no) [yes]:

Currently, only a small set of properties that display an admin action alert appear in **dsconfig** interactive mode and the administrative console. For more information on the properties, see the *PingDirectory Server Configuration Reference*, located in the server's `docs/config-guide` directory.

Using dsconfig in non-interactive mode

The **dsconfig** non-interactive command-line mode provides a simple way to make arbitrary changes to the Directory Server by invoking it from the command line.

Steps

1. To use administrative scripts to automate configuration changes, run the **dsconfig** command in non-interactive mode.

Non-interactive mode is convenient for scripting applications.

Note:

If you plan to make changes to multiple configuration objects at the same time, then the batch mode might be more appropriate.

2. Use the **dsconfig** tool to update a single configuration object using command-line arguments to provide all of the necessary information.

Example:

The following shows the general format for the non-interactive command line.

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

Note:

The `--no-prompt` argument indicates that you want to use non-interactive mode. The `{subcommand}` is used to indicate which general action to perform. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the Directory Server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on your setup. For example, using standard LDAP connections, you can invoke the **dsconfig** tool, as shown.

```
$ bin/dsconfig --no-prompt list-backends \  
  --hostname server.example.com \  
  --port 389 \  
  --bindDN uid=admin,dc=example,dc=com \  
  --bindPassword password
```

3. If your system uses SASL GSSAPI (Kerberos), invoke **dsconfig** as shown.

```
$ bin/dsconfig --no-prompt list-backends \  
  --saslOption mech=GSSAPI \  
  --saslOption authid=admin@example.com \  
  --saslOption ticketcache=/tmp/krb5cc_1313 \  
  --saslOption useticketcache=true
```

- To always display the advanced properties, use the `--advanced` command-line option.

Note:

The `{subcommandArgs}` argument contains a set of arguments specific to the particular subcommand that you want to invoke.

Global arguments can appear anywhere on the command line, including before the subcommand and after or intermingled with subcommand-specific arguments. The subcommand-specific arguments can appear anywhere after the subcommand.

Configuring the Server using `dsconfig non-interactive mode`

Use `dsconfig non-interactive mode` to modify memory and specify parent distinguished names (DNs).

Steps

- To change the amount of memory used for caching database contents and to specify common parent DN's that should be compacted in the underlying database, use the `dsconfig` command in non-interactive mode.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set db-cache-percent:40 \
  --add "compact-common-parent-dn:ou=accts,dc=example,dc=com" \
  --add "compact-common-parent-dn:ou=subs,dc=example,dc=com"
```

Viewing a list of `dsconfig` properties

Run `dsconfig` commands to view a list of properties, objects, property descriptions, and property information.

Steps

- To view the list of all `dsconfig` properties, run the `dsconfig` command with the `list-properties` option.

Note:

Remember to add the LDAP connection parameters.

Example:

```
$ bin/dsconfig list-properties
```

- To view objects at and below the menu object level, use the `dsconfig` command with the `list-properties` option and the `--complexity <menu level>` option.

Example:

```
$ bin/dsconfig list-properties --complexity advanced --includeDescription
```

Note:

You can also add the `--includeDescription` argument that includes a synopsis and description of each property in the output. Remember to add the LDAP connection parameters.

3. If the server is offline, you can run the command with the `--offline` option without needing to enter the LDAP connection parameters.

Example:

```
$ bin/dsconfig list-properties --offline --complexity advanced --includeDescription
```

4. To review the property information provided with the server, view the `<server-root>/docs/config-properties.txt` file.

Getting the equivalent dsconfig non-interactive mode command

Although the `dsconfig` non-interactive command-line mode is convenient for scripting and automating processes, obtaining the correct arguments and properties for each configuration change can be time-consuming.

About this task

For quick and easy configuration, use an option to display the equivalent non-interactive command using `dsconfig` interactive mode. The command displays the equivalent `dsconfig` command to recreate the configuration in a scripted configuration or to enter any pending changes on the command line for another server instance more quickly.

Note:

There are two other ways to get the equivalent `dsconfig` command. One way is by looking at the `logs/config-audit.log` file. It might be more convenient to configure the Directory Server the way you want and then get the `dsconfig` arguments from the log. Another way is to configure an option using the Administrative Console. The console shows the equivalent `dsconfig` command prior to applying the change.

To get the equivalent `dsconfig` non-interactive mode command:

Steps

1. Use `dsconfig` in interactive mode to make changes to a configuration, but do not enter the letter `f` to apply the changes.
2. To view the equivalent non-interactive command, enter `d`.
3. View the equivalent command, and then press Enter to continue.

Result:

Based on an example in the previous section, changes made to the `db-cache-percent` returns the following message.

```
Command line to apply pending changes to this Local DB Backend: dsconfig set-backend-prop --backend-name userRoot --set db-cache-percent:40
```

The command does not contain the LDAP connection parameters required for the tool to connect to the host because the command is presumed to be used to connect to a different remote host.

Using dsconfig batch mode

Configure the Directory Server in `dsconfig` batch mode.

About this task

The PingDirectory Server provides a `dsconfig` batching mechanism that reads multiple `dsconfig` invocations from a file and executes them sequentially.

The batch file provides advantages over standard scripting by minimizing LDAP connections and Java virtual machine (JVM) invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

If a `dsconfig` command has a missing or incorrect argument, the command fails and aborts the batch process without applying any changes to the Directory Server. The `dsconfig` command supports a `--batch-continue-on-error` option that instructs `dsconfig` to apply all changes and skip any errors.

You can view the `logs/config-audit.log` file to review the configuration changes made to the Directory Server and use them in the batch file. The batch file can have blank lines for spacing and lines starting with a pound sign (`#`) for comments. The batch file also supports a `\` line continuation character for long commands that require multiple lines.

The Directory Server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Oracle to PingDirectory Server machines.

Steps

1. Create a text file that lists each `dsconfig` command with the complete set of properties that you want to apply to the Directory Server.

Note:

The items in this file should be in the same format as those accepted by the `dsconfig` command. The batch file can have blank lines for spacing and lines starting with a pound sign (`#`) for comments. The batch file also supports a `\` line continuation character for long commands that require multiple lines.

Example:

```
# This dsconfig operation creates the exAccountNumber global attribute
index.
dsconfig create-global-attribute-index
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--index-name exAccountNumber --set prime-index:true

# Here we create the entry-count placement algorithm with the
# default behavior of adding entries to the smallest backend
# dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name example_com_entry_count
--type entry-counter
--set enabled:true
--set "poll-interval:1 m"

# Note that once the entry-count placement algorithm is created
# and enabled, we can delete the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then delete the
# original round-robin algorithm created during the setup
# procedure.

dsconfig delete-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin
```

2. To read and execute the commands, run `dsconfig` with the `--batch-file` option.

Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth tokens

Configure an access token validator to use PingFederate OAuth tokens with PingDirectory.

Before you begin

You need the following information:

- The runtime engine service port of the PingFederate server, usually 9031
- The client ID of an OAuth 2.0 client configured on the PingFederate server
- The client secret of the OAuth 2.0 client
- The IP address of the PingFederate server

About this task

After you configure a PingFederate server to issue OAuth 2 tokens, you must make these tokens compatible with SCIM 2.0 operations on PingDirectory Server or PingDirectoryProxy.

This section explains how to set up an access token validator to handle this task.

Steps

1. Register the PingFederate server using the following command.

```
dsconfig create-external-server \
  --server-name PingFederateInstance \
  --type http \
  --set base-url:https://<PingFed IP address>:<PingFed port> \
  --set hostname-verification-method:allow-all \
  --set "trust-manager-provider:Blind Trust"
```

Note:

In this example, the hostname verification method is set to `allow-all` and the Blind Trust manager provider is used for the sake of simplicity. You should not use these settings for production environments.

2. Create the access token validator using the following command.

```
dsconfig create-access-token-validator \
  --validator-name PingFederateValidator \
  --type ping-federate \
  --set enabled:true \
  --set authorization-server:PingFederateInstance \
  --set client-id:<client-id> \
  --set client-secret:<client-secret>
```

Note:

Take the `client-id` and `client-secret` values from the PingFederate OAuth 2 client that will be used with the PingDirectory Server or PingDirectoryProxy.

3. Add the access token validator to the SCIM 2 HTTP Servlet configuration with the following command.

```
dsconfig set-http-servlet-extension-prop \
```

```
--extension-name SCIM2 \
--set access-token-validator:PingFederateValidator
```

4. Test the validator by sending a GET request to `/scim/v2/ServiceProviderConfig`.

This endpoint does not require any scopes to access, just a valid bearer token. The sever should return a response similar to the following.

```
{
  "schemas": [
    "urn:ietf:params:scim:schemas:core:2.0:ServiceProviderConfig"
  ],
  "patch": {
    "supported": true
  },
  "bulk": {
    "supported": false,
    "maxOperations": 0,
    "maxPayloadSize": 0
  },
  "filter": {
    "supported": true,
    "maxResults": 0
  },
  "changePassword": {
    "supported": true
  },
  "sort": {
    "supported": false
  },
  "etag": {
    "supported": false
  },
  "authenticationSchemes": [
    {
      "name": "OAuth 2.0 Bearer Token",
      "description": "The OAuth 2.0 Bearer Token Authentication
scheme. OAuth enables clients to access protected resources by obtaining

About recurring tasks and task chains

You can use the `dsconfig create-recurring-task` command to create recurring tasks and task chains to perform regular maintenance tasks for PingDirectory Server. These tasks can perform regular backups, LDIF exports, enter and exit lockdown mode, or other static operations.

Because this process is owned by the server, tasks do not require special privileges or credentials, and they can be run when the server is offline.

Create tasks and then add them to a recurring task chain for scheduling. The task chain ensures that invocations of a task or set of tasks run in a specified order and do not overlap.

A recurring task includes:

- The task-specific object classes to include in the task entry
- The task-specific attributes to include in the task entry, if any
- Whether to alert on task start, success, or failure
- Any addresses to email on task start, success, or failure
- Whether to cancel an instance of the task if it is dependent upon another task and that task does not complete successfully

After you create a task, add one or more tasks to a task chain and schedule the chain using the **dsconfig create-recurring-task-chain** command.

A recurring task chain includes:

- An ordered list of the tasks to invoke
- The months, days, times, and time zones in which each task can be scheduled to start
- The behavior to exhibit if any of the tasks are interrupted by a server shutdown
- The behavior to exhibit if the server is offline when the start time occurs

Note:

Changing the schedule for an existing recurring task chain only takes effect the next time an instance of the chain needs to be scheduled. It does not affect any existing instances of the chain that are already scheduled. Existing scheduled instances still run at the originally scheduled time. When that run is complete, the server schedules the next iteration according to the then-current schedule logic.

Also, you cannot simply cancel the existing scheduled instance to make the next instance run earlier. When you cancel an instance of a recurring task chain, the server automatically schedules the next instance for the next time that matches the scheduling criteria. It never schedules a new instance for earlier than or the same time as one that you manually canceled.

Creating a recurring task and task chain

Use **dsconfig** to create one or more tasks and then add them to a task chain for scheduling.

Steps

1. To create a task, use **dsconfig create-recurring-task**.

Example:

The following creates a backup task.

```
$ bin/dsconfig create-recurring-task \
  --task-name backup-1 \
  --type backup \
  --set 'email-on-failure:admin1@company.com' \
  --set 'email-on-failure:admin2@company.com' \
  --set compress:true \
  --set encrypt:true \
  --set "retain-previous-full-backup-age:4 w" \
  --set retain-previous-full-backup-count:10
```

2. To create a task chain to schedule and run recurring tasks, use **dsconfig create-recurring-task-chain**.

Example:

```
$ bin/dsconfig create-recurring-task-chain \
  --chain-name "backup chain" \
```

```
--set recurring-task:backup-1 \
--set scheduled-date-selection-type:selected-days-of-the-month \
--set scheduled-day-of-the-month:last-day-of-the-month \
--set scheduled-time-of-day:02:00
```

LDIF export as a recurring task

You can create a recurring task to schedule the export of LDIF data.

For new installations, the server exports LDIF data by default every day at 1:05 a.m. in the default time zone for the Java virtual machine (JVM), which is generally the time zone configured for the underlying system. At the scheduled time, the server exports the contents of each public backend to a file in the server root `ldif` directory.

Note:

Public backends are non-administrative backends containing user-supplied data.

The server compresses and encrypts the LDIF exports if the global configuration is set to encrypt LDIF exports by default, which is enabled if encryption is configured during setup. The LDIF exports are rate limited to ten megabytes per second to minimize the impact on server performance, and exports are retained for seven days.

The recurring task chain is created in instances that are updated to this release. However, the task chain is not enabled by default.

LDIF export can export multiple backends in the same recurring task. You can use the `backend-id` property to include multiple backends. You can use the `exclude-backend-id` property to exclude one or more backends. These optional properties are mutually exclusive:

- If the `backend-id` property has one or more values, only the backends with those IDs are exported.
- If the `exclude-backend-id` property has one or more values, all public backends except those listed are exported.
- If neither the `backend-id` property nor the `exclude-backend-id` property supply values, all public backends are exported.

Lockdown mode as a recurring task

You can create recurring tasks to move a server in and out of lockdown mode. Moving a server in and out of lockdown mode is useful for scheduling other tasks while the server is mostly idle and not accepting connections from clients.

While in lockdown mode, the server reports itself as unavailable and also rejects requests from any user that doesn't have the `lockdown-mode` privilege.

The recommended flow for a recurring task chain that uses lockdown mode would be:

1. Enter lockdown mode task.
2. Delay task that waits for the work queue to report that the server is idle.
3. Run desired tasks to perform while the server is in lockdown mode.
4. Leave lockdown mode task.

The enter lockdown mode and leave lockdown mode tasks each allow one optional property that you can use to supply a description for why that the server is being moved into this mode.

File retention recurring task

You can configure a recurring task to remove files in a specified directory that match a given pattern.

You can exclude files that match count-based, time-based, or space-based retention criteria. If any files are to be removed, the oldest files are removed before the most recent file.

If the file name pattern includes a `"${timestamp}"` element, the timestamp is used to identify the file's age. If the file name pattern does not include a timestamp, then the file's age is determined by using the

file's creation time, if available, or the last modified time, if the creation time is not available. If a file's age cannot be determined, the file is not removed.

If multiple files have the same age, the server uses lexicographic ordering to differentiate between them. Lexicographic ordering is applicable only for files with no `retain-file-age` property configured or for files that are older than that age. If multiple files do not share the same age, but that age is younger than the `retain-file-age` value, then those files are retained.

When configuring a file removal task, you must specify at least one of the following properties:

- `retain-file-count`
- `retain-file-age`
- `retain-aggregate-file-size`

Using exec tasks

Exec tasks allow administrators and external users to execute a specified command on the server once or as recurring tasks.

About this task

The server restricts the kinds of commands that can be executed, and the access level of users who can execute them.

These safeguards and requirements include:

- The absolute path to the command to execute must be listed in the `<server-root>/config/exec-command-whitelist.txt` file.
- The global configuration must be updated to allow the exec task. The server does not permit it by default. The following command enables this.

```
$ bin/dsconfig set-global-configuration-prop \
  --add allowed-task:com.unboundid.directory.server.tasks.ExecTask
```

- The user scheduling the task must have the `exec-task` privilege. The server does not grant permission to run this task to any user by default, including root users.

The following configuration changes grant the `exec-task` privilege to a single root user, all root users, or a single non-root user:

Steps

- To grant the `exec-task` privilege to a single root user, run the following.

```
$ bin/dsconfig set-root-dn-user-prop --user-name "<username>" \
  --add privilege:exec-task
```

- To grant the `exec-task` privilege to all root users, run the following.

```
$ bin/dsconfig set-root-dn-prop \
  --add default-root-privilege-name:exec-task
```

- To grant the `exec-task` privilege to a single non-root user, run the following.

```
dn: <userdn>
changetype: modify
add: ds-privilege-name
ds-privilege-name: exec-task
```

- Use the `schedule-exec-task` tool to create an exec task from the command line.

Example:

The following command schedules an exec task to run the `verify-index` tool to check the integrity of the `cn` index in the backend that hosts "`dc=example,dc=com`", assuming that the server is installed in `/ds`.

```
$ bin/schedule-exec-task --hostname directory.example.com \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --promptForBindPassword \
  --waitForCompletion \
  --logCommandOutput \
  /ds/bin/verify-index --baseDN dc=example,dc=com --index cn
```

Topology configuration

Topology configuration enables automatic server grouping and configuration change mirroring. It uses a primary and secondary architecture for mirroring shared data across the topology.

All writes and updates are forwarded to the primary, which forwards them to all other servers. Reads can be served by any server in the group, and servers can be added to an existing topology at installation.

Note:

To remove a server from the topology, you must uninstall it with the `uninstall` tool.

Topology primary requirements and selection

A topology primary server receives configuration changes from other servers in the topology, verifies the changes, and then makes the changes available to all connected servers.

When updating, the primary sends a digest of its subtree contents. If the node's digest differs from the primary's, the server node knows it is not synchronized. The servers pull the entire subtree from the primary if they detect that they are not synchronized.

A server detects it is not synchronized with the primary under the following conditions:

- The server's subtree digest differs from the primary's digest at the end of its periodic polling interval.
- One or more servers have been added to or removed from the topology.

The primary of the topology is selected by prioritizing servers based on:

- Minimum supported product version
- Availability
- Server version
- Earliest start time
- Startup UUID (smaller is preferred)

After determining a primary, the topology data is reviewed from all available servers, every five seconds by default, to determine if any new information identifies a better server primary. If a new server can be the primary and no other servers have indicated that they should be the primary, it will communicate its eligibility to the other servers. This ensures that all servers accept the same primary at approximately the same time, within a few milliseconds of each other. If there is no better primary, the initial primary maintains the role.

After the best primary has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that primary.
 - The primary server itself is considered while determining this majority.
- There is only a single primary in the entire topology.

If either of these conditions is not met, the topology is without a primary and the peer polling frequency is reduced to 100 milliseconds to find a new primary as quickly as possible. If there is no primary in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as primary with the `force-as-master-for-mirrored-data` option in the Global Configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as primaries, then a `multiple-servers-forced-as-masters` alarm is raised.

Topology components

When you install a server, you can add it to an existing topology, cloning the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

Server configuration settings

Configuration settings for the topology are configured in the global configuration and in the config file handler backend. They are topology settings, but they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The global configuration object contains a single topology setting, `force-as-master-for-mirrored-data`. This should be set to `true` on only one of the servers in the topology, and is used only if the topology cannot determine a primary because most of the servers are not available. A server with this setting enabled is assigned the role of primary if no suitable primary can be determined.

The config file handler backend defines three topology `mirrored-subtree` settings:

`mirrored-subtree-peer-polling-interval`

Specifies the frequency at which the server polls its topology peers to identify any changes warranting a new primary selection. A lower value ensures a faster failover, but it also causes more traffic among the peers. The default value is 5 seconds. If no suitable primary is found, the polling frequency adjusts to 100 milliseconds until a new primary is selected.

`mirrored-subtree-entry-update-timeout`

Specifies the maximum length of time to wait for an entry update operation, such as add, delete, modify or modify-dn, to be applied by the primary on all of the servers in the topology. The default is 10 seconds, but updates can take up to twice as long if primary selection is in progress at the time the update operation is received.

`mirrored-subtree-search-timeout`

Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

Topology settings

Topology metadata is stored under the `cn=topology,cn=config` subtree and cluster data is stored under the `cn=cluster,cn=config` subtree. The only setting that can be changed is the cluster name.

Monitor data for the topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to identify changes in the topology.

Topology data includes the following:

- The server ID of the current primary, if the primary is not known
- The instance name of the current primary or if a primary is not set, a description stating why a primary is not set
- A flag indicating which server thinks that it should be the primary
- A flag indicating which server is the current primary

- A flag indicating a server that was forced as primary
- The total number of configured peers in the topology group
- The peers connected to this server
- The current availability of this server
- A flag indicating that a server is not synchronized with its primary or another node in the topology if the primary is unknown
- The amount of time in milliseconds that multiple primaries were detected by this server
- The amount of time in milliseconds that no suitable server is found to act as primary
- A SHA-256 digest encoded as a base-64 string for the current subtree contents

The following metrics are included if this server has processed any operations as primary:

- The number of operations processed by this server as primary
- The number of successful operations processed by this server as primary
- The number of operations processed by this server as primary that failed to validate
- The number of operations processed by this server as primary that failed to apply
- The average amount of time taken in milliseconds by this server to process operations as the primary
- The maximum amount of time taken in milliseconds by this server to process an operation as the primary

Servers and certificates

The following provides a detailed description of PingDirectory Server certificate types.

PingDirectory Server uses two main types of certificates:

Listener certificates

Used to secure communication through TLS.

Inter-server certificates

Used to authenticate between server instances in a topology.

Listener certificates

When a client initiates TLS negotiation with the server, the server presents a certificate chain to the client and the certificate at the head of the chain functions as a listener certificate.

Because the client decides whether to trust the certificate chain, it is recommended that the chain be signed by an issuer whom the client is likely to trust or that the client can be easily configured to trust.

You can create self-signed certificates with long lifespans, but a certificate that a certification authority signs is likely to have a relatively short lifespan. Commercial authorities typically issue certificates that are valid for only one or two years, but some authorities use shorter validity windows.

Short certificate lifespans offer some security benefits. In particular, because most clients do not verify whether a certificate has been revoked, a shorter validity window minimizes the timeframe that a compromised certificate can be used. If the process for replacing certificates is streamlined or automated, administrative inconvenience can be kept to a minimum.

Listener certificates are stored in key stores that are referenced by key manager providers, which in turn provide the logic and configuration for accessing the key stores. If a server component, like a connection handler, requires access to a certificate that it presents to a peer during the TLS negotiation process, that component must reference the key manager provider that points to the key store containing the appropriate certificate. If the key store contains multiple certificates, and if the component referencing the key store includes a property specifying the certificate's nickname, the certificate with that alias is selected. Otherwise, the server lets the Java virtual machine (JVM) select a certificate that might not be well-defined.

The server also provides trust manager providers, which determine whether to trust the certificate chains with which it is presented. A trust manager provider can reference a specified trust store file, but other options include the JVM default trust store, which uses the Java installation's default set of trusted issuers,

and the blind trust manager provider, which automatically trusts every certificate chain that is presented to it.

**Note:**

Never use a blind trust manager in a production environment because it leaves the server vulnerable to impersonation and man-in-the-middle attacks. However, a blind trust manager can be convenient in test environments when troubleshooting certain types of problems.

Replacing listener certificates

Certificate authorities typically restrict the lifespans of the certificates that they sign. If you use a certification authority to issue listener certificates, you are likely replacing the certificates on a regular basis.

About this task

The **replace-certificate** tool performs the following steps:

1. Obtain a new certificate chain.
2. Make necessary updates to the key manager provider and the connection handler configurations
3. Update the server instance listener configuration with the new certificate.

The **replace-certificate** tool offers the following modes of operation:

Interactive mode

Walks you through the process of obtaining a new certificate and installing it in the server. Interactive mode also displays the non-interactive commands that are required to achieve the same result.

Non-interactive mode

Useful when scripting the process of replacing a certificate.

Steps

- To replace a listener certificate, run the `replace-listener-certificate` subcommand of the `replace-certificate` tool.

**Note:**

You can replace certificates manually, but the `replace-certificate` tool automates the process. The `replace-certificate` tool provides information about multiple listener certificates during the transitional phase that occurs when you install them.

The `replace-listener-certificate` subcommand takes arguments that provide the following information:

- Arguments required to authenticate to PingDataSync, such as `--bindDN` and `--bindPasswordFile`
- Details about the key store that contains the new certificate
- Updates that must be made to the key and trust manager providers
- Whether to signal the HTTP connection handler to reload its certificates after the update is complete

The following arguments are available:

Argument	Description
<code>--source-key-store-file {path}</code>	Path to the Java KeyStore (JKS) or PKCS #12 file that contains the private key entry with the new certificate chain. This argument is required.
<code>--source-key-store-password {password}</code>	Clear-text password that is needed to access the contents of the source key store.
<code>--source-key-store-password-file {path}</code>	Path to the file that contains the password necessary to access the contents of the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database.
<code>--source-certificate-alias {alias}</code>	Password that is required to access the appropriate private key in the source key store. If neither the <code>--source-private-key-password</code> nor the <code>--source-private-key-password-file</code> argument is provided, the key store password is used as the private key password.
<code>--source-private-key-password-file {path}</code>	Path to the file that contains the password needed to access the appropriate private key in the source key store. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database. If neither the <code>--source-private-key-password</code> nor the <code>--source-private-key-password-file</code> argument is provided, the key store password is used as the private key password.
<code>--key-manager-provider {name}</code>	Name of the key manager provider that is updated to use the new certificate chain. The

Argument	Description
	value must identify a file-based key manager provider, and the new certificate chain must be enabled. Defaults to <code>JKS</code> if a value is not specified.
<code>--trust-manager-provider {name}</code>	Name of the trust manager provider that is updated with the information required to trust the new certificate chain. The value must identify a file-based trust manager provider, and the new certificate chain must be enabled. If neither this argument nor the <code>--use-jvm-default-trust-manager-provider</code> argument is provided, the tool assumes that the name of the trust manager provider is identical to the name of the key manager provider.
<code>--use-jvm-default-trust-manager-provider</code>	Indicates that the server must be configured to use the JVM-default trust manager provider, which trusts certificates signed by issuers in the <code>cacerts</code> trust store provided with the Java virtual machine (JVM), rather than updating an existing trust manager provider.
<code>--target-certificate-alias {alias}</code>	<p>Alias to use for the new certificate in the key manager provider's key store, and for appropriate updates in the trust manager provider's trust store. Defaults to an alias of <code>server-cert</code> if a value is not specified.</p> <div data-bbox="867 1066 1468 1318" style="border: 1px solid black; padding: 5px;"> <p> Note:</p> <p>If the key manager provider's key store, or the trust manager provider's trust store, already contains an entry with the given alias, the existing entry is renamed.</p> </div>
<code>--reload-http-connection-handler-certificates</code>	<p>Indicates that the tool is requesting that the server cause any HTTPS-based connection handlers to reload their certificates, so that the connection handlers can use the updated certificate.</p> <p>LDAP connection handlers react to the change immediately and start presenting the new certificate chain during subsequent TLS negotiations. HTTPS connection handlers continue using the former certificate until the connection handler is restarted or until the connection handler is asked specifically to reload its certificates.</p> <div data-bbox="867 1780 1468 1837" style="border: 1px solid black; padding: 5px;"> <p> Note:</p> </div>

Argument	Description
	This option might prevent clients with existing TLS sessions that were negotiated with the former certificate from being resumed.

- To remove earlier certificates from the server instance listener configuration, run the **purge-retired-listener-certificates** subcommand.

Note:

The **purge-retired-listener-certificates** subcommand does not take arguments other than the ones that are required to authenticate to the server.

By default, the **replace-certificate** tool updates the server instance listener configuration object to include the new listener certificate, and it merges the old and new certificates residing in the configuration object.

Inter-server certificates

Each server instance in a topology has an inter-server certificate that is generated during the setup process.

The inter-server certificate is not exposed to clients, so a trusted issuer does not need to sign it. Instead, the topology registry, representing a mirrored portion of the configuration with information about every PingDirectory Server instance in the environment, contains the information that each instance needs to trust the inter-server certificates for all other instances.

Inter-server certificates can be used to protect certain secrets that are shared among servers within the topology, like the secrets that are used to digitally sign log files, backups, and LDIF exports. Inter-server certificates include the encryption keys that reversible password-storage schemes use.

The inter-server certificate is generated with a long lifespan. Replace it only when you suspect that its private key is compromised.

Replacing the inter-server certificate

During the installation process, the inter-server certificate is generated with a long lifespan and does not require replacement under normal circumstances. You should replace the inter-server certificate only if you suspect that its private key is compromised.

About this task

The inter-server certificate is intended for use only between server instances within the same topology. Because it is not exposed to regular clients, the inter-server certificate does not need to be trusted.

The **replace-certificate replace-inter-server-certificate** command performs the following steps:

- Acquires the new inter-server certificate from a provided Java KeyStore (JKS) or PKCS #12 key store
- Makes the necessary updates to the `config/ads-truststore` file in the server key store
- Updates the server instance configuration object to include the new inter-server certificate

Note:

To avoid the need to replace the inter-server certificate on a regular basis, use a self-signed certificate with a long lifespan. Each server instance must possess its own, unique inter-server certificate that satisfies the following conditions:

- Uses an RSA key pair

- Has a minimum key size of 2048 bits

The following types of certificates are not allowed:

- Certificates with an elliptic curve key pair
- Certificates with an RSA key that is smaller than 2048 bits

Steps

- To replace the inter-server certificate, run the `replace-inter-server-certificate` subcommand of the `replace-certificate`.

The `replace-inter-server-certificate` subcommand takes a subset of the arguments that are used with the `replace-listener-certificate` subcommand, including the following arguments:

- `--source-key-store-file {path}--source-key-store-password {password}`
- `--source-key-store-password-file {path}`
- `--source-certificate-alias {alias}`
- `--source-private-key-password {password}`
- `--source-private-key-password-file {path}`
- To delete earlier values that are no longer needed, run the `purge-retired-inter-server-certificates` subcommand.

Note:

By default, the new inter-server certificate is merged with the existing values in the server instance configuration entry.

X.509 certificates

The server supports X.509 certificates, the most common type of certificates. [RFC 5280](#) describes X.509v3, which provides the current version of the specification.

An X.509v3 certificate includes the following components:

X.509 encoding version

Enables the differentiation between an X.509v3 certificate and one that conforms to an earlier or later version of the specification.

Serial number of the certificate

Integer value that uniquely identifies a certificate as issued by a certification authority.

Subject DN

Distinguished name for the certificate, which often provides details about the context in which the certificate is to be used. For more information, see [Certificate subject DNs](#) on page 126.

Issuer DN

Distinguished name for the issuer certificate, which is the certificate used to sign the certificate. For a self-signed certificate, this value matches the subject DN.

Validity window

Indicates the timeframe during which the certificate is considered valid. This component includes the following elements:

- **notBefore**
Specifies the earliest time at which the certificate is considered valid.

- **notAfter**

Specifies the latest time at which the certificate is considered valid.

Public key

Public portion of a pair of cryptographically linked keys. For more information, see [Certificate key pairs](#) on page 127.

Signature

A type of cryptographic proof that the certificate truly was sent from the issuer and has remained unaltered. A self-signed certificate is signed with its own private key. Otherwise, it is signed with the issuer's private key.

An X.509v3 certificate might also include the following optional components:

Subject unique ID

Uniquely identifies the certificate. This component has been deprecated in favor of the subject key identifier extension, so it is generally omitted from X.509v3 certificates.

Issuer unique ID

Subject unique ID of the issuer certificate, if available. This component has been deprecated in favor of the authority key identifier extension.

Set of extensions

Provides additional context for the certificate and the manner in which it is used. For more information, see [Certificate extensions](#) on page 128.

Certificate subject DNs

A certificate's subject distinguished name (DN) provides information about how the certificate should be used.

Like an LDAP DN, a certificate's subject DN consists of a comma-delimited series of attribute-value pairs. However, unlike an LDAP DN, the attribute names in a certificate subject DN are typically written in all uppercase characters.

A certificate's subject DN is also referred to as its subject. The following attributes commonly appear in a certificate subject.

Attribute name	Attribute description
CN	Common name  Note: For a listener certificate, the CN attribute typically identifies the host name that clients use to access the certificate. However, the subject alternative name extension is recommended more highly for accomplishing the same task. Most certificate subject DNs include at least the CN attribute.
E	Email address
OU	Name of the organizational unit, such as the relevant department
O	Name of the organization or company
L	Name of the locality, such as the appropriate city

Attribute name	Attribute description
ST	Full name of the state or province
C	ISO 3166 country code

A certificate subject includes at least one attribute-value pair, and the `CN` attribute is typically present. Other attributes can be omitted, although the `O` and `C` attributes are also common. For example, a listener certificate for a server with an address of `ldap.example.com`, which is run by the US-based company Example Corp, might have a subject of `CN=ldap.example.com,O=Example Corp,C=US`.

Certificate key pairs

Each certificate contains a key pair that consists of two keys that are linked cryptographically. If you encrypt data with one key, the data can be only decrypted with the other key.

Although a key pair can be created easily when both keys are generated simultaneously, the process of deriving one key from the other is extremely difficult, a process categorized in cryptographic terms as computationally infeasible.

When generating a key pair, one key is designated as the public key, and the other key is designated the private key. The public key can be made widely available, but the private key must be kept secret and not shared with anyone.

As long as the secrecy of the private key is maintained, the key pair can be used to perform the following functions:

- Encryption, sometimes referred to as confidentiality

If someone wants to send you a secret message without anyone else viewing it, the message can be encrypted with your public key. Only you possess the private key, so only you can decrypt the message.

- Digital signatures

If you encrypt data with your private key, it can be decrypted only with your public key. Because your public key can be made widely available, this encryption method does not actually protect the content. However, digital signatures prove that a message came from you because only your private key could have generated it.

Note:

When generating a digital signature, the entire message is generally not encrypted. Only a hash of the message is encrypted, typically by using a digest algorithm like SHA-256.

This approach protects the integrity of a message. A decrypted signature that matches the digest of the original message guarantees that the message came from you and that it has remained unaltered since you signed it.

The following public key algorithms are used primarily in certificates that facilitate TLS communication:

- RSA, which is based on the multiplication of large prime numbers
- EC, which is based on computations that involve special types of elliptical curves

Although RSA is supported more widely than EC, it is slower and requires larger keys to achieve the same level of security. To support legacy clients, you should use an RSA certificate and choose a key size of at least 2,048 bits.

If all of your clients support EC certificates, you should use an EC certificate with a key size of at least 256 bits.

Certificate extensions

Extensions provide additional context for a certificate.

Some of the more common extension types include the following:

Subject key identifier

Holds a unique identifier for the certificate, which is generally derived from the certificate's public key.

Authority key identifier

Holds the subject key identifier for the issuer certificate. This extension type helps to identify the issuer certificate, especially when presented with an incomplete certificate chain.

Subject alternative name

Holds a list of ways that clients are expected to reference a server when establishing a connection to it.

Note:

Clients must take this information into account when deciding whether to trust a server's certificate.

The most common types of values include DNS names, IP addresses, and URIs. DNS names must be fully qualified, but can optionally use an asterisk in the leftmost component to match any single name in that component. For example, `*.example.com` could match `www.example.com` or `ldap.example.com`, but would not match `ldap.east.example.com` or `example.com`.

Key usage

Provides information about the manner in which the certificate is expected to be used. The following key usages are allowed:

`digitalSignature`

Indicates that the certificate can be used for digitally signing data, excluding certificates and certificate revocation lists (CRL).

`nonRepudiation`

Indicates that the certificate can be used to prevent denying the authenticity of a message. `nonRepudiation` is also known as `contentCommitment`.

`keyEncipherment`

Indicates that the certificate can be used to protect encryption keys, such as symmetric keys that are derived during TLS key agreement.

`dataEncipherment`

Indicates that the certificate can be used for encrypting data directly.

`keyAgreement`

Indicates that the certificate's public key can be used for key agreement, such as deriving the symmetric key that protects TLS communication.

`keyCertSign`

Indicates that the certificate can act as a certification authority and be used for signing other certificates.

`cRLSign`

Indicates that the certificate can be used to sign CRLs.

`encipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for encrypting data during key agreement.

`decipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for decrypting data during key agreement.

Extended key usage

Acts as an alternative to the key usage extension and provides additional high-level functionality. The following extended key usages are allowed:

`serverAuth`

Indicates that the server can present the certificate to the client during TLS negotiation.

`clientAuth`

Indicates that the client can present the certificate to the server during TLS negotiation.

`codeSigning`

Indicates that the certificate can be used to sign source and compiled code.

`emailProtection`

Indicates that the certificate can be used to sign or encrypt email messages.

`timeStamping`

Indicates that the certificate can be used to assert the time that an event occurred.

`ocspSigning`

Indicates that the certificate can be used to sign an online certificate status protocol (OCSP) response.

Basic constraints

Indicates whether the certificate can act as a certification authority and, if so, the maximum number of intermediate certificates that can follow it in a certificate chain.

Certificate chains

A certificate chain is an ordered list of one or more certificates. In such a chain, each subsequent certificate is the issuer of the previous certificate.

During TLS negotiation, the server presents a certificate chain to the client, which determines whether to trust the chain and continue with the negotiation. The client can also present its own certificate chain to the server.

If a certificate is self-signed, its chain contains only that single certificate. If a certificate is signed by a self-signed certificate authority (CA) certificate, such as a root CA, the chain contains two certificates: the server certificate and the CA certificate that follows it. If a single intermediate CA (a CA certificate that is signed by a root CA) is present, the chain contains the server certificate, followed by the intermediate CA, and then the root CA.

Intermediate certificate authorities are useful for security purposes, especially in commercial authorities. If a client trusts a root CA certificate, it is likely to trust anything with that root CA certificate at the base of its chain. Consequently, the root CA certificate must be kept secure.

Note:

If the root CA certificate is compromised, any certificate that is directly or indirectly signed by it can no longer be trusted.

With intermediate CA certificates, the root certificate can be kept offline in secure storage and used only when a new intermediate CA certificate must be signed. The intermediate CA certificates can be used to sign end-entity certificates, but must be protected to avoid compromising any of the certificates. A compromised certificate must be revoked along with all of the certificates that it signed. In such a scenario, the root CA can be used to sign a new certificate.

Note:

The certificate chain that the server presents to the client, or that the client presents to the server, during TLS negotiation does not always need to be the complete chain. If the root CA at the end of the chain is widely trusted, the server can assume that the client already has that root CA in its default set of trusted certificates. The server can leave that root CA off the chain with the assumption that the client will retrieve it from its default trust store. While the same assumption could theoretically be true for intermediate CA certificates, only the root CA certificate is commonly omitted. When a client receives an incomplete chain, the client looks in its default trust store to determine whether the trust store contains the issuer certificate, which it can identify by using properties like the issuer distinguished name (DN) or an authority key identifier extension.

The certificate at the head of a certificate chain, which appears as the first one in the list, is often called the end-entity certificate. If this certificate appears at the head of the chain that a server presents during TLS negotiation, it is referred to as the server certificate. If the certificate appears at the head of a chain that a client presents, it is referred to as a client certificate. The certificate at the end of a complete chain must be a root CA certificate. In the case of a self-signed certificate, the chain contains only a single certificate that serves both roles.

About representing certificates, private keys, and certificate signing requests

X.509 is an encoding format that uses the ASN.1 distinguished encoding rules (DER), which exist in binary format. When writing a certificate to a file, either a raw DER format or a plaintext format called PEM can be used.

PEM encoding consists of a line that contains the text `-----BEGIN CERTIFICATE-----`, followed by a set of lines that contains the base64-encoded representation of the raw DER bytes (typically with no more than 64 characters per line), followed by a line that contains the text `-----END CERTIFICATE-----`.

The X.509 encoding contains a certificate's public key, but not its private key. The PKCS #8 specification in [RFC 5958](#) describes the encoding for private keys. This approach uses a DER encoding with a PEM variant that instead uses the following header and footer, respectively.

```
-----BEGIN PRIVATE KEY-----
-----END PRIVATE KEY-----
```

RFC 5958 also describes an encrypted representation of the private key, but that format is currently unsupported.

The PKCS #10 specification in [RFC 2986](#) describes the CSR format. This format uses a DER encoding with a PEM variant that uses the following header and footer, respectively.

```
-----BEGIN CERTIFICATE REQUEST-----
-----END CERTIFICATE REQUEST-----
```

Some implementations use the following alternate, nonstandard forms.

```
-----BEGIN NEW CERTIFICATE REQUEST-----
-----END NEW CERTIFICATE REQUEST-----
```

Certificate trust

When a server presents its certificate chain to a client during TLS negotiation, the client decides whether to trust the certificate chain and concludes whether it is communicating with a legitimate server instead of an impostor.

If a client is tricked through DNS hijacking into communicating with a rogue application instead of with a legitimate server, the application can steal the client's credentials, or can fool the client into concluding that it has performed an action that it has not performed. If a rogue application acts as a broker between the client and the legitimate server, the client might be unable to detect the change, and the malicious application might be capable of stealing data or altering the communication. Consequently, you should avoid `trust all` or `blind trust` options in a production environment.

When determining whether to trust a server certificate chain, a client performs the following steps.

Processing steps

1. Verifies that it has received the complete certificate chain.

If a server presents an incomplete chain, the client must ensure that it can complete the chain with information in an explicitly provided trust store or default trust store. If the client cannot complete the certificate chain, the chain is not trusted.

2. Verifies that each subsequent certificate in the chain is the issuer certificate for, and that its private key was used to sign, the certificate that precedes it.

 **Note:**

If a certificate chain contains extraneous certificates, or if a subsequent certificate did not issue the certificate that precedes it, the chain is not trusted.

3. Confirms that it has a reason to trust the certificate at the root of the chain.

 **Note:**

This step is generally performed by ensuring that the root certificate authority (CA) certificate can be found in either a default trust store or a trust store that is configured for use by the client. If the client has no prior knowledge of the root CA certificate, the chain is not trusted.

4. Verifies that the current time lies within the validity window for each certificate in the chain.

 **Note:**

The chain is not trusted under the following conditions:

- When the `notBefore` value of any certificate in the chain is later than the current time.
- When the `notAfter` value of any certificate in the chain is earlier than the current time.

5. Verifies that the server certificate at the head of the chain is suitable for the server with which the client thinks it is communicating.

Note:

The client must verify that the address used to connect to the server matches one of the following values:

- The CN attribute of the certificate's subject.
- One of the values of any subject alternative name extension.

These steps represent a starting point. If necessary, the client can perform additional types of validation. For example, if a root or intermediate certification authority maintains a certificate revocation list (CRL) or supports the online certificate status protocol (OCSP), the client must verify that none of the certificates in the chain has been revoked. The client can also verify that the CA certificates include the basic constraints extension, and that the server certificate does not contain too many levels. Other checks, like those that use certificate policy extensions, can also be performed.

Keystores and truststores

A keystore is a type of database that holds certificates.

The following examples represent the most common forms of keystores:

- File that uses the Java-specific Java KeyStore (JKS) format
- File that uses the standard PKCS #12 format
- Collection of files that holds certificates and private keys, typically in PEM or DER format
- Hardware security module (HSM) that makes the certificate information available through an interface like PKCS #11

The server supports file-based keystores by using the JKS and PKCS #12 formats and by using hardware security modules that are accessible through PKCS #11. The server does not currently support a keystore format that consists of individual certificate and private key files. To import these files into a JKS or PKCS #12 keystore, use the **manage-certificates** tool.

A keystore also represents a collection of entries, each of which is identified by a name that an alias calls. Keystores can have the following entry types:

Private key entries

Contain a certificate chain and a private key. When a server accepts a TLS-based connection, it uses a private key entry to obtain the certificate chain that it presents to the client. The server can also use the private key from the same entry to process its key agreement. Similarly, a client uses a private key entry when presenting its own certificate chain to a server.

Trusted certificate entries

Contain a single certificate without a private key. As the name implies, a trusted certificate entry is intended primarily for use when determining whether to trust a certificate chain that is presented during TLS negotiation.

Secret key entries

Contain a secret key only, without an associated certificate. These types of entries are not used for TLS processing. Instead, they hold symmetric encryption keys or other types of secrets.

A password, sometimes called a PIN, protects the contents of a keystore. In some cases, like with JKS keystores, some content might be accessible without a password, and a password might be required only when trying to access private keys or secret keys. In other cases, like with PKCS #12 keystores, you might need a password for any interaction with the keystore.

Additional passwords can further protect private keys. This approach is often the same as with the keystore password, but the password can be different. This tactic is useful when a single keystore is shared for multiple purposes, for example, and when merely having access to the keystore does not guarantee access to all of the data that it contains.

**Note:**

A truststore is another name for a keystore that is intended primarily for use when determining whether to trust a certificate chain that has been presented. Truststores generally contain primarily trusted certificate entries, but that case is not required.

Java runtime environments typically include a default truststore, often `jre/lib/security/cacerts` or `lib/security/cacerts`, that is prepopulated with several widely trusted certification authority certificates. When presented with a certificate that one of these authorities has signed, the default truststore can allow the certificate to be trusted without any additional configuration. When presented with a self-signed certificate, or when presented with a certificate that is signed by an issuer not in the default truststore, such as a private corporate certification authority, a separate truststore is required.

Transport Layer Security (TLS)

TLS describes a mechanism for securely communicating between two parties that might have no prior knowledge of each other.

TLS is the successor to SSL, and the two terms are often used interchangeably, even though such usage might not technically be correct.

**Note:**

SSL remains the more widely recognized term. The abbreviation TLS occasionally generates confusion with the StartTLS extended operation, particularly in LDAP.

TLS provides security in the form of the following main components:

Certificate trust

Is about reassuring a connection-initiating client that it is communicating with the server to which it intended to connect. To ensure that the server shares the same degree of confidence in the identity and legitimacy of the client, it can ask the client to present its own certificate chain. For more information, see [Certificate Trust](#).

Cipher selection

Involves choosing the cipher and the key to protect the bulk of the communication. Although a client can use a server certificate's public key to encrypt data before sending it, this approach can lead to the following issues:

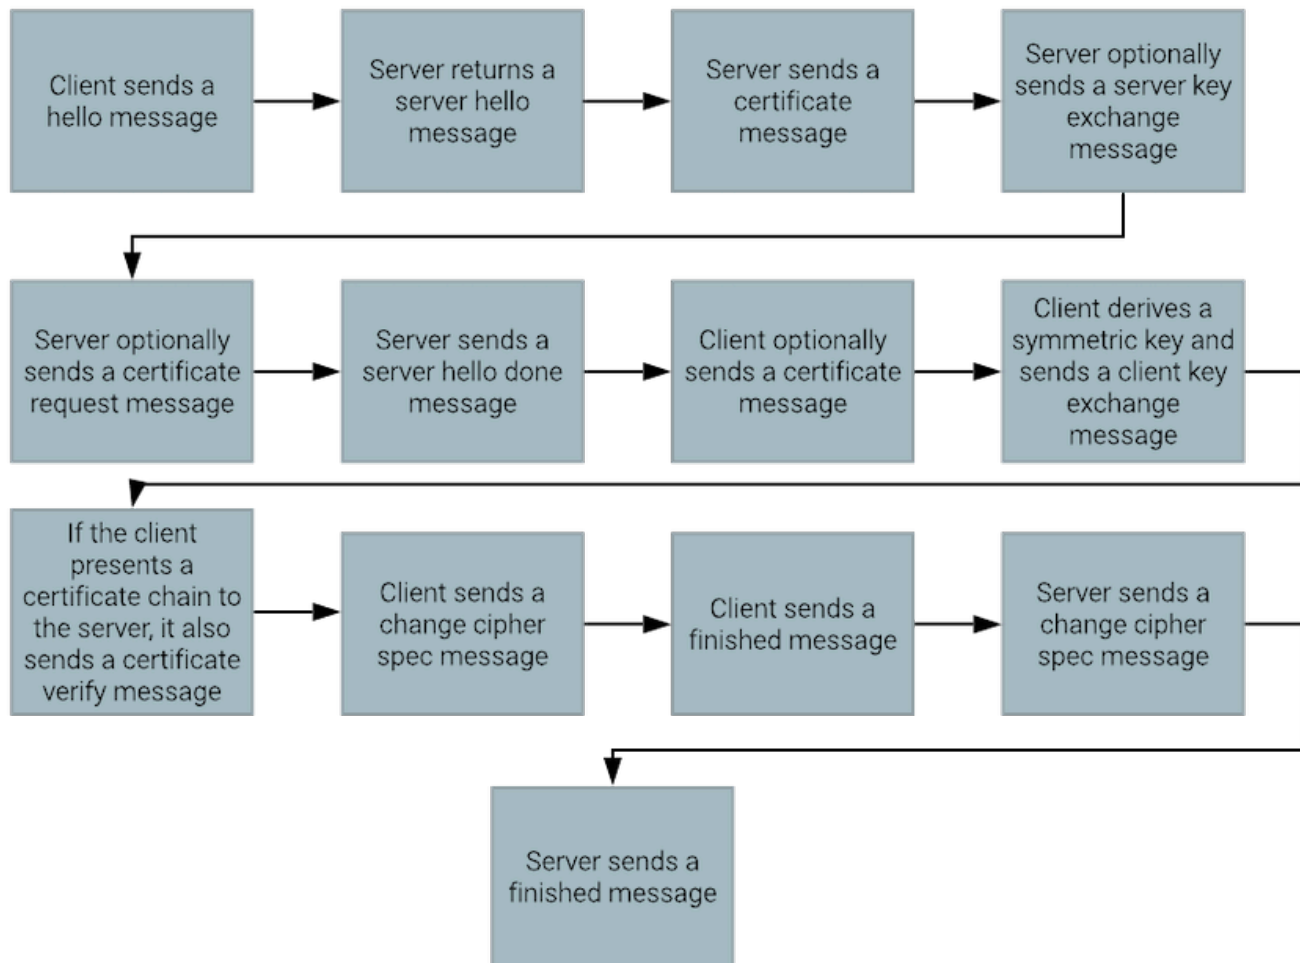

- Unless the client presents its own certificate chain to the server, the server cannot encrypt the data that it sends back to the client.
- Public key encryption is considerably slower than symmetric encryption, in which the same key is used for both encryption and decryption. Public key encryption is also called asymmetric encryption because different keys are used to encrypt and decrypt data.
- If you rely entirely on the security of a private key to ensure the secrecy of a communication, and if the private key becomes compromised, data that has been encrypted with the private key must also be considered compromised.

Rather than relying solely on public key encryption to protect communication between a client and server, the TLS negotiation process allows a client and server to agree on the type of encryption and the secret key to use after completing the negotiation process.

TLS handshakes

The process of negotiating the TLS is referred to as the handshake.

Although the exact process depends on the TLS version that is ultimately chosen, the following steps represent the basic components of a TLS 1.2 handshake:

TLS processing steps

1. The client sends a `hello` message that provides the server with the following information:
 - Highest supported version of the TLS protocol
 - The cipher suites that the client uses
 - Set of extensions with additional information:
 - The address that the client uses to communicate with the server
 - The signature algorithms and elliptic curves that the client supports
 - Whether the client supports secure renegotiation
2. The server returns a `server hello` message that provides the client with the following information:
 - The TLS protocol version that the server uses
 - The cipher suite that the server selects

The server can also provide its own extensions to the client.

3. The server sends a `certificate` message that provides its certificate chain to the client.
4. The server can optionally send a `server key exchange` message with additional information that the client might need to securely derive the same symmetric encryption key that the server generates.
5. The server can optionally send a `certificate request` message that asks the client to present its own certificate chain to the server.
6. The server sends a `server hello done` message to inform the client that it has completed its `hello` sequence.
7. The client can optionally send a `certificate` message to the server with its own certificate chain.

Note:

The client sends a `certificate` message only when the server initially sends a certificate request. If the client receives such a request, it can refuse to, and probably will not, send a certificate chain. The server decides whether to require a client certificate chain. In LDAP, the server commonly asks the client to present a certificate, but continues with TLS negotiation even if the client does not present one. This approach supports authentication methods like SASL EXTERNAL, in which a client uses the certificate chain that it presents during TLS negotiation as proof of its identity.

8. The client derives a symmetric key to use for the remainder of the encrypted processing, and sends a `client key exchange` message to the server. The `client key exchange` message includes the information that the server needs to generate the same key. Only the client and server know the value of the key, even if another entity can observe the communication that passes between the client and the server.
9. If the client presents a certificate chain to the server, it also sends a `certificate verify` message to prove that the private key for the certificate is included at the head of the chain.
10. The client sends a `change cipher spec` message to the server, which informs the server that the client will use the agreed-upon symmetric key to encrypt everything else that it sends to the server.
11. The client sends a `finished` message to the server to indicate that it has completed its portion of the handshake.
12. The server sends a `change cipher spec` message to the client, which informs the client that the server will use the agreed-upon symmetric key to encrypt everything else that it sends to the client.
13. The server sends a `finished` message to the client to indicate that it has completed its portion of the handshake.

TLS 1.3 uses a different handshake sequence that can require only a single round-trip to exchange the necessary information between the client and the server. TLS 1.2 requires two round-trips. To accomplish this task, TLS 1.3 tries to guess the type of key agreement that the server wants to use, and sends the relevant information to the server up front instead of waiting to hear from the server.

Because an extra round of communication between the client and server is eliminated, the server finishes its portion of the negotiation before the client. The server must assume that the client trusts its certificate chain. Because the server might log a successful negotiation only to discover late, through a TLS alert, that the client rejected the certificate, this approach might complicate certain types of troubleshooting.

Key agreement

Key agreement processing provides a critical component of TLS negotiation.

It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

RSA key exchange

The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.

Diffie-Hellman (DH) key exchange

The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, use ECHDE over DHE, and either of those options over RSA. The DH algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. The use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

LDAP StartTLS extended operation

In most scenarios, a client that uses TLS establishes a connection to a port that is dedicated to its use, like 636 (LDAPS) or 443 (HTTPS).

The client begins the TLS-negotiation process by sending a `client hello` message over the connection. In some scenarios, the client establishes a non-secure connection and later converts it to a secure one. In LDAP, this task is accomplished by using the `StartTLS` extended operation.

The `StartTLS` extended operation provides the following advantages over a dedicated LDAPS connection:

- To enable secure as well as insecure communication, only one port needs to be opened through a firewall.
- A client can use opportunistic encryption, in which the client performs the following steps:
 1. Queries the root DSE to determine whether the server supports StartTLS.
 2. Secures the connection, if possible.

Opportunistic encryption is useful in scenarios like following referrals because LDAP URLs do not officially support LDAPS as a scheme.

To ensure that a communication is always secure, use LDAPS instead of establishing an insecure connection that you secure later with the `StartTLS` extended operation. If you enable support for unencrypted LDAP communication, as `StartTLS` requires, a client might send a password-containing bind request or other sensitive data over an unencrypted connection. A server can be configured to reject unencrypted communication, but it cannot prevent a client from sending an unencrypted request.

Note:

Although you can use `StartTLS` to temporarily secure a connection before falling back on an unencrypted LDAP communication, the server does not support this strategy.

About the `manage-certificates` tool

The server offers a `manage-certificates` tool that enables interaction with Java KeyStore (JKS) and PKCS #12 key stores.

Although it behaves similarly to the `keytool` utility that accompanies most Java distributions, `manage-certificates` is easier to use, provides improved usage information, and offers additional functionality.

Available subcommands

The `manage-certificates` tool uses the following subcommands to indicate which function to invoke:

Subcommand	Function
<code>list-certificates</code>	Lists the certificates in a keystore.
<code>import-certificate</code>	Imports a certificate into a trusted certificate entry or imports a certificate chain and private key into a private key entry.
<code>export-certificate</code>	Exports a certificate from a keystore.
<code>export-private-key</code>	Exports a private key from a keystore.
<code>generate-self-signed-certificate</code>	Generates a self-signed certificate.
<code>generate-certificate-signing-request</code>	Generates a certificate-signing request that can be provided to a certification authority.
<code>sign-certificate-signing-request</code>	Signs a certificate-signing request with a specified issuer certificate.
<code>check-certificate-usability</code>	Checks a specified certificate in a keystore to verify whether it is suitable for use as a listener certificate.
<code>trust-server-certificate</code>	Initiates the TLS-negotiation process with a specified server to obtain its certificate chain so that a truststore can be updated with the necessary information to trust the chain.
<code>display-certificate-file</code>	Displays the contents of a file that contains one or more PEM-encoded or DER-encoded X.509 certificates.
<code>display-certificate-signing-request-file</code>	Displays the contents of a file that contains a PEM-encoded or DER-encoded PKCS #10 certificate-signing request (CSR).
<code>change-certificate-alias</code>	Changes the alias for an entry in a keystore.
<code>change-keystore-password</code>	Changes the password for a keystore.
<code>change-private-key-password</code>	Changes the password that protects the private key for a specified entry in a keystore.

Common arguments

Most of the `manage-certificates` subcommands require access to a Java KeyStore (JKS) or PKCS #12 keystore. In such instances, use the `--keystore` argument to specify the path to the keystore.

If the keystore already exists, the tool detects automatically whether it is a JKS or PKCS #12 keystore. If the operation creates a new keystore, you can specify the type explicitly by using the `--keystore-type` argument, followed by a value of `JKS` or `PKCS12`. If you do not specify the keystore type, a default value of `JKS` is used.

Some situations require you to provide the password that is needed to access the keystore. For a JKS keystore, you might need to provide a keystore password only for operations that involve creating

a keystore or accessing a private key. However, you will likely need to provide the password for all operations that involve a PKCS #12 keystore.

To provide a keystore password, use one of the following arguments:

- `--keystore-password`, followed by the clear-text password for the keystore.
- `--keystore-password-file`, followed by the path to a file that contains the password for the keystore. The file might contain the password in the clear, or it might be encrypted with a definition from the server's encryption-settings database.
- `--prompt-for-keystore-password`. If this argument is provided, the tool prompts you interactively to provide the password.

If a private key is protected with a different password than the keystore itself, specify one of the following arguments to provide the private key password:

- `--private-key-password`, followed by the plaintext password.
- `--private-key-password-file`, followed by the path to a file that contains the clear-text or encrypted password.
- `--prompt-for-private-key-password`, which causes the tool to prompt interactively for the password.

Several operations require you to specify the keystore entry to target. In such scenarios, provide the `--alias` argument, followed by the name of the alias for that entry.

Listing the certificates in a keystore

List the certificates available in a keystore.

Steps

- To list the certificates in a keystore, use the `list-certificates` subcommand.

This subcommand requires you to specify the path to the keystore file, and possibly the password that is needed to access the keystore. The following options are also available:

Option	Description
<code>--alias {alias}</code>	Specifies the alias of the certificate to display. If this value is not provided, all certificates are displayed. To list more than one specific certificate, specify this value multiple times.
<code>--display-pem-certificate</code>	Includes a PEM-encoded representation of each certificate as part of the output.
<code>--verbose</code>	Includes details about each certificate.

Example:

The following command demonstrates the basic listing of a keystore that contains a single certificate chain.

```
$ bin/manage-certificates list-certificates \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin

Alias: server-cert (Certificate 1 of 2 in a chain)
Subject DN: CN=ds1.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Certification Authority,O=Example Corp,C=US
Validity Start Time: Saturday, November 9, 2019 at 11:26:09 AM CST
                   (8 minutes, 15 seconds ago)
Validity End Time: Sunday, November 8, 2020 at 11:26:09 AM CST
                   (364 days, 23 hours, 51 minutes, 44 seconds from now)
Validity State: The certificate is currently within the validity window.
```

```

Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint:  42:f8:85:97:bf:88:bc:74:4b:5b:ce:0c:54:43:9b:44:6b:
                    81:23:a3

Generating self-signed certificates

The process of creating a self-signed certificate is straightforward because a self-signed certificate claims itself as its own issuer.

Although self-signed certificates are convenient for testing environments, clients do not trust them by default. Consequently, you should not use them as listener certificates in production environments.

The **manage-certificates** tool offers a **generate-self-signed-certificate** subcommand that can create a self-signed certificate. In addition to the arguments that provide information about the keystore, certificate alias, and optional private key password, the following arguments are available.

Argument	Description
<code>--subject-dn {subject}</code>	Subject DN for the certificate to create. This value is required.
<code>--days-valid {number}</code>	Number of days that the certificate remains valid. Defaults to 365 if no value is specified.
<code>--validity-start-time {timestamp}</code>	Indicates the time at which the certificate begins its validity window. This value is assumed to reflect the local time zone, and must be expressed in the form YYYYMMDDhhmmss , where a value of 20190102030405 indicates January 2, 2019, at 3:04:05 AM. Defaults to the current time if no value is specified.

Argument	Description
<pre>--key-algorithm {name}</pre>	<p>Name of the algorithm to use when generating the key pair. For a listener certificate, this value is typically RSA or EC.</p> <p>Defaults to RSA if no value is specified.</p> <p> Note:</p> <p>This argument cannot be used in conjunction with the <code>--replace-existing-certificate</code> argument.</p>
<pre>--key-size-bits {number}</pre>	<p>Length of the key, in bits, to generate. If the <code>--key-algorithm</code> argument is given, then <code>--key-size-bits {number}</code> must also be specified. Conversely, if the <code>--replace-existing-certificate</code> argument is given, then <code>--key-size-bits {number}</code> must not be specified.</p> <p>Typical key sizes are:</p> <ul style="list-style-type: none"> ▪ RSA key – 2048 or 4096 bits <p style="margin-left: 20px;">If a default RSA key is used but this argument is not provided, a default key size of 2048 bits is used.</p> <ul style="list-style-type: none"> ▪ Elliptic curve key – 256 or 384 bits
<pre>--signature-algorithm {name}</pre>	<p>Name of the algorithm to use to sign the certificate. If the <code>--key-algorithm</code> argument is used to specify an algorithm other than RSA, then <code>--signature-algorithm {name}</code> must also be specified.</p> <p>If the <code>--replace-existing-certificate</code> argument is used, then <code>--signature-algorithm {name}</code> must not be specified.</p> <p>Typical signature algorithms include SHA256withRSA for certificates with RSA keys, and SHA256withECDSA for certificates with elliptic curve keys. If a default key algorithm is used but the <code>--signature-algorithm {name}</code> argument is not provided, a default value of SHA256withRSA is used.</p>
<pre>--replace-existing-certificate</pre>	<p>Uses the new certificate to replace an existing certificate in the key store (within the same alias), and reuses the key for that certificate.</p>

Argument	Description
<code>--inherit-extensions</code>	Indicates that, when replacing an existing certificate, the new certificate contains the same set of extensions as the existing certificate. If the <code>--replace-existing-certificate</code> argument is provided, but the <code>--inherit-extensions</code> argument is omitted, the new certificate contains only arguments that are provided explicitly.
<code>--subject-alternative-name-dns {name}</code>	Indicates that the certificate is expected to have a subject alternative name extension with the provided DNS name. The given name must be fully qualified, although it can contain an asterisk (*) as a wildcard in the leftmost component. To include multiple DNS names in the subject alternative name extension, specify the <code>--subject-alternative-name-dns {name}</code> argument multiple times.
<code>--subject-alternative-name-ip-address {address}</code>	Indicates that the certificate is expected to have a subject alternative name extension with the provided IP address. The given address must be a valid IPv4 or IPv6 address. No wildcards are allowed. To include multiple IP addresses in the subject alternative name extension, specify the <code>--subject-alternative-name-ip-address {address}</code> argument multiple times.
<code>--subject-alternative-name-email-address {address}</code>	Indicates that the certificate is expected to have a subject alternative name extension with the provided email address. To include multiple email addresses in the subject alternative name extension, specify the <code>--subject-alternative-name-email-address {address}</code> argument multiple times.
<code>--subject-alternative-name-uri {uri}</code>	Indicates that the certificate is expected to have a subject alternative name extension with the provided URI. To include multiple URIs in the subject alternative name extension, specify the <code>--subject-alternative-name-uri {uri}</code> argument multiple times.

Argument	Description
<pre>--subject-alternative-name-oid {oid}</pre>	<p>Indicates that the certificate is expected to have a subject alternative name extension with the provided object identifier (OID). The given value must be a valid OID.</p> <p>To include multiple OIDs in the subject alternative name extension, specify the <code>--subject-alternative-name-oid {oid}</code> argument multiple times.</p>
<pre>--basic-constraints-is-ca {value}</pre>	<p>Indicates that the certificate is expected to have a basic constraints extension, with a specified value of true or false, for the flag indicating whether to consider the certificate a certification authority that can be used to sign other certificates.</p> <ul style="list-style-type: none"> ▪ For root and intermediate certificate authority (CA) certificates, the <code>--basic-constraints-is-ca {value}</code> argument must be present with a value of true. ▪ For end-entity certificates, the <code>--basic-constraints-is-ca {value}</code> argument can optionally be present with a value of false. ▪ For a self-signed certificate, specify the <code>--basic-constraints-is-ca {value}</code> argument with a value of false to indicate that the certificate is not considered a CA certificate.
<pre>--basic-constraints-maximum-path-length {number}</pre>	<p>Indicates that the basic constraints extension is expected to include a path length constraint element with the specified value. Use this argument only if <code>--basic-constraints-is-ca</code> is provided with a value of true.</p> <p>A path length constraint value of 0 indicates that the certificate can be used to issue only end-entity certificates. A path length constraint value of 1 indicates that the certificate can be used to sign end-entity certificates or intermediate CA certificates, the latter of which can be used to sign only end-entity certificates.</p> <p>A value greater than 1 indicates the presence of several intermediate CA certificates between it and the end-entity certificate at the head of the chain.</p>

Argument	Description
<code>--key-usage {value}</code>	<p>Indicates that the certificate is expected to have a key usage extension with the specified value. The following values are allowed:</p> <ul style="list-style-type: none"> ▪ digital-signature ▪ non-repudiation ▪ key-encipherment ▪ data-encipherment ▪ key-agreement ▪ key-cert-sign ▪ crl-sign ▪ encipher-only ▪ decipher-only <p>To include multiple key usages, specify the <code>--key-usage {value}</code> argument multiple times.</p>
<code>--extended-key-usage {value}</code>	<p>Indicates that the certificate is expected to have an extended key usage extension with the specified value. The following values are allowed:</p> <ul style="list-style-type: none"> ▪ server-auth ▪ client-auth ▪ code-signing ▪ email-protection ▪ time-stamping ▪ ocsp-signing

Example

For example, the following command can be used to generate a self-signed server certificate.

```
bin/manage-certificates generate-self-signed-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --keystore-type JKS \
  --alias server-cert \
  --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
  --key-algorithm EC \
  --key-length-bits 256 \
  --signature-algorithm SHA256withECDSA \
  --subject-alternative-name-dns ds.example.com \
  --subject-alternative-name-dns dsl.example.com \
  --subject-alternative-name-dns localhost \
  --subject-alternative-name-ip-address 1.2.3.4 \
  --subject-alternative-name-ip-address 127.0.0.1 \
  --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
  --key-usage digital-signature \
  --key-usage key-encipherment \
  --key-usage key-agreement \
  --extended-key-usage server-auth \
  --extended-key-usage client-auth
```

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:

```

Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=ds.example.com,O=Example Corp,C=US

```

Generating certificate signing requests

A certificate signing request (CSR) contains all of the information that a certification authority requires to issue a certificate.

[RFC 2986](#) defines the request format, also known as PKCS #10, and includes the following elements:

- Certificate signing request version
- Requested subject distinguished name (DN) for the certificate
- Public key for the requested certificate
- Requested set of extensions for the certificate
- Signature that proves the requester has the private key for the given public key

To create a certificate signing request, use the `manage-certificates generate-certificate-signing-request` command, which performs the following steps:

1. Generated a public and private key pair.
2. Stores the key pair in a key store with a given alias.
3. Outputs the certificate signing request to the terminal.
4. Optionally writes the certificate signing request to a file.

Because a certificate signing request contains many of the same elements as a certificate, the command to generate one takes most of the same arguments as for generating a self-signed certificate. The following arguments are unavailable when generating a CSR:

- `--replace-existing-certificate`
- `--days-valid {number}`
- `--validity-start-time {timestamp}`

The following arguments are available when generating a certificate signing request but not when generating a self-signed certificate:

`--output-file {path}`

Path to a file to which the certificate signing request is written. If this value is not provided, the request is written only to the terminal in PEM form.

`--output-format {value}`

Format to use when writing the certificate signing request. This value can be **PEM** or **DER**, but the DER format is used only in conjunction with the `--output-file` argument. Defaults to **PEM** if the `--output-format {value}` argument is not provided.

`--use-existing-key-pair`

Indicates that the CSR uses a key pair that already exists in the key store with the given alias, rather than generating a new key pair, in which case the specified alias must not already be in use in the key store.

The following example command creates a CSR.

```
bin/manage-certificates generate-certificate-signing-request \
  --output-file dsl-cert.csr \
  --output-format PEM \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --keystore-type JKS \
  --alias server-cert \
  --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
  --key-algorithm EC \
  --key-length-bits 256 \
  --signature-algorithm SHA256withECDSA \
  --subject-alternative-name-dns ds.example.com \
  --subject-alternative-name-dns dsl.example.com \
  --subject-alternative-name-dns localhost \
  --subject-alternative-name-ip-address 1.2.3.4 \
  --subject-alternative-name-ip-address 127.0.0.1 \
  --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
  --key-usage digital-signature \
  --key-usage key-encipherment \
  --key-usage key-agreement \
  --extended-key-usage server-auth \
  --extended-key-usage client-auth
```

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing request.

Successfully wrote the certificate signing request to file
'/ds/build/package/PingDirectory/dsl-cert.csr'.

If the contents of the resulting CSR file are made available to a certification authority to be signed, the resulting signed certificate can be imported into the key store.

To print the contents of a certificate signing request file, use the **display-certificate-signing-request-file** subcommand, which supports the following arguments:

```
--certificate-signing-request-file {path}
```

Path to the file that contains the certificate signing request to display.

```
--verbose
```

Indicates that the command is expected to display verbose information about the request, rather than a basic information set.

The following example demonstrates the basic output from the command.

```
$ bin/manage-certificates display-certificate-signing-request-file \
  --certificate-signing-request-file dsl-cert.csr

PKCS #10 Certificate Signing Request Version:  v1
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
```

The following example demonstrates the verbose output.

```
$ bin/manage-certificates display-certificate-signing-request-file \
  --certificate-signing-request-file dsl-cert.csr \
```

```

--verbose

Importing signed and trusted certificates

Use the `manage-certificates import-certificate` command to import certificates into a keystore.

This command is used to accomplish the following tasks:

- Import a certificate that a certification authority has signed into the keystore in which the key pair was generated. In this scenario, the certificate is imported into a private key entry and must be imported as a certificate chain rather than an end-entity certificate.
- Import a trusted issuer certificate into a trust store. In this scenario, the certificate is imported into a trusted certificate entry as a single certificate instead of as a chain.
- Import a certificate chain, along with the private key for the end-entity certificate. This approach imports certificates that were generated through another library, like OpenSSL.

In addition to the arguments that provide information about the key store and the alias into which the certificate or certificate chain is imported, the `manage-certificates import-certificate` command accepts the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to import. The certificate can be in PEM or DER format and can be a single certificate or a certificate chain. If the certificates in the chain reside in separate files, specify the `--certificate-file {path}` argument multiple times when you import a certificate chain.

`--private-key-file {path}`

Path to the file containing the private key that corresponds to the certificate at the head of the imported chain. The private key can be in PEM or DER format.

`--no-prompt`

Indicates that the certificate is to be imported without prompting for confirmation. By default, a summary of the certificate is displayed, and you must confirm that you want to import it.

The following example command imports a signed certificate into the key store that generates the certificate signing request.

```
$ bin/manage-certificates import-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --certificate-file ds1-cert.pem \
  --certificate-file ca-cert.pem
```

The following certificate chain will be imported into the keystore into alias 'server-cert', preserving the existing private key associated with that alias:

```
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
                    (4 minutes, 16 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
                    (364 days, 23 hours, 55 minutes, 43 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
SHA-1 Fingerprint:

                    12:7b:10:1f:26:05:b7:b9:0d:02:e0:38:3e
```

Do you want to import this certificate chain into the keystore? yes

```
Successfully imported the certificate chain.
```

If you do not provide the `--no-prompt` argument, the `manage-certificates import-certificate` tool still displays information about the certificates to import. To view additional information about a certificate before you import it, use the `display-certificate-file` subcommand, which supports the following arguments:

```
--certificate-file {path}
    Path to the file that contains the certificate to view.

--verbose
    Displays verbose information about the certificate.
```

The output of the `display-certificate-file` subcommand has the same format and content as the `list-certificates` subcommand.

Exporting certificates

Use the `export-certificate` subcommand to export a single certificate or a certificate chain from a key store to a file in PEM or DER format.

The `export-certificate` subcommand supports the normal arguments about the key store and certificate alias, in addition to the following arguments:

```
--output-file {path}
    Path to the file to which exported certificates are written. If this value is not provided, the certificates are written to standard output rather than a file.

--output-format {format}
    Format in which exported certificates are written. The value can be PEM or DER, but the DER format can be used only if the output is written to a file. Defaults to PEM if no value is specified.

--export-certificate-chain
    Indicates that a certificate chain, rather than the end-entity certificate only, is to be exported.

--separate-file-per-certificate
    Indicates the use of separate output files for each exported certificate, rather than placing all of the certificates in a single file. If this argument is provided and multiple certificates are to be exported, then .1 is appended to the path for the indicated output file for the first certificate in the chain, .2 is appended for the second certificate, and so on.
```

The following example exports a certificate chain.

```
$ bin/manage-certificates export-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --output-file server-cert.pem \
  --output-format PEM \
  --export-certificate-chain \
  --separate-file-per-certificate

Successfully exported the following certificate to '/ds/server-cert.pem.1':
Subject DN:  CN=ds.example.com,O=Example Corp,C=US

  05:b7:b9:0d:02:e0:38:3e

```

The **export-certificate** subcommand exports only the public portion of a certificate. Its private key is not included. To export the private key, use the **export-private-key** subcommand, which supports the following arguments, in addition to the usual key store and alias arguments:

```
--output-file {path}
```

Path to the file to which the exported private key is written. If this value is not provided, the key is written to standard output rather than a file.

```
--output-format {format}
```

Format in which the exported private key is written. The value can be **PEM** or **DER**, but the DER format is used only if the output is written to a file. Defaults to **PEM** if no value is specified.

The following code provides an example of the **export-private-key** subcommand .

```

$ bin/manage-certificates export-private-key \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --output-file server-cert-key.pem \
  --output-format PEM

```

```
Successfully exported the private key.
```

Using manage-certificates as a simple certification authority

If your server instances need to support an arbitrary or unknown set of clients, configure them with certificates from a trusted issuer, such as a commercial authority or the free Let's Encrypt service.

About this task

If you control every client that accesses the servers, you might want to create your own internal certification authority so that you have a common issuer for all servers. In such a scenario, the clients need to trust only the certificates that the issuer signs. Commercial and open-source software packages provide full-featured certification authority functionality, but you can use the **manage-certificates** tool to create a certificate authority (CA) certificate that you can use to sign certificate-signing requests.

Steps

1. Create a CA certificate.

A CA certificate is a self-signed certificate that possesses the following extensions:

- A key usage extension that includes at least the keyCertSign usage
- A basic constraints extension that identifies the certificate as a CA certificate

If you do not plan to use an intermediate CA certificate, the basic constraints extension must have a path length constraint of 0. If you plan to use an intermediate CA certificate, the path length constraint must be 1. Because certificates that the CA certificate signs are valid only for as long as all certificates in the chain remain valid, we recommend that you specify a long lifespan for the CA certificate.

Example:

The following example creates a new root CA certificate.

```
$ bin/manage-certificates generate-self-signed-certificate \
  --keystore /ca/root-ca-keystore \
  --keystore-password-file /ca/root-ca-keystore.pin \
  --keystore-type JKS \
  --alias root-ca-cert \
  --subject-dn "CN=Example Root CA,O=Example Corp,C=US" \
  --days-valid 7300 \
  --key-algorithm RSA \
  --key-size-bits 4096 \
  --signature-algorithm SHA256withRSA \
  --basic-constraints-is-ca true \
  --basic-constraints-maximum-path-length 1 \
  --key-usage key-cert-sign \
  --key-usage crl-sign

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:
Subject DN: CN=Example Root CA,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Monday, January 27, 2020 at 03:47:29 PM CST (0
seconds ago)
Validity End Time: Sunday, January 22, 2040 at 03:47:29 PM CST
(7299 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
SHA-1 Fingerprint:
bc:8e:5b:30:52:ec:03:63:b4:9a:aa:1a:45:a0:fc:84:49:dd:e8:64
SHA-256 Fingerprint:
d5:47:06:cd:a2:95:42:61:1f:c7:aa:04:16:1e:c1:70:41:c4:44:48:bf:74:20:5f:1c:
61:e2:aa:40:08:3a:ff
```

2. Export the public portion of the root CA certificate for future reference.

When you import a signed certificate, you can import the public portion of the root CA certificate as a standalone certificate into trust stores as well as into part of a certificate chain.

3. Create a new certificate signing request to create an intermediate CA certificate,

The certificate signing request uses essentially the same settings as the root CA. If you anticipate only a single intermediate CA, its basic constraints extension must have a path length constraint of

0, rather than 1, to indicate that it is used only to sign end-entity certificates and that it cannot create subordinate CA certificates by itself.

Example:

The following example command creates a certificate signing request.

```
$ bin/manage-certificates generate-certificate-signing-request \  
  --keystore /ca/intermediate-ca-keystore \  
  --keystore-password-file /ca/intermediate-ca-keystore.pin \  
  --keystore-type JKS \  
  --alias intermediate-ca-cert \  
  --subject-dn "CN=Example Intermediate CA,O=Example Corp,C=US" \  
  --key-algorithm RSA \  
  --key-size-bits 4096 \  
  --signature-algorithm SHA256withRSA \  
  --basic-constraints-is-ca true \  
  --basic-constraints-maximum-path-length 0 \  
  --key-usage key-cert-sign \  
  --key-usage crl-sign \  
  --output-file /ca/intermediate-ca-cert.csr \  
  --output-format PEM
```

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing request.

Successfully wrote the certificate signing request to file
'/ca/intermediate-ca-cert.csr'.

4. Use the root CA certificate to sign the certificate signing request for the intermediate CA certificate with the `sign-certificate-signing-request` subcommand.

The `sign-certificate-signing-request` subcommand takes most of the same arguments as generating a self-signed certificate. The primary differences between the argument sets are as follows:

- The key store that contains the certificate uses the provided key store arguments to sign the request. To specify the name of the certificate to use when signing the request, use the `--signing-certificate-alias` argument.
- To specify the path to the file that contains the certificate signing request file to generate, provide a `--request-input-file` argument.
- To specify the path to the file to which the signed certificate is written, provide a `--certificate-output-file` argument. If this argument is omitted, the PEM representation of the certificate is written to standard output.
- To specify the format, **PEM** or **DER**, in which the certificate is written to the output file, provide an `--output-format` argument.
- To specify the subject to use for the signed certificate, use the `--subject-dn` argument. To use the subject DN from the certificate signing request, omit this argument.
- To specify the name of the signature algorithm, use the `--signature-algorithm` argument.

Note:

Because the requester generated the key, you cannot specify the key algorithm or the key length.

- To indicate that the signed certificate includes every extension that is listed in the certificate signing request, use the `--include-requested-extensions` argument. If this argument is not provided, explicitly specify the set of extensions to include.

Example:

The following example command signs the certificate signing request for an intermediate CA certificate.

```
$ bin/manage-certificates sign-certificate-signing-request \
  --keystore /ca/root-ca-keystore \
  --keystore-password-file /ca/root-ca-keystore.pin \
  --signing-certificate-alias root-ca-cert \
  --days-valid 7300 \
  --include-requested-extensions \
  --request-input-file /ca/intermediate-ca-cert.csr \
  --certificate-output-file /ca/intermediate-ca-cert.pem \
  --output-format PEM
```

Read the following certificate signing request:

```
PKCS #10 Certificate Signing Request Version: v1
Subject DN: CN=Example Intermediate CA,O=Example Corp,C=US
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
```

```
Do you really want to sign this request? yes
```

```
Successfully wrote the signed certificate to file
'/ca/intermediate-ca-cert.pem'.
```

5. After you obtain the intermediate CA certificate, create secure, offline backups of the root CA certificate.

- Remove the root CA certificate, or at least its private key, from all systems.

Note:

Make certain that all end-entity certificates are signed with the intermediate CA certificate, and that the process is identical to the previous example. Restore the root CA certificate only if you need to sign another intermediate CA certificate.

Enabling TLS support during setup

Enable TLS support in the server.

To enable TLS support in the server, you should complete one of the following tasks during the setup procedure:

- Provide a key store that contains the certificate to use.
- Make the installer generate a self-signed certificate.

When using the `setup` tool in interactive mode, it prompts you for the information that it needs to configure secure communication, as shown in the following example.

```
Do you want to enable the Directory Server services (Available State,
Available or Degraded State, Configuration, Consent, Directory REST API,
Documentation, SCIM2, and Swagger UI) and Administrative Console over
HTTPS? After setup, you can selectively enable or disable individual
services and applications by configuring the HTTPS Connection Handler
(yes / no) [yes]: yes

On which port should the Directory Server accept connections from HTTPS
clients? [443]: 443

On which port should the Directory Server accept connections from LDAP
clients? [389]: 389

Do you want to enable LDAPS? (yes / no) [yes]: yes
On which port should the Directory Server accept connections from LDAPS
clients? [636]: 636

Do you want to enable StartTLS? (yes / no) [yes]: yes

Certificate server options:

    1) Generate self-signed certificate (recommended for testing purposes
       only)
    2) Use an existing certificate located on a Java Keystore (JKS)
    3) Use an existing certificate located on a PKCS12 keystore
    4) Use an existing certificate on a PKCS11 token

Enter option [1]: 2

Java Keystore (JKS) path: /ca/dsl-keystore
Keystore PIN: {password}

Truststore options:

    1) Generate a default JKS truststore
    2) Use an existing JKS truststore
    3) Use an existing PKCS12 truststore

Enter option [1]: 2

JKS truststore path: /ca/truststore
```

```
Truststore password (can be blank): {password}
```

When using **setup** in non-interactive mode, use the following arguments to configure TLS support.

Argument	Description
<code>--ldapsPort {port}</code>	Server enables support for LDAPS (LDAP over TLS) on the specified TCP port.
<code>--httpsPort {port}</code>	Server enables support for HTTPS for SCIM, the Directory REST API, and the web-based administration console on the specified TCP port.
<code>--enableStartTLS</code>	LDAP connection handler enables support for the StartTLS extended operation.
<code>--generateSelfSignedCertificate</code>	setup generates a self-signed certificate that is presented to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
<code>--useJavaKeyStore {path}</code>	Server uses the specified Java KeyStore (JKS) key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
<code>--usePKCS12KeyStore {path}</code>	Server uses the specified PKCS #12 key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
<code>--usePKCS11KeyStore</code>	Server uses a PKCS #11 key store, like a hardware security module, to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation. The Java Virtual Machine (JVM) must already be configured to access the appropriate key store through PKCS #11.
<code>--keyStorePassword {password}</code>	Password that is needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store. The setup tool assumes that the private key password matches the key store password.
<code>--keyStorePasswordFile {path}</code>	Path to the file that contains the password needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store.
<code>--certNickname {alias}</code>	Alias of the private key entry in the specified key store that contains the certificate chain to present to clients during TLS negotiation. This argument is optional but recommended if the key store contains multiple certificates.

Argument	Description
<code>--useJavaTrustStore {path}</code>	Server uses the specified JKS trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation.
<code>--usePKCS12TrustStore {path}</code>	Server uses the specified PKCS #12 trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation.
<code>--trustStorePassword {password}</code>	Password that is needed to interact with the specified JKS or PKCS #11 trust store.
<code>--trustStorePasswordFile {path}</code>	Path to the file that contains the password needed to interact with the specified JKS or PKCS #11 trust store.

The following example command sets up PingDirectory Server in non-interactive mode with an existing certificate.

```
$ ./setup \
  --no-prompt \
  --acceptLicense \
  --ldapPort 389 \
  --ldapsPort 636 \
  --httpsPort 443 \
  --enableStartTLS \
  --useJavaKeyStore config/keystore \
  --keyStorePasswordFile config/keystore.pin \
  --certNickname server-cert \
  --useJavaTrustStore config/truststore \
  --trustStorePasswordFile config/truststore.pin \
  --baseDN dc=example,dc=com \
  --rootUserDN "cn=Directory Manager" \
  --rootUserPasswordFile root-pw.txt \
  --maxHeapSize 10g \
  --encryptDataWithPassphraseFromFile encryption-settings-password.txt \
  --instanceName dsl \
  --location Austin \
  --noPropertiesFile
```

```
Ping Identity Directory Server 8.0.0.0
```

```
Initializing ..... Done
Configuring Directory Server ..... Done
Configuring Certificates ..... Done
Starting Directory Server ..... Done
```

```
Access product documentation from docs/index.html
```

Enabling TLS support after setup

If the server has been set up without support for TLS, enable TLS support later by completing the following tasks.

Steps

1. Obtain a certificate chain.

For more information about obtaining a certificate chain, see [Certificate chains](#) on page 129. To prepare a Java KeyStore JKS or PKCS #12 key store with an appropriate certificate chain and private key, use the `manage-certificates` tool. We also recommend that you create a trust store that the server can use.

2. Configure the key and trust manager providers.

For more information, see [Configuring key and trust manager providers](#) on page 158.

3. Configure connection handlers.

For more information, see [Configuring connection handlers](#) on page 158.

Configuring key and trust manager providers

After you have a key store, configure a key manager provider to access it.

The server is preconfigured with key manager providers, `JKS` and `PKCS12`, that you can use with JKS or PKCS #12 key stores, respectively. You can update the appropriate key manager provider in most cases to reference the key store that you plan to use. The following code provides an example.

```
dsconfig set-key-manager-provider-prop \
  --provider-name JKS \
  --set enabled:true \
  --set key-store-file:config/keystore \
  --set key-store-pin-file:config/keystore.pin
```

A similar change configures a trust manager provider to reference the appropriate trust store. The following code provides an example.

```
dsconfig set-trust-manager-provider-prop \
  --provider-name JKS \
  --set enabled:true \
  --set include-jvm-default-issuers:true \
  --set trust-store-file:config/truststore \
  --set trust-store-pin-file:config/truststore.pin
```

Note:

If all clients and servers use certificates that are signed by issuers and are included in the JVM's default trust store, you can use the `JVM-Default` trust manager provider to accomplish this task.

Configuring connection handlers

After you configure the key and trust manager providers, update the connection handlers to use the key and trust manager providers.

Steps

- For the LDAP connection handler, use the following command to enable StartTLS with a configuration change. By default, the LDAP connection handler accepts non-secure connections.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
```

```
--set allow-start-tls:true \
--set key-manager-provider:JKS \
--set trust-manager-provider:JKS \
--set ssl-cert-nickname:server-cert \
--set ssl-client-auth-policy:optional
```

- If you did not configure secure communication during setup, the LDAPS connection handler is disabled. To configure LDAPS support in this scenario, enable the connection handler and configure most of the same settings. You must set **allow-start-tls** to `false` and **use-ssl** to `true`. See the following code for an example configuration.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "LDAPS Connection Handler" \
  --set enabled:true \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert \
  --set ssl-client-auth-policy:optional
```

Example: The following example uses a similar configuration change to enable the HTTPS connection handler.

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true \
  --set listen-port:443 \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert
```

Updating the topology registry

After the server connection handlers are updated to enable TLS, update the topology registry to provide information about the new configuration.

The topology registry holds information about server instances that are part of the environment, and it helps to facilitate inter-server communication, such as replication, mirroring portions of the configuration, and PingDirectory Server's automatic backend server-discovery functionality.

The following table details the two types of entries that require updating.

Configuration types and their update descriptions

Configuration Type	Update description
Server instance listener configuration	<ul style="list-style-type: none"> ▪ Provides information that is needed to trust the TLS certificates that instances in the topology present. ▪ The server instance listener configuration must include the server certificate, which is defined as the certificate at the head of the chain. This version must be the multi-line, PEM-formatted representation of the certificate. You can use dsconfig to import the certificate from a file, as shown in the following example. <pre data-bbox="906 619 1453 892">bin/dsconfig set-server-instance-listener-prop \ --instance-name ds1 \ --listener-name ldap-listener-mirrored-config \ --set server-ldap-port:636 \ --set connection-security:ssl \ --set 'listener-certificate>/ca/ds1-cert.pem'</pre> <div data-bbox="906 934 1461 1249" style="border: 1px solid black; padding: 5px;"> <p> Note:</p> <p>The less-than operator > in the final line indicates that the value is read from a file rather than provided directly. In addition, you might not need to enclose the property name and path within single straight quotes to prevent the shell from interpreting the less-than symbol as an attempt to redirect input.</p> </div>

Configuration Type	Update description
Server instance configuration	<ul style="list-style-type: none"> ▪ Provides information about options for communicating with those instances. ▪ Update the server instance configuration object to reflect the new methods that are available for communication with the instance. For example, the <code>preferred-security</code> property identifies the mechanism by which other instances in the topology attempt to communicate with the instance. <p>The following example code sets the LDAPS and HTTPS ports, indicates that StartTLS support is enabled, and instructs other instances to use SSL (LDAPS) when communicating with the instance.</p> <pre style="background-color: #f0f0f0; padding: 10px;">dsconfig set-server-instance-prop \ --instance-name dsl \ --set ldaps-port:636 \ --set https-port:443 \ --set preferred-security:ssl \ --set start-tls-enabled:true</pre>

Troubleshooting TLS-related issues

Use this section for troubleshooting problems that might arise during TLS configuration, including communication and security issues that affect clients as well as PingDirectory Server.

- [Log messages](#)
- [manage-certificates check-certificate-usability](#)
- [ldapsearch](#)
- [Using low-level TLS debugging](#)

Log messages

The following describes how to use the server's log messages to troubleshoot TLS-related issues.

To troubleshoot TLS-related issues, start by checking the server's access log. If the client can establish a TCP connection to the server, which must occur before TLS negotiation can start, the access log shows a `CONNECT` message with the following information:

- Source and destination address and port for the connection
- Protocol
- Selected client connection policy

The `CONNECT` message does not appear

If the `CONNECT` does not appear, the client might be unable to communicate with the server. The culprit can be a network problem, a firewall that is blocking attempts to communicate, or the client is trying to use an incorrect address or port.

The `CONNECT` message does appear

If the `CONNECT` message appears in the access log, it typically includes a `conn` element that specifies the connection ID. To view additional log messages for the client connection, use the `search-logs` tool. For example, if the connection ID is `12345`, the following command displays the complete set of associated log messages.

```
$ bin/search-logs --logFile logs/access conn=12345
```

If you are using LDAPS

If you are attempting to use LDAPS, one of the following log messages appears next:

- `SECURITY-NEGOTIATION` message – Indicates that the client and server successfully completed the negotiation process and that the issue likely occurred after the TLS session was established. This message also includes details about the negotiation, including the TLS protocol and the selected cipher suite.
- `DISCONNECT` message – The issue might involve a failure in the TLS-negotiation process. In such scenarios, the message usually includes a `reason` element that provides additional information about the reason for the disconnect.

If the failure occurred during TLS negotiation, the usefulness of the `DISCONNECT` message depends in part on whether the failure occurred on the client or the server. For example, if the server decided to abort the negotiation, the message ideally contains the specific reason. If the problem occurred on the client, the log message likely contains only the general category for the failure.

Note:

The TLS protocol does not provide a mechanism for conveying detailed error messages. Instead, it offers only a basic alert mechanism with a fixed set of alert types. For example, if a client does not trust the certificate chain that the server presents to it, the server might receive a generic alert like `certificate_unknown`, even if the client knows the precise reason for rejecting the chain. In such instances, you might need to determine whether the client can provide additional details about the issue.

If the access log does not provide useful information

If the access log does not provide useful information, check the server error log. Although the error log does not normally include information about issues that relate to client communication, it provides helpful information in certain circumstances, like when an internal error within the server interferes with communication attempts.

manage-certificates check-certificate-usability

The `manage-certificates` tool offers a `check-certificate-usability` subcommand to examine a specified entry in a key store and to identify potential issues that might interfere with secure communication.

The `check-certificate-usability` tool completes the following tasks:

- Ensures that a specified entry in the key store includes a private key and a complete certificate chain
- Checks whether the certificate at the root of the chain is found in the Java virtual machine's (JVM's) default set of trusted certificates
- Ensures that the current time lies within the validity window for all certificates in the chain
- Validates the signatures for all certificates in the chain
- Warns if the end-entity certificate is self-signed
- Warns if the end-entity certificate does not contain an extended key usage extension with the `serverAuth` usage
- Warns if the issuer certificates do not have a key usage extension with the `keyCertSign` usage
- Warns if the issuer certificates do not have a basic constraints extension indicating that it can operate as a certification authority

If the chain violates a path length constraint, the `check-certificate-usability` tool reports an error.

- Ensures that the signature algorithm uses a strong message digest algorithm, like SHA-256

The `check-certificate-usability` tool reports an error for weak digest algorithms like MD5 or SHA-1, and reports a warning for unrecognized digest algorithms.

- Ensures that none of the certificates that use an RSA key pair have a key size less than 2048 bits

The following example demonstrates the usage for the `manage-certificates check-certificate-usability` command and its output when no problems are identified.

```
$ bin/manage-certificates check-certificate-usability \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert

Successfully retrieved the certificate chain for alias 'server-cert':

Subject DN: CN=ds1.example.com,O=Example Corp,C=US

OK: The certificate chain is complete. Each subsequent certificate is
the issuer for the previous certificate in the chain, and the chain ends
with a self-signed certificate.

OK: Certificate 'CN=ds1.example.com,O=Example Corp,C=US' has a valid
```

signature.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a valid signature.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a valid signature.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' will expire at Wednesday, November 11, 2020 at 03:52:44 PM CST (364 days, 23 hours, 54 minutes, 14 seconds from now), which is not in the near future.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' will expire at Monday, November 7, 2039 at 03:52:42 PM CST (7299 days, 23 hours, 54 minutes, 12 seconds from now), which is not in the near future.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' will expire at Monday, November 7, 2039 at 03:52:38 PM CST (7299 days, 23 hours, 54 minutes, 8 seconds from now), which is not in the near future.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' at the head of the chain includes an extended key usage extension, and that extension includes the serverAuth usage.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' includes a basic constraints extension, and the certificate chain satisfies those constraints.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' includes a key usage extension with the keyCertSign usage flag set to true.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes a basic constraints extension, and the certificate chain satisfies those constraints.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes a key usage extension with the keyCertSign usage flag set to true.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' has a 2048-bit RSA public key, which is considered strong.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a 4096-bit RSA public key, which is considered strong.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a 4096-bit RSA public key, which is considered strong.

No usability errors or warnings were identified while validating the certificate chain.

If any usability issues are identified, they might be responsible for communication problems.

Idapsearch

The `ldapsearch` command-line utility is a powerful tool for issuing searches against an LDAP directory server. It also provides a convenient method for troubleshooting a variety of issues, including problems that are relevant to TLS communication.

The following table details arguments that are the most useful for TLS-related communication.

TLS-related communication arguments and their descriptions

Argument	Description
<code>--hostname {address}</code>	Address of the server to which the connection is established
<code>--port {port}</code>	TCP port of the server to which the connection is established. The standard port for non-secure LDAP, or LDAP to be secured with StartTLS, is 389 , and the standard port for secure LDAPS is 636 . Many deployments use alternate ports, especially non-privileged ports above 1024 .
<code>--useSSL</code>	The tool establishes an initially insecure LDAP connection, which is secured later with the StartTLS extended operation.
<code>--trustStorePath {path}</code>	Path to the trust store that is used when determining whether to trust the certificate chain that the server presents during TLS negotiation. If neither this argument nor the <code>--trustAll</code> argument is provided, the tool prompts you interactively whether to trust server certificates that are not signed by an issuer in the Java virtual machine's (JVM's) default trust store.
<code>--trustStoreFormat {format}</code>	Format for the trust store, which is typically JKS or PKCS12 .
<code>--trustStorePassword {password}</code>	Password that is required to access the contents of the trust store.
<code>--trustStorePasswordFile {path}</code>	Path to the file that contains the password that is required to access the contents of the trust store.
<code>--trustAll</code>	The tool blindly trusts all TLS certificate chains that are presented to it. Although this argument can prove useful for troubleshooting purposes, it is not recommended for general use.

Argument	Description
<code>--keyStorePath {path}</code>	<p>Path to the key store to use if a client certificate chain is presented to the server.</p> <p> Note:</p> <p>Use this argument only when one of the following conditions is satisfied:</p> <ul style="list-style-type: none"> ▪ The server is configured to require clients to present a certificate. ▪ You intend to use the certificate to authenticate through SASL EXTERNAL.
<code>--keyStoreFormat {format}</code>	Format for the key store, which is typically JKS or PKCS12 .
<code>--keyStorePassword {password}</code>	Password to access the key store.
<code>--keyStorePasswordFile {path}</code>	Path to the file that contains the password necessary to access the key store.
<code>--certNickname {alias}</code>	Alias of the private key entry in the key store. Use when obtaining the certificate chain to present to the server.
<code>--useSASLExternal</code>	The client authenticates with the EXTERNAL SASL mechanism, which typically identifies the client using the certificate chain that is presented during TLS negotiation.
<code>--enableSSLDebugging</code>	The tool activates the low-level TLS-debugging feature that the JVM provides.

The following command provides an example of the simplest method for testing TLS communication with PingDirectory Server.

Example

```
$ bin/ldapsearch \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --baseDN "" \
  --scope base \
  "(objectClass=*)"
```

The server presented the following certificate chain:

```
Subject: CN=ds1.example.com,O=Example Corp,C=US
Valid From: Tuesday, November 12, 2019 at 08:28:08 PM CST
Valid Until: Wednesday, November 11, 2020 at 08:28:08 PM CST
SHA-1 Fingerprint:
  6a:22:2a:bd:0b:1b:09:35:63:bc:12:3e:2c:9e:e7:70:bc:a4:73:de

34:34:a1:90:83:8a:d5:12

Do you wish to trust this certificate? Enter 'y' or 'n': y
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: 8d574122-4584-4522-96d9-0cdcb9d2e339
startTime: 20191113061149Z

# Result Code: 0 (success)
# Number of Entries Returned: 1

```

Trust stores and trust-related arguments

If no trust-related arguments are provided, the tool uses the JVM's default trust store to verify whether to trust the certificate chain, based on the information that it contains. If a trusted authority has signed the server certificate, the negotiation process continues without further interaction.

If the chain cannot be trusted, based on the information in the JVM-default trust store, **ldapsearch** prompts you interactively about whether to trust the certificate. If you accept the chain, the client and server complete the negotiation process, and the client sends the search request to the server. If the search succeeds, the server can communicate over TLS.

To test with a trust store instead of being prompted interactively, use the **--trustStorePath** argument that points to the appropriate trust store. If you are using a Java Keystore (JKS) trust store, you might not need to provide the trust store password. If you are using a PKCS #12 trust store, you need to provide the trust store password. The following code provides an example.

Example

```

$ bin/ldapsearch \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --trustStorePath config/truststore.p12 \
  --trustStorePasswordFile config/truststore.pin \
  --trustStoreFormat PKCS12 \
  --baseDN "" \
  --scope base \
  "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse

```

```

startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code: 0 (success)
# Number of Entries Returned: 1

```

Client certificate chains and key stores

To present a client certificate chain to the server, either because the server's connection handler is configured with an `ssl-client-auth-policy` value of `required` or because you plan to use the certificate to authenticate by way of the SASL EXTERNAL mechanism, provide at least the key store and its corresponding password. You can also specify the alias of the certificate chain to present, which is recommended if your client key store contains multiple certificates. The following code provides an example.

Example

```

$ bin/ldapsearch \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --trustStorePath config/truststore.p12 \
  --trustStorePasswordFile config/truststore.pin \
  --trustStoreFormat PKCS12 \
  --keyStorePath client-keystore \
  --keyStorePasswordFile client-keystore.pin \
  --certNickname client-cert \
  --useSASLExternal \
  --baseDN "" \
  --scope base \
  "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code: 0 (success)
# Number of Entries Returned: 1

```

If you need to further troubleshoot a TLS-related issue

If you encounter a TLS-related issue that you cannot resolve by examining the `ldapsearch` output or the server logs, use the `--enableSSLDebugging` option to enable the JVM's support for low-level debugging of TLS processing. For more information, see [Using low-level TLS debugging](#) on page 168.

Using low-level TLS debugging

Use tools other than the command-line tools that are provided with PingDirectory Server for performing low-level TLS debugging.

Before you begin

Note:

If you need to use low-level debugging options, enable the Java Virtual Machine (JVM)'s support for TLS debugging. Many of the command-line tools that are provided with PingDirectory Server, such as `ldapsearch`, offer an `--enableSSLDebugging` argument that simplifies this process.

Steps

1. In the `config/java.properties` file, add the following line to the set of properties for the appropriate tool.

```
-Djavax.net.debug=all
```

2. For the changes to take effect, run the `bin/dsjavaproperties` command.

Next steps

The next time the tool is run, an output is generated detailing the TLS-related processing that the JVM is performing. You and the Ping Identity Corp support team can use the output to identify the issue.

Using the Configuration API

PingDirectory Server provides a Configuration API when updating the server configuration with LDAP is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers allow the `application/json` content type.

About this task

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP.

Steps

- To add the extension to one of the server's HTTP Connection Handlers, run the following code.

```
$ bin/dsconfig set-connection-handler-prop \  
  --handler-name "HTTPS Connection Handler" \  
  --add http-servlet-extension:Configuration
```

Note:

By default, the extension is enabled for new installations. You can enable the extension for existing deployments.

Result: The API is made available on the HTTPS Connection Handler's host:port in the `/config` context. Due to the potentially sensitive nature of the server's configuration, use the HTTPS Connection Handler for hosting the configuration extension.

Authentication and authorization with the Configuration API

Use this topic for how to make changes for customizing authentication and authorization access with the Configuration API.

Authentication

Clients must use HTTP basic authentication to authenticate to the Configuration API. If the username value is not a distinguished name (DN), then it resolves to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a username. To customize this behavior, either customize the default identity mapper or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. The following code provides an example.

```
$ bin/dsconfig set-http-servlet-extension-prop \  
  --extension-name Configuration \  
  --identity-mapper <identity-mapper>
```

```
--set "identity-mapper:Alternative Identity Mapper"
```

Authorization

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACL.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

The Configuration API and the `dsconfig` tool relationship

The Configuration API is designed to mirror the `dsconfig` tool, using the same names for properties and object types.

Property names are presented as hyphen case in `dsconfig` and as camel-case attributes in the API. In API requests that specify property names, case is not important. `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the `dsconfig list-connection-handlers` command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a local database backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the `dsconfig` tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the System for Cross-domain Identity Management (SCIM) specification. Request specific attributes using the `attributes` query parameter, whose value must be a comma-delimited list of properties to be returned, such as `attributes=baseDN,description`. You can exclude attributes from responses by specifying the `excludedAttributes` parameter.

Configuration API operations supported in REST APIs

HTTP Method	Description	Related <code>dsconfig</code> Example
GET	Lists the properties of an object when used with a path representing an object, such as <code>/config/global-configuration</code> or <code>/config/backends/userRoot</code> . Can also list objects when used with a path representing a parent relation, such as <code>/config/backends</code> .	<ul style="list-style-type: none"> ▪ <code>get-backend-prop</code> ▪ <code>list-backends</code> ▪ <code>get-global-configuration-prop</code>
POST	Creates a new instance of an object when used with a relation parent path, such as <code>/config/backends</code> .	<code>create-backend</code>
PUT	Replaces the existing properties of an object. A PUT operation is similar to a PATCH operation, except that the PATCH identifies the difference between an existing target object and a supplied source object. Only those properties in the source object are modified in the target object. The target object is specified using a path, such as <code>/config/backends/userRoot</code> .	<ul style="list-style-type: none"> ▪ <code>set-backend-prop</code> ▪ <code>set-global-configuration-prop</code>

HTTP Method	Description	Related dsconfig Example
PATCH	Updates the properties of an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .	<ul style="list-style-type: none"> ▪ <code>set-backend-prop</code> ▪ <code>set-global-configuration-prop</code>
DELETE	Deletes an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .	<code>delete-backend</code>

Note:

The `OPTIONS` method can also be used to determine the operations permitted for a particular path.

Object names, such as `userRoot` in the description column, must be URL-encoded for use in the path segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent, `%`, character. The following URL is for accessing the HTTP Connection Handler object.

```
/config/connection-handlers/http%20connection%20handler
```

GET example

This topic provides an example of a GET request and response concerning the `userRoot` backend for reference.

GET request

The following code example is a GET request for information about the `userRoot` backend.

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

GET response

The following code example is the response.

PATCH example

Modify the Configuration API using the HTTP PATCH method.

The PATCH request body is a JSON object formatted according to the System for Cross-domain Identity Management (SCIM) patch request. The Configuration API supports a subset of possible values for the path attribute that indicates the configuration attribute to modify.

Modify the configuration object's attributes according to the information in the following table, which details the comparable `dsconfig modify-[object]` options to each PATCH request.

Operations and PATCH requests to modify the configuration object's attributes

Operation	PATCH request	Comparable dsconfig modify- [object] options
Set the single-valued description attribute to a new value.	<pre>{ "op" : "replace", "path" : "description", "value" : "A new backend." }</pre>	<pre>\$ dsconfig set-backend- prop --backend-name userRoot \ --set "description:A new backend"</pre>
Add a new value to the multi-valued jeProperty attribute.	<pre>{ "op" : "add", "path" : "jeProperty", "value" : "je.env.backgroundReadLimit=32" }</pre>	<pre>\$ dsconfig set- backend-prop --backend- name userRoot \ --add je- property:je.env.backgroundReadLimit=32</pre>
Remove a value from a multi-valued property. In this case, path specifies a SCIM filter identifying the value to remove.	<pre>{ "op" : "remove", "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=32\" \"]" }</pre>	<pre>\$ dsconfig set-backend- prop --backend-name userRoot \ --remove je- property:je.cleaner.adjustUtilization=32</pre>
Second operation to remove a value from a multi-valued property, where the path specifies both an attribute to modify and a SCIM filter whose attribute is the following value.	<pre>{ "op" : "remove", "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\" \"]" }</pre>	<pre>\$ dsconfig set-backend- prop --backend-name userRoot \ --remove je- property:je.nodeMaxEntries=32</pre>
Option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value.	<pre>{ "op" : "remove", "path" : "id2childrenIndexEntryLimit" }</pre>	<pre>\$ dsconfig set-backend- prop --backend-name userRoot \ --reset id2childrenIndexEntryLimit</pre>

Example

The following is the full example request.

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json

{
  "schemas" : [ "urn:ietf:params:scim:api:messages:2.0:PatchOp" ],
  "Operations" : [ {
    "op" : "replace",
    "path" : "description",
```

```

    "value" : "A new backend."
  }, {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }, {
    "op" : "remove",
    "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
  }, {
    "op" : "remove",
    "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
  }, {
    "op" : "remove",
    "path" : "id2childrenIndexEntryLimit"
  } ]
}

```

Example

The API responds with the entire modified configuration object, which can include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions. The following is an example response.

```

{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],
  "id": "userRoot2",
  "meta": {

        that had already hit the previous limit."
    }
  ]
}
}
}

```

Configuration API paths

The Configuration API and supported sub-paths are available under the `/config` path.

A full listing of supported sub-paths is available when you access the base `/config/ResourceTypes` endpoint.

```
GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json
```

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted or created. These paths can be differentiated from others by their singular, rather than plural, relation name, such as `global-configuration`.

Example

The following sample response is abbreviated.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 520,
  "Resources": [
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "dsee-compat-access-control-handler",
      "name": "DSEE Compat Access Control Handler",
      "description": "The DSEE Compat Access Control
        Handler provides an implementation that uses syntax
        compatible with the Sun Java System Directory Server
        Enterprise Edition access control handler.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/dsee-
        compat-access-control-handler"
      }
    },
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "access-control-handler",
      "name": "Access Control Handler",
      "description": "Access Control Handlers manage the
        application-wide access control. The server's access
        control handler is defined through an extensible
        interface, so that alternate implementations can be created.
        Only one access control handler may be active in the server
        at any given time.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/access-
        control-handler"
      }
    }
  ],
}
```

```
{
  ...
}
```

The response's `endpoint` elements enumerate all available sub-paths. You can use the path `/config/access-control-handler` in the example to get a list of existing access control handlers and create new ones. You can use a path containing an object name, such as `/config/backends/{backendName}` (where `{backendName}` corresponds to an existing backend like `userRoot`) to obtain an object's properties, update the properties, or delete the object.

Sort and filter objects

The Configuration API supports System for Cross-domain Identity Management (SCIM) parameters for filter, sorting, and pagination.

Search operations can specify a SCIM filter to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters, or paging parameters. Include or exclude attributes can be specified in both GET and list operations.

GET Parameter	Description
filter	Values can be simple SCIM filters, such as <code>id eq "userRoot"</code> , or compound filters like <code>meta.resourceType eq "Local DB Backend" and baseDn co "dc=example,dc=com"</code> .
sortBy	Specifies a property value by which to sort.
sortOrder	Specifies either <code>ascending</code> or <code>descending</code> alphabetical order.
startIndex	1-based index of the first result to return.
count	Indicates the number of results per page.

Update properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH.

With PUT, the server computes the differences between the object in the request with the current version in the server and performs modifications where necessary. The server never removes attributes that are not specified in the request. The API responds with the entire modified object.

Example

Sample request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
  "description" : "A new description."
}
```

Sample response:

```
{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],
  "id": "userRoot",
  "meta": {
    "resourceType": "Local DB Backend",

```

```

    "location": "http://example.com:5033/config/backends/userRoot"
  },
  "backendID": "userRoot",
  "backgroundPrime": "false",
  "backupFilePermissions": "700",
  "baseDN": [
    "dc=example,dc=com"
  ],
  "checkpointOnCloseCount": "2",
  "cleanerThreadWaitTime": "120000",
  "compressEntries": "false",
  "continuePrimeAfterCacheFull": "false",
  "dbBackgroundSyncInterval": "1 s",
  "dbCachePercent": "25",
  "dbCacheSize": "0 b",
  "dbCheckpointIntervalBytes": "20 mb",
  "dbCheckpointIntervalHighPriority": "false",
  "dbCheckpointIntervalWakeup": "30 s",
  "dbCleanOnExplicitGC": "false",
  "dbCleanerMinUtilization": "75",
  "dbCompactKeyPrefixes": "true",
  "dbDirectory": "db",
  "dbDirectoryPermissions": "700",
  "dbEvictorCriticalPercentage": "5",
  "dbEvictorLruOnly": "false",
  "dbEvictorNodesPerScan": "10",

"returnUnavailableForUntrustedIndex": "true",
"returnUnavailableWhenDisabled": "true",
"setDegradedAlertForUntrustedIndex": "true",
"setDegradedAlertWhenDisabled": "true",
"subtreeDeleteBatchSize": "5000",
"subtreeDeleteSizeLimit": "100000",
"uncachedId2entryCacheMode": "cache-keys-only",
"writabilityMode": "enabled"
}

```

Administrative actions

Updating a property might require an administrative action before changes can take effect.

If you need administrative actions to update a property, the server returns 200 Success. Any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

Example

For example, changing the `jeProperty` of a backend results in the following:

```

"urn:unboundid:schemas:configuration:messages:2.0": {
  "required-actions": [
    {
      "property": "baseContextPath",
      "type": "componentRestart",
      "synopsis": "In order for this modification to take effect, the
component
must be restarted, either by disabling and re-enabling it,
or
by restarting the server"
    },
    {
      "property": {
        "property": {
          "type": "other",
          "synopsis": "If this limit is increased, then the
contents of the backend must be exported to LDIF
and re-imported to allow the new limit to be used
for any id2children keys that had already hit the
previous limit."
        }
      }
    }
  ]
}

```

Updating servers and server groups

You can configure servers as part of a server group so that configuration changes applied to a single server are applied to all servers in a group.

When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query attribute. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `single-server` or `server-group` can be specified.

Example

```

http://localhost:8082/config/backends/userRoot?applyChangeTo=single-server

```

Configuration API responses

Clients of the API should examine the HTTP response code to determine the success or failure of a request.

The following are response codes and their meanings.

Response Code	Description	Response Body
200 Success	The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the <code>urn:unboundid:schemas:configuration:messages:2.0</code> object.	List of objects, object properties, or administrative actions
204 No Content	The requested operation succeeded and no further information has been provided, as in the case of a DELETE operation.	None
400 Bad Request	The request contents are incorrectly formatted or a request is made for an invalid API version.	Error summary and optional message
401 Unauthorized	User authentication is required. Some user agents, such as browsers, might respond by prompting for credentials. If the request specified credentials in an Authorization header, they are invalid.	None
403 Forbidden	The requested operation is forbidden, either because the user does not have sufficient privileges or some other constraint, such as an object is edit-only and cannot be deleted.	None
404 Not Found	The requested path does not refer to an existing object or object relation.	Error summary and optional message
409 Conflict	The requested operation could not be performed due to the current state of the configuration. For example, an attempt was made to create an object that already exists, or an attempt was made to delete an object that is referenced by another object.	Error summary and optional message
415 Unsupported Media Type	The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.	None
500 Server Error	The server encountered an unexpected error. Report server errors to Customer Support.	Error summary and optional message

Note:

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages can change, and their presence can depend on server configuration. Use the HTTP return code and the context of the request to create a client error message.

Example

The following is an example encoded error message.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": 404,
  "scimType": null,
  "detail": "The Local DB Index does not exist."
}
```

Working with the Directory REST API

The Directory REST API is the native interface for client access to the PingDirectory Server. Instead of trying to manage directory hierarchy or require attribute mapping, the Directory REST API provides direct access to directory data in a way that is dynamic, discoverable, and efficient.

Before you begin

The Directory REST API gives developers who are more comfortable with REST than LDAP access to arbitrary directory data in a way that ensures directory data remains consistent regardless of whether it is accessed from LDAP or REST. The Directory API is enabled during server setup. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.

While both the Directory REST API and System for Cross-domain Identity Management (SCIM) provide REST access to directory data, the goals of the two protocols are different. SCIM is useful to generic, external clients that require simple, narrow access to identity data, but because it is a less common standard for identity stores, it might not offer as much functionality or be as user-friendly as the Directory REST API.

The Directory REST API can be used for the following operations.

HTTP operation	Resource endpoint	Description	Allowed query parameters
DELETE	<code>/directory/v1/{dn}</code>	Delete an entry.	
GET	<code>/directory/v1</code>	Get metadata about the API and server.	
GET	<code>/directory/v1/{dn}</code>	Retrieve a single entry.	<ul style="list-style-type: none"> ▪ <code>expand</code> ▪ <code>includeAttributes</code> ▪ <code>excludeAttributes</code>
GET	<code>/directory/v1/{dn}/subtree</code>	Search an entry's descendants.	<ul style="list-style-type: none"> ▪ <code>filter</code> ▪ <code>searchScope</code> ▪ <code>cursor</code> ▪ <code>limit</code> ▪ <code>includeAttributes</code> ▪ <code>excludeAttributes</code>
GET	<code>/directory/v1/schemas</code>	Retrieve the schemas of all available object classes.	

HTTP operation	Resource endpoint	Description	Allowed query parameters
GET	/directory/v1/schemas/{objectclass}	Retrieve schema for a specific object class.	
GET	/directory/v1/schemas/_operationalAttributes	Retrieve schema for operational attributes.	
GET	/directory/v1/me	Alias for retrieving the current user.	
PATCH	/directory/v1/{dn}	Modify an entry (add or delete values).	expand
POST	/directory/v1	Create a new entry.	expand
PUT	/directory/v1/{dn}	Modify or rename an entry.	expand

Steps

- Configure the Directory REST API with any of the following properties using **dsconfig**:

Command	Description
basic-auth-enabled	Specifies whether users can connect to the service with HTTP Basic authentication. If disabled, users need a bearer token. If changed, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled. Basic authentication is enabled by default.
identity-mapper	If HTTP Basic authentication is enabled, the identity mapper referenced by this distinguished name (DN) must be used to map the user names provided to user entries. By default, an identity mapper is provided, which maps a fully-qualified DN to an entry. For changes to take effect, the server must be restarted, or any HTTP connection handlers referencing this service disabled and re-enabled.
access-token-validator	Specifies the subset of this server's Access Token Validators (by DN), which can validate Bearer authentication tokens. By default, if no validators are specified, then any of the validators on the server can be used. For changes to take effect, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled.
access-token-scope	The scope that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, Bearer token authentication is disabled, and only Basic authentication is used. By default, no value is provided. Changes to this value take effect immediately.
audience	A string or URI audience that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, any

Command	Description
<code>max-page-size</code>	audience is acceptable. By default, no value is provided. Changes to this value take effect immediately.
<code>schemas-endpoint-objectclass</code>	The maximum number of entries to be returned in one page from the search endpoint. Actual results returned might be lower due to the limit query parameter on the request and the actual number of available results. The value must be an integer between 1 and 1000. The default value is 100. Changes to this value take effect immediately.
<code>schemas-endpoint-objectclass</code>	The list of object classes that will be returned by the <code>/schemas/</code> endpoint in the REST API. By default, no schemas are returned. Changes to this value take effect immediately.

Example:

The following example uses `dsconfig` to configure an `objectClass` entity.

```
dsconfig set-http-servlet-extension-props --extension-name "Directory
REST API" \
--add schemas-endpoint-objectclass:ubidPerson
```

Configuring the Server using the Administrative Console

The PingDirectory Server provides an administrative console for server configuration and monitoring that has the same functionality as the `dsconfig` command.

When signing on to the Administrative Console, the console does not persistently store any credentials for authenticating to the Directory Server. Instead, the console uses the credentials provided by the user when signing on.

When managing multiple directory server instances, the provided credentials must be valid for each instance.

Signing on to the Administrative Console

About this task

To sign on to the console, enter a fully qualified distinguished name (DN), for example, `cn=admin2,cn=Topology Admin Users,cn=Topology,cn=config`. For more information, see [Configuring a global administrator](#) on page 198.

Steps

1. Start the Directory Server.

```
$ bin/start-server
```
2. In a browser, go to <http://server-name:389/console/login>.

3. In the **Username** and **Password** fields, enter the root user DN credentials.

Generating a summary of configuration components

The `config-diff` tool generates a summary of the configuration in a local or remote directory server instance.

About this task

The `config-diff` tool is useful for comparing configuration settings on the directory server instance when troubleshooting issues or when verifying configuration settings on newly-added servers. The tool can interact with the local configuration regardless of whether the server is running.

Steps

- To generate a summary of configuration components, run `config-diff`
Example: `$ bin/config-diff` generates a summary of a local online server.
- To generate a comparison of the current configuration with the pre-installation configuration, run the following.

```
$ bin/config-diff --sourceLocal \  
--sourceBaseline \  
--targetLocal \  
--exclude differs-after-install \  
--outputFile configuration-steps.dsconfig
```

This comparison ignores any changes that could be made by the installer and writes the output to a file called `configuration-steps.dsconfig`.

You can use this file as the basis for a script to configure a new server identical to the local server.

- To view other available tool options, run `config-diff --help`.

Administrator account classes

Directory Server provides three different classes of administrator accounts: root user, administrator, and global administrator.

Root user

The root user is the LDAP-equivalent of a UNIX super-user account and inherits its privileges from the default root user privilege set. For more information on default root privileges, see [Default root privileges](#) on page 192. The root user account is an entry that is stored in the server's configuration under `cn=Root DNs,cn=config` and bypasses access control evaluation. It can be created manually or with the `dsconfig` tool. This account has full access to the entire set of data in the directory information tree (DIT) and to the server configuration and its operations. One important difference between other vendors' servers and Directory Server's implementation is that the root user's rights are granted through a set of privileges. This allows Directory Server to have multiple root users on its system, but the normal practice is to set up administrator user entries. The root user has no resource limits by default.

Administrator

The administrator user can have a full set of root user privileges but often has a subset of these privileges to limit the accessible functions that can be performed. The administrators' entries typically have limited access to the entire set of data in the DIT, which is controlled by access control instructions. These entries reside in the backend configuration, for example, `uid=admin,dc=example,dc=com`, and are replicated between servers in a replication topology. In some cases, administrator user accounts might be unavailable when the server enters lockdown mode unless the administrator is given the lockdown mode privilege.

Global administrator

A global administrator is primarily responsible for managing configuration server groups. A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology where configuration changes to one server can be applied to all of the servers at one time.

Global administrator entries are stored in the `cn=Topology Admin Users,cn=Topology,cn=config` backend and are always mirrored across servers in a replication topology. These users can be assigned privileges like other administrator users but are typically used to manage the data under `cn=Topology,cn=config`.

Using separate administrator accounts

Each administrator should have their own account with their own credentials tailored to the level of access needed.

The `setup` utility only creates a single root user. Some directory servers from other vendors only support a single root account so all administrators are required to share that account. However, this is a bad practice for a number of reasons, including:

- It's difficult to audit the actions of individual administrators. With separate accounts for each administrator, it's easy to see who did what.
- Credentials have to be shared across multiple administrators. Shared credentials are at a greater risk of being leaked or compromised. With separate accounts for each administrator, each has its own credentials that are not shared with anyone else.
- If the credentials for that single root account are leaked or compromised (or if someone with legitimate access to those credentials leaves their position and no longer needs that access), then those credentials need to be changed. The new credentials need to be communicated to all of the administrators sharing that account, which can be difficult to do securely. If the new credentials are not communicated in advance of the change, then administrators who have not received them won't be able to manage the server. If the new credentials are communicated in advance of the change, then the old, potentially compromised credentials remain in effect for longer than necessary.
- Using a single root account makes it more difficult to use strong authentication, such as a certificate or two-factor authentication, in a secure manner. With separate accounts for each administrator, it's easier to use strong authentication in a secure manner.
- If there is only a single root account, then that account must have a level of access that permits everything that any administrator might need to do, even if all administrators don't need the same level of access. With separate accounts for each administrator, each can be given precisely the level of access that they need.

It might also be beneficial to remove or disable the account for the initial root user created by `setup` once all of the administrators have their own accounts.

Using separate accounts is mentioned in the following `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file, which provides an example for creating a topology admin user with various restrictions.

```
# Although setup automatically creates an initial root user account that can
# be used to manage the server, we strongly recommend creating a separate
# account for each administrator rather than using a single shared account.
# This offers several benefits, including:
#
# * It is easier to determine which administrator performed a given action.
# * There is no need to share credentials or coordinate password changes.
# * It is easier to use strong authentication options like certificates or
#   two-factor mechanisms.
# * You can customize the level of access that each administrator has.
#
# We also recommend creating topology admin user accounts rather than root
# user accounts. If you create a root user account, then it is only created
```

```

# in that one instance. If you create a topology admin user, then that
# account will be available in all instances in the topology.
#
# Because administrative accounts are very powerful, they are high-priority
# targets for attackers to try to compromise. They should be required to
# have
# strong credentials, and you may wish to require that they use strong
# authentication mechanisms (see other dsconfig batch files for configuring
# password validators and other password policy features). You may also
# want
# to give them usernames that are not likely to be guessed by an attacker,
# even if they know information about the individuals administering the
# service. For example, you may not want to use their name in the DN or
# username, choosing instead something that is less predictable or even
# completely random like a UUID.
#
# Once each administrator has their own account, we recommend that you
# disable
# or remove the initial root user created during setup. See the
# disable-or-remove-the-initial-root-user.dsconfig batch file for more
# information about that.

#
# NOTE: Do not edit this file directly. Changing this file could prevent
# it
# from being updated during a server upgrade. If you want to alter the
# dsconfig commands below before applying the configuration changes, copy
# this
# file to another directory and edit that copy.
#

# Create a new topology administrator account. In this example, the user
# will
# be able to read the configuration but will not be allowed to update it,
# and
# will be given the bypass-read-acl privilege rather than bypass-acl, which
# only ensures they will be able to read entries but they will not be
# permitted to update them unless permitted by the server's access control
# configuration. They will also only be permitted to communicate with the
# server over a secure connection, and they will only be permitted to
# authenticate with the EXTERNAL or UNBOUNDID-TOTP mechanisms.
dsconfig create-topology-admin-user \
  --user-name "[USER_NAME]" \
  --set "password:[PASSWORD]" \
  --set "first-name:[FIRST_NAME]" \
  --set "last-name:[LAST_NAME]" \
  --set "user-id:[USER_NAME]" \
  --set inherit-default-root-privileges:true \
  --set privilege:bypass-read-acl \
  --set privilege:-bypass-acl \
  --set privilege:-config-write \
  --set search-result-entry-limit:0 \
  --set time-limit-seconds:0 \
  --set look-through-entry-limit:0 \
  --set idle-time-limit-seconds:0 \
  --set require-secure-authentication:true \
  --set require-secure-connections:true \
  --set "allowed-authentication-type:SASL EXTERNAL" \
  --set "allowed-authentication-type:SASL UNBOUNDID-TOTP"

```

Unpredictable identifiers for server administrators

You can prevent online password guessing attacks by using unpredictable identifiers for users.

If an attacker doesn't know the name of the account, then it's another obstacle to overcome before they can authenticate as them.

An entry's DN is the most common identifier used to authenticate, as it's required for simple binds and is often used for SASL binds. For regular users, you should name accounts with the entryUUID attribute. However, this isn't feasible for root users or topology administrators because the configuration framework requires these entries to use `cn` as the naming attribute. Further, many SASL mechanisms allow identifying users with a username, which is correlated to the associated entry using an identity mapper, so using an unpredictable DN might not be enough to sufficiently interfere with an attacker's ability to target a server administrator.

The best way to obscure identifiers for root users and topology administrators is to choose unpredictable values for the `cn` attribute in their accounts and not include any predictable alternate bind DN values for those accounts. Although it is possible to use randomly generated `cn` values, it should be sufficient to use more memorable strings as long as they aren't something an attacker is likely to guess even if they know the identities of those administrators.

Secure communication for server administrators

Requiring secure communication for server administrators is recommended to prevent unencrypted communication.

While you should only permit secure access to the server, many environments might still allow access to unencrypted communication. Unencrypted communication is potentially dangerous for any kind of client because it could be observed and altered by a malicious third party, but it's especially dangerous for administrative accounts. Even if the server is configured to allow some clients to issue insecure requests, you should ensure that administrative accounts always use secure communication.

The best way to require that a user only be permitted to communicate with the server over a secure connection is to include the `ds-auth-require-secure-connection` operational attribute in that user's entry with a value of `true`. Although the password policy configuration includes `require-secure-authentication`, and `require-secure-password` changes properties, those properties can only guarantee the safety of authentication credentials. They don't guarantee secure communication for other operations processed by that user. This is because it's possible to authenticate in a manner that the server considers secure, without exposing credentials to an observer, without using a secure connection such as using a SASL mechanism like GSSAPI.

Note:

CRAM-MD5 and DIGEST-MD5 also currently fall into this category, but for this purpose they are no longer considered secure.

Although it's possible to enable this by default for root users and topology administrators, you shouldn't do so at the risk of affecting backward compatibility with existing deployments that expect to be able to use insecure communication for these accounts. If the server is configured to only accept secure connections, or to reject insecure requests, then this setting is not as necessary.

Managing root user accounts

PingDirectory Server provides a default root user, `cn=Directory Manager`, that is stored in the server's configuration file, such as under `cn=Root DNs,cn=config`.

About this task

The root user is the LDAP-equivalent of a UNIX superuser account and inherits its read-write privileges from the default root privilege set.

Steps

- To create or update root users, use the `dsconfig` tool.

Example:

```
bin/dsconfig create-root-dn-user --user-name "Joanne Smith" \
  --set last-name:Smith \
  --set first-name:Joanne \
  --set user-id:jsmith \
  --set 'email-address:jsmith@example.com' \
  --set mobile-telephone-number:8889997777 \
  --set home-telephone-number:5556667777 \
  --set work-telephone-number:4445556666
```

Note:

Root user entries are stored in the server's configuration.

- To limit full access to all of Directory Server, create separate administrator accounts with limited privileges so that you can identify the administrator responsible for a particular change.

Note:

Separate user accounts for each administrator make it possible to enable password policy functionality, such as password expiration, password history, and requiring secure authentication, for each administrator.

Default root privileges

The PingDirectory Server contains a privilege subsystem that allows for a more fine-grained control of privilege assignments.

Note:

Creating restricted root user accounts requires assigning privileges and necessary access controls for actions on specific data or backends. Access controls are determined by how the directory is configured and the structure of your data. See Chapter 16: Managing Access Controls for more information.

The following set of root privileges are available to each root user DN:

Default Root Privileges

Privilege	Description
audit-data-security	Allows the associated user to execute data security auditing tasks.
backend-backup	Allows the user to perform backend backup operations.
backend-restore	Allows the user to perform backend restore operations.
bypass-acl	Allows the user to bypass access control evaluation.
config-read	Allows the user to read the server configuration.
config-write	Allows the user to update the server configuration.
disconnect-client	Allows the user to terminate arbitrary client connections.
ldif-export	Allows the user to perform LDIF export operations.

Privilege	Description
ldif-import	Allows the user to perform LDIF import operations.
lockdown-mode	Allows the user to request a server lockdown.
manage-topology	Allows the user to modify topology setting.
metrics-read	Allows the user to read server metrics.
modify-acl	Allows the user to modify access control rules.
password-reset	Allows the user to reset user passwords but not their own. The user must also have privileges granted by access control to write the user password to the target entry.
permit-get-password-policy-state-issues	Allows the user to access password policy state issues.
privilege-change	Allows the user to change the set of privileges for a specific user, or to change the set of privileges automatically assigned to a root user.
server-restart	Allows the user to request a server restart.
server-shutdown	Allows the user to request a server shutdown.
soft-delete-read	Allows the user access to soft-deleted entries.
stream-values	Allows the user to perform a stream values extended operation that obtains all entry DN's and/or all values for one or more attributes for a specified portion of the DIT.
third-party-task	Allows the associated user to invoke tasks created by third-party developers.
unindexed-search	Allows the user to perform an unindexed search in the Oracle Berkeley DB Java Edition backend.
update-schema	Allows the user to update the server schema.
use-admin-session	Allows the associated user to use an administrative session to request that operations be processed using a dedicated pool of worker threads.

The Directory Server provides other privileges that are not assigned to the root user DN by default but can be added using the `ldapmodify` tool (see Modifying Individual Root User Privileges) for more information.

Other Available Privileges

Privilege	Description
bypass-pw-policy	Allows the associated user bypass password policy rules and restrictions.
bypass-read-aci	Allows the associated user to bypass access control checks performed by the server for bind, compare, and search operations. Access control evaluation may still be enforced for other types of operations.
jmx-notify	Allows the associated user to subscribe to receive JMX notifications.
jmx-read	Allows the associated user to perform JMX read operations.
jmx-write	Allows the associated user to perform JMX write operations.

Privilege	Description
permit-externally-processed-authentication	Allows the associated user accept externally processed authentication.
permit-proxied-mschapv2-details	Allows the associated user to permit MS-CHAP V2 handshake protocol.
proxied-auth	Allows the associated user to accept proxied authorization.

Configuring administrator accounts

An administrator account is any account in the user backend that is assigned one or more privileges or is given access to read and write operations beyond that of a normal user entry.

The privilege mechanism is the same as that used for root distinguished name (DN) accounts and allows individual privileges to be assigned to an administrator entry.

Typically, administrator user entries are controlled by access control evaluation to limit access to the entire set of data in the directory information tree (DIT). You can grant fine-grained read and write access using the access control definitions available through the `aci` attribute. Administrator entries reside in the backend configuration, for example, `uid=admin,dc=example,dc=com`, and are replicated between servers in a replication topology.

The following examples show how to configure administrator accounts:

- The first procedure shows how to set up a single, generic `uid=admin,dc=example,dc=com` account with limited privileges.

Note:

If you generated sample data at install, you can view an example `uid=admin` entry using `ldapsearch`.

- The second example shows a more realistic example where the user is part of the administrators group.

Note:

Both examples are based on a simple DIT. Actual deployment cases depend on your schema.

Setting up a single administrator account

About this task

To create an example of a single, generic administrator account:

Steps

1. Create an LDIF file with an example administrator entry.

Example:

```
dn: uid=admin,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
givenName: Admin
uid: admin
cn: Admin User
```

```
sn: User
userPassword: password
```

2. To add the entry, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --defaultAdd --filename admin.ldif
```

3. To add the access control instruction (ACI) to the root suffix or base DN to give full access to the new administrator, create another LDIF file.

Note:

The ACI grants full access to all user attributes, but not to operational attributes. To grant access to operational attributes as well as user attributes, use `(targetattr = "*"|+)` in the access control instruction.

Example:

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr = "*")
      (version 3.0; acl "Grant full access for the admin user";
       allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

4. To add the entry, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --filename admin.ldif
```

5. To verify the additions, use the `ldapsearch` tool.

Example:

In the following example, the first command searches for the entry that contains `uid=Admin` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including ACIs, associated with the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=admin)"
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base
  "(objectclass=*)" "+"
```

6. Add specific privileges to the administrator account, then to process the modify operation press **CTRL-D**.

Example:

For this example, add the `password-reset` privilege to the administrator account from the command line.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset
```

Result:

```
Processing MODIFY request for uid=admin,dc=example,dc=com
```

```
MODIFY operation successful for DN uid=admin,dc=example,dc=com
```

7. Assign a password policy for the administrator account.

Example:

Create an Admin Password Policy, then add the password policy to the account.

```
$ bin/dsconfig create-password-policy \
  --policy-name "Admin Password Policy" \
  --set "description:Password policy for administrators" \
  --set password-attribute:userpassword \
  --set "default-password-storage-scheme:Salted SHA-256" \
  --set password-change-requires-current-password:true \
  --set force-change-on-reset:true \
  --set "max-password-age:25w 5d" \
  --set grace-login-count:3 \
  --no-prompt
```

8. To apply the password policy to the account, run the `ldapmodify` command.

Example:

Execute the `ldapmodify` command with a bind DN that has sufficient rights, such as a root DN, as in the following example.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn>Password
Policies,cn=config
```

Changing the administrator password

About this task

Root users are governed by the root password policy and by default, their passwords never expire. To change a root user password, use the `ldappasswordmodify` tool.

Steps

1. Open a text editor and create a text file containing the new password.

Example:

For this example, name the file `rootuser.txt`.

```
$ echo password > rootuser.txt
```

2. To change the root user's password, run `ldappasswordmodify`.

Example:

```
$ bin/ldappasswordmodify --port 1389 --bindDN "cn=Directory Manager" \
  --bindPassword secret --newPasswordFile rootuser.txt
```

3. Remove the text file.

Example:

```
$ rm rootuser.txt
```

Setting up an administrator group

About this task

The following example shows how to set up a group of administrators that have access rights to the whole Directory Server.

Note:

The example uses a static group using the `GroupOfUniqueNames` object class.

Steps

1. Create an LDIF file with an example administrator group.

Example:

For this example, name the file `admin-group.ldif`

```
dn: ou=Groups,dc=example,dc=com
objectClass: organizationalunit
objectClass: top
ou: Groups

dn: cn=Dir Admins,ou=Groups,dc=example,dc=com
objectClass: groupofuniqueNames
objectClass: top
uniqueMember: uid=user.0, ou=People, dc=example,dc=com
uniqueMember: uid=user.1, ou=People, dc=example,dc=com
cn: Dir Admins
ou: Groups
```

2. To add the entries, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --defaultAdd --filename admin-group.ldif
```

3. To add the ACL to the root suffix or base DN to provide full access to the Directory Server to the new administrator, create another LDIF file.

Example:

For this example, name the file `admin-aci.ldif`.

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (target="ldap:///dc=example,dc=com")
(targetattr != "aci")
(version 3.0; acl "allow all Admin group";
allow(all) groupdn = "ldap:///cn=Dir
Admins,ou=Groups,dc=example,dc=com";)
```

4. To add the ACL, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --filename admin-aci.ldif
```

- To verify the additions, use the `ldapsearch` tool.

Example:

In the following example, the first command searches for the entry that contains `cn=Dir Admins` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including ACIs, associated with the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(cn=Dir Admins)"
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base \
  "(objectclass=*)" "+"
```

- To add specific privileges to each administrator account, use an LDIF file.

Example:

For this example, name the file `admin-priv.ldif`.

For this example, add the `password-reset` privilege to the `user.0` administrator account from the command line. To add the privilege, use the `ldapmodify` tool. Repeat the process for the other administrators configured in the administrator group.

```
dn: uid=user.0,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset

$ bin/ldapmodify --filename admin-priv.ldif
```

Result:

```
Processing MODIFY request for uid=user.0,dc=example,dc=com
MODIFY operation successful for DN uid=user.0,dc=example,dc=com
```

- To assign a password policy for the administrator account, use an LDIF file. Save the file as `admin-pwd-policy.ldif`.

Example:

For example, create an `Admin Password Policy`, then add the password policy to the account. To apply the password policy to the account, use the `ldapmodify` tool.

```
dn: uid=user.0,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password
Policies,cn=config

$ bin/ldapmodify --filename admin-pwd-policy.ldif
```

Configuring a global administrator

A global administrator is created when replication is enabled and is responsible for managing configuration server groups.

A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology where configuration changes to one server can be applied to all of the servers at a time.

Global administrators are stored in the topology registry. These entries are always mirrored between servers in a topology. Global administrators can be assigned privileges like other administrator users but are typically used to manage the data under `cn=topology`, `cn=config` and `cn=config`. You can create

new or remove global administrators using the **dsconfig** tool. The global administrator entries are located in the `cn=Topology Admin User, cn=topology,cn=config` branch.

Creating a global administrator

Steps

1. To create a new global administrator, use the `create-topology-admin-user` option with **dsconfig**.

Example:

```
$ bin/dsconfig create-topology-admin-user \
  --user-name admin2 \
  --set alternate-bind-dn:cn=admin2 \
  --set password:rootPassword
```

2. To verify the creation of the new administrator, use the `list-topology-admin-users` option with **dsconfig**.

Example:

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
-----:-----
admin                : generic
admin2               : generic
```

Removing a global administrator

Steps

1. To delete a global administrator, use the `delete-topology-admin-user` option with **dsconfig**.

Example:

```
$ bin/dsconfig delete-topology-admin-user --user-name admin2
```

2. To verify the deletion of the global administrator, use the `list-topology-admin-users` option with **dsconfig**.

Example:

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
-----:-----
admin                : generic
```

Configuring server groups

The PingDirectory Server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group.

About this task

After you have set up a server group, you can make an update on one server using **dsconfig**, then apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the **dsconfig** non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using **dsconfig** in interactive command-line mode, you are asked if you want to apply the change to a single server or to all servers in the server group.

You can create an administrative server group using the `dsconfig` tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group, as outlined in [Replication Configuration](#).

The following example procedure adds three PingDirectoryProxy Server instances into the server group labeled "group-one".

Steps

1. Create a group called "group-one" using `dsconfig`.

Example:

```
$ bin/dsconfig create-server-group --group-name group-one
```

2. Add any directory server to the server group.

If you have set up replication between a set of servers, these server entries are created by the `dsreplication enable` command.

Example:

```
$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server1

$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server2

$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server3
```

3. Set a global configuration property for each of the servers that should share changes in this group.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set configuration-server-group:group-one
```

4. Test the server group.

In this example, enable the log publisher for each directory server in the group "server-group" by using the `--applyChangeTo server-group` option.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
  --applyChangeTo server-group
```

5. View the property on the first directory server instance.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
-----:-----
enabled : true
```

6. Repeat step 5 on the second and third directory server instances.
7. Test the server group by disabling the log publisher on the first directory server instance by using the `--applyChangeTo single-server`.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:disabled \
  --applyChangeTo single-server
```

8. View the property on the first directory server instance.

The first directory server instance should be disabled.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
-----:-----
enabled : false
```

9. View the property on the second directory server instance.

Repeat this step on the third directory server instance to verify that the property is still enabled on that server.

Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

Result:

```
Property : Value(s)
-----:-----
enabled : true
```

Client connection policy configuration

Client connection policies help distinguish what portions of the DIT the client can access.

They enforce restrictions on what clients can do in the server. A client connection policy specifies criteria for membership based on information about the client connection, including client address, protocol, communication security, and authentication state and identity. The client connection policy, however, does not control membership based on the type of request being made.

Every client connection is associated with exactly one client connection policy at any given time, which is assigned to the client when the connection is established. The choice of which client connection policy to use is reevaluated when the client attempts a bind to change its authentication state or uses the StartTLS extended operation to convert an insecure connection to a secure one. Any changes you make to the client connection policy do not apply to existing connections. The changes only apply to new connections.

Client connections are always unauthenticated when they are first established. If you plan to configure a policy based on authentication, you must define at least one client connection policy with criteria that match unauthenticated connections.

When a client has been assigned to a policy, you can determine what operations they can perform. For example, your policy might allow only SASL bind operations. Client connection policies are associated with one or more subtree views, which determine the portions of the DIT a particular client can access. For example, you might configure a policy that prevents users connecting over the extranet from accessing configuration information. The client connection policy is evaluated in addition to access control, so even a root user connecting over the extranet would not have access to the configuration information.

About the client connection policy

Client connection policies are based on two factors.

Connection criteria

The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can be used in other instances when the server needs to perform matching based on connection-level properties, such as filtered logging. A single connection can match multiple connection criteria definitions.

Evaluation order index

If multiple client connection policies are defined in the server, then each of them must have a unique value for the `evaluation-order-index` property. The client connection policies are evaluated in order of ascending evaluation order index. If a client connection does not match the criteria for any defined client connection policy, then that connection will be terminated.

If the connection policy matches a connection, then the connection is assigned to that policy and no further evaluation occurs. If, after evaluating all of the defined client connection policies, no match is found, the connection is terminated.

When a client connection policy is assigned

A client connection policy can be associated with a client connection at the following times.

- When the connection is initially established. This association occurs exactly once for each client connection.
- After completing processing for a StartTLS operation. This association occurs once at most for a client connection because StartTLS cannot be used more than once on a particular connection. You can not stop using StartTLS while keeping the connection active.
- After completing processing for a bind operation. This association occurs zero or more times for a client connection because the bind request can be processed many times on a given connection.

StartTLS and bind requests are subject to whatever constraints are defined for the client connection policy that is associated with the client connection at the time that the request is received. When they have completed, then subsequent operations are subject to the constraints of the new client connection policy assigned to that client connection. This policy might not be the same client connection policy that was associated with the connection before the operation was processed. That is, any policy changes do not apply to existing connections and only apply when the client reconnects.

All other types of operations are subject to whatever constraints are defined for the client connection policy used by the client connection at the time that the request is received. The client connection policy assigned to a connection never changes as a result of processing any operation other than a bind or StartTLS. The server does not re-evaluate the client connection policy for the connection in the course of processing an operation. For example, the client connection policy is never re-evaluated for a search operation.

Restricting the type of search filter used by clients

You can restrict the types of search filters that a given client might be allowed to use to prevent the use of potentially expensive filters, like range or substring searches.

You can use the `allowed-filter-type` property to provide a list of filter types that can be included in the search requests from clients associated with the client connection policy. This setting is only used if search is included in the set of allowed operation types. This restriction only applies to searches with a

scope other than `baseObject`, such as searches with a scope of `singleLevel`, `wholeSubtree`, or `subordinateSubtree`.

You can use the `minimum-substring-length` property to specify the minimum number of non-wildcard characters in a substring filter. Any attempt to use a substring search with an element containing fewer than this number of bytes is rejected. For example, you can configure the server to reject filters like `"(cn=a*)"` and `"(cn=ab*)"`, but to allow `"(cn=abcde*)"`. This property setting is only used if `search` is included in the set of allowed operation types and at least one of `sub-initial`, `sub-any`, or `sub-final` is included in the set of allowed filter types.

There are two primary benefits to enforcing a minimum substring length:

- Allowing short substrings can require the server to perform more expensive processing. The search requires more server effort to assemble a candidate entry list for short substrings because the server has to examine more index keys.
- Allowing short substrings makes it easier for a client to put together a series of requests to retrieve all the data from the server, a process known as "trawling". If a malicious user wants to obtain all the data from the server, then it is easier to issue 26 requests like `"(cn=a*)"`, `"(cn=b*)"`, `"(cn=c*)"`, ..., `"(cn=z*)"` than if the user is required to do something like `"(cn=aaaaa*)"`, `"(cn=aaaab*)"`, `"(cn=aaaac*)"`, ..., `"(cn=zzzzz*)"`.

Resource limits

Client connection policies can specify resource limits, helping to ensure that no single client monopolizes server resources.

You can limit the total number of connections to a server from a particular client or from clients that match specified criteria. You can also limit the duration of the connection.

A client connection policy can only be used to enforce additional restrictions on a client connection. You cannot use it to grant a client capabilities that it would not otherwise have.

Any change to any of these new configuration properties only impacts client connections that are assigned to the client connection policy after the change is made. Any connection associated with the client connection policy before the configuration change was made continues to be subject to the configuration that was in place at the time it was associated with that policy.

Resource Limiting Properties

Property	Description
<code>maximum-concurrent-connections</code>	<p>Specifies the maximum number of client connections that can be associated with that client connection policy at any given time. The default value of zero indicates that no limit is enforced.</p> <p>If the server already has the maximum number of connections associated with a client connection policy, then any attempt to associate another connection with that policy, such as newly-established connections or an existing connection that has done something to change its client connection policy, such as perform a bind or StartTLS operation, causes that connection to be terminated.</p>
<code>terminate-connection</code>	<p>Specifies that any client connection for which the client connection policy is selected, such as whether it is a new connection or an existing connection that is assigned to the client connection policy after performing a bind or StartTLS operation, is immediately terminated.</p> <p>This property can be used to define criteria for connections that you do not want to be allowed to communicate with the Directory Server.</p>

Property	Description
<p>maximum-connection-duration</p>	<p>Specifies the maximum length of time that a connection associated with the client connection policy can remain established to the Directory Server, regardless of the amount of activity on that connection.</p> <p>A value of "0 seconds" (default) indicates that no limit is enforced. If a connection associated with the client connection policy has been established for longer than this time, then it is terminated.</p>
<p>maximum-idle-connection-duration</p>	<p>Specifies the maximum length of time that a connection associated with the client connection policy can remain established with the Directory Server without any requests in progress.</p> <p>A value of "0 seconds" (default) indicates that no additional limit is enforced on top of whatever idle time limit might already be in effect for an associated connection. If a nonzero value is provided, then the effective idle time limit for any client connection is the smaller of the <code>maximum-idle-connection-duration</code> from the client connection policy and the idle time limit that would otherwise be in effect for that client.</p> <p>This property can be used to apply a further restriction on top of any value that might be enforced by the <code>idle-time-limit</code> global configuration property which defines a default idle time limit for client connections, or the <code>ds-rlim-idle-time-limit</code> operational attribute which might be included in a user entry to override the default idle time limit for that user.</p>
<p>maximum-operation-count-per-connection</p>	<p>Specifies the maximum number of operations that a client associated with the client connection policy is allowed to request. A value of zero (default) indicates that no limit is enforced. If a client attempts to request more than this number of operations on the same connection, then that connection will be terminated.</p>
<p>maximum-concurrent-operations-per-connection</p>	<p>Specifies the maximum number of operations that might be active at any time from the same client. This limit only applies to clients that use asynchronous operations with multiple outstanding requests at any given time.</p> <p>A value of zero (default) indicates that no limit is enforced.</p> <p>If a client already has the maximum number of outstanding requests in progress and issues a new request, then that request is delayed or rejected based on the value of the <code>maximum-concurrent-operation-wait-time-before-rejecting</code> property.</p>

Property	Description
<code>maximum-concurrent-operation-wait-time-before-rejecting</code>	<p>Specifies the maximum length of time that a client connection should allow an outstanding operation to complete if the maximum number of concurrent operations for a connection are already in progress when a new request is received on that connection.</p> <p>A value of "0 seconds" (default) indicates that any new requests received while the maximum number of outstanding requests are already in progress for that connection are immediately rejected.</p> <p>If an outstanding operation completes before this time expires, then the server might be allowed to process that operation. If the time expires, the new request is rejected.</p>
<code>maximum-ldap-join-size-limit</code>	<p>Specifies the maximum number of entries that can be directly joined with any individual search result entry. A value of zero indicates that no LDAP join size limit is enforced. The limit can be overridden on a per-user basis using the <code>ds-rlim-ldap-join-size-limit</code> operational attribute. The LDAP join size limit is also restricted by the search operation size limit. If a search result entry is joined with more entries than allowed, the join result control has a "size limit exceeded" (integer value 4) result code.</p>
<code>allowed-request-control</code>	<p>Specifies the OIDs of the request controls that clients associated with the client connection policy are allowed to use.</p> <p>If any <code>allowed-request-control</code> OIDs are specified, then any request that includes a control not in that set is rejected. If no <code>allowed-request-control</code> values are specified (default), then any control whose OID is not included in the set of <code>denied-request-control</code> values is allowed.</p>
<code>denied-request-control</code>	<p>Specifies the OIDs of the request controls that clients associated with the client connection policy are not allowed to use. If there are any <code>denied-request-control</code> values, then any request containing a control whose OID is included in that set is rejected.</p> <p>If there are no <code>denied-request-control</code> values (default), then any request control is allowed if the <code>allowed-request-control</code> property is also empty, or only those controls whose OIDs are included in the set of <code>allowed-request-control</code> values are allowed if at least one <code>allowed-request-control</code> value is provided.</p>

Property	Description
<code>allowed-filter-type</code>	<p>Specifies the types of components that might be used in filters included in search operations with a non-base scope that are requested by clients associated with the client connection policy. Any non-base scoped search request whose filter contains a component not included in this set is rejected. The set of possible filter types include:</p> <ul style="list-style-type: none"> ▪ and ▪ or ▪ not ▪ equality ▪ sub-initial ▪ sub-any ▪ sub-final ▪ greater-or-equal ▪ less-or-equal ▪ approximate-match ▪ extensible-match <p>By default, all filter types are allowed.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;">  Note: No restriction is placed on the types of filters that might be used in searches with a base scope. </div>
<code>allow-unindexed-searches</code>	<p>Specifies whether clients associated with the client connection policy are allowed to request searches that cannot be efficiently processed using the configured set of indexes.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;">  Note: Clients must still have the <code>unindexed-search</code> privilege, so this option does not grant the ability to perform unindexed searches to clients that would not have otherwise had that ability, but it might be used to prevent clients associated with the client connection policy from requesting unindexed searches when they might have otherwise been allowed to do so. </div> <p>By default, this has a value of "true", indicating that any client associated with the client connection policy that has the <code>unindexed-search</code> privilege is allowed to request unindexed searches.</p>
<code>minimum-substring-length</code>	<p>Specifies the minimum number of bytes, which might be present in any sub-Initial, subAny, or subFinal element of a substring search filter component in a search with a non-baseObject scope. A value of one (which is the default) indicates that no limit is enforced. This property might be used to prevent clients from issuing overly-vague substring searches that might require installing the Directory Server to examine too many entries over the course of processing the request.</p>

Property	Description
maximum-search-size-limit	<p>Specifies the maximum number of entries that might be returned from any single search operation requested by a client associated with this client connection policy.</p>
	<p> Note:</p> <p>This property only specifies a maximum limit and never increases any limit that might already be in effect for the client through the <code>size-limit</code> global configuration property or the <code>ds-rlim-size-limit</code> operational attribute.</p>
	<p>A value of zero (default) indicates that no additional limit is enforced on top of whatever size limit might already be in effect for an associated connection.</p> <p>If a nonzero value is provided, then the effective maximum size limit for any search operation requested by the client is the smaller of the size limit from that search request, the <code>maximum-search-size-limit</code> from the client connection policy, and the size limit that would otherwise be in effect for that client.</p>

Defining the operation rate

Configure the maximum operation rate for individual client connections and collectively for all connections associated with a client connection policy.

If the operation rate limit is exceeded, the Directory Server can either reject the operation or terminate the connection. You can define multiple rate limit values, making it possible to fine tune limits for both a long term average operation rate and short term operation bursts. For example, you can define a limit of one thousand operations per second and one million operations per day, which works out to an average of fewer than twelve operations per second, but with bursts of up to one thousand operations per second.

Specify rate limit strings as a maximum count, followed by a slash and a duration. The count portion must contain an integer and can be followed by the following multipliers:

- k (to indicate that the integer should be interpreted as thousands)
- m (to indicate that the integer should be interpreted as millions)
- g (to indicate that the integer should be interpreted as billions)

The duration portion must contain a time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w) and can be preceded by an integer to specify a quantity for that unit.

For example, the following are valid rate limit strings:

- 1/s (no more than one operation over a one-second interval)
- 10K/5h (no more than ten thousand operations over a five-hour interval)
- 5m/2d (no more than five million operations over a two-day interval)

You can provide time units in many different formats. For example, a unit of seconds can be signified using s, sec, sect, second, and seconds.

Client connection policy deployment example

In this example scenario, we assume the following:

1. Two external LDAP clients are allowed to bind to the Directory Server.
2. Client 1 should be allowed to open only one connection to the server.
3. Client 2 should be allowed to open up to five connections to the server.

For more information on this client connection policy deployment example, see the following topics:

- [Define the connection policies](#) on page 208
- [How the policy is evaluated](#) on page 208
- [Configuring a client connection policy using the console](#) on page 209
- [Configuring a client connection policy using dsconfig](#) on page 210
- [Restricting server access based on client IP address](#) on page 211

Define the connection policies

Set a per-client connection policy limit on the number of connections that can be associated with a particular client connection policy

Define at least two client connection policies, one for each of the two clients. Each policy must have different connection criteria for selecting the policy with which a given client connection should be associated.

Because the criteria is based on authentication, you must create a third client connection policy that applies to unauthenticated clients because client connections are always unauthenticated as soon as they are established and before they have sent a bind request. Clients are not required to send a bind request as their first operation.

Define the following three client connection policies:

- Client 1 Connection Policy, which only allows client 1, with an evaluation order index of 1
- Client 2 Connection Policy, which only allows client 2, with an evaluation order index of 2
- Unauthenticated Connection Policy, which allows unauthenticated clients, with an evaluation order index of 3

Define simple connection criteria for the Client 1 Connection Policy and the Client 2 Connection Policy with the following properties:

- The `user-auth-type` must not include `none` so that it only applies to authenticated client connections.
- The `included-user-base-dn` should match the bind DN for the target user. This distinguished name (DN) can be full DN for the target user, or it can be the base DN for a branch that contains a number of users that you want treated in the same way.

Tip:

To create more generic criteria that match more than one user, you could list the DNs of each of the users explicitly in the `included-user-base-dn` property. If there is a group that contains all of the pertinent users, then you could instead use the `[all|any|not-all|not-any]-included-user-group-dn` property to apply to all members of that group. If the entries for all of the users match a particular filter, then you could use the `[all|any|not-all|not-any]-included-user-filter` property to match them.

How the policy is evaluated

Whenever a connection is established, the server associates the connection with exactly one client connection policy.

The server does this by iterating over all of the defined client connection policies in ascending order of the evaluation order index. Policies with a lower evaluation order index value are examined before those with a higher evaluation order index value. The first policy that the server finds whose criteria match the client connection is associated with that connection. If no client connection policy is found with criteria matching the connection, then the connection is terminated.

So, in this example, when a new connection is established, the server first checks the connection criteria associated with the Client 1 Connection Policy because it has the lowest evaluation order index value. If it finds that the criteria do not match the new connection, the server then checks the connection criteria associated with the Client 2 Connection Policy because it has the second lowest evaluation order

index. If these criteria do not match, the server finally checks the connection criteria associated with the Unauthenticated Connection Policy because it has the third lowest evaluation order index. It finds a match, so the client connection is associated with the Unauthenticated Connection Policy.

After the client performs a bind operation to authenticate to the server, then the client connection policies are re-evaluated. If Client 2 performs the bind, then the Client 1 Connection Policy does not match, but the Client 2 Connection Policy does, so the connection is re-associated with that client connection policy. Whenever a connection is associated with a client connection policy, the server checks to see if the maximum number of client connections have already been associated with that policy. If so, then the newly-associated connection is terminated.

For example, Client 1 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. Client 1 then sends a bind request. The determination of whether the bind operation is allowed is made based on the constraints defined in the Unauthenticated Connection Policy because it is the client connection policy already assigned to the client connection. When the bind has completed, the server re-evaluates the client connection policy against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to the Client 1 Connection Policy.

Next, Client 2 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. When Client 2 sends a bind request, the operation is allowed based on the constraints defined in the Unauthenticated Connection Policy. When the bind is complete, the client connection is evaluated against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria do not match, so the Client 2 connection is evaluated against the connection criteria associated with Client 2 Connection Policy because it has the next lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to Client 2 Connection Policy.

Client 1 sends a search request. The Client 1 Connection Policy is used to determine whether the search operation should be allowed because this is the client connection policy assigned to the client connection for Client 1. The connection is not re-evaluated before or after processing the search operation.

Configuring a client connection policy using the console

Configure a client connection policy using the PingDirectory Administrative Console.

Steps

1. From the Administrative Console, in the **Core Server** section, click **Client Connection Policies**.

Tip:

If you do not see **Client Connection Policies** on the menu, change the **Object Types** filter to **Standard**.

2. To add a new policy, click **Add New**.
3. Enter a **Policy ID**.
If you want to base your new client connection policy on an existing policy, select it from the **Template** menu.
4. Configure the properties of the client connection policy, then to enable the policy, select **Enabled**.
5. Enter the order in which you want the new policy to be evaluated in the **Evaluation Order Index** box, and then click **Continue**.

A policy with a lower index is evaluated before a policy with a higher index. The Directory Server uses the first evaluated policy that applies to a client connection.

6. Select the connection criteria that match the client connection for this policy.
 - a. To change the criteria, click **View** and **Edit**.
 - b. To add new criteria, click **Select New**.
 - c. Select the operations allowed for clients that are members of this connection group.
 - d. To make operations available to clients, use the **Add** and **Remove** buttons.
 - e. Specify the extended operations that clients are allowed and denied to use.
7. Enter the type of authorization allowed and the SASL mechanisms that are allowed and denied in response to client requests.
8. Select the **Include Backend Subtree Views** check box if you want to automatically include the subtree views of backends configured in the Directory Server.

You can also choose to include and exclude specific base DN's using the appropriate fields.

9. Save your changes.
Choose from:
 - To review the `dsconfig` command equivalent and save your changes, click **Confirm then Save**.
 - To save your changes without first reviewing the `dsconfig` output, click **Save Now**.

Configuring a client connection policy using dsconfig

Configure a client connection policy using the `dsconfig` tool.

About this task

Configure a client connection policy using the `dsconfig` tool in interactive mode from the command line. You can access the **Client Connection Policy** menu on the **Standard objects** menu.

Steps

1. Use the `dsconfig` tool to create and configure a client connection policy.
Specify the host name, connection method, port number, and bind distinguished names (DN's) described in previous procedures.
2. To change to the **Standard objects** menu, from the Directory Server main menu, enter `o`, and then enter the number for the **Standard** menu.
3. From the Directory Server main menu, enter the number associated with **Client Connection Policy**.
4. From the **Client Connection Policy management** menu, enter the number corresponding to **Create a new connection policy**.
5. To create a new client connection policy from scratch, enter `n`.
6. Enter a name for the new client connection policy.
7. To enable the connection policy, from the **Enabled Property** menu, select **True**.
8. To set the evaluation order for the policy, from the **Evaluation-Order Property** menu, enter a value between 0 and 2147483647.

A client connection policy with a lower evaluation-order is evaluated before one with a higher number. For this example, enter `9999`.
9. From the **Client Connection Policy** menu, review the configuration.
 - a. If you want to make any further modifications, enter the number corresponding to the property.
 - b. To finish the creation of the client connection policy, enter `f`.

Any changes that you make to the client connection policy do not apply to existing connections. They only apply to new connections.

Restricting server access based on client IP address

Two methods are available to limit client access to the Directory Server.

Connection Handlers

You can limit the IP addresses using the LDAP or LDAPS connection handlers. The connection handlers provide an `allowed-client` property and a `denied-client` property. The `allowed-client` property specifies the set of allowable address masks that can establish connections to the handler. The `denied-client` property specifies the set of address masks that are not allowed to establish connections to the handler.

Client Connection Policies

For a more fine-grained approach, restrict access by configuring a new client connection policy. Then, create a new connection criteria and associate it with the connection policy. A connection criteria defines sets of criteria for grouping and describing client connections based on a number of properties, including the protocol, client address, connection security, and authentication state for the connection. Each client connection policy can be associated with zero or more connection criteria. Server components can use connection criteria to indicate which connections to process and what kind of processing to perform, such as to select connections and operations for filtered logging or to classify connections for network groups.

Restricting server access using the connection handlers

Use `dsconfig` to set the `allowed-client` property for the LDAP connection handler.

Steps

- Set the `allowed-client` property for the LDAP connection handler using `dsconfig`.
- Specify the address mask for the range of allowable IP addresses that can establish connections to the Directory Server.
- To configure the server using the `dsconfig` tool on the local host, specify the loopback address to 127.0.0.1.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --set "allowed-client:10.6.1.*" \
  --set allowed-client:127.0.0.1
```

Restricting server access using client connection policies

A client-established connection to the PingDirectory server is associated with a client connection policy. Use client connection policies to restrict the kinds of requests that the client can issue and impose resource limits for that connection.

Steps

1. Create a simple connection criteria.

Example:

The following example uses the `dsconfig` tool in non-interactive mode. It allows only the Directory Server's IP address and loopback to have access.

```
$ bin/dsconfig set-connection-criteria-prop \
  --criteria-name allowed-ip-addr \
  --add included-client-address:10.6.1.80 \
  --add included-client-address:127.0.0.1
```

2. Assign the criteria to the client connection policy.

Example:

```
$ bin/dsconfig set-client-connection-policy-prop \
  --policy-name new-policy \
  --set connection-criteria:allowed-ip-addr
```

Result: After you have run the command, access is denied to remote IP addresses. The Directory Server does not require a restart.

3. Add a remote IP range to the criteria.

Note:

For the following example, add 10.6.1.*.

Example:

```
$ bin/dsconfig set-connection-criteria-prop \
  --criteria-name allowed-ip-addr \
  --add "included-client-address:10.6.1.*"
```

Result: Access from any remote servers is allowed. The Directory Server does not require a restart.

4. To restore default behavior, remove the criteria from the connection policy.

Example:

Tip:

Include the LDAP or LDAPS connection parameters, such as host name, port, bindDN, bindPassword, with the **dsconfig** command.

Example:

```
$ bin/dsconfig set-client-connection-policy-prop \
  --policy-name new-policy --remove connection-criteria:allowed-ip-addr
```

Result: The Directory Server does not require a restart.

Automatically authenticating clients that have a secure communication channel

The Directory Server provides the option to automatically authenticate clients that have a secure communication channel, either SSL or StartTLS, and to present their own certificate.

About this task

By default, this option is disabled. When enabled, the net effect is as if the client issued a SASL EXTERNAL bind request on that connection.

Note:

This option is ignored if the client connection is already authenticated, such as when using StartTLS, but the client had already performed a bind before the StartTLS request. If the bind attempt fails, the connection remains unauthenticated but usable. If the client subsequently sends a bind request on the connection, it's processed as normal, and any automatic authentication is destroyed.

Steps

- Run the following `dsconfig` command.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAPS Connection Handler" \
  --set "auto-authenticate-using-client-certificate:true"
```

Securing the Server with lockdown mode

The Directory Server provides tools to enter and leave lockdown mode if the server requires a security lockdown.

About this task

In lockdown mode, only users with the `lockdown-mode` privilege can perform operations. Users who do not have the privilege are rejected. By default, root users have this privilege. You can give other administrators this privilege. Users with this privilege can configure lockdown mode as a recurring task.

Some configuration problems can lead to inadvertent exposure of sensitive information, such as an access control rule that cannot be properly parsed, and cause the server to place itself in lockdown mode. This ensures that an administrator can manually correct the problem. Lockdown mode does not persist across restarts.

Steps

- To perform some administrative operations and ensure that other client requests are not allowed to access any data in the server, manually place the Directory Server into lockdown mode.

Result:

Any client request to the Directory Server in lockdown mode receives an `Unavailable` response.

- To take the directory server out of lockdown mode, use either of the following options:
 - Use the `leave-lockdown-mode` command.
 - Restart the server.
- To start a server in lockdown mode, use the `start-server --lockdownMode` option.

Entering lockdown mode manually

Steps

- To enter lockdown mode, run `enter-lockdown-mode`.

Example:

```
$ bin/enter-lockdown-mode
```

Leaving lockdown mode

Steps

- To leave lockdown mode, run `leave-lockdown-mode`.

Example:

```
$ bin/leave-lockdown-mode
```

Starting a server in lockdown mode

Steps

- To start a server in lockdown mode, run the `start-server` command with the `--lockdownMode` option.

Example:

```
$ bin/start-server --lockdownMode
```

Configuring maximum shutdown time

The Directory Server provides an option for administrators to set a maximum time for a shutdown process to take.

Before you begin

During shutdown, some database checkpointing and cleaning threads might remain active even after the default time period on systems with large or busy database backends. If checkpointing or cleaning is aborted prematurely, it can lead to significantly longer startup times for the Directory Server. When a shutdown process is initiated, the server begins stopping all of its internal components and waits up to 5 minutes for all threads to complete before exiting.

About this task

Use the `dsconfig` tool to configure the maximum shutdown time to allow database operations to complete.

Steps

- To increase the maximum shutdown time for your system, choose from one of the following options. Choose from:
 - Run the `dsconfig` tool.

Note:

The following command increases the maximum shutdown time from 5 minutes to 6 minutes. The command allows time values of w (weeks), d (days), h (hours), m (minutes), s (seconds), ms (milliseconds).

Include the LDAP or LDAPS connection parameters, such as host name, port, bindDN, and bindDN password, with the `dsconfig` command.

```
$ bin/dsconfig set-global-configuration-prop --set "maximum-shutdown-time:6 m"
```

- Change the `maximum-shutdown-time` property using the `dsconfig` tool in interactive mode. From the main menu, select **Global Configuration**, and then select the option to display advanced properties.

About working with referrals

A referral is a redirection mechanism that tells client applications that a requested entry or set of entries is not present on the Directory Server but can be accessed on another server.

Use referrals when entries are located on another server. The Directory Server implements two types of referrals depending on the requirement:

Referral on Update plugin

The Directory Server provides a Referral on Update plugin to create any referrals for update requests, such as `add`, `delete`, `modify`, or `moddn` operations, on read-only servers. For example, given two replicated directory servers where one server is a primary with read-write capabilities, and the other is a read-only server. You can configure a referral for any client update requests on the second directory server to point to the primary server. For example, if a client application sends an add request on the second directory server, the directory server responds with a referral that indicates any updates should be made on the primary server. All read requests on the read-only server process normally.

Smart referrals

The Directory Server supports smart referrals that map an entry or a specific branch of a directory information tree (DIT) to an LDAP URL. Any client requests (reads or writes) targeting at or below the branch of the DIT send a referral to the server designated in the LDAP URL.

Specifying LDAP URLs

Referrals use LDAP URLs to redirect a client application's request to another server.

LDAP URLs have a specific format, described in RFC 4516 and require that all special characters be properly escaped and any spaces indicated as "%20". LDAP URLs have the following syntax.

```
ldap[s]://hostname:port/base-dn?attributes?scope?filter
```

`ldap[s]`

Indicates the type of LDAP connection to the Directory Server. If the Directory Server connects over a standard, non-encrypted connection, then LDAP is used. If it connects over SSL, then LDAPS is used.

Note:

Any search request initiated by means of an LDAP URL is anonymous by default unless an LDAP client provides authentication.

`hostname`

Specifies the host name or IP address of the Directory Server.

`port`

Specifies the port number of the Directory Server. If no port number is provided, the default LDAP port (389) or LDAPS port (636) is used.

`base-dn`

Specifies the distinguished name (DN) of an entry in the directory information tree (DIT). The Directory Server uses the base DN as the starting point entry for its searches. If no base DN is provided, the search begins at the root of the DIT.

`attributes`

Specifies those attributes for which the Directory Server should search and return. You can indicate more than one attribute by providing a comma-separated list of attributes. If no attributes are provided, the search returns all attributes.

`scope`

Specifies the scope of the search, which could be one of the following:

`base`

Only searches the specified base DN entry.

one

Only search one level below the specified base DN.

sub

Searches the base entry and all entries below the specified base DN.

If no scope is provided, the server performs a base search.

filter

Specifies the search filter to apply to entries within the scope of the search. If no filter is provided, the server uses +.

Creating referrals

Create a smart referral by adding an entry with the `referral` and `extensibleObject` object classes or adding the object classes to a specific entry.

About this task

The `referral` object class designates the entry as a referral object. The `extensibleObject` object class allows you to match the target entry by matching any schema attribute. The following example shows how to set up a smart referral if a portion of a directory information tree (DIT) is located on another server.

To create a referral:

Steps

1. Create an LDIF file with an entry that contains the `referral` and `extensibleObject` object classes.

Example:

```
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
objectClass: top
objectClass: referral
objectClass: extensibleObject
ou: Engineering Team1
ref: ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

2. On the first server, add the referral entry using the `ldapmodify` command.

Example:

```
$ bin/ldapmodify --defaultAdd --fileName referral-entry.ldif
```

3. To verify the addition, search for a user.

Example:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com "(uid=user.4)"
```

Result:

```
SearchReference(referralURLs={ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com??sub?})
```

Modifying a referral

Run a modify command to modify a referral.

Steps

- To modify the `ref` attribute on the referral entry, run `ldapmodify` with the `manageDSAIT` control.

Example:

```
$ bin/ldapmodify --control manageDSAIT
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
changetype: modify
replace: ref
ref: ldap://server3.example.com/
ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

Deleting a referral

Run `ldapdelete` to delete a referral.

Steps

- To delete the referral entry, run `ldapdelete` with the `manageDSAIT` control.

Example:

```
$ bin/ldapdelete \
  --control manageDSAIT "ou=EngineeringTeam1,ou=People,dc=example,dc=com"
```

Configuring a read-only server

The PingDirectory Server provides a means to configure a hub-like, read-only directory server for legacy systems that require it.

About this task

The read-only directory server participates in replication but cannot respond to any update requests from an external client. You can configure the Directory Server by setting the writability mode to `internal-only`, which makes the server operate in read-only mode. Read-only mode directory servers can process update operations from internal operations but reject any write requests from external clients. Because the Directory Server cannot accept write requests, you can configure the server to send a referral, which redirects a client's request to a primary server. The client must perform the operation again on the server named in the referral.

Note:

For Implementers of third party extensions, many Server SDK extensions use the `InternalConnection` interface to process operations in the server, rather than issuing LDAP requests over the network. If an extension does so in response to an external update request, then any Directory Server using that extension will effectively respond to external update requests, even though the Directory Server is configured to operate in read-only mode, as described previously. One possible workaround is to split the extension into two extensions, one for reads and one for writes, and then to disable (or not to deploy) the write-only extension when configuring a Directory Server in read-only mode.

Steps

1. Install two replicating directory servers.

For more information on various ways to set up your servers, see [Enabling Replication](#).

2. On the second server, run the `dsconfig` command to set the writability mode of the server to `internal-only`.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
--set writability-mode:internal-only
```

3. On the second server, run the `dsconfig` command to create a referral that instructs the server to redirect client write requests under `dc=example,dc=com` to `server1.example.com:1389`.

The referral itself is defined as a plugin of type `referral-on-update`. This command sets up the server to process read operations but redirects all write operations under `dc=example,dc=com` to another server.

Example:

```
$ bin/dsconfig create-plugin --plugin-name "Refer Updates" \
--type referral-on-update \
--set enabled:true \
--set referral-base-url:ldap://server1.example.com:1389/ \
--set "base-dn:dc=example,dc=com"
```

4. To test the referral, attempt to modify an entry and confirm that the server responds with the result code of 10.

The resulting message is available in the server's access log.

Example:

```
$ bin/ldapmodify -p 2389 -D "cn=Directory Manager" -w password
dn: uid=user.12,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 408 555 1155
```

Result:

```
[06/Aug/2012:15:28:21.468 -0400] MODIFY
RESULT conn=86 op=1 msgID=1 requesterIP="127.0.0.1"
dn="uid=user.12,ou=People,dc=example,dc=com" resultCode=10
referralURLs="ldap://server1.example.com:1389/uid=user.12,
ou=People,dc=example,dc=com" etime=0.223
```

Configuring HTTP access for the Directory Server

Although most clients communicate with the PingDirectory Server using LDAP, the server also provides support for an HTTP connection handler that uses Java servlets to serve content to clients over HTTP.

Ping Identity offers an extension that uses this HTTP connection handler to add support for the System for Cross-domain Identity Management (SCIM) protocol. Third-party developers can also use the Server SDK to write extensions that leverage this HTTP support.

The following sections describe how to configure HTTP servlet extensions and how to configure an HTTP connection handler.

For more information, see the following topics:

- [Configuring HTTP Servlet Extensions](#) on page 219
- [Configuring HTTP operation loggers](#) on page 220
- [Example HTTP log publishers](#) on page 221
- [Configuring HTTP connection handlers](#) on page 223

Configuring HTTP Servlet Extensions

You must first configure one or more servlet extensions to use the HTTP connection handler.

Servlet extensions are responsible for obtaining Java servlets, using the Java Servlet 3.0 specification as described in JSR 315, and registering them to be invoked using one or more context paths. If you plan to deploy the System for Cross-domain Identity Management (SCIM) extension, follow the instructions in [Managing the SCIM 2.0 Servlet Extension](#) on page 1209. For custom servlet extensions created using the Server SDK, the process varies based on whether you are using a Java-based or Groovy-scripted extension.

Configuring web application servlet extensions

About this task

A web application can be deployed either as a WAR file that has been packaged according to the standard layout and containing a `web.xml` deployment descriptor, or from a directory containing the application's source components arranged in the standard layout.

Steps

- When deploying a web application from a directory, specify the location of the `web.xml` deployment descriptor if it is not in the standard location.
- Specify the directory used by the server for temporary files.

Result

At runtime, the web application has access to the server classes.

Configuring Java-based servlet extensions

About this task

For Java-based extensions, first use the Server SDK to create and build the extension bundle as described in the Server SDK documentation.

Steps

- Use the `manage-extension` tool to install it.

Example:

```
$ bin/manage-extension --install/path/to/extension.zip
```

The Java-based extension can then be configured for use in the server using `dsconfig` or the Administrative Console. Create a new Third Party HTTP Servlet Extension, specifying the fully-qualified name for the `HTTPServletExtension` subclass in the `extension-class` property, and providing any appropriate arguments in the `extension-argument` property.

Note:

Web application and Servlet extensions run in a shared embedded web application server environment. Incompatibilities or conflicts might arise from use of different versions of commonly used JARs or including frameworks such as loggers, Spring components, JAX-RS implementations or other resources that might require a dedicated Java virtual machine (JVM) environment. After introducing a custom extension, check the server error log for an indication that the extension loaded successfully. The error log might also contain debug information if the extension failed to load with an initialization exception or did not complete initialization.

Configuring Groovy-scripted extensions

Steps

1. For Groovy-scripted extensions, place the necessary Groovy scripts in the appropriate directory based on the package for those scripts after the `lib/groovy-scripted-extensions` directory.
2. Create a new Groovy Scripted HTTP Servlet extension, specifying the fully-qualified Groovy class name for the `script-class` property, and providing any appropriate arguments in the `script-argument` property.

Configuring HTTP operation loggers

Interactions between servlet extensions and HTTP clients are generally not recorded in the server access log unless a servlet extension performs internal operations to interact with data held in the directory server.

About this task

To capture information about communication with HTTP clients, you must configure one or more HTTP operations loggers.

By default, the server comes with a single HTTP operation logger implementation, which uses the standard W3C common log format. It records messages in the following format.

```
127.0.0.1 - - [01/Jan/2012:00:00:00 -0600] "GET/hello HTTP/1.1" 200 113
```

The log message contains the following elements:

- The IP address of the client that issued the request
- The RFC 1413 (ident) identity of the client

Because the ident protocol is not typically provided by HTTP clients, the HTTP connection handler never requests this information. This identity is always represented as a dash to indicate that information is not available.
- The authenticated identity determined for the request by HTTP authentication or a dash to indicate that the request was not authenticated
- The time that the request was received
- The request issued by the client, including the HTTP method, path and optional query string, and the HTTP protocol version used
- The integer representation of the HTTP status code for the response to the client
- The number of bytes included in the body of the response to the client

Steps

- To configure an HTTP operation logger to use this common log format, create a new instance of a Common Log File HTTP Operation Log Publisher object.
 - a. Specify the path and name for the active log file.
 - b. Specify the rotation and retention policies to manage the log files.

Note:

Properties for Common Log File HTTP Operation Log Publisher objects generally have the same meaning and use as they do for other kinds of loggers.

- To create custom Java-based or Groovy-scripted HTTP operation loggers using the Third Party HTTP Operation Log Publisher and Groovy Scripted HTTP Operation Log Publisher object types, use the Server SDK.

Example HTTP log publishers

When troubleshooting HTTP connection handler issues, start with the logs to determine any potential problems.

About this task

The following examples walk you through how to use various **dsconfig** commands and their associated options to configure log files to use for troubleshooting connection handler issues.

The following section shows some **dsconfig** commands and their corresponding log files.

Steps

- To configure a default detailed HTTP Log Publisher with default log rotation and retention policies, use the `create-log-publisher` option with **dsconfig**.

Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Detailed Access Logger" \
  --type detailed-http-operation \
  --set enabled:true \
  --set log-file:logs/http-detailed-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "retention-policy:Size Limit Retention Policy"
```

Result:

The corresponding log file provides access information below. The log message contains the following elements:

- The time that the request was received
- The request ID issued by the client, including the IP address, port, HTTP method, and URL
- The authorization type, request content type, and status code
- The response content length
- The redirect URI
- The response content type

The HTTP log file shows the following.

```
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300604
  from="10.5.1.10:53269"
  method="GET" url="https://10.5.1.129:443/Gimel/Users/
  uid=user.402914,ou=People,
  dc=gimel" authorizationType="Basic" requestContentType="application/
  json"
  statusCode=200 etime=4.145 responseContentLength=1530
  redirectURI="https://
  x2270-11.example.lab:443/Gimel/Users/uid=user.402914,ou=people,dc=gimel"
  responseContentType="application/json"
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300605
  from="10.5.1.10:53269"
  method="PUT" url="https://10.5.1.129:443/Gimel/Users/
  uid=user.207585,ou=people,
  dc=gimel" authorizationType="Basic" requestContentType="application/
  json"
  statusCode=200 etime=4.872 responseContentLength=1532
  redirectURI="https://
  x2270-11.example.lab:443/Gimel/Users/uid=user.207585,ou=people,dc=gimel"
```

```
responseContentType="application/json"
[23/Feb/2012:11:31:18 -0600] RESULT requestID=4309872 from="10.5.1.10:3
```

- To configure a detailed HTTP Log Publisher with request and response header names and values, including the Content-Type request header, use the set-log-publisher-prop option with dsconfig.

Note:

The Content-Type request header is suppressed by default.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "HTTP Detailed Access Logger" \
  --set log-request-headers:header-names-and-values \
  --remove suppressed-request-header-name:Content-Type \
  --set log-response-headers:header-names-and-values
```

Result:

The following is a log example of a query request by a SCIM Server using the property, scim-query-rate. The log message contains the basic log elements shown in the first example plus the following additional information:

- The request header for the host, HTTP method, content type, connection, user agent
- The response header for the access-control credentials

```
[23/Oct/2012:11:39:41-0600] RESULT requestID=4665307
from="10.5.0.20:56044"
method="GET" url="https://10.5.1.129:443/Beth/Users?
attributes=username,title,
emails,urn:scim:schemas:extension:custom:1.0:descriptions,urn:scim:schemas:
extension:enterprise:1.0:manager,groups,urn:scim:schemas:extension:custom:1.0:
blob&filter=username+eq+%22user.18935%22" requestHeader="Host:
x2270-11.example.
lab:443" requestHeader="Accept: application/json" requestHeader="Content-
Type:
application/json" requestHeader="Connection: keep-alive"
requestHeader="User-Agent: Wink Client v1.1.2" authorizationType="Basic"
requestContentType="application/json" statusCode=200 etime=140.384
responseContentLength=11778 responseHeader="Access-Control-Allow-
Credentials:
true" responseContentType="application/json"
```

Another log example shows an example user creation event. The client is curl.

```
[23/Oct/2016:11:50:11-0600] RESULT requestID=4802791
from="10.8.1.229:52357"
method="POST" url="https://10.2.1.113:443/Aleph/Users/"
requestHeader="Host: x2270-
11.example.lab" requestHeader="Expect: 100-continue"
requestHeader="Accept: applica-
tion/xml" requestHeader="Content-Type: application/xml"
requestHeader="User-Agent:
curl/7.21.4 (universal-apple-darwin11.0) libcurl/7.21.4 OpenSSL/0.9.8r
zlib/1.2.5"
authorizationType="Basic" requestContentType="application/xml"
requestContent-
Length=1773 statusCode=201 etime=11.598 responseContentLength=1472
redirec-
```

```
tURI="https://x2270-11.example.lab:443/Aleph/Users/
b2cef63c-5e46-11e1-974b-
60334b1a0d7a" responseContentType="application/xml"
```

The final example shows a user deletion request. The client is the Sync Server.

```
[23/Oct/2016:11:38:06-0600] RESULT requestID=4610261
  from="10.5.1.114:34558"
method="DELETE" url="https://10.2.1.113:443/Aleph/Users/
b8547525-24e0-41ae-b66b-
0b441800de70" requestHeader="Host: x2270-11.example.lab:443"
  requestHeader="Accept:

  requestHeader="Con-
nection: keep-alive" requestHeader="User-Agent: DataSync-6.0.0.0 (Build
20121022173845Z, Revision 11281)" authorizationType="Basic"
  requestContentType="appli-
cation/json" statusCode=200 etime=10.615 responseContentLength=0
```

Configuring HTTP connection handlers

HTTP connection handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. HTTP connection handlers can be used to host web applications on the server.

Each HTTP connection handler should be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this does not prevent the entire Directory Server from starting. Directory Server's **start-server** tool outputs any errors to the error log. This allows Directory Server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with an HTTP connection handler include the following:

listen-address

Specifies the address on which the connection handler listens for requests from clients. If not specified, then requests are accepted on all addresses bound to the system.

listen-port

Specifies the port on which the connection handler listens for requests from clients. Required.

use-ssl

Indicates whether the connection handler uses SSL/TLS to secure communications with clients, such as whether it uses HTTPS rather than HTTP. If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.

http-servlet-extension

Specifies the set of servlet extensions that are enabled for use with the connection handler. You can have multiple HTTP connection handlers listening on different address/port combinations with identical or different sets of servlet extensions. You must configure at least one servlet extension.

http-operation-log-publisher

Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers are used.

key-manager-provider

Specifies the key manager provider that is used to obtain the certificate presented to clients if SSL is enabled.

trust-manager-provider

Specifies the trust manager provider that is used to determine whether to accept any client certificates presented to the server.

num-request-handlers

Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads are automatically selected based on the number of CPUs available to the Java virtual machine (JVM).

web-application-extension

Specifies the web applications hosted by the server.

Configuring an HTTP connection handler

About this task

An HTTP connection handler has two dependent configuration objects:

- One or more HTTP servlet extensions
- An HTTP log publisher

The log publisher is optional, but in most cases, you should configure one or more logs to troubleshoot any issues with your HTTP connection.

Note:

You must configure the HTTP servlet extension and log publisher before configuring the HTTP connection handler.

Steps

1. To configure your HTTP servlet extensions, use the `create-http-servlet-extension` option with **dsconfig**.

Example:

This example uses the `ExampleHTTPServletExtension` example in the Server SDK.

```
$ bin/dsconfig create-http-servlet-extension \
  --extension-name "Hello World Servlet" \
  --type third-party \
  --set "extension-
class:com.unboundid.directory.sdk.examples.ExampleHTTPServletExtension" \
  --set "extension-argument:path=/" \
  --set "extension-argument:name=example-servlet"
```

2. To configure one or more HTTP log publishers, use the `create-log-publisher` option with **dsconfig**.

Example:

This example configures two log publishers: one for common access and one for detailed access. Both log publishers use the default configuration settings for log rotation and retention.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access Logger" \
  --type common-log-file-http-operation \
  --set enabled:true \
  --set log-file:logs/http-common-access \
```

```

--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig create-log-publisher \
--publisher-name "HTTP Detailed Access Logger" \
--type detailed-http-operation \
--set enabled:true \
--set log-file:logs/http-detailed-access \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy"

```

3. To configure the HTTP connection handler, specify the HTTP servlet extension and log publishers using the `create-connection-handler` option with `dsconfig`.

Note:

You can update some configuration properties later as needed, but for others, like `listen-port`, you must disable and then re-enable the HTTP Connection Handler for the change to take effect.

Example:

```

$ bin/dsconfig create-connection-handler \
--handler-name "Hello World HTTP Connection Handler" \
--type http \
--set enabled:true \
--set listen-port:8443 \
--set use-ssl:true \
--set "http-servlet-extension:Hello World Servlet" \
--set "http-operation-log-publisher:HTTP Common Access Logger" \
--set "http-operation-log-publisher:HTTP Detailed Access Logger" \
--set "key-manager-provider:JKS" \
--set "trust-manager-provider:JKS"

```

4. To monitor the connection handler, use the `ldapsearch` tool.

Note:

By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE` by default.

Example:

```

$ bin/ldapsearch --baseDN "cn=monitor" \
"(objectClass=ds-http-connection-handler-statistics-monitor-entry)"

```

Configuring an HTTP connection handler for web applications

About this task

To host web applications on the server, use HTTP connection handlers.

Steps

1. To create the web application servlet extension, use the `create-web-application-extension` option with `dsconfig`.

Example:

```
$ bin/dsconfig create-web-application-extension \
  --extension-name "Hello Web Application" \
  --set "base-context-path:/hello-app" \
  --set "document-root-directory:/opt/hello-web-app"
```

2. To monitor the connection handler, use the `ldapsearch` tool.

Note:

By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE`.

Example:

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

HTTP correlation IDs

Correlation IDs make it easier to track log messages across a software system request that passes through multiple subsystems.

Scattered and intermingled log messages create challenges for tracing the request flow on distributed systems. A correlation ID can be assigned to a request and added to all associated operations as the request is processed. A correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP or HTTPS Connection Handler.

When an HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID might also be passed to the LDAP subsystem.

The correlation ID appears with associated requests in LDAP logs in the `correlationID` key for the following REST APIs:

- SCIM 1
- Delegated admin
- Consent
- Directory

The correlation ID is used as the default client request ID value in intermediate client request controls used by the following REST APIs:

- SCIM 2
- Consent
- Directory

Values related to the intermediate client request control appear in the LDAP logs in the `via` key and are forwarded to downstream LDAP servers when received by PingDirectoryProxy Server. The correlation ID header is also added to requests forwarded by the PingDataGovernance gateway.

For Server SDK extensions that have access to the current `HttpServletRequest`, the current correlation ID can be retrieved as a string through the `HttpServletRequest.com.pingidentity.pingdata.correlation_id` attribute, as shown.

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

Configuring HTTP correlation ID support

About this task

Correlation ID support is enabled by default for each HTTP Connection Handler.

Steps

- To enable or disable correlation ID support for the HTTPS Connection Handler, use the `set-connection-handler-prop` option with `dsconfig`.

Example:

This example shows how to enable correlation ID support.

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set use-correlation-id-header:true
```

Example:

This example shows how to disable correlation ID support.

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set use-correlation-id-header:false
```

- To customize the response header name for the correlation ID, use the `set-connection-handler-prop` option with `dsconfig`.

Note:

The server generates a correlation ID for every HTTP request and sends it in the response through the **Correlation-Id** response header.

Example:

This example changes the `correlation-id-response-header` property value to `X-Request-Id`.

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set correlation-id-response-header:X-Request-Id
```

- To designate the names of one or more HTTP request headers that contain an existing correlation ID value, use the `set-connection-handler-prop` option with `dsconfig`.

Note:

This enables the server to integrate with a larger system consisting of every servers using correlation IDs.

By default, the server generates a new, unique correlation ID for each HTTP request and ignores any correlation ID that might be set on the request.

Example:

```
$ dsconfig set-connection-handler-prop --handler-name "HTTPS Connection
Handler" \
--set correlation-id-request-header:X-Request-Id \
--set correlation-id-request-header:X-Correlation-Id \
--set correlation-id-request-header:Correlation-Id \
--set correlation-id-request-header:X-Amzn-Trace-Id
```

HTTP correlation ID example

In this example, a request to the directory REST API is made and the correlation ID enables finding HTTP-specific log messages that also have LDAP-specific log messages. The response to the API call includes a `Correlation-Id` header with the value `ee919049-6710-4594-9c66-28b4ada4b127`.

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
Accept: */*
Accept-Encoding: gzip, deflate
Authorization: Bearer ...
Connection: keep-alive
Host: localhost:1443
User-Agent: HTTPie/0.9.9

HTTP/1.1 200 OK
Content-Length: 266
Content-Type: application/hal+json
Correlation-Id: ee919049-6710-4594-9c66-28b4ada4b127
Date: Fri, 02 Nov 2018 15:16:50 GMT
Request-Id: 369

DNS caching

You can use two global configuration properties to control the caching of host name-to-numeric IP address or DNS lookup results returned from the name resolution services of the underlying operating system.

About this task

Steps

1. To configure these properties, use the `dsconfig` tool.

Global configuration properties and their descriptions

Global configuration property	Description
<code>network-address-cache-ttl</code>	Sets the Java system property <code>networkaddress.cache.ttl</code> , and controls the length of time in seconds that a host name-to-IP address mapping can be cached. By default, it keeps resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.
<code>network-address-outage-cache-enabled</code>	Caches host name-to-IP address results in the event of a DNS outage. By default, this is set to true, meaning name resolution results are cached. Unexpected service interruptions might occur during planned or unplanned maintenance, network outages, or an infrastructure attack. This cache can allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

2. To reduce delays due to unnecessary DNS lookups, follow these recommendations:
 - a. Maintain a connection pool in the client app rather than opening new connections for each bind.
 - b. Add appropriate records to DNS, including PTR records.
 - c. Add options `timeout:1` or options `single-request` in the `/etc/resolv.conf` file.
 - d. If IPv6 requests are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory Server's `config/java.properties` file, so that running `bin/dsjavaproperties` and restarting the server no longer issues IPv6 PTR requests.

IP address reverse name lookups

The PingDirectory Server performs numeric IP address-to-host name lookups.

Numeric IP address-to-host name lookups

The following are some of the numeric IP address-to-host name lookups:

- Binding to the Directory: Decoding, examining, or evaluating a DNS bind rule
- Logging: Logging information to certain monitors or writing to the error log
- Java Management Extension (JMX): Creating a server socket
- Key Management: Generating a trust store
- Replication Server: Creating an SSL socket
- Replication Session Management: Obtaining a session or performing a handshake with a replication server
- Simple Authentication and Security Layer (SASL) Authentication: Applying configuration changes
- SMTP Alert Handler: Initializing or sending an alert notification

Configuring address masks

Address masks configured in Access control instructions (ACIs), connection handlers, connection criteria, and certificate handshake processing might trigger implicit reverse name lookups.

For more information about how address masks are configured in the server, see the following information for each server:

- ACI DNS: bind rules in [Managing Access Control](#) on page 437 for Directory Server and Directory Proxy Server
- `ds-auth-allowed-address`: [Restricting access through operational attributes in user entities](#) for Directory Server
- Connection Criteria: [Restricting server access based on client IP address](#) on page 211 for Directory Server and Directory Proxy Server
- Connection Handlers: [Restricting server access using the connection handlers](#) on page 211 for a configuration reference guide for all servers

Configuring traffic through a load balancer

To record the actual client's IP address to the trace log, enable `X-Forwarded-*` handling in both the intermediate HTTP server and the PingDirectory Server.

By default, when a PingDirectory Server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, it logs incoming requests as originating with the intermediate HTTP server instead of the client that sent the request.

When you set the `use-forwarded-headers` property and enable an HTTP connection handler to use `Forwarded` or `X-Forwarded-*` headers, many intermediate HTTP servers add information about the original request that would otherwise be lost.

If `use-forwarded-headers` is set to `true`, the server uses the client IP address and port information in the `Forwarded` or `X-Forwarded-*` headers instead of the address and port of the entity that's sending the request (the load balancer). This client address information shows up in logs, such as in the `from` field of the `HTTP REQUEST` and `HTTP RESPONSE` messages.

Note:

If both the `Forwarded` and `X-Forwarded-*` headers are included in the request, the `Forwarded` header takes precedence. The `X-Forwarded-Prefix` header only overrides the context path for HTTP servlet extensions, not for web application extensions.

Configuring traffic through a load balancer using `dsconfig`

About this task

To configure PingDirectory Server to get traffic through a load balancer and to record the actual client's IP address:

Steps

1. Edit the HTTP or HTTPS connection handler object and set `use-forwarded-headers` to `true` by running `dsconfig`.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set use-forwarded-headers:true
```

2. To finalize the changes to the HTTP or HTTPS connection handler, use `dsconfig` to restart the connection handler.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:false

dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true
```

3. To provide the `X-Forwarded-*` information to your load balancer, consult your provider's guide on configuring the load balancer settings.

Configuring traffic through a load balancer using the administrative console

About this task

To configure PingDirectory Server to get traffic through a load balancer and to record the actual client's IP address:

Steps

1. On the PingDirectory administrative console **Configuration** page, click **Connection Handlers**.
2. To edit your HTTP or HTTPS connection handler, in the **Connection Handlers** list, select the connection handler you want to edit.
3. To enable `Forwarded` headers, go to **Use Forwarded Headers** and select the **Enabled** check box.
4. Click **Save**.
5. To finalize the changes to the HTTP or HTTPS connection handler, use `dsconfig` to restart the connection handler.

Example:

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:false

dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
```

```
--set enabled:true
```

**Note:**

Because disabling the connection handler brings down the administrative console, you must complete this step in the command line instead of the administrative console.

6. To provide the `X-Forwarded-*` information to your load balancer, consult your provider's guide on configuring the load balancer settings.

Working with the Referential Integrity plugin

Referential Integrity is a plugin mechanism that maintains the distinguished name (DN) references between an entry and a group member attribute. If you have a group entry consisting of member attributes specifying the DNs of printers, you can enable the referential integrity plugin to ensure that the group entry is automatically removed if a printer entry is removed from the Directory Server.

Before you begin

By default, the Referential Integrity plugin is disabled. When enabled, the plugin performs integrity updates on the specified attributes, such as `member` or `uniquemember`, after a delete, modify DN, or a rename, such as subordinate `modifyDN`, operation is logged to the `logs/ referint` file. If an entry is deleted, the plugin checks the log file and makes the corresponding change to the associated group entry.

Important points about the Referential Integrity plugin:

- Index all specified attributes that are configured for Referential Integrity.
- On replicated servers, the Referential Integrity plugin configuration is not propagated to other replicas. You must manually enable the plugin on each replica.
- The plugin settings must be identical on all machines.
- If the Referential Integrity plugin is enabled and configured to operate in synchronous mode, subtree delete operations are not allowed. You must configure the plugin to operate in asynchronous mode by specifying a nonzero update interval for subtree delete operations to perform.

About this task

Enable the Referential Integrity plugin.

Steps

1. Determine the attributes needed for your system.

By default, the `member` and the `uniquemember` attributes are set for the plugin.

2. To enable the Referential Integrity plugin, run the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
--set enabled:true
```

Working with the Unique Attribute plugin

The Unique Attribute plugin enforces uniqueness constraints on the values of one or more attributes across a portion of the Directory Server. The plugin checks for uniqueness prior to an add, modify, or modify

distinguished name (DN) request and instructs the server to reject the request if a constraint violation is found.

About this task

By default, the plugin is disabled because it can affect performance in heavy write load environments. After the plugin is enabled, it does not check for attribute uniqueness on existing entries, only on new `ADD`, `MODIFY`, or `MODDN` operations. To ensure that no such conflicts exist in the data, administrators can use the `identify-unique-attribute-conflicts` command.

Important:

Ensure all attributes to enforce for uniqueness are indexed for equality in all backends. Use the LDAP SDK uniqueness request control for enforcing uniqueness on a per-request basis. For more information on the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control, see [Use the server SDK and LDAP SDK](#). See the ASN.1 specification to implement support for it in other APIs.

You can enforce attribute uniqueness in replicated environments in which each replica contains the complete set of data for which to provide uniqueness, regardless of whether clients communicate directly with the server or interact with it through a Directory Proxy Server. In such environments, all servers have identical uniqueness configurations.

Note:

It is not possible to prevent conflicts that arise from simultaneous writes on separate replicas. However, such conflicts are detected after the changes have been replicated and then triggers administrative alert notifications.

For proxied environments that do not have the complete set of data on all servers, such as environments that use entry balancing or that store different portions of the DIT on different servers, implement the Global Uniqueness Attribute plugin on the Directory Proxy Server instead of enabling the attribute uniqueness plugin on the PingDirectory Server Admin Guide. For more information, see the [PingDirectory Server Admin Guide](#) and the [PingDirectoryProxy Server Admin Guide](#).

To enable the Unique Attribute plugin:

Steps

1. Determine which attributes must be unique in your data.
2. To enable the plugin, run the `dsconfig` tool.

By default, the plugin type property is set to `postsynchronizationadd`, `postsynchronizationmodify`, `postsynchronizationmodifydn`, `preoperationadd`, `preoperationmodify`, and `preoperationmodifydn`.

Example: The following example checks for attribute uniqueness prior to `ADD` operation using the `--set plugin-type:preoperationadd` option.

```
$ bin/dsconfig set-plugin-prop --plugin-name "UID Unique Attribute" \
--set enabled:true
```

- a. If you want to set one plugin type, use the `--set plugin-type:<operation-type>` option.

Working with the Purge Expired Data plugin

Use the Purge Expired Data plugin to delete expired entries or attribute values and cleanup expired PingFederate Persistent Access Grants.

When the plugin is enabled, a background thread in the plugin periodically searches for and purges expired data. For optimal performance, enable the Purge Expired Data plugin on multiple servers in a topology. For example, you can configure one server to delete data while others are searching for expired data.

Create and configure the Purge Expired Data plugin with the `dsconfig` tool. Configuration options include the base distinguished name (DN) and filter, the items to be purged, how to identify expired data, and the frequency for polling and purging. You must index the search for expired data. An alarm is raised if the server purging data falls behind the configured `max-updates-per-second`. Monitoring information is available in the Admin Console, or `cn=monitor`.

Configuring the Purge Expired Data plugin for expired entries

About this task

Use the Purge Expired Data plugin to delete all unverified account entries that have not been accessed in the past eight weeks. This is useful for the following scenarios:

- Accounts that potential customers started to create through an application's registration process but then did not complete.
- The phone number or email address that was provided during registration was not verified and should be allowed to be used by another account.

Steps

1. If necessary, enable the Last Access Time plugin:

The server can track the last access time automatically in the `ds-last-access-time` attribute by enabling the Last Access Time plugin.

Example:

```
$ bin/dsconfig set-plugin-prop \
  --plugin-name "Last Access Time" \
  --set enabled:true
```

2. To determine expiration order, create an index on the date attribute.

The Purge Expired Data plugin requires the date attribute that is used to determine expiration to be indexed for ordering.

Example:

```
$ bin/dsconfig create-local-db-index \
  --backend-name userRoot \
  --index-name ds-last-access-time \
  --set index-type:ordering
```

3. If there is data present in the directory, rebuild the index.

Example:

```
$ bin/rebuild-index \
  --baseDN dc=example,dc=com \
  --index ds-last-access-time
```

4. Create the plugin that purges account entries `objectclass=account` that are not verified.

Example:

The following example purges account entries `verified=false` after eight weeks of inactivity.

```
$ bin/dsconfig create-plugin \
  --plugin-name "Purge Old Unvalidated Accounts" \
  --type purge-expired-data \
  --set enabled:true \
  --set datetime-attribute:ds-last-access-time \
  --set "expiration-offset:8 w" \
  --set "filter:(&(objectClass=account)(verified=false))"
```

Configuring the Purge Expired Data plugin for expired attribute values

About this task

Use the Purge Expired Data plugin to delete values of an attribute that have expired. For example, an application can track information about an employee's session and then expire the session after 24 hours. There can be multiple active sessions tracked across different devices with session information as shown in the following example.

In this example, the LDAP attribute is `sessioninfo` and the JSON field that stores the timestamp is `creationTime`. These are used to configure the Purge Expired Data plugin.

```
sessionInfo: { "sessionId" : "E85FAC04E331FFCA55549B10B7C7A4FA",
  "ipAddress": "10.0.0.00", "userAgent": "Mozilla/5.0 (iPad; U; CPU OS 3_2
  like Mac OS X; en-us)
  AppleWebKit/531.21.10 (KHTML, like Gecko) Version/4.0.4 Mobile/7B367
  Safari/531.21.10",
  "creationTime" : "2018-03-31T13:10:15Z" }
```

Create the plugin to purge the JSON attribute values after 24 hours, rather than the entire session entry.

Steps

1. Create an index on the `creationTime` field of the `sessioninfo` attribute.

Example:

```
$ bin/dsconfig create-json-attribute-constraints \
  --attribute-type sessioninfo \
  --set enabled:true
```

Example:

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type sessioninfo \
  --json-field creationTime \
  --set index-values:true \
  --set value-type:string
```

2. Create and enable the plugin.

Example:

```
$ bin/dsconfig create-plugin \
  --plugin-name "Purge Old Session Data Plugin" \
  --type purge-expired-data \
  --set enabled:true \
  --set "custom-datetime-format:yyyy-MM-dd'T'HH:mm:ss'Z'" \
  --set datetime-attribute:sessioninfo \
```

```
--set datetime-format:custom \  
--set datetime-json-field:creationTime \  
--set "expiration-offset:1 d" \  
--set purge-behavior:delete-json-attribute-values
```

Configuring uniqueness across attribute sets

Configure attribute uniqueness across a set of attributes using the `multiple-attribute-behavior` property.

Before you begin

About this task

To enable uniqueness across attribute sets:

Steps

- To configure the UID unique attribute plugin to apply across multiple attributes, use the `dsconfig` tool.

The following table details the `multiple-attribute-behavior` property and the values it can take.

The `multiple-attribute-behavior` property values, descriptions, and examples

Value	Description	Example
<code>unique-within-each-attribute</code>	If multiple attributes are specified, then uniqueness is enforced for all values of each attribute, but the same value might appear in different attributes in the same entry or in different entries.	<p>For example, assume you have an existing entry that has attributes <code>telephoneNumber=123-456-7890</code> and <code>mobile=123-456-7891</code>.</p> <p>If you set the uniqueness plugin to have <code>--set "multiple-attribute-behavior:unique-within-each-attribute"</code> and add:</p> <ul style="list-style-type: none"> ▪ An entry with a <code>telephoneNumber</code> value that matches the <code>telephoneNumber</code> attribute in the existing entry, then the add request fails. ▪ An entry with a <code>mobile</code> value that matches the <code>mobile</code> attribute in the existing entry, then the request fails. ▪ An entry with the same <code>telephoneNumber</code> and <code>mobile</code> attribute values, such as <code>123-456-7893</code>, but differs from the values in the existing entry, then the add request succeeds.

Value	Description	Example
<code>unique-across-all-attributes-including-in-same-entry</code>	<p>If multiple attributes are specified, then uniqueness is enforced across all of those attributes. If a value appears in one of those attributes that value might not be present in any other of the listed attributes in the same entry, nor in any of the listed attributes in other entries.</p>	<p>For example, assume you have an existing entry that has attributes, <code>telephoneNumber=123-456-7890</code> and <code>mobile=123-456-7891</code>.</p> <p>If you set the uniqueness plugin to have <code>--set "multiple-attribute-behavior:unique-across-all-attributes-including-in-same-entry"</code> and add:</p> <ul style="list-style-type: none"> ▪ An entry with a <code>telephoneNumber</code> value, such as <code>123-456-7890</code>, that matches the <code>telephoneNumber</code> attribute in an existing entry, then the add request fails. ▪ An entry with a <code>mobile</code> value that matches the <code>mobile</code> attribute in an existing entry, then the request fails. ▪ An entry with a <code>mobile</code> value, such as <code>123-456-7890</code>, that matches the <code>telephoneNumber</code> attribute in an existing entry, then that fails. ▪ An entry with the same <code>telephoneNumber</code> and <code>mobile</code> attribute values, such as <code>123-456-7893</code>, but differ from the values in an existing entry, then the add request fails.

Value	Description	Example
<code>unique-across-all-attributes-except-in-same-entry</code>	<p>If multiple attributes are specified, then uniqueness is enforced across all of those attributes. So, if a value appears in one of those attributes, that value might not be present in any of the listed attributes in other entries. However, the same value might appear in multiple attributes in the same entry.</p>	<p>For example, assume you have an existing entry that has attributes, <code>telephoneNumber=123-456-7890</code> and <code>mobile=123-456-7891</code>.</p> <p>You set the uniqueness plugin to have <code>--set "multiple-attribute-behavior:unique-across-all-attributes-except-in-same-entry"</code> and add:</p> <ul style="list-style-type: none"> ▪ An entry with a <code>telephoneNumber</code> value, such as <code>123-456-7890</code>, that matches the <code>telephoneNumber</code> attribute in an existing entry, then the add request fails. ▪ An entry with a <code>mobile</code> value that matches the <code>mobile</code> attribute in the existing entry, then the request fails. ▪ An entry with a <code>mobile</code> value, such as <code>123-456-7890</code>, that matches the <code>telephoneNumber</code> attribute in an existing entry, then the request fails. ▪ An entry with a <code>telephoneNumber</code> value, such as <code>123-456-7891</code>, that matches the <code>mobile</code> attribute in an existing entry, then the request fails. ▪ An entry with the same <code>telephoneNumber</code> and <code>mobile</code> attribute values, such as <code>123-456-7893</code>, but that differs from the values in an existing entry, then the add request succeeds.

Example:

The `multiple-attribute-behavior` property is set to `unique-within-each-attribute`, which indicates that uniqueness is enforced for all values of each attribute, such as `telephoneNumber=123-456-7890` and `mobile=123-456-7891`, but the same value, such as either `123-456-7890` or `123-456-7891` might appear in different attributes in the same entry or in different entries.

```
$ dsconfig create-plugin \
  --plug-in "Unique telephoneNumber and mobile" \
```

```
--type "unique-attribute" \
--set "enabled:true" \
--set "type:telephoneNumber" \
--set "type:mobile" \
--set "multiple-attribute-behavior:unique-within-each-attribute" \
--no-prompt
```

Working with the Last Access Time plugin

Use the Last Access Time plugin to record the timestamp of the last activity targeting an entry. The plugin updates the `ds-last-access-time` attribute of the entry when accessing it using an `ADD`, `BIND`, `COMPARE`, `MODIFY`, `MODIFY DN`, or `SEARCH` operation.

Before you begin

Consider the following before using this plugin:

- An updated `ds-last-access-time` attribute value is replicated like any other change to an entry.
- The `ds-last-access-time` attribute is not returned from a search, unless included in the attributes list explicitly, or given the "+" specification for operational attributes.
- The `ds-last-access-time` value format is `yyyyMMddHHmmss.SSS'Z'`, which provides millisecond-level accuracy, such as `20131207144135.821Z`.
- The `ds-last-access-time` attribute can be indexed with a local database index. The ordering index type is the most relevant, but might require a higher index entry limit (default is 4000) to accommodate searches for entries that are not accessed for a long period of time. The ordering index type with a short time range or high index entry limit results in indexed search results for requests, such as `(ds-last-access-time)>=20131207144135.821Z`.

About this task

Use the plugin with the Directory Server Uncached Attribute Criteria or any application that needs to determine the last access time of an entry. The plugin also enables defining request criteria to limit the scope of tracking the last access time. The `max-search-result-entries-to-update` property also prevents mass updates of `ds-last-access-time` when searches contain many results, but might not reflect end-user access.

Steps

- Enable the plugin on all servers that have the same configuration.

Important:

For deployments earlier than version 4.5 that use the Last Access Time plugin, disable the plugin before upgrading, and then re-enable it after the update is complete. If servers are running different versions, the `last-access-time` updates might occur with a higher frequency than intended.

Working with pass-through authentication

PingDirectory Server provides support for passing through LDAP simple bind attempts to an external service for authentication processing, either instead of or in addition to the processing that it typically performs against the locally stored data.

Pass-through authentication can be useful when migrating to the Directory Server from a different type of datastore, especially when that datastore doesn't provide a means of directly migrating passwords.

The server provides pass-through authentication support for other LDAP servers (including Active Directory, Oracle DSEE, OpenLDAP, and any other standards-compliant LDAPv3 server) and PingOne by

default. You can also use the Server SDK to implement support for custom pass-through authentication handlers for interacting with other types of external services.

Configuration properties for pass-through authentication to LDAP servers

When used with the LDAP pass-through authentication handler, the pluggable pass-through authentication plugin can forward LDAP simple bind requests to another type of LDAP server for processing.

The following table contains the pluggable pass-through authentication plugin configuration properties.

Property	Description
<code>pass-through-authentication-handler</code>	The pass-through authentication handler that is used to interact with the external service. For passing through authentication to an LDAP directory server, create an LDAP pass-through authentication handler.
<code>included-local-entry-base-dn</code>	The base distinguished names (DNs) of subtrees containing local entries for which pass-through authentication is attempted. If this isn't provided, then all regular user entries (excluding root users and topology administrators) might be passed through.
<code>connection-criteria</code>	Optional connection criteria that can be used to indicate which clients can have their bind attempts passed through.
<code>request-criteria</code>	Optional request criteria that can be used to indicate which bind requests should be passed through.
<code>try-local-bind</code>	Indicates whether to try the bind attempt against the entry in the local server, only passing through to the external service if the local attempt fails. If this is <code>false</code> , then only pass-through authentication is used for applicable requests and local credentials aren't evaluated.
<code>override-local-password</code>	Indicates whether to pass through bind attempts for local accounts that have passwords. If this is set to <code>false</code> , bind attempts will only be passed through for accounts that don't have local passwords. This only applies if <code>try-local-bind</code> is <code>true</code> .
<code>update-local-password</code>	Indicates whether to update the password for the local account if authentication succeeds against the external service. This only applies if <code>try-local-bind</code> is <code>true</code> .

Property	Description
<code>update-local-password-dn</code>	The DN to use as the authorization identity when updating local passwords, which can be helpful if you want to synchronize other types of changes between the Directory Server and the external repository. If this isn't provided, an internal root account is used.
<code>allow-lax-pass-through-authentication-passwords</code>	Indicates whether to update the password for the local account even if it wouldn't have otherwise been accepted by the server (for example, if the password doesn't satisfy the configured set of password validators). This only applies if <code>update-local-password</code> is <code>true</code> .
<code>ignored-password-policy-state-error-condition</code>	Optionally allows pass-through authentication attempts to proceed against local accounts that are in certain states that don't allow them to authenticate locally (for example, if the account is locked or the password is expired).

The following table contains the LDAP pass-through authentication handler configuration properties.

Property	Description
<code>server</code>	The LDAP external servers to which bind attempts should be passed through.
<code>server-access-mode</code>	The mechanism that the server should use when choosing the order that the servers should be selected for pass-through authentication attempts.
<code>dn-map</code>	An optional mapping that can be used to construct the remote bind DN from the local Directory Server entry when authenticating to the external servers.
<code>bind-dn-pattern</code>	An optional pattern that can be used to construct the remote bind DN from the local Directory Server entry when authenticating to the external servers.
<code>search-base-dn</code>	The search base DN to use when searching for the corresponding entry in the external servers.
<code>search-filter-pattern</code>	An optional pattern you can use to construct a filter to search for the entry in the external servers that corresponds to an entry in the local Directory Server.
<code>initial-connections</code>	The initial number of connections to establish to each of the LDAP external servers.

Property	Description
<code>max-connections</code>	The maximum number of connections to maintain to each of the LDAP external servers.
<code>use-location</code>	Indicates whether to consider each server's location relative to the local Directory Server instance location when choosing the order that servers should be selected for pass-through authentication attempts.
<code>maximum-allowed-local-response-time</code>	The maximum length of time to wait for a response from an external server in the same location as the local Directory Server.
<code>maximum-allowed-nonlocal-response-time</code>	The maximum length of time to wait for a response from an external server in a different location from the local Directory Server.
<code>use-password-policy-control</code>	<p>Indicates whether to include the password policy request control in bind requests forwarded to the external LDAP servers.</p> <p>This control can improve the server's ability to categorize authentication failures against the remote server, but not all types of LDAP servers support it.</p> <p>By default, the server includes the password policy request control if the server's root DSA-specific entry (DSE) advertises support for it.</p>

At most one of the `dn-map`, `bind-dn-pattern`, and `search-filter-pattern` properties can be provided to indicate how the server should identify the entry in the remote server that corresponds to the entry in the local server. If none of these properties are provided, the local entry DN is used as the remote entry DN.

Configuring pass-through authentication to LDAP servers

To enable pass-through authentication to LDAP servers, create and configure at least one LDAP external server, a pass-through authentication handler, and a pluggable pass-through authentication plugin instance.

Steps

1. To create an LDAP external server, run `dsconfig create-external-server`.

Note:

If you already have an LDAP external server to use for pass-through authentication, proceed to step 2.

Example:

The following example creates two LDAP external servers.

```
dsconfig create-external-server \
  --server-name ds1.example.com:636 \
  --type ldap \
```

```

--set server-host-name:ds1.example.com \
--set server-port:636 \
--set connection-security:ssl \
--set key-manager-provider:Null \
--set trust-manager-provider:JKS \
--set authentication-method:none

dsconfig create-external-server \
--server-name ds2.example.com:636 \
--type ldap \
--set server-host-name:ds2.example.com \
--set server-port:636 \
--set connection-security:ssl \
--set key-manager-provider:Null \
--set trust-manager-provider:JKS \
--set authentication-method:none

```

2. To create an LDAP pass-through authentication handler, run `dsconfig create-pass-through-authentication-handler`.

Example:

```

dsconfig create-pass-through-authentication-handler \
--handler-name LDAP \
--type ldap \
--set server:ds1.example.com:636 \
--set server:ds2.example.com:636 \
--set server-access-mode:round-robin

```

3. To create a pluggable pass-through authentication plugin instance, run `dsconfig create-plugin`.

Example:

```

dsconfig create-plugin \
--plugin-name "Pluggable Pass-Through Authentication" \
--type pluggable-pass-through-authentication \
--set enabled:true \
--set pass-through-authentication-handler:LDAP

```

The PingOne Pass-Through Authentication plugin

The PingOne Pass-Through Authentication plugin allows users to authenticate to the Directory Server with a password from PingOne and can optionally update the passwords in PingDirectory after successfully validating it in PingOne.

Although PingDataSync Server supports bidirectional synchronization between PingDirectory Server and PingOne, and it can synchronize password changes from PingDirectory to PingOne, it can't sync password changes from PingOne to PingDirectory. However, you can use the PingOne Pass-Through Authentication plugin to authenticate to the Directory Server with a PingOne password, and can optionally update the password in PingDirectory after successfully validating it in PingOne.

This plugin features a mandatory `try-local-bind` configuration property that enables one of the following modes of operation:

- When `try-local-bind` is `true`, the plugin attempts to authenticate locally first. It sends a request to PingOne only if the local bind attempt fails.
- When `try-local-bind` is `false`, the plugin attempts to authenticate with PingOne first.

The following table identifies and describes the configuration properties associated with the PingOne Pass-Through Authentication plugin.

The PingOne Pass-Through Authentication plugin properties and their descriptions

Property	Description	Required	Default
<code>api-url</code>	URL that PingDirectory Server uses to communicate with PingOne.	Yes	N/A
<code>auth-url</code>	URL that PingDirectory Server uses to authenticate to PingOne.	Yes	N/A
<code>oauth-client-id</code>	OAuth client ID that PingDirectory Server uses to authenticate to PingOne.	Yes	N/A
<code>oauth-client-secret</code>	OAuth client secret that PingDirectory Server uses to authenticate to PingOne.	Yes	N/A
<code>environment-id</code>	Identifier for the PingOne environment that contains the users for whom pass-through authentication is attempted.	Yes	N/A
<code>included-local-entry-base-dn</code>	<p>If this value is set, authentication attempts are passed to PingOne only for users in a specified distinguished name (DN).</p> <p>If this value is set, only users who exist within a specified base DN allow their authentication attempts to be passed through to PingOne.</p>	No	All public naming contexts (if not set)
<code>connection-criteria</code>	<p>Reference to a connection criteria object to use to identify the bind requests to pass-through to PingOne based on the server's knowledge of the client expected to be the address, protocol, and security level.</p> <p>If this property is defined, only client connections that match the criteria are included. If this property is not defined, all clients are included.</p>	No	N/A
<code>request-criteria</code>	<p>Reference to a request criteria object to use to identify the bind requests to pass through to PingOne, based on the contents of the request.</p> <p>If this property is defined, only bind requests that match the criteria are included. If this property is not defined, all bind requests are included.</p>	No	N/A
<code>try-local-bind</code>	<p>Indicates whether PingDirectory Server tries to process the bind locally before forwarding the bind request to PingOne.</p> <p>If this value is set to <code>true</code> and the bind succeeds locally, PingDirectory Server does not make a request to PingOne. If this value is set to <code>false</code>, PingDirectory Server ignores local credentials and attempts to authenticate only to PingOne.</p>	Yes	<code>True</code>

Property	Description	Required	Default
override-local-password	<p>Indicates whether PingDirectory Server attempts to bind to PingOne if the local account has a password.</p> <p>This property is used if <code>try-local-bind</code> is <code>true</code>. If it has a value of <code>false</code>, the plugin attempts to authenticate to PingOne only if the local user account doesn't have a password.</p> <p>If the local bind attempt fails while this value is set to <code>true</code>, the server tries to authenticate to PingOne even if the local account has a password.</p>	Yes	True
update-local-password	<p>Indicates whether PingDirectory Server attempts to set the password for the local user account, regardless of whether one is already set, when the local authentication attempt fails but the attempt to authenticate with PingOne succeeds.</p> <p>This property is used only if <code>try-local-bind</code> is <code>true</code>.</p> <p>If the on-premise PingDirectory Server is the authoritative source for passwords, set this property to <code>false</code> and configure PingDataSync Server to synchronize password changes from PingDirectory Server into PingOne. If the passwords differ, either the local password or the password for PingOne allows the user to authenticate.</p> <p>If PingOne is the authoritative source for passwords, set this property to <code>true</code>. To ensure that a pass-through attempt to PingOne doesn't override local changes, make all password changes in PingOne.</p>	Yes	False
allow-lax-pass-through-authentication-passwords	<p>Indicates whether PingDirectory Server bypasses the normal password-validation process when setting the local password from PingOne. This property is used only when both <code>try-local-bind</code> and <code>update-local-password</code> are <code>true</code>.</p> <p>If this value is <code>true</code> when a local bind attempt fails but the authentication attempt with PingOne succeeds, the user's password is updated locally even if a local attempt to change the password to the same value is rejected because the password is considered too weak.</p> <p>If this value is <code>false</code>, pass-through authentication succeeds only if the authentication to PingOne succeeds, and if the password is accepted by the local password validators. If the PingOne password does not satisfy the configured set of password validators, the pass-through authentication attempt fails.</p>	Yes	True

Property	Description	Required	Default
<code>ignored-password-policy-state-error-condition</code>	Set of zero or more password policy state error conditions that are ignored for pass-through authentication. For a list of values and their descriptions, see the following table.	No	N/A
<code>user-mapping-local-attribute</code>	Name of an LDAP attribute that is used to map local user entries to the corresponding PingOne account. This property must include the same number of values as the <code>user-mapping-remote-json-field</code> property, and the order of their values is correlated. If multiple values are specified, all attributes must be present in the local entry, and the plugin performs an AND search in PingOne to locate the user account with all the values in the corresponding fields. The <code>entryDN</code> attribute can be used to represent the DN of the local entry.	Yes	N/A
<code>user-mapping-remote-json-field</code>	The name of a PingOne field used to map local user entries to the corresponding PingOne account. This property must include the same number and order of values as the <code>user-mapping-local-attribute</code> property.	Yes	N/A
<code>additional-user-mapping-scim-filter</code>	The System for Cross-domain Identity Management (SCIM) filter included in the search and used to identify the PingOne account that corresponds to the local user entry. If a value is provided for this property, it is used with the SCIM filter that was created to map the local user entry to a PingOne account. If a value is not provided for this property, no additional filter is used.	No	N/A

The following table identifies the values to use with the optional configuration property `ignored-password-policy-state-error-condition` and describes the scenarios in which a user is permitted to bind when using pass-through authentication.

Optional configuration property and the scenarios for use when using pass-through authentication

Property	Scenario in which a user can still bind by using pass-through authentication
<code>temporarily-locked-due-to-failures</code>	The account is locked temporarily because of too many failed attempts.
<code>permanently-locked-due-to-failures</code>	The account is locked permanently because of too many failed attempts.
<code>locked-due-to-idle-interval</code>	The account is locked because the user has not authenticated recently.

Property	Scenario in which a user can still bind by using pass-through authentication
<code>locked-due-to-maximum-reset-age</code>	The account is locked because an administrator recently reset the password, and the user failed to specify a new password within the allotted time frame.
<code>password-is-expired</code>	The password is expired.

Example

Configuring the PingOne Pass-Through Authentication plugin

To create and configure the PingOne Pass-Through Authentication plugin, run `dsconfig create-plugin` in a command similar to the following.

```
dsconfig create-plugin \
  --plugin-name "PingOne Pass-Through Authentication" \
  --type ping-one-pass-through-authentication \
  --set enabled:true \
  --set "api-url:<API URL>" \
  --set "auth-url:<Auth URL>" \
  --set "oauth-client-id:<Client ID>" \
  --set "oauth-client-secret:<Client Secret>" \
  --set "environment-id:<Environment ID>" \
  --set user-mapping-local-attribute:entryUUID \
  --set user-mapping-remote-json-field:externalId
```

Configuring pass-through authentication to custom services

PingDirectory Server provides support for passing through LDAP simple bind attempts to an external service for authentication processing, either instead of or in addition to the processing that it typically performs against the locally stored data. Use the Server SDK to implement support for custom pass-through authentication handlers for interacting with other types of external services.

About this task

To create a custom pass-through authentication handler, use the Server SDK. To configure your pass-through handler in the server:

Steps

1. Create an instance of a third-party pass-through authentication handler and set its `extension-class` property by running a command similar to the following.

Example:

```
dsconfig create-pass-through-authentication-handler \
  --handler-name "<Example Handler>" \
  --type third-party \
  --set extension-
class:<com.example.ExamplePassThroughAuthenticationHandler> \
  --set extension-argument:<argName1=argValue1> \
```

```
--set extension-argument:<argName2=argValue2>
```

The third-party pass-through authentication handler supports the following configuration properties.

Property	Description
extension-class	The fully-qualified name of the Java class that provides the custom pass-through authentication handler implementation. This class must be a subclass of <code>com.unboundid.directory.sdk.ds.api.PassThroughA</code>
extension-argument	An optional set of name-value pairs that provide arguments needed to configure the custom pass-through authentication handler.

- Optional: Set any further configuration needs, as determined by your custom implementation, through the `extension-argument` property.
- After you have configured the third-party pass-through authentication handler, configure a pluggable pass-through authentication plugin instance to use it, using a command similar to the following.

Example:

```
dsconfig create-plugin \
  --plugin-name "Pluggable Pass-Through Authentication" \
  --type pluggable-pass-through-authentication \
  --set enabled:true \
  -- set "pass-through-authentication-handler:<Example Handler>"
```

Note:

For more information about the configuration properties for the pluggable pass-through authentication plugin, see [Working with pass-through authentication](#) on page 241.

Troubleshooting server performance issues

The following are the most common reasons that customers encounter performance issues and some suggestions for diagnosing and addressing these issues.

Slow password storage schemes

Slow password storage schemes are configurable schemes designed to use a lot of CPU and memory to thwart attackers, but they can affect legitimate operations like password validation and authentication.

The following password storage schemes are intentionally expensive:

- PBKDF2
- bcrypt
- scrypt
- Argon2
- The MD5, SHA-2-256 and SHA-2-512 variants of the crypt scheme

These schemes are designed to consume a significant amount of CPU, and memory in some cases, to increase the amount of resources an attacker must expend to crack a password if they happen to get access to the password's encoded representation. This same cost is also incurred for legitimate operations involving the password, including encoding clear-text passwords during account creation and password changes and when validating passwords during authentication. You can configure these schemes to adjust the amount of resources they consume, and you should configure them so that the resource consumption under expected peak load does not exceed the capacity of the topology.

Additionally, if you are initially populating the server using an LDIF import that contains clear-text passwords, using one of these schemes can cause the LDIF import to proceed at a small fraction of the rate that could be achieved with a faster storage scheme, such as one that uses a 256-bit or 512-bit salted SHA-2 digest. In such cases, you might import the data using a faster scheme and then change the configuration to make the desired scheme the new default, and mark the scheme used for import as deprecated. As a result, accounts with passwords encoded using the import scheme are automatically re-encoded with the new scheme the first time that the user successfully authenticates using that password.

Database size versus memory capacity

Best performance is achieved when the contents of the database can be fully cached in memory.

If possible, the amount of memory allocated to PingDirectory Server should be large enough so that all of the data can fit in the database cache. Memory sizing estimates appear at the end of the output when you run the `import-ldif` tool.

If the amount of data that needs to be stored exceeds the available memory capacity of the individual systems on which the server runs, there are a couple options:

- Break up the data into segments that are small enough to be fully cached on their own, and use PingDirectoryProxy Server's entry balancing functionality to make them appear as a single logical set.
- Tune the server so that the most frequently accessed information can be served from memory while disk access might be required for other data. In disk-bound deployments, you can use backend configuration options such as cache mode, uncached attribute criteria, and uncached entry criteria to help prioritize what data should remain in memory versus what can be retrieved from disk.

Large number of access control rules

As the number of access control rules increases, so does the potential costs of determining whether a client is allowed to request a given operation and of paring down search result entries based on the data that the client is permitted to access.

The server might need to re-evaluate all access control rules after certain update operations, including modify DN operations, to determine whether these are affected by the change.

In many cases, deployments with an extremely large number of access control rules, especially those with large numbers of branches in which the same structure might be repeated across each of these branches, might be able to leverage parameterized access control instructions (ACIs) to dramatically reduce the number of access control rules that need to be defined and evaluated. In other cases, it is possible to refactor the access control configuration to achieve the same effect but with far fewer rules.

Large static groups

PingDirectory Server supports large static groups with hundreds of thousands of members or more, but these can have a significant impact on performance. Consider replacing large static groups with dynamic groups.

It can be expensive in terms of system resources to update the large static group to add or remove members because each update requires rewriting the entire entry. It can also be expensive to decode the entry when retrieving it from the database, even if it is held in the database cache, and to return the list of members to a client in search results.

If possible, consider replacing large static groups with dynamic groups. Dynamic groups automatically determine their membership based on criteria defined in LDAP URLs. A dynamic group consumes little memory and disk space and does not need to be altered as entries are created, updated, and removed. In some cases, it is possible to use virtual static groups in conjunction with dynamic groups to create entries that behave like static groups for read operations. This lets you maintain compatibility with applications that only understand static groups but use dynamic groups behind the scenes to determine membership.

If it is not possible to eliminate large static groups, you can enable the static group entry cache. While this does not reduce the performance impact of updating large static groups, it can make it much more efficient to access those groups for read operations.

Large index ID sets

Indexes store data that make it possible to quickly retrieve matching entries during a search. As the size of an ID set increases, so does the potential resource cost of accessing the ID set.

Each index record maps an index key to a list of the entry IDs for the entries that match that key. If you have an equality index for a given attribute, there is a key for each unique value for that attribute and the values for each key of the IDs of the entries that contain that value. For substring indexes, there can be multiple keys for the same attribute value (one for each unique six-character substring within the value), and the same substring can apply to many different values of the same attribute.

For an attribute index, you can store ID sets in one of two ways that each affect performance differently:

- In the regular (non-exploded) case, each index key occurs once, and the value of this key is the entire list of IDs for entries that match the key. The ID set for a non-exploded index key can be retrieved quickly because only a single database read is required. However, as the size of the ID set grows, the cost of updating it grows because it is necessary to replace the entire set, which requires larger amounts of disk I/O and can place an increased burden on the database cleaner.
- In the exploded case, the same key can be stored multiple times (one for each entry that matches that key), with each instance of the key associated with a different entry ID. Updating the ID set for an exploded key is always fast because the writes are small, but the cost of reading the ID set increases with the number of IDs.

You can also use composite indexes. These offer many advantages over attribute indexes and when they can be used. Some of these advantages, such as the ability to configure a base DN or combinations of attributes, do not have any effect on performance with regard to large ID sets. They use a hybrid of the exploded and non-exploded approaches to maintaining the ID set, such that a large set can be split into multiple pieces, but each piece can have up to 5000 IDs rather than just one. This means that retrieving a large ID set from a composite index can be thousands of times cheaper than retrieving the same ID set from an exploded attribute index. Updating a large ID set in a composite index should be cheaper in terms of systems resources than updating the same ID set in a non-exploded attribute index because the write is much smaller.

In environments with performance problems related to very large index ID sets, you might consider the following options as a way to help improve performance:

- Consider reducing the index entry limit for that index. The index entry limit specifies the maximum number of IDs that an ID set can have for an index key.
 - If a key matches more entries than this limit, the server stops maintaining the index for that key, and attempts to access it behave as if it were unindexed, while the index continues to be maintained for keys matching smaller numbers of entries. If you don't have searches that depend only on those keys, then this is an excellent way of eliminating the cost of maintaining large ID sets. It isn't logical to set the index entry limit to a value that is a large percentage of the total number of entries in the server. In such cases, there might not be a significant performance difference between indexed and unindexed search performance, but there would be no need to maintain the associated large ID sets.
- If there are cases in which you need a large index entry limit, then consider increasing the limit only for that index, rather than increasing the default limit for all indexes in the backend.
 - The `index-entry-limit` property in the backend applies to all indexes that don't specify their own limit, but each index also offers an `index-entry-limit` property that, if set, overrides the index entry limit configured for the backend. As such, if you need a higher index entry limit for a particular index, set a higher limit just for that one index instead of raising the default limit for all indexes in the backend.
- For attribute indexes with keys matching a large number of entries, consider converting it to a composite index when possible.
 - Composite indexes can completely replace equality and ordering attribute indexes, and they can support "starts with" substring searches, regardless of whether they have "contains" or "ends with"

components. Composite indexes can't currently replace approximate match indexes or substring searches that don't have a "starts with" component.

- Consider eliminating any unnecessary substring indexes.
 - As previously noted, substring indexes are more likely to have large ID sets than equality, ordering, or approximate match indexes because substring keys are generally smaller and any given substring key can apply to multiple attribute values. It's also not commonly understood that equality attribute indexes and equality composite indexes are used for substring searches with a "starts with" component. As such, a substring index is not used for substring searches with a "starts with" unless there isn't an equality index for that attribute.
 - If a substring index is defined for an attribute that isn't targeted by substring searches, or that is only targeted by substring searches that contain a "starts with" component (regardless of whether it also includes "contains" or "ends with" components), then that substring index is not necessary and can be removed. You can use access logs to determine the types of searches that clients are performing, and the `summarize-access-log` and `search-logs` tools might help with that.
- If a substring index is needed for a given attribute, then consider increasing the substring length for that index.
 - By default, the server creates a separate substring key for each unique six-character substring in an attribute value, and there might be cases in which the same six-character substring appears in several different values. If that occurs and causes substring keys to have large ID sets, then increasing the substring length for that index reduces the number of values that might share the any given key and can reduce the number of IDs associated with that key.
- As a last resort, consider tuning the exploded index threshold for an index (the number of entries that an ID set needs to have for a given key before it will transition from a non-exploded set to an exploded one) based on the expected usage for that index.
 - If search performance is more important than update performance for an attribute with large ID sets, then raising the exploded index threshold helps keep the ID set stored as a monolithic block of IDs. On the other hand, if update performance is more important than search performance, then lowering the exploded index threshold might help.

Missing indexes

Maintain indexes to determine if an index is missing.

Maintaining unneeded indexes can have a detrimental effect on performance, but it can also be detrimental if a needed index is missing.

The best way to identify expensive searches processed in the server is to examine the access logs for search operations with a high `etime` (elapsed processing time) value. After you identify these search operations, you can filter out any of these operations that do not need to be fast. For example, you might have applications that generate reports by performing inefficient searches, such as searches to retrieve all entries, and it is usually more acceptable for those searches to be slow.

For any remaining searches that are slow or that should be faster, the best way to understand why the search is expensive is to issue a search with the same base DN, scope, and filter, but request only the `debugsearchindex` attribute.

Note:

`debugsearchindex` is a special attribute that makes the server return debug information about the index processing that is being performed in the course of evaluating the search, and how long it took to complete each step of the evaluation.

From this output, you can see which indexes were used and which could not be used because there was either no applicable index or the index entry limit had been exceeded for the target key. You can see expensive accesses to exploded indexes and identify indexes you want to add, indexes that can benefit from being converted to composite indexes, or indexes where you might need to increase the index entry

limit. Alternatively, you can determine a different way to perform the search so that it does not depend on components that are unindexed or that match a large number of entries.

Configuring the Directory Server for Oracle compatibility

Configure the Directory Server for Oracle compatibility.

About this task

For companies that are migrating from an Oracle server to the PingDirectory Server, the PingDirectory Server provides a `dsconfig` batch file, `sun-ds-compatibility.dsconfig`, which describes the various components that can be configured to make the server exhibit behavior closer to an Oracle configuration.

Administrators can use the `sun-ds-compatibility.dsconfig` batch file to apply the Directory Server's configuration with the necessary `dsconfig` commands by uncommenting the example commands listed in the file and then running the `dsconfig` command specifying the batch file.

Note:

This batch file is not comprehensive and must be used together with the `migrate-sun-ds-config` tool, located in the `bin` folder, or `bat` folder for Windows systems, during the migration process. Both the tool and the batch file overlap in some areas but provide good initial migration support from the Oracle server to a Ping Identity server.

Another useful tool is the `migrate-ldap-schema` tool in the `bin` folder, or `bat` folder for Windows systems, which migrates schema information from an existing LDAP server onto this instance. All attribute type and object class definitions that are contained in the source LDAP server are added to the targeted instance or written to a schema file.

Steps

1. From the Directory Server server root directory, open the `sun-ds-compatibility.dsconfig` file in the `docs` folder.

You can use a text editor to view the file.

2. Read the file completely.
3. Apply any changes to the file by removing the comment symbol at any `dsconfig` command example, and then applying the `dsconfig` command specifying the batch file.

Example:

```
$ bin/dsconfig --no-prompt --bindDN "cn=Directory Manager" \
  --bindPassword "password" --batch-file /path/to/dsconfig/file
```

4. Run the `migrate-ldap-schema` tool to move the schema definitions on the source server to the destination Ping Identity server.

Example:

```
$ bin/migrate-ldap-schema
```

5. Run the `migrate-sun-ds-config` tool to see what differences exist in the Ping Identity configuration versus the Oracle configuration.
6. On the PingDirectory Server, run the following command.

Example:

```
$ bin/migrate-sun-ds-config
```

7. Test the server instance for further settings that might not have been set with the batch file, the `migrate-ldap-schema` tool, or the `migrate-sun-ds-config` tool.
8. If you notice continued variances in your configuration, contact your authorized support provider.

Supporting unindexed search requests

By default, the Directory Server denies all unindexed search requests, except for those issued by the bind distinguished names (DNs) that have the `unindexed-search` privilege.

About this task

This default behavior keeps the server from tying up worker threads on time-consuming, unindexed searches. However, you can turn off the enforcement of the `unindexed-search` privilege to allow any client to perform an unindexed search.

Steps

1. Set the `disabled-privilege` global configuration property to `unindexed-search` as follows.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set disabled-privilege:unindexed-search
```

2. If you choose to allow unindexed searches, cap the maximum number of concurrent unindexed search requests using the `maximum-concurrent-unindexed-searches` global configuration property.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set maximum-concurrent-unindexed-searches:2
```

3. Limit unindexed search privileges for particular clients using the `allow-unindexedsearches` property of the client connection policy.

For more information about configuring client connection policies, see [Client connection policy configuration](#).

Syncing passwords to PingOne

To sync passwords with PingOne, PingDirectory Server maps the `userPassword` attribute to the `password` attribute through a direct attribute mapping.

About this task

To sync passwords from PingDirectory Server to PingOne: .

Steps

- To create a direct attribute mapping, run the following.

```
dsconfig create-attribute-mapping \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name password \
  --type direct \
  --set from-attribute:userPassword
```

PingDataSync Server can synchronize passwords that have been encrypted by PingDirectory Server or a hashed version of the password, depending on how an administrator chooses to store passwords on PingDirectory Server.

- To sync passwords from a generic relational database management system (RDBMS), create a direct attribute mapping with the **from-attribute** being whichever attribute the RDBMS uses to store the password.

**Note:**

RDBMS passwords cannot be encrypted and should be hashed with a scheme that PingDirectory Server recognizes.

**Important:**

PingDataSync Server cannot synchronize passwords between PingOne systems because PingDataSync Server cannot retrieve passwords from PingOne.

Example:

In the following example, the RDBMS uses the `dbPassword` attribute to store the password.

```
dsconfig create-attribute-mapping \
--map-name Generic_RDBMS_to_PingOne_User_Map \
--mapping-name password \
--type direct \
--set from-attribute:dbPassword
```

Single sign-on with the PingDirectory Server administrative console

The OpenID Connect (OIDC) protocol enables single sign-on (SSO) with the PingDirectory Server administrative console using either PingOne or a custom authorization server.

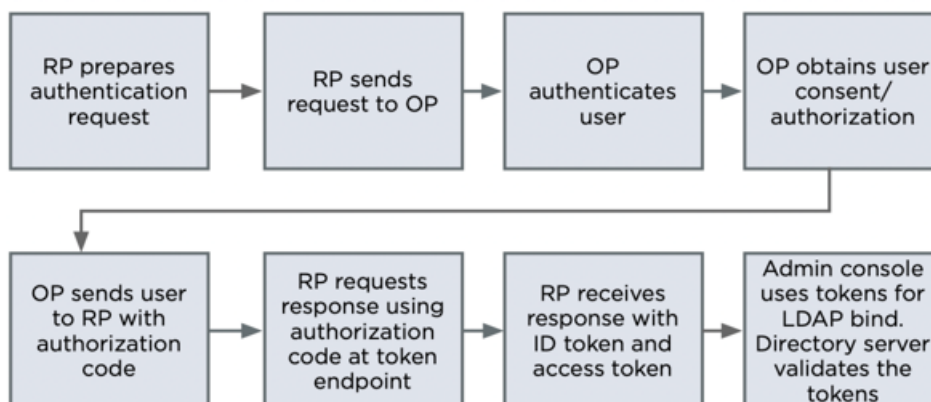

Overview of OpenID Connect

OIDC is a protocol that allows client applications (called relying parties or RPs) to confirm that a user is who they say they are by contacting an authorization server (called an OpenID Provider or OP).

The authorization code flow

The PingDirectory Server administrative console uses the authorization code flow implementation of the protocol.

The following is the basic authorization code flow where the PingDirectory Server administrative console acts as the RP in steps 1-7, the managed directory server acts as the RP in step 8, and PingOne or your custom authorization server acts as the OP.

1. The PingDirectory Server administrative console (RP) prepares an authentication request containing the desired request parameters.
2. The administrative console (RP) sends the request to the authorization server.
3. The authorization server (OP) authenticates the user.
4. The authorization server (OP) obtains user consent/authorization.
5. The authorization server (OP) sends the user back to the administrative console with an authorization code.
6. The administrative console (RP) requests a response using the authorization code at the token endpoint.
7. The administrative console (RP) receives a response that contains an ID token and access token in the response body.
8. The administrative console attempts to use the tokens to perform an LDAP bind with the directory server (RP) through the OAUTHBEARER SASL mechanism. While establishing this LDAP bind, the directory server (RP) validates the tokens.

Configuring OIDC with the PingDirectory Server administrative console

The authorization server must be configured with the following settings.

Configuration requirement	Description
An OIDC client with a client ID, client secret, and a Redirection URI.	<p>The client ID and client secret are used by the authorization server to confirm that the authentication and token requests are coming from a valid source.</p> <p>Set the redirection URI value to <code>https://<hostname>:<HTTPS_port>/console/oidc/cb</code>, where <code>https://<hostname>:<HTTPS_port>/console/</code> is where you access the console.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> Note:</p> <p>The redirection URI value is used by the authorization server in steps 3 and 5 when sending the end user back to the RP. If the value is incorrect, the authorization server displays an error.</p> </div>
The authorization server must be able to return an ID token that maps to a user on the managed PingDirectory server.	The <code>sub</code> field in the ID token must be mappable.

The PingDirectory Server administrative console must be configured with the following settings.

application.yml configuration name	Embedded console setting name	Settings required
PingData.SSO.OIDC.enabled	SSO Enabled	<p>true. Necessary for the console to start the OIDC login flow.</p> <div style="border: 1px solid black; padding: 5px;"> <p> Note: If SSO Enabled is set to false, the console asks for a username and password.</p> </div>
PingData.SSO.OIDC.issuerUri	OIDC Issuer URI	Allows the client to use OIDC discovery to determine the correct addresses to send the authentication request to in step 2 and the token request in step 6.
PingData.SSO.OIDC.clientID	OIDC Client ID	Value obtained from the authorization server. This is sent in the authentication request in step 2.
PingData.SSO.OIDC.clientSecret	OIDC Client Secret	Value obtained from the authorization server. This is sent in the token request in step 6.
ldap.server	LDAP Server	<p>Set to the managed PingDirectory server's hostname and LDAPS port.</p> <p>Used in step 8 when the administrative console attempts to perform an LDAP bind to the managed PingDirectory server using the OAUTHBEARER SASL mechanism.</p>

The managed PingDirectory server must be configured with the ability to accept LDAPS connections and with the following additional configuration properties.

Configuration requirement	Description
A configured ID token validator	<p>For PingOne SSO: the PingOne ID token validator.</p> <p>For general OIDC provider SSO: the OpenID Connect ID token validator.</p> <div style="border: 1px solid black; padding: 5px;"> <p> Note: The ID token validator must be configured with an identity mapper that is able to map the sub value in the token to an LDAP user on the server.</p> </div>

Configuration requirement	Description
A configured OAUTHBEARER SASL mechanism	<p>Set the mechanism's ID token validator configuration property to the previously configured OIDC ID token validator.</p> <p> Note:</p> <p>The OAUTHBEARER SASL mechanism is used in step 8 when the PingDirectory server processes the LDAP bind.</p>

Setting up SSO to the PingDirectory administrative console

To set up SSO using PingOne, see [Setting up SSO to PingDirectory from PingOne](#) on page 259.

To set up SSO using a generic OP, see [Setting up SSO to PingDirectory from a generic OpenID Connect provider](#) on page 264.

Setting up SSO to PingDirectory from PingOne

To set up single sign-on (SSO) access from the administrative console home page to PingDirectory, configure PingOne and test the sign-on experience.

Before you begin

Ensure that you have:

- A PingDirectory server that accepts LDAPS connections
 - This server will host the admin console that is being configured for SSO.
- A PingOne account
 - For more information, see [Getting Started with PingOne](#).

Tip:

You can use groups to organize user identities, as explained in [Groups](#). You can also set access to applications, as explained in [Application access control](#).

About this task

During this setup:

- Step 2 sets up a matching user between PingOne and the PingDirectory environments that allows the server's `All Admin Users` identity mapper to map the PingOne ID token to a Directory Server LDAP user.
- Steps 3-8 set up the OpenID Connect (OIDC) client as described in [Single sign-on with the PingDirectory Server administrative console](#) on page 256.
- Steps 9-11 configure both the administrative console's configuration requirements (except for the `ldap.server` property) and the PingDirectory server's configuration requirements.

Note:

These configuration properties are outlined in more detail in [Single sign-on with the PingDirectory Server administrative console](#) on page 256.

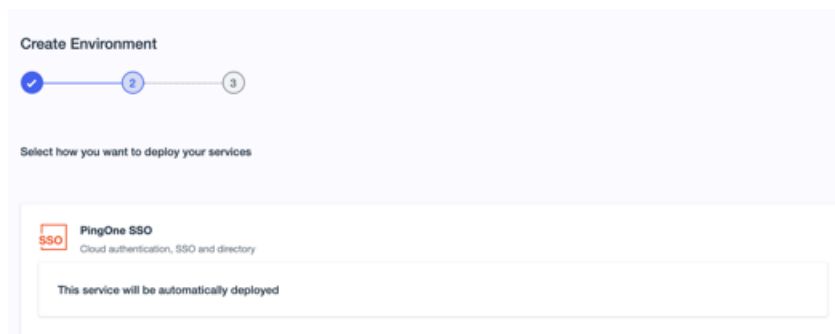

To set up SSO to the PingDirectory administrative console from PingOne:

Steps

1. From the admin console home page, add PingOne and PingDirectory:
Choose from:

- To add a new environment for PingOne SSO and PingDirectory:
 - a. On the PingOne console home page, click **Add Environment**.
 - b. Select **Customer solution**, and then click **Next**.
 - c. Click **Next**.
 - d. Enter an **Environment Name** and **Description**, then in the labeled lists, select an **Environment Type, Region, and License**.
 - e. Click **Finish**.

PingOne SSO, PingOne Risk, PingOne Verify, and PingOne MFA are automatically deployed.

- f. On the PingOne console home page, in the **Your Environments** list, select your new environment, and then click the **+** icon.
- g. Click **Add** next to **PingDirectory**.

**Note:**

Services that have been already added have a green **check mark** icon next to the service name instead of **+ Add**.

- h. Click **Finish**.
- To add PingOne SSO and PingDirectory to an existing environment:
 - a. On the PingOne console home page, in the **Your Environments** list, select the environment, and then click the **+** icon.
 - b. Click **Add** next to **PingOne SSO** and **PingDirectory**.

**Note:**

Services that have been already added have a green **check mark** icon next to the service name instead of **+ Add**.

- c. Click **Finish**.
- a. Click **Add Admin UI Link**, and in the **Enter Admin URL** field, enter `https://<hostname>:<port>/console/login`, replacing the bracketed variables with the PingDirectory server's hostname and HTTP port.

**Tip:**

You can specify the LDAP server to bind to using the query parameters `ldap-hostname` and `ldaps-port` when the administrative console is configured for SSO. By binding to the LDAP server, you can use a single console instance to administer multiple PingDirectory servers. An

LDAPS scheme is always assumed because an encrypted connection is always required for SSO. Using these parameters, you can specify the URL as follows.

```
https://<hostname>:<port>/console?ldap-hostname=<my-ldap-host>&ldaps-port=<my-ldaps-port>
```

- b. Click **Save**.
2. To configure the matching administrator accounts for PingOne and the PingDirectory server, go to the PingOne dashboard for the environment that will be used with the PingDirectory server and repeat the following steps for each PingOne user for whom you want to enable SSO:
 - a. On the admin console home page, select the appropriate environment and click the **PingOne** icon.
 - b. In PingOne, go to **Identities**.
 - c. Select the administrative user you want to configure and click the **Expand** icon.
 - d. Run the following **dsconfig** command and replace the bracketed fields with the values of the administrative user.

```
~/<pd_install>/dsconfig create-root-dn-user --user-name <Username> \
--set first-name:<Given Name> \
--set last-name:<Family Name>
```

3. Register the admin console with PingOne.
 - a. Go to [Add an application - Web application](#) and follow the instructions in the **Add an OIDC application** subsection.
 - b. Enter the application properties, as shown in this table.

Property	Value
Application Name	PingDirectory Administrative Console
Description	Application for the PingDirectory Administrative Console
Redirect URLs	https://<hostname>:<port>/console/oidc/cb
	<div style="border: 1px solid #ccc; padding: 5px;"> <p> Note:</p> <p>Replace the bracketed values in Redirect URLs with your PingDirectory server's hostname and HTTP port. To find the port, run the status command from the <code>bin</code> directory.</p> <pre>0.0.0.0:11443 : HTTPS : Enabled : HTTPS Connection Handler</pre> </div>
Attribute Mapping	'Username' = 'sub'

 **Note:**

No OIDC scopes are required for PingOne to grant access to the PingDirectory console.

4. Select the newly-created **PingDirectory Administrative Console** application in the **Applications** list, and go to the **Configuration** tab.

- To edit the listed configuration properties, click the **Pencil** icon.

Edit the configuration properties using the values in this table.

Property	Value
Response Type	Select the Code check box.
Grant Type	Select the Authorization Code check box.
Token Endpoint Authentication Method	Click Client Secret Basic .

Note:

For more information about updating the properties of your new application, see [Edit an application - OIDC](#) in the *PingOne Administration Guide*.

- Click **Save**.
- Click the toggle to enable user access to the application.
- On the **Configuration** tab, record the values for these application properties to use in step 10:
 - Issuer**
 - Client ID**
 - Client Secret**
- Create a copy of the `PingDirectory/config/sample-dsconfig-batch-files/enable-pingone-admin-console-sso.dsconfig` file, leaving the source file as-is.
- Open the copy of the file and replace the bracketed values with the values from step 8.

```
# Create an ID token validator suitable for verifying ID tokens generated
# by the PingOne service. The "All Admin Users" identity mapper will be
# used
# to match users that authenticate with PingOne to either root DN users
# or
# topology admin users defined in the server configuration.
dsconfig create-id-token-validator \
--validator-name "PingOne ID Token Validator" \
--type ping-one \
--set enabled:true \
--set "identity-mapper:All Admin Users" \
--set evaluation-order-index:1 \
--set issuer-url:[PING_ONE_APPLICATION_ISSUER_URL]

[...]

# Configure the Administrative Console with your application's client
# credentials and issuer URI.
dsconfig set-web-application-extension-prop \
--extension-name Console \
--set sso-enabled:true \
--set oidc-client-id:[PING_ONE_APPLICATION_CLIENT_ID] \
--set oidc-client-secret:[PING_ONE_APPLICATION_CLIENT_SECRET] \
--set oidc-issuer-url:[PING_ONE_APPLICATION_ISSUER_URL]
```

- Run the file using the following command.

```
dsconfig --batch-file \
  enable-pingone-admin-console-sso-copy.dsconfig \
  --no-prompt
```

12. Select the link to the PingDirectory server from the PingOne solutions home page.

Result:

A PingOne sign-on page opens.

13. Sign on using the administrative user credentials.

Result:

The PingDirectory Server administrative console home page opens.

Setting up SSO to PingDirectory from a generic OpenID Connect provider

To set up single sign-on (SSO) access to the PingDirectory administrative console from your OpenID Connect (OIDC) provider, configure the OIDC provider and PingDirectory and test the sign-on experience.

Before you begin

Ensure that you have:

- A PingDirectory server that accepts LDAPS connections
 - This server will host the administrative console that is being configured for SSO.
- An OIDC provider that supports OIDC discovery

About this task

For more information on the configuration properties you are setting up with this task, see [Single sign-on with the PingDirectory Server administrative console](#) on page 256.

Steps

1. Configure your OIDC provider to access the PingDirectory administrative console:
 - a. Set the redirect URL to `https://<hostname>:<port>/console/oidc/cb` where `<hostname>` and `<port>` are for the PingDirectory server.
 - b. Set the JSON web token (JWT) signing algorithm.
 - c. Record the client ID, client secret, and issuer URL for use in step 5.
2. Create a token validator on the PingDirectory server by running a command similar to the following.

Example:

```
dsconfig create-id-token-validator \
  --validator-name "OpenID Token Validator" \
  --type openid-connect \
  --set enabled:true \
  --set "identity-mapper:All Admin Users" \
  --set evaluation-order-index:1 \
  --set issuer-url:<OIDC_Provider_Issuer_URL> \
  --set allowed-signing-algorithm:<JWT_signing_algorithm>
```

Provide your own values for `<OIDC_Provider_Issuer_URL>` and `<JWT_signing_algorithm>`, where the algorithm is the one you set in the previous step.

Although not shown in the example, the command must also set the properties in one of the rows in the following table.

Properties	Descriptions
<code>openid-connect-provider</code> and <code>jwt-keyset-endpoint-path</code>	An OpenID Connect provider, which refers to an HTTP External Server, and a JWKS (JSON web key set) endpoint path

Properties	Descriptions
signing-certificate	A signing certificate

- To create an LDAP user in `cn=Root DNs, cn=config` that the OIDC provider can send an ID token for, use the following `dsconfig` command.

If, in the previous step, you use the `All Admin Users` identity mapper and the ID token validator's `subject-claim-name` is `sub` (the default), then the `sub` value of the ID token that the OIDC provider sends must be the `cn` of an admin user on the PingDirectory server. For example, assume the OIDC provider sends an ID token with the claim `sub=admin-user`. Then, there must be an LDAP user in `cn=Root DNs, cn=config` or in `cn=Topology Admin Users, cn=topology, cn=config` who has `cn=admin-user`.

```
dsconfig create-root-dn-user --user-name admin-user
```

- Create a SASL mechanism handler on the PingDirectory server to use the validator you just created by running a command similar to the following.

Example:

```
dsconfig create-sasl-mechanism-handler \
  --handler-name OAUTHBEARER \
  --type oauth-bearer \
  --set enabled:true \
  --set "id-token-validator:OpenID Token Validator" \
  --set require-both-access-token-and-id-token:false
```

- Run the following command, substituting values for the ID, secret, and issuer URL.

```
dsconfig set-web-application-extension-prop \
  --extension-name Console \
  --set sso-enabled:true \
  --set oidc-client-id:<OIDC_Client_ID> \
  --set oidc-client-secret:<OIDC_Client_Secret> \
  --set oidc-issuer-url:<OIDC_Provider_Issuer_URL>
```

- To finalize your changes, disable and re-enable the HTTPS Connection Handlers with the following commands.

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:false

dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true
```

- Test the sign on.

Result:

The administrative console should open.

Configuring Soft Deletes

PingDirectory Server 3.2.4 and later supports a soft-delete feature.

This feature preserves a deleted entry's attribute and uniqueness characteristics so it can be undeleted or permanently removed at a later date.

About soft deletes

Soft deletes preserve a deleted entry's attribute and uniqueness characteristics so it can be undeleted or permanently removed at a later date.

The standard implementation of an LDAP server allows adding, renaming, modifying, searching, comparing, and deleting one or more entries. By specification, the `delete` operation permanently removes an entry and its attributes in a Directory Information Tree (DIT) but records the changes in access, and optionally, audit and change logs. The `delete` operation severs any associations such as references and group memberships. Meta attributes, such as operational attributes, which can be unique to an entry like `entryUUID`, are lost or different if the same entry is re-added to the Directory Server.

There are cases where a company might want to preserve their deleted entries to allow for possible undeletion at a later date. For example, a company might want to retain account and subscriber entries for their users who leave but later rejoin. Artifacts that a user creates such as account histories, web pages, notes, can be tracked and recovered while a user is deleted or when the user returns as an active customer. Soft deletes facilitate this use-case.

A delete request can result in a soft delete either by the client explicitly requesting a soft delete or by the request matching criteria defined in an active soft delete policy. The soft-deleted entries are renamed by prefixing an `entryUUID` operational attribute to the DN and adding an auxiliary object class to the entry, `ds-soft-delete-entry`, which saves the entry in a hidden state. All active references and group memberships are then removed. While in this hidden state, clients cannot access soft-deleted entries under normal operating conditions. Only clients with the `soft-delete-read` privilege can interact with soft-deleted entries.

To allow soft deletes, the Directory Server's attribute uniqueness function has been relaxed to allow for the co-existence of a soft-deleted entry and an active entry with identical naming attributes, such as `uid`. For example, if a user John Smith was soft deleted, but a different John Smith was added to the user accounts system, both entries can reside in the DIT without conflict. One entry would exist in a soft-deleted state and the other in an active state. The Directory Server extends this capability by allowing multiple users with the same DN, who would normally conflict if active, to reside in the soft-deleted state.

Soft-deleted entries can be restored with an `undelete` operation. The same uniqueness constraints that apply when adding a new user to the Directory Server are enforced when a soft-deleted entry is undeleted. In the previous example, John Smith was soft-deleted, but a different John Smith with the same `uid` as the original John Smith was later added to the system. If the original John Smith was undeleted from its soft-deleted state, it would result in a conflict with the active John Smith entry. Administrators must modify the DN of the soft-deleted entry to avoid such conflicts.

Administrators can permanently remove a soft-deleted entry by performing a regular `delete` operation on it. This operation, called a hard delete, permanently removes a soft-deleted entry from the server. You can also permanently remove a regular non-soft-deleted entry using a hard delete. This is useful when the server is configured with a soft-delete policy that would otherwise turn a regular delete request into a soft delete.

The Directory Server provides tool arguments that can use the soft delete request control, the hard delete request control, and other controls necessary to process these operations. Procedures to show how to use these options are presented later in this section.

For replicated topologies, when a participating directory server soft deletes an entry, it notifies the other replicas in the topology to soft delete the same entry on its respective machine. The changelog backend also records these entries by annotating them using an attribute that indicates its soft-deleted state. Modification and hard deletes of soft-deleted entries are not recorded by default in the changelog but can be enabled in the server. For maximum compatibility, make sure all servers in the replication cluster support soft deletes and have identical soft delete configurations.

General tips on soft deletes

Administrators should be aware of the following tips about soft deletes:

- The LDAP SDK and Server SDK both fully support soft-deletes.

- There is little performance difference between retrieving a regular entry and a soft-deleted entry. However, there might be a performance impact when a search operation has to match criteria, such as `uid=john.smith`, for both active entries and soft-deleted entries. For example, if there is one active `uid=john.smith` entry and two soft-deleted `uid=john.smith` entries, it might take the server more time to retrieve and try to match the criteria before it can return the results.
- The soft delete feature fully supports uncached attributes and uncached entries. For more information, see [Uncached Attributes and Entries](#).
- Soft-deletion is allowed for leaf nodes only. Soft-deletion of any parent entry is not allowed. Likewise, soft-deleted entries that have soft-deleted sub-entries are not allowed.
- There are two available state options for soft-deletes:
 - Administrators can permanently delete a soft-deleted entry or undelete the entry.
 - Administrators cannot soft-delete an already soft-deleted entry, which returns an `UNWILLING_TO_PERFORM` result code.
- Soft-deleted users have no privileges. Soft-deleted users do not have the ability to bind to the Directory Server or have authentication access. They cannot change their passwords and cannot undelete themselves. Soft-deleted entries also cannot be used as an authorization identity using the proxied authorization or immediate client control. The soft-delete process does not destroy privilege assignment. If a soft-deleted entry is undeleted, the restored entry retains the same privileges it originally had before being soft deleted. One possible exception to this are privileges assigned by virtual attributes that no longer match the newly-undeleted entry. Those entries do not retain their original privileges.
- Soft-deleted entries might not be accessible from alternate access methods like SCIM.
- Soft-deleted entries can be modified but not renamed. Administrators can search for all soft-deleted entries and the original source entry attributes can be updated as long as the administrator has modify privileges and access to the `soft-delete-read` privilege. Any attempt to rename a soft-deleted entry using a `modify DN` operation results in an `UNWILLING_TO_PERFORM` result code.
- Replication has access to the LDAP operations with soft delete controls. These operations are transmitted, processed, and replayed as high-level requests, which are re-played on remote replicated servers. The replication conflict-resolution mechanism handles soft-deleted entries like any regular entries. For example, if a soft delete is executed independently on two servers and is then replicated, this results in a replication conflict. For maximum compatibility, all servers in a replication cluster should support soft deletes and have identical soft delete configuration.
- Soft-deletes are supported in transactions. The processing workflow uses the transactions mechanism and maintains the context information necessary to rollback failures to soft delete or undelete.
- There are no special configuration steps to configure soft deletes on the Directory Proxy Server. The soft-deleted entry is routed directly to the underlying Directory Server. There is one exception: in an entry-balancing deployment, the Directory Proxy Server is responsible for routing the soft-deleted entry to the Directory Server containing the originally soft-deleted item. As with standard entry-balanced deployments, it is not possible to use `moddn` to undelete an entry to a different Directory Server.
- The default behavior includes soft-deleted entries as part of the `export-ldif` operation. If soft-deleted entries are to be excluded from export, administrators can use the `--excludeSoftDeleteEntries` option to filter out the entries.
- The soft delete feature can be used with users who have proxied authorization privileges.
- For customers using the PingDataSync Server, soft-deleted entries are not synchronized by the server. Modifications or deletes of a soft-deleted entry are ignored by the Data Sync Server, and do not appear in the changelog by default. An actual soft delete operation appears to the changelog as a regular `delete` operation, and an actual undelete operation appears in the changelog as a regular `add` operation.
- References to a deleted DN are not restored by the referential integrity plugin when you undelete a soft-deleted entry. For example, if you have referential integrity enabled and you soft-delete a DN that is a member of a static group, the referential integrity plugin removes this DN from the group's list of members. When you undelete the soft-deleted entry, the plugin does not add the entry back to the group.

- The soft delete policy configuration supports two new properties, `soft-delete-retention-time` and `soft-delete-retain-number-of-entries`, that perform the purging of soft-deleted entries. For more information, see [Configuring Soft-Delete Automatic Purging](#).
- The root user account, such as `cn=Directory Manager`, has access to all of the controls needed to run the soft delete operations by default. For non-root users, you must grant access to these soft delete controls using access control rules. An example is shown in step 1 of [To Configure Soft Deletes as a Global Configuration](#). The following soft delete controls are available to non-root users:

Soft delete request control

Allows the user to perform a soft delete operation. The object identifier (OID) for the control is 1.3.6.1.4.1.30221.2.5.20.

Soft delete response control

Allows the server to hold the DN of the soft-deleted entry that results from a soft delete request. The OID for the control is 1.3.6.1.4.1.30221.2.5.21.

Hard delete request control

Allows the user to run a hard delete operation on the entry, regardless if it is a regular or soft-deleted entry. The OID for the control is 1.3.6.1.4.1.30221.2.5.22.

Undelete request control

Allows the user to undelete a soft-deleted entry using an ADD request. The OID for this control is 1.3.6.1.4.1.30221.2.5.23.

Soft-deleted entry access request control

Allows the user to search for any soft-deleted entries. The OID for this control is 1.3.6.1.4.1.30221.2.5.24.

Note:

A bind DN with the `stream-values` privilege can perform operations that can reveal soft-deleted entries, even if that bind DN does not have permission to use the soft-deleted entry access request control. For example, if a user can successfully run `dump-dns` or `ldap-diff`, then that user can get a list of soft-deleted entry DNs or soft-deleted entry contents through the output of one of those tools.

Configuring soft deletes on the Server

Steps

- Use any of the following methods to configure soft deletes on the Directory Server.

Method	Description
Using a soft-delete policy and global configuration property	Configure soft deletes by creating a soft-delete policy and a global configuration property. The soft-delete policy enables the feature on the server, while the global configuration property sets the controls used for the soft-delete requests. To enter a soft delete request, the <code>ldapmodify</code> or <code>ldapdelete</code> command requires the <code>--useSoftDelete</code> option. A delete request that does not have the <code>--useSoftDelete</code> option is treated as a hard delete, which permanently removes the entry.

Method	Description
	For more information, see Configuring soft deletes as a global configuration on page 269.
Using connection criteria	<p>Configure soft deletes by defining connection criteria within a client connection policy. Any clients that meet the criteria have their deletes processed as soft deletes.</p> <p>For more information, see Configuring soft deletes by connection criteria on page 277.</p>
Using request criteria	<p>Configure soft deletes by defining request criteria within a client connection policy. Any client requests that meet the criteria have their deletes processed as soft deletes.</p> <p>For more information, see Configuring soft deletes by request criteria on page 278.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> Note:</p> <p>You can define both connection criteria and request criteria. When both criteria exist within a soft-delete policy, connection criteria is processed first, then request criteria.</p> </div>

Configuring soft deletes as a global configuration

Configure the soft delete feature by creating a soft delete policy and then setting the configuration property on the server. The presence of the soft-delete policy enables the feature on the server and allows the global configuration property to send the necessary soft delete requests.

About this task

For this configuration, use the `--useSoftDelete` option used with the `ldapmodify` or `ldapdelete` commands to send the delete using the soft delete request control. Without the `--useSoftDelete` option, any delete is processed as a hard delete.

To configure soft deletes as a global configuration:

Steps

1. Configure a soft delete policy using the `dsconfig` command.

The soft delete configuration requires a soft delete policy, which enables the feature on the server.

Example:

```
$ bin/dsconfig create-soft-delete-policy \
  --policy-name default-soft-delete-policy
```

2. Configure the soft delete as a global configuration property using the `dsconfig` command.

This command sets up the soft delete controls necessary to send them as a request.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
```

```
--set soft-delete-policy:default-soft-delete-policy
```

Configuring a user to use soft or hard delete controls

To use soft deletes, a user must have access to the appropriate controls. By default, only the Directory Manager has access to these controls.

About this task

The user must also have the `soft-delete-read` privilege. Access control instructions (ACIs) allow the user to:

- Modify target entries
- Use the soft delete and undelete controls
- Use the soft-deleted entry access control to modify soft-deleted entries
- Use the hard delete request control to permanently delete an soft-deleted entry

The `uid=admin,dc=example,dc=com` user that is installed with the sample data during setup already has an ACI giving it access to user entries as follows.

```
(targetattr="*")(version 3.0; acl "Grant full access for the admin user";
allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

Steps

1. Add the following ACIs to the base suffix or other point in the directory information tree (DIT) to restrict the scope as required.

Example:

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.21")
(version 3.0; acl "Allow admins to use the Soft Delete Request Control and
Soft Delete Response Control";
allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.22") (version 3.0; acl "Allow admins
to use the Hard Delete
Request Control";allow (read) userdn="ldap:///
uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.23") (version 3.0; acl "Allow admins
to use the Undelete
Request Control";allow (read) userdn="ldap:///
uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.24") (version 3.0; acl "Allow admins
to use the Soft-Deleted
Entry Access RequestControl"; allow (read) userdn="ldap:///
uid=admin,dc=example,dc=com";)
```

2. Add the `ds-privilege-name` attribute to the user with the value `soft-delete-read`.

Example:

```
$ ./bin/ldapmodify -s -p 1389 -D uid=admin,dc=example,dc=com -w password
# Successfully connected to localhost:1389.

dn: uid=user.10,ou=people,dc=example,dc=com
changetype: delete

# Deleting entry uid=user.10,ou=people,dc=example,dc=com ...
# Result Code: 0 (success)
# Soft Delete Response Control:
#     OID: 1.3.6.1.4.1.30221.2.5.21
```

```
# Soft-Deleted Entry DN: entryUUID=8dbe8cb4-1aa3-41c5-88ec-
a6280eeff918+uid=user.10,ou=People,dc=example,dc=com
```

Searching for soft deletes

Soft-deleted entries are excluded from normal LDAP searches because they represent deleted entries. The updated `ldapsearch` tool supports these types of searches.

About this task

There are three different ways to search for soft-deleted entries.

Steps

- To perform a base-level search on a soft-deleted entry by distinguished name (DN), run the `ldapsearch` command and specify the base DN of the specific soft-deleted entry that you are searching for.
- To filter your search by `ds-soft-delete-entry` object class, run a search for all soft-deleted entries with the `ldapsearch` command with a filter on the `ds-soft-delete-entry` object class.
- To return soft-deleted entries, use the `soft-delete-entry-access-control` with the LDAP search.

The `ldapsearch` tool provides a shortcut option, `--includeSoftDeletedEntries`, that sends the control to the server for processing. The control allows for the following search possibilities:

- Return only soft-deleted entries.
- Return non-deleted entries along with soft-deleted entries.
- Return only soft-deleted entries in undeleted form.

Running a base-level search on a soft-deleted entry

Use the command line to run a base-level search on a soft-deleted entry.

Steps

- Run the `ldapsearch` command using the base distinguished name (DN) of the specified soft-deleted entry.

Example:

```
$ bin/ldapsearch \
  --baseDN entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com \
  --searchScope base "(objectClass=*)"
```

Result:

```
# Soft-deleted entry DN:
# entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-soft-delete-entry
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239

st: TN

```

Running a filtered search by soft-delete-entry object class

Retrieve all soft-deleted entries using the `ds-soft-delete-entry` object class.

Steps

- Run the `ldapsearch` command to retrieve all soft-deleted entries using the `ds-soft-delete-entry` object class.

Example:

```

$ bin/ldapsearch --baseDN dc=example,dc=com \
  "(objectclass=ds-soft-delete-entry)"

```

Running a search using the soft delete entry access control

The following examples use the `--includeSoftDeleteEntries {with-non-deleted-entries | without-non-deleted-entries | deleted-entries-in-undeleted-form}` option, which uses the soft delete entry access control.

About this task

You can use the `--control` option with the soft delete entry access control symbolic name, `softdeleteentryaccess`, or the `--control` option with the actual soft delete entry access control OID, `1.3.6.1.4.1.30221.2.5.24`.

Steps

- To return only soft-deleted entries, run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `without-non-deleted-entries`.

Example:

```

$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries without-non-deleted-entries \
  --searchScope sub "(objectclass=*)"

```

- To return non-deleted entries along with soft-deleted entries, run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `with-non-deleted-entries`.

Example:

```

$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries with-non-deleted-entries \
  --searchScope sub "(objectclass=*)"

```

- To return only soft-deleted entries in undeleted form, run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `deleted-entries-in-undeleted-form`.

Some applications require access to all entries in the server, including both active and soft-deleted entries.

Example:

The following command returns all entries that were soft-deleted but presents it in a form that is similar to a regular entry with the soft-delete DN in comments. This regular entry format does not show the actual soft-deleted DN but displays it in an "undeleted" form even though it is not actually "undeleted". The object class, `ds-soft-delete-entry`, is also not displayed.

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries deleted-entries-in-undeleted-form \
  --searchScope sub "(ds-soft-delete-from-dn=*)"

# Soft-deleted entry DN:
# entryUUID=2b5511e2-7616-389b-ab0c-025c805ad32c
+uid=user.14,ou=People,dc=exam-
ple,dc=com
dn: uid=user.14,ou=People,dc=example,dc=com

```

Undeleting a soft-deleted entry using the same RDN

When you decide to undelete a soft-deleted entry, if the original Relative Distinguished Name (RDN), such as `uid=user.1`, is still available, you can perform the undelete using that same RDN.

About this task

To undelete a soft-deleted entry, use `ldapmodify` with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore. In an LDIF file or from the command line, specify the `dn:<target entry>` attribute, which is the distinguished name (DN) that the entry is undeleted to, and the `ds-undelete-from-dn` attribute, which is the entry that is undeleted from. An undelete requires the `add changetype` so that the entry can be re-added to the server.

Steps

- To undelete a soft-deleted entry using the same RDN, run the command `ldapmodify` with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore.

Example:

The first DN is the entry to undelete to and the `ds-undelete-from-dn` is the soft-delete entry to undelete from.

```
$ bin/ldapmodify --allowUndelete
dn: uid=user.1,ou=People,dc=example,dc=com
changetype:add
ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

Result: The `--allowUndelete` option sends the soft undelete request control to the server.

Undeleting a soft-deleted entry using a new RDN

In some cases, you can allocate the original Relative Distinguished Name (RDN), `uid=user.1`, to a new user. This is permitted when the entry is in a soft-deleted state. To properly undelete this entry, you must specify a new RDN value you can use to restore the entry.

About this task

In this case, specifying the RDN of `uid=user.5` undeletes the original entry, but with the new distinguished name (DN) in the following example, and the `uid` attribute on the entry is updated with the new value of `user.5`. All other attributes of the users entry, including the `entryUUID`, remain unchanged.

To undelete a soft-deleted-entry using a new RDN:

Steps

- Run the command `ldapmodify` to undelete a soft-deleted entry that has an original RDN, `uid=user.1`, to a new RDN, `uid=user.5`.

Note:

If you specify a DN that already exists in the Directory Server as a normal entry, this leads to an `entry already exists` error. Ensure the DN that you are undeleting the entry to does not already exist.

Example:

```
$ bin/ldapmodify --allowUndelete
dn: uid=user.5,ou=People,dc=example,dc=com
changetype:add
ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

- To view the results, run `ldapsearch`.

Example:

```
dn: uid=user.5,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239
postalCode: 66239
```

```

description: This is the description for Aartjan Aalders.
uid: user.5
userPassword: {SSHA}RdBCwQ2kIw57LukRthjrFBS/oFylJARnmTnorA==
employeeNumber: 1
initials: AKA
givenName: Aartjan
pager: +1 197 025 3730
mobile: +1 890 430 9077
cn: Aartjan Aalders
sn: Aalders
telephoneNumber: +1 094 100 7524
street: 59748 Willow Street
homePhone: +1 332 432 4295
l: Green Bay
mail: user.3@maildomain.net
st: TN
entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4

```

Result: The RDN and the `uid` attribute has changed.

Modifying a soft-deleted entry

Modify a soft-deleted entry the same as a regular entry using the `ldapmodify` tool. The entry remains hidden in its soft-deleted state after the change.

About this task

Soft-deleted entries can be modified like any regular entry. The only restriction is that you cannot change the distinguished name (DN) or run a `moddn` operation. To move a soft-deleted entry from one machine to another, use the `move-subtree` command and specify the DN of the soft-deleted entry. For more information, see [To Move an Entry from One Machine to Another](#).

Note:

To modify a soft-deleted entry, the user needs the `soft-delete-read` privilege to access the soft-deleted entry.

Steps

- To modify a soft-deleted entry, run the `ldapmodify` command and specify the soft-deleted DN.

Example:

```

$ bin/ldapmodify
dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 390 103 6918
# Processing MODIFY request for entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
# MODIFY operation successful for DN entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com

```

Hard deleting a soft-deleted entry

Use this section for instructions on hard deleting a soft-deleted entry from the server when soft-deleted entries are configured as global configuration for requests or configured using a connection or request criteria.

About this task

Consider the following when hard deleting a soft-deleted entry:

Steps

- To permanently remove a soft-deleted entry from the server, run `ldapdelete` on the soft-deleted entry for soft-deleted entries.
- To hard delete a soft-deleted entry, use `ldapdelete` with the `--useHardDelete` option.

The Hard Delete Request Control works with soft deletes. It applies when soft delete policies are in place as a means to override soft deletes requests. If soft deletes are configured, running `ldapdelete` with the Hard Delete Request Control, such as using the `--useHardDelete` option, guarantees that any entry permanently deletes.

Hard deleting a soft-deleted entry (global configuration)

About this task

Permanently remove a soft-deleted entry from the Directory Server.

Steps

- To permanently remove a soft-deleted entry, run `ldapdelete` on the soft-deleted entry.

Example:

The following example assumes that you configured soft deletes as a global configuration for requests.

```
$ bin/ldapdelete \
  entryUUID=4e9b7847-edcb-3791-
  b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com

Processing DELETE request for entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
DELETE operation successful for DN entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

Note:

You cannot soft-delete an already soft-deleted entry. If you use the `--useSoftDelete` subcommand with the `ldapdelete` operation on a soft-deleted entry, an error message generates.

```
DELETE operation failed. Result Code: 53 (Unwilling to Perform) Diagnostic
Message: DELETE operation failed.
```

Hard deleting a soft-deleted entry (connection or request criteria)

About this task

Permanently remove a soft-deleted entry from the Directory Server.

Steps

- To permanently remove a soft-deleted entry run `ldapdelete` with the `--useHardDelete` subcommand on the soft-deleted entry.

Example:

The following example assumes that you configured soft deletes using a connection or request criteria.

```
$ bin/ldapdelete --useHardDelete \
  entryUUID=4e9b7847-edcb-3791-
  b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

Configuring soft deletes by connection criteria

Use this section for instructions on enabling and disabling soft deletes with connection criteria.

The Directory Server supports soft deletes where any delete operation is treated as a soft-delete request as long as the LDAP client meets the connection criteria.

To configure soft deletes:

- Define the connection criteria used in a client connection policy.
- Configure the soft delete connection criteria in the soft-delete policy.

Enabling soft deletes by connection criteria

Before you begin

Configure a soft-delete policy and global configuration, as shown in [Configuring Soft Deletes as a Global Configuration](#).

Steps

1. Create a connection criteria using `dsconfig` and name it `Internal Applications`.

Example:

In the following example the soft delete connection criteria is configured for a member of a line of business (LOB) applications group connecting from the 10.8.1.0 network.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Internal Applications" \
  --type simple \
  --set included-client-address:10.8.1.0/8 \
  --set "all-included-user-group-dn:cn=LOB
  Applications,ou=Groups,dc=example,dc=com"
```

2. Set the `auto-soft-delete-connection-criteria` property to the soft-delete connection criteria you created in step 1.

Example:

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set "auto-soft-delete-connection-criteria:Internal Applications"
```

Disabling soft deletes by connection criteria

About this task

Disable soft deletes by connection criteria.

Steps

- Reset the `auto-soft-delete-connection-criteria` property on the soft-delete policy.

Example:

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset auto-soft-delete-connection-criteria
```

Configuring soft deletes by request criteria

Soft deletes can be configured using request criteria within a client connection policy. All delete requests that meet the request criteria are treated as a soft delete.

The presence of a soft delete by connection criteria is exclusive of the soft delete by request criteria.

Note:

Both a soft delete by connection criteria and a soft delete by request criteria can be present in a soft delete policy.

Enabling soft deletes by request criteria

Before you begin

[Configure a soft-delete policy and global configuration.](#)

Steps

- To configure request criteria for soft deletes, use the `create-request-criteria` option with `dsconfig`.

Example:

In this example, the soft delete request criteria is configured for an external delete request from a member of the internal applications group matching an entry with object class `inetorgperson` with the request excluding the Soft Delete Request Control and the Hard Delete Request Control.

```
$ bin/dsconfig create-request-criteria \
  --criteria-name "Soft Deletes" \
  --type simple \
  --set "description:Requests for soft delete" \
  --set operation-type:delete \
  --set operation-origin:external-request \
  --set "connection-criteria:Internal Applications" \
  --set not-all-included-request-control:1.3.6.1.4.1.30221.2.5.20 \
  --set "all-included-target-entry-filter:(objectClass=inetorgperson)"
```

- In the soft delete policy you previously created, set the `auto-soft-delete-connection-criteria` property to the simple criteria created in the previous step.

Example:

```
$ bin/dsconfig create-soft-delete-policy \
  --policy-name default-soft-delete-policy \
  --set "auto-soft-delete-request-criteria:Soft Deletes"
```

Disabling soft deletes by request criteria

Steps

- To disable soft deletes by request criteria, reset the soft delete policy.

Example:

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset auto-soft-delete-request-criteria
```

Configuring soft-delete automatic purging

By default, Directory Server retains soft-deleted entries indefinitely.

For companies that want to set up automatic purging of soft-deleted entries, the server provides two configurable properties on the soft delete policy: the maximum retention time for all soft-deleted entries and the retained number of soft-deleted entries.

Note:

These changes take effect without requiring a server restart.

Configuring soft-delete automatic purging

About this task

To enable automatic purging, you can change the retention time, the retained number of entries, or both. By default, both are set to an indefinite retention time and number of entries. The time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w), can be preceded by an integer to specify a quantity for that unit, such as "1 d", "52 w", etc.

Note:

After you configure the properties, the changes take effect immediately without the need for a server restart.

The server deletes all of the soft-deleted entries according to the policy in effect. If the policy is changed while entries are in the process of being deleted, the new policy takes effect after the in-process batch of entries is deleted and applies to any remaining soft-deleted entries going forward, according to the new policy.

Steps

1. To retrieve the name of the soft delete policy in effect, use the `get-global-configuration-prop` option with `dsconfig`.

Example:

In this example, the soft delete policy is called `default-soft-delete-policy`.

```
$ bin/dsconfig get-global-configuration-prop \
  --property soft-delete-policy
```

2. To set the retention time or retained number of soft-deleted entries, use the `set-soft-delete-policy-prop` option with **dsconfig**.

Example:

This example shows how to set the retention time for soft-deleted entries.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set "soft-delete-retention-time:52 w"
```

Example:

This example shows how to set the retained number of soft-deleted entries.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set soft-delete-retain-number-of-entries:1000000
```

3. If it has not been assigned yet, assign the soft delete policy to the global configuration.

Example:

This example assigns `default-soft-delete-policy` to the global configuration.

```
$ bin/dsconfig set-global-configuration-prop \
  --set soft-delete-policy:default-soft-delete-policy
```

Disabling soft-delete automatic purging

About this task

The change takes effect immediately without the need of a server restart. If the server is in the middle of an automatic soft-delete purging, it might continue to purge entries until the next time it evaluates the soft delete policy.

Steps

- To disable soft-delete automatic purging, use the `set-soft-delete-policy` option with **dsconfig**.
- To reset the soft delete policy properties that control automatic purging, use the `set-soft-delete-policy-prop` with **dsconfig**.

Example:

This example resets the `soft-delete-retention-time` and `soft-delete-retain-number-of-entries` properties.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset soft-delete-retention-time \
  --reset soft-delete-retain-number-of-entries
```

Soft and hard delete processes

See the following tables for the results of actions taken during the soft and hard delete processes.

If no automatic soft delete criteria is configured

The following table summarizes the resulting actions of a `DELETE` operation for soft deletes.

Action	Result
Delete	Performs a hard delete on the entry.
Delete with the Soft Delete Request Control	Performs a soft delete on the entry.
Delete of a soft-deleted entry	Performs a hard delete on the entry.
Delete of a soft-deleted entry with the Soft Delete Request Control	Not allowed. Generates an UNWILLING_TO_PERFORM error.
Delete with a Hard Delete Request Control	Performs a hard delete on the entry.
Delete of a soft-deleted entry with the Hard Delete Request Control.	Performs a hard delete on the entry.

If soft delete connection or request criteria is configured

The following table summarizes the resulting actions of a `DELETE` operation for soft deletes configured by connection criteria or request criteria.

Action	Result
Delete not matching criteria	Performs a hard delete on the entry.
Delete matching criteria	Performs a soft delete on the entry.
Delete of a soft-deleted entry not matching criteria	Performs a hard delete on the entry.
Delete of a soft-deleted entry matching criteria	Performs a hard delete on the entry.
Delete not matching criteria with the Hard Delete Request Control	Performs a hard delete on the entry.
Delete matching criteria with the Hard Delete Request Control	Performs a hard delete on the entry.
Delete with Soft and Hard Delete Request Controls	Not allowed. Generates an UNWILLING_TO_PERFORM error.

Soft delete controls and tool options

See the following tables for summaries of soft delete controls and tools.

Soft delete OIDs

The following table shows the OpenIDs (OIDs) for each soft delete control. The soft delete OIDs are defined in the LDAP SDK generated API documentation.

OID Type	OID
Soft Delete Request Control	1.3.6.1.4.1.30221.2.5.20
Soft Delete Response Control	1.3.6.1.4.1.30221.2.5.21
Hard Delete Request Control	1.3.6.1.4.1.30221.2.5.22
Soft Undelete Request Control	1.3.6.1.4.1.30221.2.5.23
Soft Delete Entry Access Control	1.3.6.1.4.1.30221.2.5.24

Soft delete tool options

The following table shows the new tool options available for the soft delete operations.

Operation	Options
ldapdelete / ldapmodify	<p>--useSoftDelete/-s. Process <code>DELETE</code> operations with the Soft Delete Request Control, whereby entries are renamed and hidden instead of being permanently deleted. The Directory Server must be configured to allow soft deletes.</p> <p> Note: Any entries in the LDIF file with the changetype of <code>delete</code> are processed as a soft-delete request.</p>
ldapdelet	<p>--useHardDelete. Process <code>DELETE</code> operations with the Hard Delete Request Control, which bypasses any soft delete policies and processes the delete request immediately without retaining the entry as a soft-deleted entry. The Directory Server must be configured to allow soft deletes.</p>

Operation	Options
ldapsearch	<p><code>--includeSoftDeletedEntries</code> {with-non-deleted-entries without-non-deleted-entries deleted-entries-in-undeleted-form}. Process search operations with the soft delete entry access control. Soft delete search options are as follows:</p> <p><code>with-non-deleted-entries</code></p> <p>Returns all entries matching the search criteria with the results, including non-deleted and soft-deleted entries.</p> <p><code>without-non-deleted-entries</code></p> <p>Returns only soft-deleted entries matching the search criteria.</p> <p><code>deleted-entries-in-undeleted-form</code></p> <p>Returns only soft-deleted entries matching the search criteria with the results returned in their undeleted entry form.</p> <p>Users must have access to the Soft Delete Entry Access Control to search for soft-deleted entries.</p>
ldapmodify	<p><code>--allowUndelete</code>. Process ADD operations, which include the <code>ds-undelete-from-dn</code> attribute as undelete requests. Undelete requests re-add previously soft-deleted entries back to the server as non-deleted entries by providing the Undelete Request Control with the ADD operation. The Directory Server must be configured to allow soft deletes to process any undelete requests and the client user must have the <code>soft-delete-read</code> privilege.</p>

Soft delete OID symbolic names using with the `--control/-J` option

The following table shows the symbolic names that can be used with the server's LDAP commands using the `--control/-J` option.

Control	Symbolic Name
Soft Delete Request Control	softdelete
Hard Delete Request Control	harddelete
Soft Undelete Request Control	undelete
Soft Delete Entry Access Control	softdeleteentryaccess

Monitoring soft deletes

The Directory Server provides monitoring entries and logs to track all soft delete operations. The access and debug logs do not have any options specific for soft deletes.

New monitor entries

Two new monitor entries are present for a backend monitor entry.

Administrators see the following additional monitor entries on `cn=userRoot Backend, cn=monitor`:

`ds-soft-delete-entry-operations-count`

Displays the number of soft deletes performed on the backend since server startup.

`ds-undelete-operations-count`

Displays the number of undeletes performed on the backend since server startup.

`ds-backend-soft-deleted-entry-count`

Displays the current number of soft-deleted entries in the database.

`ds-auto-purged-soft-deleted-entry-count`

Displays the current number of soft-deleted entries purged since the backend or server was restarted.

Monitoring soft deletes

Monitor soft deletes using the `ldapsearch` command.

Steps

- Run `ldapsearch` on the `cn=userRoot Backend, cn=monitor` branch using a search criteria targeting the `ds-backend-monitor-entry` object class.

Example:

```
$ bin/ldapsearch --baseDN "cn=userRoot Backend, cn=monitor" \
  --searchScope sub "(objectclass=ds-backend-monitor-entry)"
```

Result:

```
dn: cn=userRoot Backend, cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-backend-monitor-entry
objectClass: extensibleObject
cn: userRoot Backend
ds-backend-id: userRoot
ds-backend-base-dn: dc=example, dc=com
ds-backend-is-private: FALSE
ds-backend-entry-count: 200001
ds-backend-soft-deleted-entry-count: 1000
ds-soft-delete-operations-count: 40
ds-undelete-operations-count: 20
ds-auto-purged-soft-deleted-entry-count: 0
ds-base-dn-entry-count: 200001 dc=example, dc=com
ds-backend-writability-mode: enabled
```

Access logs

The access log records the LDAP operations corresponding to soft delete and undelete for `DELETE`, `SEARCH`, `MODIFY`, and `ADD` operations with the related soft-deleted values.

The access log does not require any configuration for soft delete.

DELETE (soft-delete) operations

The access log displays the following.

```
[14/May/2012:09:40:16.942 -0500] DELETE RESULT conn=18 op=1 msgID=2
```

```
dn="uid=user.1,ou=People,dc=example,dc=com" resultCode=0 etime=30.367
softDeleteEntryDN="entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,
ou=People,dc=example,dc=com"
```

SEARCH operations for soft-deleted entries

The access log displays the following.

```
[14/May/2012:09:40:52.320 -0500] SEARCH RESULT conn=19 op=1 msgID=2
base="dc=example,dc=com" scope=2 filter="(objectclass=ds-soft-delete-
entry)"
attrs="ALL" resultCode=0 etime=1.631 entriesReturned=1
```

MODIFY operations of soft-deleted entries

The access log displays the following.

```
[14/May/2012:09:42:43.679 -0500] MODIFY RESULT conn=20 op=1 msgID=1
dn="entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=exam-
ple,dc=com" resultCode=0 etime=2.639 changeToSoftDeletedEntry=true
```

ADD (soft-undelete) operations

The access log displays the following.

```
[14/May/2012:09:58:16.728 -0500] ADD RESULT conn=25 op=1 msgID=1
dn="uid=user.0,ou=People,dc=example,dc=com" resultCode=0 etime=22.700
undeleteFromDN="entryUUID=ad55a34a-763f-358f-93f9-
da86f9ecd9e4+uid=user.0,
ou=People,dc=example,dc=com"
```

Audit logs

The audit log captures any `MODIFY` and `DELETE` operations of soft-deleted entries.

These changes are recorded as fully commented-out audit log entries. The audit log does not require any configuration for soft deletes.

For any soft-deleted entry, the audit log entry displays the `ds-soft-delete-entry-dn` property and its soft-deleted entry distinguished name (DN).

```
# 14/May/2012:10:57:09.054 -0500; conn=30; op=1
# ds-soft-delete-entry-dn: entryUUID=68147342-1f61-3465-8489-
3de58c532130+uid=user.2,ou=People,dc=example,dc=com
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: delete
```

For any `MODIFY` changes made, the log displays the LDIF, the modifier's name, and update time.

```
# 14/May/2012:10:58:33.566 -0500; conn=33; op=1
# dn:
  entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
ple,dc=com
# changetype: modify
# replace: homePhone
# homePhone: +1 003 428 0966
#-
# replace: modifiersName
# modifiersName: uid=admin,dc=example,dc=com
#-
```

```
# replace: modifyTimestamp
# modifyTimestamp: 20131010020345.546Z
```

For any undelete of a soft-deleted entry, the log displays the `ds-undelete-from-dn` attribute plus the entry unique ID, create time, and creator's name.

```
# 14/May/2012:10:59:21.754 -0500; conn=34; op=1
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: add
uid: user.2
ds-undelete-from-dn:
  entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=Peo-
  ple,dc=example,dc=com
ds-entry-unique-id:: vw1jg801S7GWrTiS3UE5DA==
createTimestamp:: 20131010181148.630Z
creatorsName: uid=admin,dc=example,dc=com
```

For hard (permanent) deletes of a soft-deleted entry, the log displays the soft-deleted entry DN that was removed.

```
# 14/May/2012:11:00:14.055 -0500; conn=36; op=1
# dn:
  entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
  ple,dc=com
# changetype: delete
```

Configuring the file-based audit log for soft deletes

Configure the file-based audit log for soft deletes.

Steps

1. Enable the audit log if it is disabled.

Example:

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
  Logger" \
  --set enabled:true
```

2. View the audit log.

The `soft-delete-entry-audit-behavior` property is set to `commented` by default and provides additional information in comments about the soft-deleted entry that was either created or undeleted.

Example:

```
# 11/May/2012:15:33:17.552 -0500; conn=13; op=1
# ds-soft-delete-entry-dn:entryUUID=54716bfd-fbc4-3108-ac37-
  bf6b1b166e37+uid=user.15,ou=People,dc=example,dc=com
dn: uid=user.15,ou=People,dc=example,dc=com
changetype: delete
```

Changelog

You can configure the changelog to capture soft-delete changes to entries so that external clients, such as PingDataSync Server, can access these changes.

The `ds-soft-delete-entry` attribute represents an entry that has been soft-deleted and is part of the source entry passed into the changelog to indicate the entry has been soft-deleted.

All soft-delete operations appear in the changelog as regular DELETE operations. When a soft delete occurs, the resulting changelog entry includes a `ds-soft-delete-entry-dn` operational attribute with

the value of the soft-deleted entry DN. PingDataSync Server recognizes the `ds-soft-delete-entry-dn` attribute and does nothing with it.

The changelog backend `soft-delete-entry-included-operation` property determines whether MODIFY or DELETE operations of soft-deleted entries appear in the changelog. This property is disabled by default.

Configuring soft deletes on the changelog backend

Steps

1. To configure soft deletes on the changelog backend, run the following.

```
$ bin/dsconfig set-backend-prop \
--backend-name changelog \
--set soft-delete-entry-included-operation:delete \
--set soft-delete-entry-included-operation:modify
```

2. Run a soft-delete operation on an entry.
3. To review the changelog for the soft-deleted entry, run the following.

```
$ bin/ldapsearch --baseDN cn=changelog \
"(objectclass=*)" "+"
```

Result:

```
dn: cn=changelog
subschemaSubentry: cn=schema
entryUUID: 9920f7e9-5a04-392a-82a8-32662d7d3863
ds-entry-checksum: 304022441
dn: changeNumber=1,cn=changelog
targetUniqueId: 94f634df-c90e-39aa-bd4a-9183c29746d0
changeTime: 20120511154141Z
ds-soft-delete-entry-dn: entryUUID=94f634df-c90e-39aa-bd4a-
9183c29746d0+uid=user.9,ou=People,dc=example,dc=com
modifyTimestamp: 20131010020345.546Z
createTimestamp:: 20131010181148.630Z
localCSN: 000001373C90085200000000000003
modifiersName: uid=admin,dc=example,dc=com
entry-size-bytes: 298
subschemaSubentry: cn=schema
entryUUID: 459b06c6-89f3-307e-a515-22433eb420b6
createTimestamp: 20120511154141.431Z
modifyTimestamp: 20120511154141.431Z
ds-entry-checksum: 1157320579
```

Disabling soft deletes as a global configuration

To disable soft deletes on your Directory Server, reset the global configuration property and then remove the soft-delete policy.

About this task

From that point, PingDirectory processes all deletes as hard deletes by default. Any use of the soft-deleted options with the LDAP tools results in an error. Any existing soft-deleted entries that are present after the global configuration remain in the server as latent entries.

Note:

Be sure to include the LDAP bind parameters for your system when running each of these commands.

Steps

1. To reset the global configuration property, run the following **dsconfig** command.

Example:

```
$ bin/dsconfig set-global-configuration-prop --reset soft-delete-policy
```

2. To reset the global configuration property, run the following **dsconfig** command.

Example:

```
$ bin/dsconfig delete-soft-delete-policy --policy-name default-soft-delete-policy
```

Importing and exporting data

The PingDirectory Server supports import or export of the database backends in LDIF.

You can use the **bin/import-ldif** and **bin/export-ldif** tools to create or export database backends for online or offline servers. The tools support options that can restrict the input or output to a subset of the entries or a subset of the attributes within entries. The tools also provide features to compress, encrypt, or digitally sign the data.

Importing data

The PingDirectory Server provides initialization mechanisms to import database files.

The **import-ldif** command line tool imports data from an LDIF file. You can import all or a portion of the entries contained in the LDIF file, including a subset of the entries, a subset of the attributes within entries, or both. The command also supports importing data that has been compressed, encrypted or digitally signed, or both.

You can run the **import-ldif** utility with the server offline or online. If the server is online, administrators can initiate the import from a local or remote client. The LDIF file that contains the import data must exist on the server system. During an online import, the target database repository, or backend, is removed from service and data held in that backend is not available to clients.

The **import-ldif** tool has been modified to help guard against accidental overwriting of existing backend data with the addition of the `--overwriteExistingEntries` option. You must include this option when performing an import into a backend with a branch that already contains entries. If a branch contains just a single base entry, the `--overwriteExistingEntries` option is not required.

Validating an LDIF file

Prior to importing data, you can validate an import file using Directory Server's **validate-ldif** tool.

About this task

The tool binds to the Directory Server locally or remotely and validates the LDIF file to determine whether it violates the server's schema. Elements that do not conform to the schema are rejected and written to standard output. You can specify the output filepath to which the rejected entries and reasons for their rejection are written. The **validate-ldif** tool works with regular non-compressed LDIF files or gzip-compressed LDIF files.

Steps

- To validate an LDIF file, run the `validate-ldif` tool.

Note:

Make sure the server is online before running this command.

To process large files faster, you can set the number of threads for validation. The tool also provides options to skip specified schema elements if you are only validating certain items, such as attributes only.

Example:

```
$ bin/validate-ldif --ldifFile /path/to/data.ldif \
  --rejectFile rejectedEntries
```

- Optional: To view the arguments, use the `--help` option.

Result:

```
1 of 200 entries (0 percent) were found to be invalid.
1 undefined attributes were encountered.
Undefined attribute departmentname was encountered 1 times.
```

About the database cache estimate

After successful completion of an import, the `import-ldif` command lists detailed information about the database cache usage characteristics of the imported data set.

To guide decisions for changing Java virtual machine (JVM) size and database-cache-percent for the backend, the current server configuration is considered along with the capabilities of the underlying hardware.

The `/logs/tools` directory contains additional files that describe the database cache characteristics in more detail.

Tracking skipped and rejected entries

During import, skip entries if they do not belong in the specified backend or if they are part of an excluded base distinguished name (DN) or filter.

Steps

- To write skipped entries to a specified file, use the `--skipFile {path}` option on the command line.

You can add a comment indicating why the entries were skipped.

- To write information about rejected entries and the reasons for rejection to a specified file, use the `--rejectFile {path}` option.

You can reject an entry if:

- It violates the server's schema constraints.
- Its parent entry does not exist.
- Another entry already exists with the same DN.
- It was rejected by a plugin.

Running an offline import

To import LDIF data encoded with the UTF-8 character set, run the `import-ldif` tool offline.

This data can come from LDIF files, compressed LDIF files (GZIP format), or from data generated with a MakeLDIF template.

**Note:**

You do not need to authenticate as an administrator when performing offline LDIF imports.

Performing an offline import

Steps

1. Confirm the Directory Server is offline.
2. To import data from an LDIF file, use the `import-ldif` command.

Do not specify any connection arguments when running the command.

Example:

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
  --rejectFile /path/to/reject.ldif --skipFile /path/to/skip.ldif
```

Performing an offline LDIF import using a compressed file

Steps

1. Confirm the Directory Server is offline.
2. To import data from a compressed gzip formatted file, use the `import-ldif` command.

**Note:**

You must include the `--isCompressed` option to indicate that the input file is compressed.

Do not specify any connection arguments when running the command.

Example:

```
$ bin/import-ldif --backendID userRoot --isCompressed \
  --ldifFile /path/to/data.gz --rejectFile /path/to/reject.ldif \
  --skipFile /path/to/skip.ldif
```

Performing an offline LDIF import using a MakeLDIF template

Steps

1. Confirm the Directory Server is offline.
2. Use the `import-ldif` command to import data from a MakeLDIF template, which is located in the `<server-root>/config/MakeLDIF` directory.

Do not specify any connection arguments when running the command.

Example:

The following example uses the standard data template and generates 10,000 sample entries, and then imports the file to the server.

```
$ bin/import-ldif --backendID userRoot \
  --templateFile config/MakeLDIF/example.template
```

Running an online LDIF import

You can run LDIF imports while the server is online from another remote server.

The online import is similar to the offline import, except that you must provide information about how to connect and authenticate to the target server.

To schedule an LDIF file to begin importing at a specific time, use the `--task` and `--start YYYYMMDDhhmmss` options of the `import-ldif` tool.

You can also specify email addresses of users to notify when the import process completes. You can notify them regardless of success or failure or only if the import fails. To set up SMTP notifications, see [Working with the SMTP Account Status Notification Handler](#).

Performing an online LDIF import

Steps

1. Confirm the Directory Server is online.
2. To import data from an LDIF, use the `import-ldif` command.

Example:

```
$ bin/import-ldif --task --hostname server1 --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --backendID userRoot --ldifFile userRoot.ldif
```

Scheduling an online import

Steps

1. Confirm the Directory Server is online.
2. To import data from an LDIF file at a scheduled time, use the `import-ldif` command.

Note:

To specify a time in the UTC time zone, include a trailing `Z`. Otherwise, the time zone defaults to the time zone configured on the server.

Example:

```
$ bin/import-ldif --task \
  --hostname server1 \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --bindPassword password \
  --backendID userRoot \
  --ldifFile /path/to/data.ldif \
  --start 20111026010000 \
  --completionNotify import-complete@example.com \
  --errorNotify import-failed@example.com
```

Result:

```
Import task 2011102617321510 scheduled to start Oct 26, 2011 1:00:00 AM
CDT
```

- To confirm that you successfully scheduled your import task, use the **manage-tasks** command to view a summary of all tasks on the system.

Example:

```
$ bin/manage-tasks --summary
```

Result:

```

ID                Type      Status
-----
2011102617321510 Import  Waiting on start time

```

- To monitor the progress of this task, use the **manage-tasks** tool.

Note:

Use the task ID of the import task. If you cannot find the task ID, use the `--summary` option to view a list of all tasks scheduled on the Directory Server.

Example:

```
$ bin/manage-tasks --info 2011102617321510
```

Result:

```

Task                Details
-----
ID                  2011102617321510
Type                Import
Status              Waiting on start time
Scheduled Start Time Oct 26, 2011 1:00:00 AM CDT
Actual Start Time
Completion Time
Dependencies Failed None
Dependency Action   None
Email Upon Completion admin@example.com
Email Upon Error    admin@example.com

Import              Options
-----
LDIF File           /path/to/data.ldif
Backend ID          userRoot

```

Canceling a scheduled import

Steps

- To cancel the scheduled task, run the **manage-tasks** tool.

Example:

```
$ bin/manage-tasks --cancel 2011102417321510
```

Adding entries to an existing Directory Server

To add entries to an existing Directory Server while preserving operational attributes such as `createTimestamp` or `modifiersName`, attach the `Ignore No User Modification` control to the request.

About this task

The `Ignore No User Modification` control allows modification of certain attributes that have the `No User Modification` constraint.

The `Ignore No User Modification` only applies to `ADD` requests. If you use the control to modify an existing entry, it results in an operational attribute change and fail.

To append entries to an existing Directory Server, perform the following steps:

Steps

- Run the `ldapmodify` command with the `Ignore No User Modification` control.

Example: The OpenID is `1.3.6.1.4.1.30221.2.5.5`.

```
$ bin/ldapmodify --control 1.3.6.1.4.1.30221.2.5.5 \
--filename change-record.ldif
```

Filtering data import

The `import-ldif` command lets you include or exclude specific attributes and entries during an import.

The `import-ldif` arguments are summarized in the following table.

Inclusion and Exclusion Arguments for import-ldif

Argument	Description
<code>--includeBranch</code>	Base distinguished name (DN) of a branch to include in the LDIF import. Can be specified multiple times.
<code>--excludeBranch</code>	Base DN of a branch to exclude from the LDIF import. Can be specified multiple times.
<code>--includeAttribute</code>	Attribute to include in the LDIF import. Can be specified multiple times.
<code>--excludeAttribute</code>	Attribute to exclude from the LDIF import. Can be specified multiple times.
<code>--includeFilter</code>	Search filter to identify entries to include in the LDIF import. Can be specified multiple times.
<code>--excludeFilter</code>	Search filter to identify entries to exclude from the LDIF import. Can be specified multiple times.
<code>--excludeOperational</code>	Exclude operational attributes from the LDIF import.
<code>--excludeReplication</code>	Exclude replication attributes from the LDIF import.

Argument	Description
<code>--excludeSoftDelete</code>	Exclude soft delete entries from the LDIF import.

Exporting data

The PingDirectory server `export-ldif` command line tool exports data from the server backend to an LDIF file for backups, exporting data to other applications, or reinitializing servers in a replicated topology.

The `export-ldif` tool supports the `--task` argument, which initiates the export process from within the PingDirectory server. When `export-ldif` is run as a task, extra information is available:

- Output from the export process is included in the error log.
- There is a task entry (accessible below the `cn=tasks` base [MISSING glossAcronymn or glossSurfaceform for gDN]) with information about the success or failure of the export along with log messages.

Note:

An `ldif-export` task can be run from the server system or a remote system. Even if it's run from a remote system, the exported LDIF file is still written to the server system.

The `export-ldif` tool exports a point-in-time snapshot of the backend that is guaranteed to provide a consistent state of the database in LDIF. If necessary, you can re-import with `import-ldif`. The data exported by `export-ldif` can include all or some of the entries (a subset of the entries, or a subset of the attributes within entries, or both) contained in the backend. You accomplish this by specifying branches, filters, and attributes to include or exclude. You can compress, encrypt, or digitally sign the exported LDIF.

Tip:

You can configure LDIF exports as [recurring tasks](#) with `dsconfig create-recurring-task`. You can schedule them to run by adding them to a recurring task chain.

Performing an export

Export data to an LDIF file.

Steps

- To export data to an LDIF file, run the `export-ldif` tool.

Example:

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif
```

Performing an export from specific branches

Steps

- To export data to an LDIF file under a specific branch from the `userRoot` backend of the local Directory Server into a compressed file, run the `export-ldif` tool.

Example:

In addition to including a specific branch, the following command excludes operational attributes from the exported data and wraps long lines at column 80.

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif.gz --
compress \
  --includeBranch ou=people,dc=example,dc=com --excludeOperational \
  --wrapColumn 80
```

Encrypting LDIF exports and signing LDIF files

You can encrypt data during an LDIF export and digitally sign the LDIF file.

The Directory Server provides features to encrypt data during an LDIF export using the `export-ldif --encryptLDIF` option. It also allows the encrypted LDIF file to be imported on the same instance, or another server in the same replication topology, using the `import-ldif` tool. You can use a `--doNotEncrypt` argument to force an LDIF export to be unencrypted even if automatic encryption is enabled. The `--maxMegabytesPerSecond` argument can be used to impose a limit on the rate at which the LDIF file can be written to disk.

You can use the `export-ldif` tool with the `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, and `--encryptionSettingsDefinitionID` arguments to specify which key to use for encrypting the export. The `import-ldif` tool automatically detects encryption and compression and has `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile` options as well.

The Directory Server also provides an additional argument that digitally signs the contents of the LDIF file, which ensures that the content has not been altered since the export. To digitally sign the contents of the exported LDIF file, use the `export-ldif --sign` option. To allow a signed LDIF file to be imported onto the same instance or another server in the same topology, use the `import-ldif --isSigned` option.

Note:

There is little added benefit to signing and encrypting the same data because encrypted data cannot be altered without destroying the ability to decrypt it.

Encrypting an LDIF export

Steps

- To encrypt the data during an export to an output LDIF file, run the `export-ldif` tool with the `--encryptLDIF` option.

Example:

The following command runs an offline export of the `userRoot` backend and encrypts the file when written to an output file called `data.ldif`.

```
$ bin/export-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
  --encryptLDIF
```

Importing an encrypted LDIF file

Use the `import-ldif` tool to import an encrypted LDIF file.

About this task

You can import an encrypted LDIF file into the same instance from which it was exported or into another server in the same replication topology with that instance. You cannot import an encrypted LDIF file into a server that is not connected to the instance from which it was exported.

Steps

- Run the `import-ldif` tool to import the encrypted LDIF file from [Encrypting an LDIF export](#) on page 295.

Note:

The command imports the `data.ldif` file and decrypts the contents while overwriting the existing contents to the `userRoot` backend. The tool automatically determines encryption and compression, and it can automatically identify the correct key for exports that were encrypted with a key obtained from an encryption settings definition or an internal topology key.

Example:

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \  
--overwriteExistingEntries
```

Signing an export

Steps

- To digitally sign the data during an export to an output LDIF file, run the `export-ldif` tool with the `-sign` option.

Example:

The following command runs an offline export of the `userRoot` backend and signs the content when written to an output file called `data.ldif`.

```
$ bin/export-ldif --backendID userRoot \  
--ldifFile /path/to/data.ldif --sign
```

Importing a signed LDIF file

Steps

- To import the signed LDIF file (`data.ldif`) from [Signing an export](#) on page 296, run the `import-ldif` tool with the `--isSigned` option.

The tool imports the `data.ldif` file and checks the signature of the contents while overwriting the existing contents to the `userRoot` backend.

Note:

The command requires the `--isSigned` option, which instructs the tool that the contents of the LDIF file are signed.

Example:

```
$ bin/import-ldif --backendID userRoot \
  --ldifFile /path/to/data.ldif \
  --overwriteExistingEntries --isSigned
```

Filtering data exports

The `export-ldif` command is analogous to the `import-ldif` command to provide a way to include or exclude specific attributes or entries during an export.

Inclusion and Exclusion Arguments for export-ldif

Argument	Description
<code>--includeBranch</code>	Base distinguished name (DN) of a branch to include in the LDIF export (can be specified multiple times).
<code>--excludeBranch</code>	Base DN of a branch to exclude from the LDIF export (can be specified multiple times).
<code>--includeAttribute</code>	Attribute to include in the LDIF export (can be specified multiple times).
<code>--excludeAttribute</code>	Attribute to exclude from the LDIF export (can be specified multiple times).
<code>--includeFilter</code>	Filter to identify entries to include in the LDIF export (can be specified multiple times).
<code>--excludeFilter</code>	Filter to identify entries to exclude from the LDIF export (can be specified multiple times).
<code>--excludeOperational</code>	Exclude operational attributes from the LDIF export.
<code>--excludeReplication</code>	Exclude replication attributes from the LDIF export.
<code>--excludeSoftDelete</code>	Exclude soft delete entries from the LDIF export.

Scrambling data files

The Directory Server `transform-ldif` tool provides backward compatibility with the former `scramble-ldif` tool, with additional functionality for configuring input and output files.

The `transform-ldif` tool reads data from one or more source LDIF files and writes the transformed data to a single output file.

Using this tool to scramble data lets you:

- Obscure the values of certain attributes so that it's difficult to determine the original values in the source data.
- Preserve the characteristics of the associated attribute syntax.

This process is repeatable, so if the same value appears multiple times, it yields the same scrambled representation each time. You can apply scrambling to both LDIF entries and LDIF change records.

The process of scrambling data is not the same as encryption. Only use scrambling to provide simple obfuscation of data. The following are general guidelines for scrambling attributes:

- If the attribute is `userPassword` and its value starts with a schema name surrounded by curly braces, such as `{SSHA256}XrgyNd13fid7KYdhd/Ju47KJQ5PYZqlU1yzxQ28f/QXUnNd9fupj9g==`, the schema name is left unchanged and the rest of the value is treated like a generic string.
- If the attribute is `authPassword` and its value contains at least two dollar signs, such as `SHA256$QGbtDCi1i4=$8/X7XRGaFCovC5mn7ATPDY1kVoocDD06Zy31bD4Ao04=`, the portion up to the first dollar sign (which represents the name of the encoding schema) is preserved and the remainder of the value is treated like a generic string.
- If an attribute has a Boolean syntax, the scrambled value will be either `TRUE` or `FALSE`. Scrambling Boolean values is not repeatable because the determination to use a value of `TRUE` or `FALSE` is random. By randomizing the scrambling for Boolean values, the syntax and obfuscation of the original value is preserved.
- If an attribute has a distinguished name syntax (or a related syntax, such as a name and optional UID), scrambling is applied to the values of relative distinguished name (RDN) components for any attributes to be scrambled.

For example, if you configure the tool to scramble both the `member` and `uid` attributes, and an entry has a `member` attribute with a value of `uid=john.doe,ou=People,dc=example,dc=com`, that `member` value is scrambled in a way that only obscures the `john.doe` portion but leaves the attribute names and all values of non-scrambled attributes intact.

- If an attribute has a generalized time syntax, that value is replaced with a randomized timestamp using the same format (the same number of digits and the same time zone indicator). The randomization is over a time range that is double the difference between the time the `transform-ldif` tool launches and the timestamp is scrambled. For values where that time difference is less than one day, one day is added to the difference before it is doubled.
- If an attribute has an integer, numeric string, or telephone number syntax, scrambling is only applied to numeric digits while all other characters are left intact. If there are multiple digits, then the first digit is nonzero.
- If an attribute has an octet string syntax, it's scrambled as follows:
 - Each byte that represents a lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
 - Each byte that represents an uppercase ASCII letter is replaced with a randomly-selected uppercase ASCII letter.
 - Each byte that represents an ASCII digit is replaced with a randomly-selected ASCII digit.
 - Each byte that represents a printable ASCII symbol is replaced with a randomly-selected printable ASCII symbol.
 - Each byte that represents an ASCII control character is replaced with a randomly-selected ASCII letter, digit, or symbol.
 - Each non-ASCII byte will be replaced with a randomly-selected non-ASCII byte.

- If an attribute has a value that represents a valid JSON object, the resulting value is also a JSON object. All field names are left intact, and only the values of those fields can be scrambled. If the `--scrambleJSONField` argument is provided, only the specified fields have values scrambled. Otherwise, the values of all fields are scrambled. Field values are scrambled as follows:
 - Null values aren't scrambled.
 - Boolean values are replaced with randomly-selected Boolean values. As with attributes with a Boolean syntax, these values are non-repeatable.
 - Number values have only their digits replaced with randomly-selected digits and all other characters (minus sign, decimal point, exponentiation indicator) are left unchanged.
 - String values are replaced with a randomly-selected generic string.
 - Array values have scrambling applied as appropriate for each value in the array. If the array field itself should be scrambled, then all values in the array are scrambled. Otherwise, only JSON objects contained inside the array have scrambling applied to appropriate fields.
 - JSON values have scrambling applied as appropriate for their fields.
- If an attribute does not match any of the previous criteria, it is scrambled as follows:
 - Each lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
 - Each uppercase ASCII letter replaced with a randomly-selected uppercase ASCII letter.
 - Each ASCII digit is replaced with a randomly-selected ASCII digit.
 - All other characters are left unchanged.

Example

The following example reads from an LDIF file named `original.ldif`, scrambles the values of the `telephoneNumber`, `mobile`, and `homeTelephoneNumber` attributes, and writes the results to `scrambled.ldif`.

```
$ bin/transform-ldif --sourceLDIF original.ldif \
  --targetLDIF scrambled.ldif \
  --scrambleAttribute telephoneNumber \
  --scrambleAttribute mobile \
  --scrambleAttribute homeTelephoneNumber \
  --randomSeed 0
```

Backing Up and Restoring Data

PingDirectory Server provides efficient **backup** and **restore** command line tools that support full and incremental backups.

You can schedule backups using either the UNIX-based **cron** scheduler or Directory Server's task-based scheduler.

The Directory Server can run backups while the server is online and processing other requests, so there is no need to shut down the server or place it in read-only mode before starting a backup.

About backing up and restoring data

Administrators should make a comprehensive backup strategy and schedule that consist of daily, weekly, and monthly backups. The plan should include:

- Incremental backups of the directory server data, configuration, and backends
- Full backups of the directory server data, configuration, and backends
- A backup plan for the underlying file system

This dual purpose approach provides excellent coverage in the event that a server database must be restored for any reason.

**Note:**

You can use `dsconfig create-recurring-task` to configure backups as recurring tasks and schedule those tasks as part of a recurring task chain.

If you back up more than one backend, the `backup` tool creates a subdirectory within a specified backup directory for each backend. If you back up only a single backend, then the backup files are placed in the specified directory. A single directory can only contain files from one backend, so you cannot have backup files from multiple different backends in the same backup directory.

When performing a backup, the server records information about the current state of the server and backend, including:

- The server product name
- The server version
- The backend ID
- The set of base distinguished names (DNs) for the backend
- The Java class used to implement the backend logic

The backup descriptor also includes information about the Berkeley DB Java edition version and information about the attribute and virtual list view (VLV) indexes that have been defined.

When restoring a backup, the server compares the descriptor obtained from the backup with the current state of the server and backend. If any problems are identified, the server generates warnings or errors.

You can choose to ignore warnings using the `ignoreCompatibilityWarnings` option to the `restore` tool. Errors always cause the restore operation to fail.

For example, restoring a newer backup into an older version of the server results in a warning. Restoring an older backup into a new version of the server does not result in a warning, but because the `config` and `schema` backends require special handling, the server generates an error if the server versions do not match exactly the major, minor, point, and patch version numbers.

Both the `backup` and `restore` tools provide encryption options that can be used to specify which key to use for encrypting the backup:

- `--promptForEncryptionPassphrase`
- `--encryptionPassphraseFile`
- `--encryptionSettingsDefinitionID`

For backups encrypted with an encryption settings definition or an internal topology key, the server automatically determines the correct key.

Alternately, you can use the `--doNotEncrypt` argument to force a backup to be unencrypted even if automatic encryption is enabled.

If necessary, you can use the `--maxMegabytesPerSecond` argument to impose a limit on the rate at which the backup can be written to disk.

Retaining backups

The backup tool can use the `--retainPreviousFullBackupCount` or `--retainPreviousFullBackupAge` arguments to identify which previous backups to preserve.

Any other backups in that directory are removed. A new backup is always preserved. If the new backup is an incremental backup, then any other backups it depends on are also preserved. However, older backups in the same directory are eligible to be removed.

If you include the `--retainPreviousFullBackupCount` argument, that number of the most recent previous full backups are preserved, along with any incremental backups that depend on them. Any other previous full backups, and their dependent incremental backups, are removed. A value of zero can be

specified for the `--retainPreviousFullBackupCount` argument so that only the most recent backup is preserved, along with its dependencies, and all previous backups are removed.

If you include the `--retainPreviousFullBackupAge` argument, its value must be a duration represented as an integer followed by a time unit. Any full backups (and their dependent incremental backups) created longer ago than that duration are eligible to be removed.

If you include both the `--retainPreviousFullBackupCount` and `--retainPreviousFullBackupAge` arguments, then only backups that don't satisfy either condition are deleted.

The `remove-backup` tool also supports the `--retainFullBackupCount` and `--retainFullBackupAge` arguments to delete any backups outside the provided retention criteria.

Listing the available backups on the system

Use the `restore` tool to list the backups in a `backup` directory.

Steps

- To list the existing backups in a specific backup directory, run the following command.

```
$ bin/restore --listBackups --backupDirectory </mybackups>
```

Result:

```
[13:26:21] The console logging output is also available in '/ds/PingDirectory/logs/tools/restore.log'
```

```
Backup ID:          20120212191715Z
Backup Date:       12/Feb/2012:13:17:19 -0600
Is Incremental:    false
Is Compressed:     false
Is Encrypted:      false
Has Unsigned Hash: false
Has Signed Hash:  false
Dependent Upon:    none
Backup ID:          20120212192411Z
Backup Date:       12/Feb/2012:13:24:16 -0600
Is Incremental:    true
Is Compressed:     false
Is Encrypted:      false
Has Unsigned Hash: false
Has Signed Hash:  false
Dependent Upon:    20120212191715Z
```

Backing up all backends

Use `backup` to save the all of the server's backends.

About this task

The `--compress` option can reduce the amount of space that the backup consumes, but can also significantly increase the time required to perform the backup.

Steps

- To back up all backends and compress the backups, run the following.

```
$ bin/backup --backUpAll --compress --backupDirectory </path/to/backup>
```

Backing up a single backend

Use the `--backendID` argument to specify a single backend to back up.

Steps

- To back up the userRoot directory and compress the backup, use the following command.

```
$ bin/backup --backendID userRoot --compress --backupDirectory </path/to/backup>
```

Performing an offline restore

Use the `restore` command to restore a backed up backend.

About this task

Only a single backend can be restored at a time.

The Directory Server must be shut down before performing an offline restore.

Note:

The server root directory should never be restored from a file system backup or snapshot.

Steps

1. To stop the Directory Server run the following command.

```
$ bin/stop-server
```

2. To restore a saved backup, run the following command.

```
$ bin/restore --backupDirectory </path/to/backup/userRoot>
```

3. To start the server, run the following command.

```
$ bin/start-server
```

Assigning an ID to a backup

Use the `--backupID` argument to assign an ID to a backup.

Steps

- To back up the userRoot directory, run the following command.

```
$ bin/backup --backupDirectory </path/to/backups/>userRoot \
  --backendID userRoot --backupID weekly
```

The `--backupID` argument identifies the backup being created as "weekly".

Result: The backup file appears under `backups/userRoot` directory as `userRoot-backup-weekly`.

Running an incremental backup on all backends

The Directory Server provides support for incremental backups, which only backs up items that have changed since the last full or incremental backup on the system or since an earlier specified backup.

About this task

You must place incremental backups in the same backup directory as the full backup on which they are based.

Note:

Not all backends support incremental backups. If a backend does not support incremental backups, the `--incremental` option has no effect, and a full backup occurs.

Steps

- To run an incremental backup on all backends based on the most recent backup, run the following command.

```
$ bin/backup --backUpAll --incremental --backupDirectory /path/to/backup
```

Running an incremental backup on a single backend

Steps

- To save the single backend, `userRoot`, in the server root directory, run the `backup` tool.

Example:

```
$ bin/backup --backendID userRoot --incremental --backupDirectory /path/to/backup
```

Running an incremental backup based on a specific prior backup

You can run an incremental backup based on a specific prior backup that is not the most current version on the system.

Steps

- To get the backup ID, run the `restore` tool with the `--listBackups` option.

Example:

```
$ bin/backup --backUpAll --incremental --backupDirectory /path/to/backup \
  --incrementalBaseID backup-ID
```

Restoring an incremental backup

Restoring an incremental backup is the same process as restoring a full backup for both online and offline restore types.

Steps

- To automatically ensure that the full backup and any intermediate incremental backups are restored before restoring the final incremental backup, use the **restore** tool.

Note:

The tool does not restore any files in older backups that no longer exist in the final data set.

Scheduling an online backup

About this task

You can schedule a backup to run as a task by specifying the timestamp with the `--task` and `--start` options. The option is expressed in "YYYYMMDDhhmmss" format. If the option has a value of 0, then the task is scheduled for immediate execution. Because you can't run recurring tasks, you must run daily operations using cron or another system that can submit the task.

For online (remote) backups, you can conduct the backup operation while PingDirectory Server is online if you provide information about how to connect and to authenticate to the target Directory Server.

Steps

- To schedule the backup to occur at a specific time, use the task-based `--start YYYYMMDDhhmmss` option.

Note:

To specify a time in the UTC time zone format, add a trailing `Z` to the time. Otherwise, the time is treated as a local time in the time zone configured on the server.

Example:

```
$ bin/backup --backUpAll --task --start 20111025010000 \
  --backupDirectory /path/to/backup --completionNotify admin@example.com \
  --errorNotify admin@example.com
```

Result:

```
Backup task 2011102500084110 scheduled to start Oct 28, 2011 1:00:00 AM
CDT
```

Scheduling an online restore

About this task

To perform an online restore, use the Tasks subsystem and enter connection and authentication information and an optional start time.

Note:

The server must be online.

The Tasks subsystem allows you to schedule certain operations, such as **import-ldif**, **backup**, **restore**, **start-server**, and **stop-server**.

Steps

- Schedule an online restore.

Example:

```
$ bin/restore --task --start 20111025010000 \
  --backupDirectory /path/to/backup/userRoot \
  --completionNotify admin@example.com --errorNotify admin@example.com
```

You can schedule a restore to run as a task by specifying the timestamp with the **--task** and **--start** options. The option is expressed in **YYYYMMDDhhmmss** format. If the option has a value of 0, then the task is scheduled for immediate execution. You can't run recurring tasks, so you must run daily operations using cron or another system that can submit the task.

Note:

To specify a time in the UTC time zone, add a trailing **z** to the time. If you do not specify a time, the configured time zone on the server will be set to a local time.

The backend is unavailable while the restore is in progress.

Encrypting a backup

About this task

To encrypt a backup:

Steps

- Go to the server root directory and use the **backup** tool to back up the single backend, **userRoot**, and encrypt it with the **--encrypt** option.

Example:

```
$ bin/backup --encrypt --backendID userRoot --compress --
  backupDirectory /path/to/backup
```

Signing a hash of the backup

Run the **backup** tool to backup a backend and generate and digitally sign the hash of the backup contents.

Steps

- To backup the single backend from the server root directory, run the **backup** tool. Choose from:
 - To generate and digitally sign the hash of the backup contents, run the **-signHash** option.

```
$ bin/backup --signHash --backupDirectory backups/userRoot --backendID
  userRoot \
  --backupDirectory /path/to/backup
```

- To only generate a hash of the backup contents, run **backup** with the **--hash** option.

Restoring a backup

You can use the `restore` command to restore a backup created with the `backup` command.

About this task

You can only restore a single backend at a time, and that backend will be offline for the duration of the restore process. The directory containing the backup used for the restoration includes a `backup.info` file with information about the backup, including when the backup was generated and whether the backup is compressed, signed, or encrypted.

You can use the `restore` command for the following data recovery scenarios:

Steps

- To restore a single backend in a replicated topology, run the `dsreplication initialize` command.

This command streams the contents of the backend database from the source to the destination and ensures that the server receives the most up-to-date version of the data.

- To restore a backup in a non-replicated instance, run the `restore` command and specify the path to the directory containing the backup.

Example:

```
$ bin/restore --backupDirectory /path/to/backup
```

- To restore a backup to a point-in-time:
 - a. Run `dsreplication pre-external-initialization` on a server in the topology.
 - b. Choose the required `baseDN`.
 - c. Stop the server.
 - d. Restore that server to your desired point-in-time backup.
 - e. Re-start the server.
 - f. Run `dsreplication initialize-all`.
 - g. Initialize all other servers in the topology from the restored server.
 - h. Run `dsreplication post-external-initialization` on the restored server.
- If all of your servers have been compromised:
 - a. Build a directory server.
 - b. Restore from the latest backup.
 - c. If available, use the `extract-data-recovery-log-changes` command to replay changes in the data recovery log.

For more information, see [Reverting or replaying changes](#) on page 310.
 - d. Add and initialize new directory servers from the one that you just restored.

Moving or restoring a user database

Part of any disaster recovery involves the restoration of the user database from one server to another.

You should have a well-defined backup plan that takes into account whether or not your data is replicated among a set of servers. A plan is the best insurance against significant downtime or data loss in the event of an unrecoverable database issue.

Note:

The server root directory should never be restored from a file system backup or snapshot. External backup methods, such as virtual machine (VM) snapshots, are not recommended, especially if data was corrupted during a transaction.

Keep in mind the following general points about database recovery:

Regular backup from local replicated Directory Server

Take a backup from a local replicated directory server and restore to the failed server. This is more recent than any other backup you have.

Restore the most recent backup

Restore the most recent backup from a local server. In some cases, this might be preferred over taking a new backup if that would adversely impact performance of the server being backed up although it takes longer for replication to play back changes.

Contact support

If all else fails, contact your authorized support provider and they can work with you, and possibly in cooperation with the Oracle Berkeley DB JE engineers, to try a low-level recovery, including tools that attempt to salvage whatever data they can obtain from the database.

Using VM snapshots

Although VM snapshots are not recommended for disaster recovery, remember the following in case you must use them:

- Snapshotting the VM should never result in a corrupted PingDirectory server.
- Shutting down the DB before snapshotting is only recommended for speeding up recovery time.

Comparing the data in two Directory Servers

The PingDirectory Server provides an `ldap-diff` tool to compare the data on two LDAP servers to determine any differences that they might contain.

The differences are identified by first issuing a subtree search on both servers under the base distinguished name (DN) using the default search filter (`objectclass=*`) to retrieve the DNs of all entries in each server. When the tool finds an entry that is on both servers, it retrieves the entry from each server and compares all of its attributes. The tool writes any differences it finds to an LDIF file in a format that could be used to modify the content of the source server so that it matches the content of the target server. Any non-synchronized entries can be compared again for a configurable number of times with an optional pause between each attempt to account for replication delays.

You can control the specific entries to be compared with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. You can also exclude specific attributes by prepending a `^` character to the attribute. On Windows operating systems, excluded attributes must be quoted, such as `"^attrToExclude"`. The `@objectClassName` notation is used to compare only attributes that are defined for a given `objectclass`.

The `ldap-diff` tool can be used on servers actively being modified by checking differing entries multiple times without reporting false positives due to replication delays. By default, it re-checks each entry twice, pausing two seconds between checks. You can configure these settings with the `--numPasses` and `--secondsBetweenPass` options. If the utility cannot make a clean comparison on an entry, it lists any exceptions in comments in the output file.

The Directory Server user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the Directory Server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry.

```
ds-cfg-default-root-privilege-name: unindexed-search
ds-cfg-default-root-privilege-name: bypass-acl
ds-rlim-size-limit: 0
ds-rlim-time-limit: 0
ds-rlim-idle-time-limit: 0
ds-rlim-lookthrough-limit: 0
```

The `ldap-diff` tool tries to make efficient use of memory, but it must store the DN's of all entries in memory. For Directory Servers that contain hundreds of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. You can customize the memory used by the `ldap-diff` tool by editing the `ldap-diff.java-args` setting in the `config/java.properties` file and running the `dsjavaproperties` command.

If you do not want to use a subtree search filter, you can use an input file of DN's for the source, target, or both. The format of the file can accept various syntaxes for each DN.

```
dn: cn=this is the first dn
dn: cn=this is the second dn and it is wrapped cn=this is the third dn
# The following DN is base-64 encoded dn::
Y249ZG9uJ3QgeW91IGhhdmUgYmV0dGVyIHRoaW5ncyB0byBkbyB0aGFuIHNlZSB3aGF0IHRoaXMgc2F5cw==
# There was a blank line above dn: cn=this is the final entry.
```

CAUTION:

Do not manually update the servers when the tool identifies differences between two servers involved in replication. First contact your authorized support provider for explicit confirmation because manual updates to the servers risk introducing additional replication conflicts.

Comparing two Directory Servers using `ldap-diff`

Steps

1. Use `ldap-diff` to compare the entries in two Directory Server instances.

Ignore the `userpassword` attribute due to the one-way password hash used for the password storage scheme.

Example:

```
$ bin/ldap-diff --outputLDIF difference.ldif \
--sourceHost server1.example.com --sourcePort 1389 \
--sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
--targetHost server2.example.com --targetPort 2389 \
--targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
--baseDN dc=example,dc=com --searchFilter "(objectclass=*)"
"^userpassword"
```

2. Open the output file in a text editor to view any differences.

The file is set up so that you can re-apply the changes without any modification to the file contents. The file shows any deletes, modifies, and adds from the perspective of the source server as the authoritative source.

Example:

```
# This file contains the differences between two LDAP servers.
#
# The format of this file is the LDIF changes needed to bring server
# ldap://server1.example.com:1389 in sync with server
# ldap://server2.example.com:2389.
#
# These differences were computed by first issuing an LDAP search at
# both
# servers under base DN dc=example,dc=com using search filter
# (objectclass=*)
# and search scope SUB to first retrieve the DN's of all entries. And then
# each
```

```

# entry was retrieved from each server and attributes: [^userpassword]
were
# compared. # # Any entries that were out-of-sync were compared a total
of 3 times
# waiting a minimum of 2 seconds between each attempt to account for
replication
# delays.
#
# Comparison started at [24/Feb/2010:10:34:20 -0600]
# The following entries were present only on ldap://
server2.example.com:2389 and
# need to be deleted. This entry existed only on ldap://
server1.example.com:1389
# Note: this entry might be incomplete. It only includes attributes:
# [^userpassword]dn: uid=user.200,ou=People,dc=example,dc=com
# objectClass: person
# objectClass: inetOrgPerson
... (more attributes not shown) ...
# st: DC
dn: uid=user.200,ou=people,dc=example,dc=com
changetype: delete

# The following entries were present on both servers but were out of
sync.

dn: uid=user.199,ou=people,dc=example,dc=com
changetype: modify
add: mobile
mobile: +1 300 848 9999

# The following entries were missing on ldap://server2.example.com:2389
and need
# to be added. This entry existed only on ldap://
server2.example.com:2389
# Note: this entry might be incomplete. It only includes attributes:

# [^userpassword]
dn: uid=user.13,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
... (more attributes not shown) ...
# Comparison completed at [24/Feb/2010:10:34:25 -0600]

```

Comparing configuration entries using config-diff

Steps

- Use **config-diff** to compare Directory Server configurations and produce a **dsconfig** batch file needed to bring the source inline with the target.

Example:

The following example compares the current configurations of server1 and server2. The changes necessary to bring server1's configuration inline with server2 are written to the console. The same credentials are used to connect to both servers.

```

$ bin/config-diff --sourceHost server1 --sourceBindDN "cn=Directory
Manager" \

```

```
--sourceBindPassword password --targetHost server2
```

For more information about runtime options, see [Available command-line tools](#) on page 806 or the `config-diff` tool help.

Comparing entries using source and target DN files

Steps

- To compare the entries in two Directory Server instances, use `ldap-diff`.

In the following example, the utility uses a single distinguished name (DN) input file for the source and target servers, so that no search filter is used. Ignore the `userpassword` attribute because of the password storage scheme that uses a one-way hashing algorithm.

Example:

```
$ bin/ldap-diff --outputLDIF difference.ldif \
  --sourceHost server1.example.com --sourcePort 1389 \
  --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
  --targetHost server2.example.com --targetPort 2389 \
  --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
  --baseDN "dc=example,dc=com" --sourceDNsFile input-file.ldif \
  --targetDNsFile input-file.ldif "^userpassword"
```

Comparing Directory Servers for missing entries only using ldap-diff

Steps

- To compare two Directory Servers and return only those entries that are missing on one of the servers, use `ldap-diff` with the `--missingOnly` option.

This can significantly reduce the runtime for this utility.

Example:

```
$ bin/ldap-diff --outputLDIF difference.ldif \
  --sourceHost server1.example.com --sourcePort 1389 \
  --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
  --targetHost server2.example.com --targetPort 2389 \
  --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
  --baseDN dc=example,dc=com --searchFilter "(objectclass=*)" \
  "^userpassword" \
  --missingOnly
```

Reverting or replaying changes

The PingDirectory Server provides support for an audit logger that records information about the changes to data within the server.

The data is formatted as LDIF, and it can be replayed with tools such as `ldapmodify` or `parallel-update`. The data includes information encoded as comments that provide additional context about the changes. By default, the log records the changes as requested by clients, but it can log the changes in reversible form so that they can be undone.

This audit logger can be useful for the following scenarios:

- If one or more undesirable changes have been made, such as by a malicious or defective client, it can obtain the necessary changes to revert those operations.
- If a catastrophic loss of all servers in the topology occurs that leaves an audit log available with newer data than any backup or LDIF export, such as concurrent database corruption across all instances, it can recover changes that might not otherwise be available.

- Automating the process of identifying changes made in one topology that can be replayed into another topology, such as to replay production changes into an isolated server or topology for testing purposes or to attempt to reproduce a problem.
- Analytics and reporting purposes.

To assist with these and other uses, the LDAP SDK for Java provides an API for consuming, parsing, and reverting audit log messages. This API can be used for the analytics and reporting. Also available is the **extract-data-recovery-log-changes** tool that can extract audit log changes matching a specified set of criteria so that they can be replayed, either as they were originally processed or in a reversible form that makes it possible to revert those changes.

The Data Recovery Log

The **setup** tool automatically creates an audit logger for data recovery purposes in `logs/data-recovery`. The log is always compressed, and it is encrypted if data encryption is enabled within the server. The logger has the following properties:

- Log files are written into the `logs/data-recovery` directory so that they are isolated from other log files. The active log file is named `data-recovery.gz.encrypted` while rotated files are named `data-recovery.{timestamp}.gz.encrypted`.
- The log files are gzip-compressed. If data encryption is enabled, they are encrypted with a key obtained from the server's preferred encryption settings definition.
- Each log file contains no more than 10 MB of data, and is rotated after 24 hours. Keeping the log files small ensures that the entire contents of a log file easily fits into the **extract-data-recovery-log-changes** tool's memory.
- The server retains rotated data recovery log files for no more than one week. However, as a safeguard against consuming too much disk space in periods of extremely heavy and prolonged write activity, the server also retains no more than 1,000 data recovery log files for a maximum of 500 MB of disk space.
- Changes are logged in reversible form and include the authentication and authorization identity of the requester, as well as the IP address. If present, the log message includes details from any intermediate client request control included in the request, which can provide information about the downstream client.

The `extract-data-recovery-log-changes` Tool

The **extract-data-recovery-log-changes** tool creates an LDIF file (compressed and encrypted by default) with a specified subset of changes from the server's data recovery log. That LDIF file can then be applied to the server using either the `ldapmodify` or `parallel-update`. Before applying the changes, the output file can be decrypted and examined to ensure that the changes it contains look correct. This tool can be useful for disaster recovery.

The **extract-data-recovery-log-changes** tool provides arguments for input and output of the extracted changes, including encryption settings, location, and compression.

The direction of whether changes should be extracted in forward mode or reverse mode is also configured. In forward mode (replay), the audit log messages are traversed from oldest to newest, and extracted changes are presented as they were originally requested. In reverse mode (revert), the audit log messages are traversed from newest to oldest, and extracted changes are converted to a form that reverts the original changes. Regardless of the direction chosen, additional arguments enable identifying the changes to extract by time, requester address or DN, connection ID, origin, content type, or alterations.

The following is a sample command to revert all changes by user

`uid=malicious,ou=People,dc=example,dc=com` between noon and 2 pm on October 15, 2018.

```
$ bin/extract-data-recovery-log-changes \
  --auditLogFile logs/data-recovery/data-
  recovery.201810161234.567.gz.encrypted \
  --outputFile revert-malicious-user-changes.ldif \
  --direction revert \
```

```
--startTime 201810151200.000 \  
--endTime 201810151359.999 \  
--includeAuthorizationDN "uid=malicious,ou=People,dc=example,dc=com"
```

Working with Groups

LDAP groups are special types of entries that represent collections of users. This section provides an overview of Directory Server groups concepts and procedures on setting up and querying groups in Directory Server.

Groups are often used by external clients to control who has access to a particular application or features. Internally, they might be used by the server to control its behavior. Groups can be used by the access control, criteria, or virtual attribute subsystems.

The specific ways in which clients create and interact with a particular group depends on the type of group being used. There are three primary ways in which clients attempt to use groups:

- To determine whether a specified user is a member of a particular group
- To determine the set of groups in which a specified user is a member
- To determine the set of all users that are members of a particular group

Overview of groups

Directory Server provides three types of groups: static, dynamic, and virtual static groups.

A description of each group type follows:

Static groups

A static group is an entry that contains an explicit list of member or uniquemember attributes, depending on its structural object class. Static groups are ideal for small, infrequently changing elements. When the membership list grows, static groups become more difficult to manage because any change in a member base distinguished name (DN) must then be changed in the group. Static groups use one of three structural object classes: `groupOfNames`, `groupOfUniqueNames`, and `groupOfEntries`.

Directory Server also supports nested groups, in which a parent group entry contains child attributes whose DNs reference another group. Nested groups are a flexible means to organize entries that provide inherited group membership and privileges. To maintain good performance throughout, a group cache is enabled by default. The cache supports static group nesting that includes other static, virtual static, and dynamic groups.

Dynamic groups

A dynamic group has its membership list determined by search criteria using an LDAP URL. Dynamic groups solve the scalability issues for static groups because searches are efficient, constant-time operations. However, searches that range over a large set of data might affect performance.

Virtual static groups

A virtual static group is a combination of both static and dynamic groups, in which each member in a group is a virtual attribute that is dynamically generated when invoked. Virtual static groups solve the scalability issues for clients that can only support static groups and are best used when the application targets a search operation for a specific member. Avoid using virtual static groups for applications that need to retrieve the entire membership list because the process for constructing the entire membership list can be expensive.

About the `isMemberOf` and `isDirectMemberOf` virtual attribute

PingDirectory Server can generate either `isMemberOf` or `isDirectMemberOf` virtual attributes in user entries.

The existence of static, nested, dynamic, and virtual static groups can make it complex to work with groups in the server because the ways you interact with them are so different. Static groups can use three different structural object classes, not counting the auxiliary class for virtual static groups, which can further complicate things. PingDirectory Server's virtual attributes simplify the group-related determination process for consistency across all types of groups.

The value of the `isMemberOf` virtual attribute is a list of distinguished names (DNs) of all groups, including static, nested, dynamic, and virtual static groups, in which the associated user is a member. The value of the `isDirectMemberOf` virtual attribute is a subset of the values of `isMemberOf`, which represents the groups for which the entry is an explicit or direct member. Both are enabled by default.

Because `isMemberOf` and `isDirectMemberOf` are operational attributes, only users who have been granted the privilege can see them. The default set of access control rules do not allow any level of access to user data. The only access that is granted is what is included in user-defined access control rules, which is generally given to a `uid=admin` administrator account. You should restrict access to operational and non-operational attributes to the minimal set of users that need to see them. The root bind DN, `cn=Directory Manager`, has the privilege to view operational attributes by default.

The `rewrite-search-filters` `isMemberOf` configuration property

The `rewrite-search-filters` property allows `isMemberOf` searches targeting dynamic groups to be processed more efficiently because you can substitute the filter of the dynamic group into the original search filter. This speeds up paged searches across a large dynamic group.

The following table shows the three possible settings for the `rewrite-search-filters`.

Setting	Description
<code>always</code>	<p>Always enhance search filters to include the dynamic group filter components.</p> <p> Note: This often speeds up searches on dynamic groups, but in rare cases can make search processing slower. An example is if the dynamic group filter matches many entries, but the dynamic group base distinguished name (DN) and scope do not.</p>
<code>within-group-scope</code>	<p>The default value. Enhances search filters to include dynamic group filter components only when the base DN and scope of the dynamic group.</p> <p> Note: Although this doesn't improve performance for search requests whose scope is larger than that of the dynamic group, it should never lead to slower dynamic group search processing</p>
<code>never</code>	<p>Never enhance search filters to include the dynamic group filter components.</p>

To use the `rewrite-search-filters` configuration property:

- To set the `rewrite-search-filters` configuration property to the desired setting, run `dsconfig`.

```
dsconfig set-virtual-attribute-prop --name isMemberOf --set rewrite-search-filters:<always | never | within-group-scope>
```

- To optionally keep the server from archiving configurations where only this attribute is changing, you can declare the `rewrite-search-filter` attribute as insignificant by running `dsconfig`.

```
dsconfig set-backend-prop --backend-name config --add insignificant-config-archive-attribute:ds-cfg-rewrite-search-filters
```

Determine if a user is a member of a specified group

To determine if a user is a member of a specified group using the `isMemberOf` virtual attribute, perform a base-level search against the user's entry with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group. The following table illustrates this base-level search.

Search Parameter	Value
Base DN	<code>uid=john.doe,ou=People,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)</code>
Requested Attributes	<code>1.1</code>

If this search returns an entry, then the user is a member of the specified group. If no entry is returned, then the user is not a member of the given group.

Determine the set of all groups in which a user is a member

To determine the set of all groups in which a user is a member, retrieve the user's entry with a base-level search and include the `isMemberOf` attribute.

Search Parameter	Value
Base DN	<code>uid=john.doe,ou=People,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(objectclass=*)</code>
Requested attributes	<code>isMemberOf</code>

Determine the set of all members for a specified group

To determine the set of all members for a specified group, issue a subtree search with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group and requesting the attributes you wish to have for member entries.

Search Parameter	Value
Base DN	<code>ou=People,dc=example,dc=com</code>

Search Parameter	Value
Scope	sub
Filter	(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)
Requested Attributes	cn, mail

The `isDirectMemberOf` virtual attribute can be used in the previous examples in place of `isMemberOf` if you only need to find groups that users are an actual member of. You must use `isMemberOf` for nested group membership.

 **Note:**

If this filter targets a dynamic group using an unindexed search, then this might be an expensive operation. However, it is not more expensive than retrieving the target group and then issuing a search based on information contained in the member URL.

For static groups, this approach has the added benefit of using a single search to retrieve information from all user entries. Otherwise, it would be required to retrieve the static group and then perform a separate search for each member's entry.

Using static groups

A static group contains an explicit membership list where each member is represented as a distinguished name (DN)-valued attribute.

There are three types of static groups supported for use in the Directory Server: `groupOfNames`, `groupOfUniqueNames`, and `groupOfEntries`. A description for each follows:

`groupOfNames`

A static group that is defined with the `groupOfNames` structural object class and uses the `member` attribute to hold the DNs of its members.

RFC 4519 requires that the `member` attribute is in an entry. Directory Server has relaxed this restriction by making the `member` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfNames` object class.

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfNames
cn: Test Group
member: uid=user.1,ou=People,dc=example,dc=com
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

`groupOfUniqueNames`

A static group that is defined with the `groupOfUniqueNames` structural object class and uses the `uniquemember` attribute to hold the DNs of its members

RFC 4519 requires that the `uniquemember` attribute is in an entry. Directory Server has relaxed this restriction by making the `uniquemember` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfUniqueNames` object class.

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
```

```
objectClass: groupOfUniqueNames
cn: Test Group
uniquemember: uid=user.1,ou=People,dc=example,dc=com
uniquemember: uid=user.2,ou=People,dc=example,dc=com
uniquemember: uid=user.3,ou=People,dc=example,dc=com
```

groupOfEntries

A static group that is defined with the `groupOfEntries` object class and uses the `member` attribute to hold the DNs of its members

This group specifies that the `member` attribute is optional to ensure that the last member can be removed from the group. Although the draft proposal (draft-findlay-ldap-groupofentries-00.txt) has expired, the Directory Server supports this implementation. The following entry depicts a group defined with the `groupOfEntries` object class.

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfEntries
cn: Test Group
member: uid=user.1,ou=People,dc=example,dc=com
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

Creating static groups

Using an LDIF file, you can configure a static group. Static groups contain a membership list of explicit distinguished names (DNs) specified by the `uniquemember` attribute.

Creating a static group

About this task

To create a static group:

Steps

1. Open a text editor and create a group entry in LDIF.
 - a. Include the `groupOfUniqueNames` object class and `uniquemember` attributes.
 - b. Optional: If you did not have `ou=groups` set up in your server, add it in the same file.
 - c. Save the file.

Example:

In the following example, the file is named `static-group.ldif`.

This example LDIF file creates two groups: `cn=Development` and `cn=QA`.

```
dn: ou=groups,dc=example,dc=com
objectclass: top
objectclass: organizationalunit
ou: groups

dn: cn=Development,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Development
ou: groups
uniquemember: uid=user.14,ou=People,dc=example,dc=com
uniquemember: uid=user.91,ou=People,dc=example,dc=com
uniquemember: uid=user.180,ou=People,dc=example,dc=com

dn: cn=QA,ou=groups,dc=example,dc=com
```

```
objectclass: top
objectclass: groupOfUniqueNames
cn: QA
ou: groups
uniquemember: uid=user.0,ou=People,dc=example,dc=com
uniquemember: uid=user.1,ou=People,dc=example,dc=com
uniquemember: uid=user.2,ou=People,dc=example,dc=com
```

2. To add the group entries to the server, use the **ldapmodify** tool.

Example:

```
$ bin/ldapmodify --defaultAdd --filename static-group.ldif
```

3. To verify the configuration, use the virtual attribute **isDirectMemberOf** that checks membership for a non-nested group.

The virtual attribute is disabled by default, but you can enable it using **dsconfig**.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name isDirectMemberOf --set
enabled:true
```

4. To determine if a user is a member of a certain group, use **ldapsearch** to search the **isDirectMemberOf** virtual attribute.

Example:

This example inquires if `uid=user.14` is a member of the `cn=Development` group.

This example assumes that the administrator has the privilege to view operational attributes.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)"
isDirectMemberOf
```

Result:

```
dn: uid=user.14,ou=People,dc=example,dc=com
isDirectMemberOf: cn=Development,ou=groups,dc=example,dc=com
```

5. Use the group as a target in access control instructions (ACI).
 - a. Open a text editor and create an `aci` attribute in an LDIF file.
 - b. Save the file.
 - c. To add the file, use the **ldapmodify** tool.

Example:

In this example, the file is named `dev-group-aci.ldif`.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target ="ldap:///ou=People,dc=example,dc=com")
(targetattr != "cn || sn || uid")
(targetfilter ="(ou=Development)")
(version 3.0; acl "Dev Group Permissions");
```

```
allow (write) (groupdn = "ldap:///
cn=Development,ou=groups,dc=example,dc=com");)
```

**Note:**

You can create a similar ACI for the QA group, which is not shown in the previous example, but is shown in the example for step 1.

- To add the file, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --filename dev-group-aci.ldif
```

Adding a new member to a static group**Steps**

- To add a new member to the group, add a new value for the `uniquemember` attribute that specifies the DN of the new user.

Example:

This example adds a new `uniquemember:user.4`.

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
add: uniquemember
uniquemember: uid=user.4,ou=People,dc=example,dc=com
```

Removing a member from a static group**Steps**

- To remove a member from a static group, remove that user's DN from the `uniquemember` attribute.

Example:

This example removes the DN of `user.1`.

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
delete: uniquemember
uniquemember: uid=user.1,ou=People,dc=example,dc=com
```

Searching static groups

The following section provides a description of how to compose searches to determine if a user is a member of a static group, to determine all the static groups in which a user is a member, and to determine all the members of a static group

Determining if a user is a static group member

Steps

- To determine if a user is a member of a specified group, perform a base-level search to retrieve the group entry with an equality filter looking for the membership attribute of a value equal to the distinguished name (DN) of the specified user.

Note:

For best performance, include a specific attribute list, using either `cn`, or a `1.1` request that no attributes be returned, so that the entire member list is not returned.

Example:

This table contains the search criteria to determine if the user `uid=john.doe,ou=People,dc=example,dc=com` is a member of the `groupOfNames` static group `"cn=Test Group,ou=Groups,dc=example,dc=com"`.

Base DN	<code>cn=Test Group,ou=Groups,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(member=uid=john.doe,ou=People,dc=example,dc=com)</code>
Requested attributes	<code>1.1</code>

Example:

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com"
  --searchScope base "(member=uid=john.doe,ou=People,dc=example,dc=com) "
  "1.1"
```

Result:

If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group.

- If you do not know if the membership attribute for the specified group is `member` or `uniqueMember`, then revise the filter to allow either attribute.

Example:

This example adjusts the filter from the previous step's example to expand the membership attribute to allow for `member` and `uniqueMember` attributes.

```
( | (member=uid=john.doe,ou=People,dc=example,dc=com)
  (uniqueMember=uid=john.doe,ou=People,dc=example,dc=com) )
```

Determining the static groups to which a user belongs

Steps

- To determine the set of all static groups in which a user is specified as a member, perform a subtree search based at the top of the directory information tree (DIT).

Tip:

Configure the search filter to match any type of static group in which the specified user is a member.

Example:

The following table contains the search criteria to determine the set of all static groups in which the user `uid=john.doe,ou=People,dc=example,dc=com` is a member.

Base DN	<code>dc=example,dc=com</code>
Scope	<code>sub</code>
Filter	<code>((& (objectClass=groupOfNames) (member=uid=john.doe,ou=People,dc=example,dc=com)) (& (objectClass=groupOfUniqueNames) (uniqueMember=uid=john.doe,ou=People,dc=example,dc=com)) (& (objectClass=groupOfEntries) (member=uid=john.doe,ou=People,dc=example,dc=com)))</code>
Requested attributes	<code>1.1</code>

Example:

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" --searchScope sub \
" ( | (& (objectClass=groupOfNames)
(member=uid=john.doe,ou=People,dc=example,dc=com) ) \
(& (objectClass=groupOfUniqueNames) \
(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com) ) \
(& (objectClass=groupOfEntries) \
(member=uid=john.doe,ou=People,dc=example,dc=com) ) ) " "1.1"
```

Result:

Entries returned from the search represent each static group in which the specified user is a member.

Note:

A base level search of the user's entry for `isMemberOf` or `isDirectMemberOf` virtual attributes gives the same results. You can also use the virtual attributes with virtual static groups.

Determining the members of a static group

Steps

- To determine all of the members for a static group, retrieve the group entry, including the membership attribute.

 **Tip:**

To retrieve attributes from member entries, search all users whose `memberOf` attribute contains the group DN, returning the attributes desired.

To retrieve additional information about the members, such as attributes from member entries, issue a separate search for each member to retrieve the user entry and the desired attributes.

Example:

This table contains the search criteria to retrieve the list of all members for the group `cn=Test Group,ou=Groups,dc=example,dc=com`.

Base DN	<code>cn=Test Group,ou=Groups,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(objectClass=*)</code>
Requested attributes	<code>member uniqueMember</code>

Example:

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com" \
  --searchScope base "(objectclass=*)" uniqueMember
```

Result:

The returned entry includes the DNs of all users that are members of that group.

Using dynamic groups

Dynamic groups contain a set of criteria to identify members rather than maintaining an explicit list of group members.

If a new user entry is created, or if an existing entry is modified so that it matches the membership criteria, then the user is considered a member of the dynamic group. Similarly, if a member's entry is deleted, or if it is modified so that it no longer matches the group criteria, then the user is no longer considered a member of the dynamic group.

In the Directory Server, dynamic groups include the `groupOfURLs` structural object class and use the `memberurl` attribute to provide an LDAP URL that defines the membership criteria. The base, scope, and filter of the LDAP URL is used in the process of making the determination, and any other elements present in the URL are ignored.

Example

For example, the following entry defines a dynamic group in which all users below `dc=example,dc=com` with an `employeeType` value of `contractor` are considered members of the group.

```
dn: cn=Sales Group,ou=groups,dc=example,dc=com
objectClass: top
```

```
objectClass: groupOfURLs
cn: Sales Group
memberURL: ldap:///dc=example,dc=com??sub?(employeeType=contractor)
```

Assuming that fewer than 80,000 entries have the `employeeType` of `contractor`, you must create the following index definition to evaluate the dynamic group.

```
$ bin/dsconfig create-local-db-index --backend-name userRoot \
--index-name employeeType --set index-entry-limit:80000 \
--set index-type:equality
```

Creating dynamic groups

Configure a dynamic group in the same manner as static groups using an LDIF file.

About this task

Dynamic groups contain a membership list of attributes determined by search filter using an LDAP URL. You must use the `groupOfURLs` object class and the `memberURL` attribute.

Steps

1. Use `ldapsearch` to verify that `uid=user.15` is not part of any group.

- a. Assume that `uid=user.15` is not part of any group.

You add the user to the dynamic group in a later step.

Result:

```
dn: uid=user.15,ou=People,dc=example,dc=com
```

- b. Assume for this example that `uid=user.0` has an `ou=Engineering` attribute indicating that he or she is a member of the engineering department.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
"(uid=user.0)" ou isMemberOf
```

Result:

```
dn: uid=user.0,ou=People,dc=example,dc=com
ou: Engineering
```

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
"(uid=user.15)" ou
```

2. Open a text editor, and then create a dynamic group entry in LDIF. Save the file as `add-dynamic-group.ldif`.

The LDIF defines the dynamic group to include all users who have the `ou=Engineering` attribute.

Example:

```
dn: cn=eng-staff,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfURLs
ou: groups
cn: eng-staff
memberURL: ldap:///ou=People,dc=example,dc=com??sub?(ou=Engineering)
```

3. Use `ldapmodify` to add the group entry to the server.

Example:

```
$ bin/ldapmodify --defaultAdd --filename add-dynamic-group.ldif
```

4. Use `ldapsearch` to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.0` is a member of the `cn=Engineering` group or any other group.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" isMemberOf
```

Result:

```
dn: uid=user.0,ou=People,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

5. Run the following command to return the DNs of entries that are part of the `cn=eng-staff` dynamic group and sort them in ascending order by the `sn` attribute.

If your data is relatively small (under 1 million entries), you can search for all users in the group that meet the search criteria (`ou=Engineering`). For larger databases, it is not practical to run a database-wide search for all users as there can be a performance hit on the Directory Server.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --sortOrder sn \
"(isMemberOf=cn=eng-staff,ou=groups,dc=example,dc=com)" dn
```

6. Add `uid=user.15` to the `eng-staff` group by adding an `ou=Engineering` attribute to the entry.

This step highlights an advantage of dynamic groups: you can make a change in an entry without explicitly adding the DN to the group as you would with static groups. The entry is automatically added to the `eng-staff` dynamic group.

Example:

```
$ bin/ldapmodify
dn: uid=user.15,ou=People,dc=example,dc=com
changetype: modify
add: ou
ou: Engineering
```

7. Use `ldapsearch` to check if the user is part of the `cn=eng-staff` dynamic group.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
"(uid=user.15)" isMemberOf
```

Result:

```
dn: uid=user.15,ou=People,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

Searching dynamic groups

The following sections describe how to compose searches to determine if a user is a member of a dynamic group, to determine all the dynamic groups in which a user is a member, and to determine all the members of a dynamic group.

Determining if a user is a dynamic group member

Steps

- To determine whether a user is a member of a specific dynamic group, run a base-level search to verify that the user's entry is both within the scope of the member URL and that it matches the filter contained in that URL.

Tip:

You can verify that a user's entry is within the scope of the URL using simple client-side only processing. Evaluating the filter against the entry on the client side is more complicated. While possible, especially in clients able to perform schema-aware evaluation, a simple alternative is to perform a base-level search to retrieve the user's entry with the filter contained in the member URL.

Example:

This table contains the search criteria to determine if the user `uid=john.doe,ou=People,dc=example,dc=com` is a member of the dynamic group with the desired member URL.

Base DN	<code>uid=john.doe,ou=People,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(ou=Engineering)</code>
Requested Attributes	<code>1.1</code>

Example:

```
$ bin/ldapsearch --baseDN "uid=john.doe,ou=People,dc=example,dc=com" \
  --searchScope base "(ou=Engineering)" "1.1"
```

Note:

The search requires the user DN to be under the search base defined in the `memberurl` attribute for the user to be a member.

Result:

If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group.

Determining the dynamic groups to which a user belongs

Steps

- To determine the set of all dynamic groups in which a user is a member, perform a search to find all dynamic group entries defined in the server using a subtree search with a filter of `(objectClass=groupOfURLs)`.

 **Tip:**

You should retrieve the `memberURL` attribute so that you can use the logic described in the previous section to determine whether the specified user is a member of each of those groups.

Example:

The following table contains the search criteria to determine the set of all dynamic groups defined in the `dc=example,dc=com` tree.

Base DN	<code>dc=example,dc=com</code>
Scope	<code>sub</code>
Filter	<code>(objectClass=groupOfURLs)</code>
Requested Attributes	<code>memberURL</code>

Example:

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" \
  --searchScope sub "(objectClass=groupOfURLs)" "memberURL"
```

Result:

Each entry returned is a dynamic group definition. You can use the base, scope, and filter of its `memberURL` attribute to determine whether the user is a member of that dynamic group.

Determining the members of a dynamic group

Steps

- To determine all members of a dynamic group, issue a search using the base, scope, and filter of the member URL.

 **Note:**

The set of requested attributes should reflect the attributes desired from the member user entries or `"1.1"` if no attributes are needed.

Example:

This table contains the search criteria to retrieve the list of all members of the group `dc=example,dc=com` with the `cn` and `mail` attributes.

Base DN	<code>dc=example,dc=com</code>
Scope	<code>sub</code>

Filter	(employeeType=contractor)
Requested Attributes	cn, mail

Example:

CAUTION:

This search might be extensive if the associated filter is not indexed or if the group contains a large number of members.

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" \
  --searchScope sub "(employeeType=contractor)" "cn, mail"
```

Using dynamic groups for internal operations

Use dynamic groups for internal operations, such as Access control instruction (ACI) or component evaluation.

The Directory Server performs the `memberurl` parsing and internal LDAP search. However, the internal search operation cannot be performed with access control instructions applied to it.

For example, the following dynamic group represents an organization's employees within the same department.

```
dn: cn=department 202,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: department 202
owner: uid=user.1,ou=people,dc=example,dc=com
owner: uid=user.2,ou=people,dc=example,dc=com
memberURL: ldap:///ou=People,dc=example,dc=com??sub?
  (&(employeeType=employee)(departmentNumber=202))
description: Group of employees in department 202
```

The above group could be referenced from within the ACI at the `dc=example, dc=com` entry, as in the following example.

```
dn:dc=example,dc=com
aci: (targetattr="employeeType")
  (version 3.0; acl "Grant write access to employeeType" ;
    allow (all) groupdn="ldap:///cn=department
  202,ou=groups,dc=example,dc=com";)
```

Any user matching the filter can bind to the server with their entry and modify the `employeeType` attribute within any entry under `dc=example, dc=com`.

Using virtual static groups

Virtual static groups make it possible to get the efficiency and ease of management of a dynamic group while allowing clients to interact with them as a static group.

About this task

Static groups can be easier to interact with than dynamic groups, but large static groups can be expensive to manage and require a large amount of memory to hold in the internal group cache. Directory Server provides a third type of group: a virtual static group, which references another group and provides access to the members of that group as if it was a static group.

Steps

- To create a virtual static group, create an entry that has a structural object class of either `groupOfNames` or `groupOfUniqueNames` and an auxiliary class of `ds-virtual-static-group`.

Note:

It should include a `ds-target-group-dn` attribute, whose value is the group from which the virtual static group should obtain its members.

You must also enable a virtual attribute that allows the `member` attribute to be generated based on membership for the target group.

Example:

This example creates a virtual static group that exposes the members of the `cn=Sales Group,ou=Groups,dc=example,dc=com` dynamic group as if it were a static group.

```
dn: cn=Virtual Static Sales Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfNames
objectClass: ds-virtual-static-group
cn: Virtual Static Sales Group
ds-target-group-dn: cn=Sales Group,ou=Groups,dc=example,dc=com
```

- To enable a configuration object for the virtual static member attribute, use the `set-virtual-attribute-prop` option with `dsconfig`.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member"
\
  --set enabled:true
```

Note:

A configuration object for this virtual attribute is in the server configuration but is disabled by default.

If you want to use virtual static groups with the `groupOfUniqueNames` object class, enable the `Virtual Static uniqueMember` virtual attribute in the same way.

Creating virtual static groups

If your application only supports static groups but has scalability issues, using a virtual static group is a possible solution.

About this task

A virtual static group uses a virtual attribute that is dynamically generated when called after which the operations that determine group membership are passed to another group, such as a dynamic group. You must use the `ds-virtual-static-group` object class and the `ds-target-group-dn` virtual attribute.

Virtual static groups are best used when determining if a single user is a member of a group. Do not use it if an application accesses the full list of group members due to the performance expense at constructing the list.

Note:

If you have a small database and an application that requires that the full membership list be returned, enable the `allow-retrieving-membership` property for the Virtual Static `uniqueMember` virtual attribute using the `dsconfig` tool.

To create a virtual static group:

Steps

1. In a text editor, create a group entry in LDIF, and then save the file.

Example:

In this example, the entry contains the `groupOfUniqueNames` object class, but in place of the `uniqueMember` attribute is the `ds-target-group-dn` virtual attribute, which is part of the `ds-virtual-static-group` auxiliary object class.

In this example, the file is named `add-virtual-static-group.ldif`.

```
dn: cn=virtualstatic,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
objectclass: ds-virtual-static-group
ou: groups
cn: virtual static
ds-target-group-dn: cn=eng-staff,ou=groups,dc=example,dc=com
```

2. To add the virtual static group entry to the server, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify -h server1.example.com -p 389 -D
"uid=admin,dc=example,dc=com" \
-w password -a -f add-virtual-static-group.ldif
```

3. To enable the Virtual Static `uniqueMember` attribute, use the `set-virtual-attribute-prop` option with `dsconfig`.

Note:

This attribute is disabled by default.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set enabled:true
```

4. To determine if a user is part of a virtual static group, use `ldapsearch`.

Example:

In [Creating dynamic groups](#) on page 322, the example sets up `uid=user.0` to be part of the `cn=eng-staff` dynamic group. This example determines if `uid=user.0` is part of the virtual static group using the `isMemberOf` virtual attribute.

```
$ bin/ldapsearch -h server1.example.com -p 389 -D "cn=Directory Manager"
\
```

```
-w secret -b dc=example,dc=com" "(uid=user.0)" isMemberOf
```

Example:

The following example determines if `uid=user.0` is part of the virtual static group without using the `isMemberOf` virtual attribute in the `ldapsearch`.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
-b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
"(&(objectclass=groupOfUniqueNames) \
(uniqueMember=uid=user.0,ou=People,dc=example,dc=com))"
```

Result:

Using the `isMemberOf` virtual attribute returns the following.

```
dn: uid=user.0,ou=People,dc=example,dc=com
isMemberOf: cn=virtualstatic,ou=groups,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

Note:

You should see the returned `cn=virtualstatic` entry if successful.

- Optional: To try searching for a user that is not part of the `cn=eng-staff` dynamic group, use `ldapsearch`.

Example:

This example searches for `uid=user.20`.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
-b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
"(&(objectclass=groupOfUniqueNames) \
(uniqueMember=uid=user.20,ou=People,dc=example,dc=com))"
```

Result:

No entries are returned.

Searching virtual static groups

Virtual static groups behave like static groups, so the process for determining whether a user is a member of a virtual static group is identical to that of a member in a static group.

The process for determining all virtual static groups in which a user is a member is similar to the process for standard static groups in which a user is a member. The query provided in the static groups discussion returns virtual static groups in addition to standard static groups because the structural object class of a virtual static group is the same as the structural object class for a static group.

You can retrieve a list of all members of a virtual static group in the same way as a standard static group: retrieve the `member` or `uniqueMember` attribute of the desired group. However, because virtual static groups are backed by dynamic groups and the process for retrieving member information for dynamic groups can be expensive, virtual static groups do not allow retrieving the full set of members by default.

To make the configuration change to allow full membership retrieval, update the virtual attribute used to expose membership.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
--set allow-retrieving-membership:true
```

**Note:**

This can be an expensive operation, so you should leave the option to allow retrieving virtual static group membership as disabled unless it is required.

Creating nested groups

PingDirectory Server supports nested groups where the distinguished name (DN) of an entry that defines a group is included as a member in the parent entry.

About this task

The following example shows a nested static group, such as `cn=Engineering Group`, that has `uniquemember` attributes consisting of other groups, such as `cn=Developers Group` and the `cn=QA Group` respectively.

```
dn: cn=Engineering Group,ou=Groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=Groups,dc=example,dc=com
uniquemember: cn=QA,ou=Groups,dc=example,dc=com
```

By default, nested group support is enabled on the Directory Server.

The Directory Server uses a group cache to support nested groups without the performance hit. The cache supports static group nesting that includes other static, virtual static, and dynamic groups. The Directory Server provides a new monitoring entry for the group cache, `cn=Group Cache,cn=Monitor`.

In practice, nested groups are not commonly used for the following reasons:

- LDAP specifications do not directly address the concept of nested groups, and some servers do not provide any level of support for them.
- Supporting nested groups in LDAP clients is not trivial, and many directory server-enabled applications that can interact with groups do not provide any support for nesting.

**Tip:**

Disable this support if:

- Nesting support is not needed in your environment.
- Nesting support is only required for clients but is not needed for server-side evaluation, such as for groups used in access control rules, criteria, virtual attributes, or other ways that the server might need to make a membership determination.

To create nested static groups:

Steps

1. Open a text editor, and create a group entry in LDIF.
 - a. Include the `groupOfUniqueNames` object class and `uniquemember` attributes.
 - b. If you did not have `ou=groups` set up in your server, then add it in the same file.
 - c. Save the file as `nested-group.ldif`.

Assume that the static groups, `cn=Developers Group` and `cn=QA Group`, have been configured.

Example:

The following example shows how to set up a nested static group, which is a static group that contains `uniquemember` attributes whose values contain other groups (static, virtual static, or dynamic).

```
dn: ou=groups,dc=example,dc=com
objectclass: top
objectclass: organizationalunit
ou: groups

dn: cn=Engineering Group,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=groups,dc=example,dc=com
uniquemember: cn=QA,ou=groups,dc=example,dc=com
```

2. To add the group entry, use `ldapmodify`.

Example:

```
$ bin/ldapmodify --defaultAdd --filename nested-static-group.ldif
```

3. Using the `isMemberOf` virtual attribute that checks the group membership for an entry, verify the configuration.

By default, the virtual attribute is enabled. Use `ldapsearch` to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.14` is a member of the `cn=Development` group.

Example:

In this example, assume that the administrator has the privilege to view operational attributes.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)" isMemberOf

dn: uid=user.14,ou=People,dc=example,dc=com
isMemberOf: cn=Development,ou=groups,dc=example,dc=com
```

4. In a text editor, create an Access control instruction (ACI) in LDIF. Save the file as `eng-group-aci.ldif`.

Tip:

Use the group as a target in ACI.

Example:

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target ="ldap:///ou=People,dc=example,dc=com")
      (targetattr != "cn || sn || uid")
      (targetfilter ="(ou=Engineering Group)")
      (version 3.0; aci "Engineering Group Permissions";
```

```
allow (write) (groupdn = "ldap:///cn=Engineering
Group,ou=groups,dc=example,dc=com");)
```

5. Add the file using the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --filename eng-group-aci.ldif
```

Note:

When nesting dynamic groups, you cannot include other groups as members of a dynamic group. You can only support nesting by including the members of another group with a filter in the member URL. For example, if you have two groups, `cn=dynamic1` and `cn=dynamic2`, you can nest one group in another by specifying it in the member URL.

```
cn=dynamic1,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
memberURL: ldap:///dc=example,dc=com??sub?
(isMemberOf=cn=dynamic2,ou=groups,dc=example,dc=com)
```

The members included from the other group using this method are not considered nested members and are returned even when using `isDirectMemberOf` when retrieving the members.

Maintaining referential integrity with static groups

The Directory Server automatically updates references to an entry whenever that entry is removed or renamed in the referential integrity process.

About this task

If a user entry is deleted, the referential integrity plugin removes that user from any static groups in which the user was a member. This is not necessary for dynamic groups because no explicit membership is maintained. Similarly, if a modify distinguish name (DN) operation is performed to move or rename a user entry, then referential integrity updates static groups in which that user is a member with the new user DN.

In the default configuration, the referential integrity processing performs synchronously. Because the necessary cleanup work must complete before the response to the original operation returns, the throughput and response time of delete and modify DN operations might be adversely impacted. To alleviate this performance impact, change the configuration to use a non-zero update interval. As a result, the referential integrity process uses a separate background thread and does not significantly delay the response to delete or modify DN operations.

Performing referential integrity processing in a background thread can introduce a race condition that might adversely impact clients that delete a user and then immediately attempt to re-add it and establish new group memberships. For example, if referential integrity processing has not yet been completed for the delete, then newly-established group memberships might be removed along with those that existed for the previous user. Similarly, if the newly-created user is to be a member of one or more of the same groups as the previous user, then the client attempts to re-establish those memberships can fail if the referential integrity processing has not removed the previous membership. Use the default synchronous behavior unless the performance impact associated with synchronous referential integrity processing is unacceptable or clients might be affected by delayed referential integrity processing.

Other configuration attributes for this plugin include:

Referential integrity plugin configuration attributes and their descriptions

Configuration attribute	Description
<code>attribute-type</code>	This attribute specifies the names or OIDs of the attribute types for which referential integrity will be maintained. By default, referential integrity is maintained for the <code>member</code> and <code>uniqueMember</code> attributes. Any attribute types specified must have a syntax of either distinguished name (OID "1.3.6.1.4.1.1466.115.121.1.12") or name and optional UID (OID "1.3.6.1.4.1.1466.115.121.1.34"). The specified attribute types must also be indexed for equality in all backends for which referential integrity is to be maintained.
<code>base-dn</code>	This attribute specifies the subtrees for which referential integrity will be maintained. If one or more values are provided, then referential integrity processing will only be performed for entries which exist within those portions of the DIT. By default, if no values are provided then entries within all public naming contexts will be included.
<code>log-file</code>	This attribute specifies the path to a log file that may be used to hold information about the DNs of deleted or renamed entries. If the plugin is configured with a nonzero update interval, this log file helps ensure that appropriate referential integrity processing occurs even if the server is restarted.
<code>update-interval</code>	This attribute specifies the maximum length of time that a background thread may sleep between checks of the referential integrity log file to determine whether any referential integrity processing is required. By default, this attribute has a value of "0 seconds", which indicates that all referential integrity processing is to be performed synchronously before a response is returned to the client. A duration greater than 0 seconds indicates that referential integrity processing will be performed in the background and will not delay the response to the client.

By default, referential integrity support is disabled. To enable the support:

Steps

- Use the `dsconfig` tool as shown.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
```

```
--set enabled:true
```

Note:

The internal operations of the referential integrity plugin are not replicated. In a replicated topology, you must enable the referential integrity plugin on all servers in the topology to ensure that changes made by the referential integrity plugin are passed along to a replication server.

For more information about administering the referential integrity plugin, see [Configuring the Server](#) in PingDirectory Server Administration Guide.

Monitoring the group membership cache

At startup, the Directory Server logs information about the group membership cache's memory consumption.

The hard-coded cache contains information about the group memberships for internal processing, such as Access control instructions (ACIs). By default, the group membership cache is enabled.

The information about this cache logs to the standard output log `server.out` and the standard error log. When using groups, use the log information to tune the server for best performance. At startup, the server logs a message to the `server.out` log.

The following is a sample standard output log.

```
[16/Aug/2011:17:14:39.462 -0500] category=JEB severity=NOTICE
msgID=1887895587
msg="The database cache now holds 3419MB of data and is 32 percent full"
```

The following is a sample error log.

```
[16/Aug/2011:18:40:39.555 -0500] category=EXTENSIONS severity=NOTICE
msgID=1880555575
msg="'Group cache (174789 static group(s) with 7480151 total memberships and
1000002
unique members, 0 virtual static group(s), 1 dynamic group(s))' currently
consumes
149433592 bytes and can grow to a maximum of 149433592 bytes"
```

Using the entry cache to improve the performance of large static groups

The PingDirectory Server provides an entry cache implementation, which allows for fine-grained control over entries that are held in the cache.

You can define filters to specify the entries included in or excluded from the cache, and you can restrict the cache so that it holds only entries with at least a specified number of values for a given set of attributes.

For most circumstances, use the Directory Server without an entry cache. In most cases, the Directory Server efficiently retrieves and decodes entries from the database. The database cache is more space-efficient than the entry cache, and heavy churn in the entry cache can adversely impact garbage collection behavior.

Entry caches with large static groups

If the Directory Server contains large static groups, such as those containing thousands or millions of members, and clients need to frequently retrieve or otherwise interact with these groups, enable an entry cache that holds only large static groups.

In servers containing large static groups, define an entry cache to hold only those large static groups. To define this entry cache, include a filter that matches only group entries, as shown in the following example.

```
(| (objectclass=groupOfNames) (objectclass=groupOfUniqueNames)
(objectclass=groupOfEntries))
```

The filter contains a minimum value count so that only groups with a large number of members, such as those with at least 100 `member` or `uniqueMember` values are included. By default, the Directory Server entry cache implementation with these settings is disabled. To use this implementation, you must enable these settings.

Enabling the entry cache

Steps

- To enable the entry cache, use the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-entry-cache-prop --cache-name "Static Group Entry
Cache" \
--set enabled:true
```

Creating your own entry cache for large groups

Steps

- To create your own entry cache for large groups, use the `dsconfig create-entry-cache` subcommand.

Example:

```
# bin/dsconfig create-entry-cache --type fifo \
--set enabled:true \
--set cache-level:10 \
--set max-entries:175000 \
--set "include-filter:(objectClass=groupOfUniqueNames)" \
--set min-cache-entry-value-count:10000 \
--set min-cache-entry-attribute:uniquemember
```

Monitoring the entry cache

Steps

- To monitor the memory consumed by your entry cache, use the `entry-cache-info` property in the periodic stats logger.
 - To retrieve the monitor entry over LDAP, issue a search on `baseDN="cn=monitor"` using `filter="(objectClass=ds-fifo-entry-cache-monitor-entry)"`.

Note:

By default, the entry cache memory is set to 75% with a maximum of 90%.

Example:

```
dn: cn=Static Group Entry Cache Monitor,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-fifo-entry-cache-monitor-entry
```

```

objectClass: extensibleObject
cn: Static Group Entry Cache Monitor
cacheName: Static Group Entry Cache
entryCacheHits: 6416407
entryCacheTries: 43069073
entryCacheHitRatio: 14
maxEntryCacheSize: 12723879900
currentEntryCacheCount: 1
maxEntryCacheCount: 175000
entriesAddedOrUpdated: 1
evictionsDueToMaxMemory: 0
evictionsDueToMaxEntries: 0
entriesNotAddedAlreadyPresent: 0
entriesNotAddedDueToMaxMemory: 0
entriesNotAddedDueToFilter: 36652665
entriesNotAddedDueToEntrySmallness: 0
lowMemoryOccurrences: 0
percentFullMaxEntries: 0
jvmMemoryMaxPercentThreshold: 75
jvmMemoryCurrentPercentFull: 24
jvmMemoryBelowMaxMemoryPercent: 51
isFull: false
capacityDetails: NOT FULL: The JVM is using 24% of its available memory.
  Entries can be
  added to the cache until the overall JVM memory usage reaches the
  configured limit of
  75%. Cache has 174999 remaining entries before reaching the configured
  limit of 175000.

```

Tuning the index entry limit for large groups

The Directory Server uses indexes to improve database search performance and to provide consistent search rates regardless of the number of database objects stored in the directory information tree (DIT).

About this task

You can specify an index entry limit property that defines the maximum number of entries allowed to match a given index key before the server no longer maintains it.

Steps

- When the index keys have reached the default limit of 4000, rebuild the indexes using the **rebuild-index** tool.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index objectclass
```

- For Directory Server environment directories containing more than 4000 groups with the same structural object class, such as more than 4000 entries, 4000 `groupOfUniqueNames` entries, 4000 `groupOfEntries` entries, or 4000 `groupOfURLs` entries, increase the index entry limit for the

`objectClass` attribute so that it has a value larger than the maximum number of group entries of each type by setting the `index-entry-limit` property in the command line.

Note:

For most Directory Server environments, the default index entry limit value of 4000 entries is sufficient. However, group-related processing might be necessary to increase the index entry limit.

Example:

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name objectClass --set index-entry-limit:175000
```

- As an alternative, create a separate backend to hold these group entries so that an unindexed search in that backend yields primarily group entries.

Note:

If you make no changes, then the internal search performed at startup to identify all groups and any user searches looking for groups of a given type can be expensive.

- For directories in which any single user is be a member of more than 4000 static groups of the same type, increase the index entry limit for the `member` or `uniqueMember` attribute to a value larger than the maximum number of groups in which any user is a member.

Note:

If you do not increase the limit, searches to retrieve the set of all static groups in which the user is a member can be unindexed and therefore expensive.

Summary of commands to search for group membership

The following summary of commands show the fastest way to retrieve direct or indirect member distinguished names (DNs) for groups.

- To retrieve direct member, non-nested DN's of group `cn=group.1,ou=groups,dc=example,dc=com`, run the following.

```
$ bin/ldapsearch --baseDN "cn=group.1,ou=Groups,dc=example,dc=com"
  "(objectClass=*)" uniqueMember member
```

- To retrieve direct member entries or non-nested under `dc=example,dc=com` of group `cn=group.1,ou=groups,dc=example,dc=com`, run the following.

```
$ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com"
  "(isDirectMemberOf=cn=group.1,ou=Groups,dc=example,dc=com) "
```

This is useful when attributes from member entries are used in the filter or being returned.

- To retrieve group DN's in which user `uid=user.2,ou=people,dc=example,dc=com` is a direct member or non-nested, static groups, run the following.

```
$ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com"
  "(objectClass=*)" isDirectMemberOf
```

- To retrieve all member entries under `ou=people,dc=example,dc=com` of group `cn=group.1,ou=groups,dc=example,dc=com`, run the following.

```
$ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com"
"(isMemberOf=cn=group.1,ou=Groups,dc=example,dc=com)"
```

- To retrieve the group DNs in which user `uid=user.2,ou=people,dc=example,dc=com` is a member, run the following.

```
$ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com"
"(objectClass=*)" isMemberOf
```

Migrating Oracle groups

The following sections outline the procedures for migrating static groups to both Ping Identity static groups and virtual static groups as well as how to migrate dynamic groups.

You can migrate Oracle static and dynamic groups to PingDirectory Server groups. For more information about the differences in access control evaluation between Oracle and PingDirectory Server, see [Migrating ACIs from Oracle to the Server](#) on page 465.

Migrating static groups

About this task

PingDirectory Server supports static LDAP groups with structural object classes of `groupOfNames`, `groupOfUniqueNames`, or `groupOfEntries`. In general, you can import static groups without modification.

You can enable a First-In, First-Out (FIFO) entry cache to cache group-to-user mappings, which improves performance when accessing large entries at the expense of greater memory consumption. PingDirectory Server provides an out-of-the-box FIFO entry cache object for this purpose. You must enable this object using `dsconfig` as described in [Using the Entry Cache to Improve the Performance of Large Static Groups](#).

To migrate static groups:

Steps

1. To enumerate any schema differences between the DSEE deployment and the Ping Identity deployment, use the `migrate-ldap-schema` tool.
2. To enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment, use the `migrate-sun-ds-config` tool.
3. Import or configure any necessary schema or configuration changes recorded by the tools in steps 1 and 2.
4. Import the existing users and groups using the `import-ldif` tool.
5. From the PingDirectory Server root directory, open the `docs/sun-ds-compatibility.dsconfig` file using a text editor.
6. Go to the **FIFO Entry Cache** section.
 - a. Read the accompanying comments.
 - b. To enable the corresponding `dsconfig` command, delete the comment character ("`#`").

Example:

```
$ bin/dsconfig set-entry-cache-prop \
--cache-name "Static Group Entry Cache" --set enabled:true
```

- To ensure that references to an entry are updated automatically when the entry is deleted or renamed, enable the Referential Integrity plugin.

Example:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" --
set enabled:true
```

Next steps

If the Directory Server is part of a replication topology, enable the Referential Integrity plugin for each replica.

Migrating static groups to virtual static groups

About this task

In many cases, using virtual static groups in place of static groups can produce marked performance gains without having to update client applications. Migrating to virtual static groups varies depending on the original directory information tree (DIT), but the general approach involves identifying common membership traits for all members of each group and then expressing those traits in the form of an LDAP URL.

For this task, consider the following:

- The common membership trait for all members of the `All Users` group is the parent distinguish name (DN) `ou=People,dc=example,dc=com`.
- In other cases, a common attribute might need to be used. For example, groups based on the location of its members could use the `l` location or `st` state attribute.
- The common case of an `All Users` group, which contains all entries under the parent DN `ou=People,dc=example,dc=com`.
- When implemented as a virtual static group, this group can have a large membership set without incurring the overhead of a static group.

To migrate Oracle Directory Server Enterprise Edition static groups to virtual static groups:

Steps

- Create a dynamic group.

Example:

```
dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: Dynamic All Users
memberURL: ldap:///ou=People,dc=example,dc=com??sub?(objectClass=person)
```

- Create a virtual static group that references the dynamic group.

Example:

```
dn: cn=All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
objectClass: ds-virtual-static-group
cn: All Users
ds-target-group-dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
```

3. To populate the All Users group with `uniqueMember` virtual attributes, enable the `Virtual Static uniqueMember` virtual attribute.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set enabled:true
```

4. To confirm that the virtual static group is correctly configured, check a user's membership in the group.

Example:

```
$ bin/ldapsearch --baseDN "cn=All Users,ou=Groups,dc=example,dc=com" \
--searchScope base
"(uniqueMember=uid=user.0,ou=People,dc=example,dc=com)" 1.1
```

Result:

```
dn: cn=All Users,ou=Groups,dc=example,dc=com
```

5. If a client application requires it, enable the ability to list all members of a virtual static group.

By default, this feature is disabled.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set allow-retrieving-membership: true
```

Tip:

You can implement the virtual static group using the `groupOfNames` object class instead of `groupOfUniqueNames`. To do this, update the `Virtual Static member` configuration object instead of the `Virtual Static uniqueMember` configuration object.

Migrating dynamic groups

About this task

The PingDirectory Server supports dynamic groups with the `groupofURLs` object class. In general, you can import dynamic groups without modification.

To migrate dynamic groups:

Steps

1. To enumerate any schema differences between the Directory Server Enterprise Edition (DSEE) deployment and the Ping Identity deployment, run the `migrate-ldap-schema` tool.
2. To enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment, run the `migrate-sun-ds-config` tool.
3. Import or configure any necessary schema and configuration changes recorded by the tools used in steps 1 and 2.
4. Import the existing users and groups using the `import-ldif` tool.

Working with Indexes

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the directory information tree (DIT).

Indexes are associated with attributes and stored in database index files, which are managed separately for each base distinguished name (DN) in the Directory Server.

Overview of indexes

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the directory information tree (DIT).

Indexes are associated with attributes and stored in database index files, which are managed separately for each base distinguished name (DN) in the Directory Server. The Directory Server automatically creates index files when you initialize a base DN or run the `dsconfig` tool to create a local DB backend. During modify operations, the Directory Server updates the database index files.

Note:

If you enable encryption on the server, indexes will be encrypted.

The PingDirectory Server comes with the following types of indexes:

Default system indexes

Ensures that the server operates efficiently. Indexes consist of database files that contain index keys mapping to the list of entry IDs.

Default Local DB indexes

Created for each database suffix. Modify the index to meet your system's requirements using the `dsconfig` tool.

Local DB VLV indexes

Allows a client to request the server to send search results using the virtual list view (VLV) control.

Filtered Indexes

Provides the ability to index an attribute, but only for entries that match a specified filter based on an equality index. You can only use the filtered index for searches containing your specified filter. The filtered index can be maintained independently of the equality index for the attribute even if a normal equality index is not maintained for the attribute.

General tips on indexes

Important critical indexes

The Directory Server has several built-in indexes on the local DB backend that are critical to internal server processing and should never be removed.

```
aci, ds-entry-unique-id, objectClass
```

Built-in indexes for efficient queries

The Directory Server has built-in indexes on the local DB backend. Internal processing of the server relies on the `aci`, `ds-soft-delete-from-dn`, `ds-soft-delete-timestamp`, `entryUUID`, `member`, `objectClass`, and `uniqueMember` indexes, which must not be removed. You can remove the `mail` and `uid` indexes, but these attributes are referenced from the Password Modify Extended Operation and their

removal causes problems with components, such as the Exact Match Identity Mapper. If you remove the `mail` or `uid` indexes, additional configuration changes might be necessary to ensure that the server starts properly. You can safely remove the `cn`, `givenName`, `mail`, `sn`, and `telephoneNumber` indexes if clients do not query on these attributes. This reduces the size of the database both on disk and in memory.

Online rebuilds

When an online index rebuild is in progress, the data in that backend is available and writable although the index being rebuilt is not used. Searches that attempt to use that attribute might be unindexed.

Index rebuild administrative alert

The Directory Server generates an administrative alert when the rebuild process begins and ends. It has a degraded-alert-type of `index-rebuild-in-progress` so that a Directory Proxy Server, such as the Directory Server can avoid using that server while the rebuild is in progress.

System indexes cannot be rebuilt

The contents of the backend must be exported and re-imported in order to rebuild system indexes. For more information, see the list of [System indexes](#) on page 344.

Indexing certain attributes

Ensure that the following recommendations are used when setting up the indexes:

- Do not use equality and substring indexes for attributes that contain binary data.
- Avoid approximate indexes for attributes containing numbers, such as telephone numbers.

Unindexed searches

Unindexed attributes result in longer search times as the database itself has to be searched instead of the database index file. Only users with the `unindexed-search` privilege are allowed to carry out unindexed searches. In general, you should prevent applications from performing unindexed searches so that searches that are not indexed would be rejected rather than tying up a worker thread. Ways to achieve this include the following:

- Make sure that only the absolute minimum set of users have the `unindexed-search` privilege. This privilege can be used without any other restrictions.
- To allow unindexed searches with some control, the Permit Unindexed Search request control can be used with the `unindexed-search-with-control` privilege. With this privilege, a user is only permitted to request an unindexed search if the search request includes the Permit Unindexed Search request control. The `unindexed-search` privilege allows a client to request an unindexed search without this control.
- You can use the Reject Unindexed Search request control to explicitly indicate that a client does not want the server to process an unindexed search request, regardless of privileges. For information about these controls, see the LDAP SDK. These capabilities are also available with the `ldapsearch` tool.
- Make sure that `allow-unindexed-searches` property is set to `false` in all client connection policies, in which unindexed searches should never be necessary. If the client connection policy should allow unindexed searches, set the `allow-unindexed-searches-with-control` property to `true`. If `allow-unindexed-searches` is `false` but, `allow-unindexed-searches-with-control` is `true`, the policy only permits an unindexed search if the request includes the Permit Unindexed Search request control. For more information, see the LDAP SDK and the `ldapsearch` tool.
- Set a nonzero value for the `maximum-concurrent-unindexed-searches` global configuration property to ensure that if unindexed searches are allowed, only a limited number of them are active at

any given time. Administrators can configure the maximum number of concurrent unindexed searches by setting a property under Global Configuration.

To change the maximum number of concurrent unindexed searches, use the **dsconfig** tool to set a value for the number. A default value of "0" represents no limit on the number of concurrent unindexed searches.

```
$ bin/dsconfig set-global-configuration-prop \
  --set maximum-concurrent-unindexed-searches:2
```

Index entry limit

The Directory Server specifies an index entry limit property. This property defines the maximum number of entries that are allowed to match a given index key before it is no longer maintained by the server. If the index keys have reached this limit (default value is 4000), then you must rebuild the indexes using the **rebuild-index** tool. If an index entry limit value is set for the local DB backend, it overrides the value set for the overall JRE backend index entry limit configuration, such as 4000.

To change the default index entry limit, use the **dsconfig** tool, as in the following example.

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name cn --set index-entry-limit:5000
```

Rebuild index vs. full import

Expect a limited amount of database growth due to the existence of old data when running **rebuild-index** versus doing a full import of your database.

Index types

PingDirectory Server supports several types of indexes to quickly find entries that match search criteria in LDAP operations.

Entry IDs

Directory Server uses an attribute's matching rules to normalize its values and uses those values as index keys to a list of matching entry IDs.

Entry IDs are integer values that are used to uniquely identify an entry in the backend by means of a set of database index files.

Entry IDs can look like the following:

- id2entry
- dn2id
- dn2uri
- id2children
- id2subtree

Index types

Matching rules are elements defined in the schema that tell the server how to interact with the particular attribute. For example, the `uid` attribute has an equality matching rule and thus has an equality index maintained by the Directory Server. The following table describes the index types.

Directory Server Index Types

Index Type	Description
Approximate	Used to efficiently locate entries that are approximately equal to a given assertion. Approximate indexes can only be applied to attributes that have a corresponding approximate matching rule.
Equality	Used to efficiently locate entries are exactly equal to a given assertion. Equality indexes can only be applied to attributes that have a corresponding equality matching rule.
Filtered	Uses a defined search filter for a specific attribute. This is an offshoot of the equality index, but you can maintain it independently of the equality index for a specific attribute.
Ordering	Used to efficiently identify which entries have a relative order of values for an attribute. Ordering indexes can only be applied to attributes that have a corresponding ordering matching rule.
Presence	Used to efficiently locate entries that have at least one value for a specified attribute. There is only one presence index key per attribute.
Substring	Used to efficiently locate entries that contain specific substrings to a given assertion. Substring indexes can only be applied to attributes that have a corresponding substring matching rule.

System indexes

PingDirectory Server contains a set of system database index files that ensure that the server operates efficiently. These indexes cannot be modified or deleted.

System Indexes

Index	Description
dn2id	Allows quick retrieval of distinguished names (DNs). The <code>dn2id</code> database has one record for each entry. The key is the normalized entry DN and the value is the entry ID.
id2entry	Allows quick retrieval of entries. The <code>id2entry</code> database contains the LDAP entries. The database key is the entry ID and the value is the entry contents.
referral	Allows quick retrieval of referrals. The referral database called <code>dn2uri</code> contains URIs from referral entries. The key is the DN of the referral entry and the value is that of a labeled URI in the <code>ref</code> attribute for that entry.
id2children	Allows quick retrieval of an entry and its children. The <code>id2children</code> database provides a mapping between an entry's unique identifier and the entry unique identifiers of the corresponding entry's children.
id2subtree	Allows quick retrieval of an entry's subtree. The <code>id2subtree</code> database provides a mapping between an entry's unique identifier and the unique identifiers in its subtree.

Viewing the system indexes

Steps

- To view the system and user indexes, use the `dbtest` command.

Example:

```
$ bin/dbtest list-index-status --baseDN dc=example,dc=com --backendID
userRoot
```

The index status indicates whether or not an index is trusted. An untrusted index requires rebuilding.

Managing local DB indexes

To modify the local database (DB) indexes to meet your system's requirements, use the `dsconfig` tool. If you are using the `dsconfig` tool in interactive command-line mode, access the **Local DB Index** menu from the **Basic object** menu.

Viewing the list of local DB indexes

Steps

- To view the default list of indexes, run `dsconfig` with the `list-local-db-indexes` option.

Example:

```
$ bin/dsconfig list-local-db-indexes --backend-name userRoot
```

Result:

Local DB Index	Type	index-type
aci	generic	presence
cn	generic	equality, substring
ds-entry-unique-id	generic	equality
givenName	generic	equality, substring
mail	generic	equality
member	generic	equality
objectClass	generic	equality
sn	generic	equality, substring
telephoneNumber	generic	equality
uid	generic	equality
uniqueMember	generic	equality

Viewing a property for all local DB indexes

Steps

- To view a property assigned set for all local DB indexes, run `dsconfig` with the `--property` option.

Repeat the option for each property that you want to list.

Example:

In this example, the `prime-index` property specifies if the backend is configured to prime the index at startup.

```
$ bin/dsconfig list-local-db-indexes --property index-entry-limit \
--property prime-index --backend-name userRoot
```

Viewing the configuration parameters for local DB index

Steps

- To view the configuration setting of a local DB index, run **dsconfig** with the `get-local-db-index-prop` option and the `--index-name` and `--backend-name` properties.

Tip:

To view the advanced properties, add the `--advanced` option to your command.

Example:

```
$ bin/dsconfig get-local-db-index-prop --index-name aci \
  --backend-name userRoot
```

Modifying the configuration of a local DB index

About this task

To modify an index, run the **dsconfig** tool. Any modification or addition of an index requires rebuilding the indexes. In general, an index only needs to be built once after it has been added to the configuration.

Note:

If you add an index and then import the data using the **import-ldif** tool, the index is automatically rebuilt. If you add an index and then add the data using a different method, you must rebuild the index using the **rebuild-index** tool.

Steps

- To modify an index, run **dsconfig** with the `set-local-db-index-prop` option and the `--index-name` and `--backend-name` properties.

Example:

This example updates the `prime-index` property, which loads the index at startup. To access this command, use the `--advanced` option.

```
$ bin/dsconfig set-local-db-index-prop --index-name uid \
  --backend-name userRoot --set prime-index:true
```

- To view the index and verify the change, run **dsconfig** with the `get-local-db-index-prop` option.

Example:

```
$ bin/dsconfig get-local-db-index-prop --index-name uid \
  --backend-name userRoot
```

3. Stop the Directory Server.

**Note:**

Although you can rebuild an index with the server online, it is not recommended. For more information, see [General tips on indexes](#) on page 341.

Example:

```
$ bin/stop-server
```

4. To rebuild the index, run the **rebuild-index** tool.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index uid
```

5. Restart the Directory Server.

Example:

```
$ bin/start-server
```

Creating a new local DB index

Steps

1. To create a new local DB index, run **dsconfig** with the `--create-local-db-index` option and the `--index-name`, `--backend-name`, and `--set index-type:<value>` options.

Example:

```
$ bin/dsconfig create-local-db-index \
  --index-name roomNumber --backend-name userRoot \
  --set index-type:equality
```

2. To view the index, run **dsconfig** with the `get-local-db-index-prop` option.

Example:

```
$ bin/dsconfig get-local-db-index-prop \
  --index-name roomNumber --backend-name userRoot
```

3. Stop the Directory Server.

**Note:**

Although you can rebuild an index with the server online, it is not recommended. For more information, see [General tips on indexes](#) on page 341.

Example:

```
$ bin/stop-server
```

4. To rebuild the index, run the **rebuild-index** tool.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index roomNumber
```

5. Restart the Directory Server.

Example:

```
$ bin/start-server
```

Deleting a local DB index

About this task

Check that no plugin applications are using the index before deleting it.

Note:

When the index is deleted, the corresponding index database is also deleted. The disk space is reclaimed after the cleaner threads begin.

Steps

- To remove an index from the database, run **dsconfig** with the `delete-local-db-index` option.

Example:

```
$ bin/dsconfig delete-local-db-index \
  --index-name roomNumber --backend-name userRoot
```

Composite indexes

A PingDirectory Server composite index can generate from multiple pieces of information, such as a combination of multiple filter components or a combination of filter components and a base distinguished name (DN), or from a single piece of information.

Note:

Because composite indexes are much more efficient than exploded indexes when dealing with large numbers of identical keys, use composite indexes for data sets where large numbers of entries (several thousand or more) share the same value for an indexed attribute.

To improve the performance of searches in directories with a large number of entries, especially with a large number of non-leaf entries, use equality composite indexes to combine a mandatory equality filter pattern with an optional base DN pattern.

Equality composite indexes offer two advantages over existing equality attribute indexes in the these types of deployments, a base DN pattern and index pages.

Base DN pattern

If a directory environment has many branches, but searches are often done within specific individual branches, use the base DN pattern to make search processing more efficient. The server only needs to search entries within a target branch.

For example, if the directory contains an `"ou=Customers,dc=example,dc=com"` branch with separate branches below that for sets of customers, such as `"ou=ACME,ou=Customers,dc=example,dc=com"` and `"ou=SHOPCO,ou=Customers,dc=example,dc=com"`, you can define a composite index with a filter pattern of `"(sn=?)"` and a base DN pattern of `"ou=?,ou=Customers,dc=example,dc=com"`. Then use a search with a filter of `"(sn=Smith)"` and a base DN of `"ou=ACME,ou=Customers,dc=example,dc=com"` to narrow the search to the Smiths in the ACME branch.

Index Pages

If many entries have the same value for a specific attribute, you can use composite indexes to break large ID sets up across multiple pages, unlike a traditional attribute index.

Using the previous example, if a search of the directory returns 50,000 Smiths, the results can be served in blocks of 5,000 IDs. An attribute index returns either:

- One Smith record whose value is a block that contains all 50,000 of the matching entry IDs when the index isn't exploded.

Note:

The exploded form is efficient for writing, for example, adding or removing a Smith involves just that one entry ID, but it is expensive for searching because it takes 50,000 reads to get all entry IDs for all of the Smiths.

- 50,000 Smith records that each have a value of the matching entry ID when the index is exploded.

Note:

The non-exploded form is efficient for searching because all of the entry IDs return in a single read, but it is expensive for writing. If a Smith must be added or removed, the entire block of 50,000 entry IDs must be rewritten.

Composite indexes break up the block of entry IDs across multiple pages, a page size of up to 5000. If the directory contains 50,000 Smiths, instead of having to choose between one block of 50,000 IDs or 50,000 blocks of one ID, the composite index returns 10 blocks of 5,000 IDs. This improves the efficiency of a read or write across many entries.

There is little performance overhead to the paging mechanism. Use an equality composite index for an attribute that has a lot of entries that have the same value, such as `givenName` or `sn`. Do not use an equality composite index for an attribute with very few entries with the same value, such as `id` or `mail`. For attributes in which all of the values match a small number of entries, use an equality attribute index.

Rebuilding indexes

When rebuilding specific non-attribute indexes, it is important to include any appropriate prefixes or postfixes with the index name to avoid errors.

- To rebuild a composite index, use the **rebuild-index** tool. The index name must be preceded by `composite`.

```
bin/rebuild-index --index composite.thisIndexName
```

Note:

For the exact name to use in rebuilding the index, run the **dbtest** tool with the `list-database-containers` option and `--backendID` property.

```
bin/dbtest list-database-containers --backendID {backendID}
```

Define the following properties when configuring a composite index.

Composite Index Properties	Description
<code>index-filter-pattern</code> (required)	Specifies a single-valued filter property used to identify a portion of the index criteria. You can only specify this at the time that the index definition is created.
<code>index-base-dn-pattern</code> (optional)	Specifies a single-valued DN property that indicates that the index is scoped to a specific subtree or subtree pattern. You can only specify this at the time the index definition is created.

JSON indexes

JSON indexing is similar to general attribute indexing. Where a general attribute can be indexed several ways and requires a separate database for each index type, with JSON indexing, there is a single database for each JSON field to use for different JSON filter types.

This database primarily behaves like the database for an equality attribute index. Each database entry key is the normalized form for a value for the target JSON field. The corresponding database entry value is a list of the entry IDs for all entries in which the associated attribute type has a JSON object with that value for the target field. The database is configured with a comparator based on the data type for the target field that enables iterating through values in a logical order to facilitate inequality and subinitial searches.

When the JSON field constraint indicates to index a JSON field, JSON indexes are automatically created. View indexes with the following command.

```
$ bin/dbtest list-index-status \
  --backendID userRoot \
  --baseDN dc=example,dc=com
```

The JSON object filter types that can be enhanced through the use of JSON indexes include:

`equals`

Identifies entries that have a specific value for the target field. This filter type only requires retrieving a single index key. Depending on the nature of the search filter, the ID list might contain references to entries that do not actually match the filter, such as if the field is a string and if the filter is configured to use case-sensitive matching.

`equalsAny`

Identifies entries that have a specified set of values for the target field. This filter type only requires retrieving the index keys that correspond to the target values in the filter and merging their ID lists.

`greaterThan/lessThan`

Identifies entries that have at least one value for the target field that is greater or less than (or possibly equal to) a specified value. This index is similar in use to the `containsField` index, but it only needs to iterate through a subset of the keys. A filter can contain both `greaterThan` and `lessThan` filters to represent a bounded range.

`substring`

Identifies entries that have a string value for the target field that matches a given `substring`. The index can only be used for substring filters that include a `subInitial` component. In this case, the server iterates through all of the index keys that match the `startsWith` component and manually compares values against the remainder of the substring assertion.

JSON indexing is available in local database backends backed by Berkeley DB Java Edition. This includes:

- Add, delete, modify, and modify distinguish name (DN) operations that make changes to JSON objects stored in the server.
- LDIF imports that include JSON objects, including updates to the cache size estimates for the JSON indexes.
- The **rebuild-index** tool and corresponding backend code make it possible to generate and rebuild indexes for JSON data. It must be possible to build all JSON indexes for all or a specified subset of fields associated with a given attribute type. The **verify-index** tool also works with JSON indexes to make it possible to check their validity.
 - When rebuilding a JSON index with the **rebuild-index** tool, the attribute name must be followed by `.json`. Optionally, you can also add `.<fieldName>`, where `<fieldName>` is replaced by the name of the JSON field.

```
bin/rebuild-index --index <attributeName>.json.<fieldName>
```

**Note:**

For the exact name to use in rebuilding the index, run the **dbtest** tool with the `list-database-containers` option and `--backendID` property.

```
bin/dbtest list-database-containers --backendID {backendID}
```

- Matching entry count control and `debugsearchindex` return attribute provide information about relevant JSON index usage.
- Support for monitoring index content and usage.

**Note:**

Exploded indexes and the entry balancing global index do not support JSON objects.

Working with local DB VLV indexes

Local database (DB) virtual list view (VLV) indexes allow a client to request a subset of results from a sorted list that match a specific search base, scope, and filter.

The client can navigate through the list by passing a context back to the server with the virtual list view control. The local DB VLV index can be used only when the client request contains the VLV control and the client has been authorized with an access control instruction (ACI) with a `targetcontrol` of `2.16.840.1.113730.3.4.9`.

**Note:**

A client request, which includes a virtual list view control, can be successfully processed without a matching local DB VLV index if the search is completely indexed. This is not an efficient means of using VLV since the server has to retrieve each entry twice.

Viewing the list of local DB VLV indexes

Steps

- To view the default list of indexes, use **dsconfig** with the `list-local-db-indexes` option.

Example:

In this example, no VLV indexes are defined.

```
$ bin/dsconfig list-local-db-ylv-indexes --backend-name userRoot
```

Creating a new local DB VLV index

Steps

- Use **dsconfig** with the `create-local-db-ylv-index` option and the `--index-name`, `--backend-name`, and `--set index-type:(propertyValue)` options.

Note:

If you do not set any property values, the default values are assigned.

Example:

```
$ bin/dsconfig create-local-db-ylv-index \
  --index-name givenName --backend-name userRoot --set base-
dn:dc=example,dc=com \
  --set scope:whole-subtree --set filter:"(objectclass=*)" \
  --set sort-order:givenName
```

- Rebuild the index using the **rebuild-index** tool.

Note:

You must add the `ylv.` prefix to the index name to rebuild the VLV index.

Example:

The following command can be run with the server on or offline with the addition of the `--task` and `connection` options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index vlv.givenName
```

Modifying a VLV index's configuration

Steps

- Use **dsconfig** with the `set-local-db-ylv-index-prop` option and the `--index-name` and `--backend-name` properties.

Example:

In this example, update the `base-dn` property.

```
$ bin/dsconfig set-local-db-ylv-index-prop --index-name givenName \
  --backend-name userRoot --set base-dn:ou=People,dc=example,dc=com
```

2. Rebuild the index using the **rebuild-index** tool.

 **Note:**

You must add the prefix `vlv.` to the index name.

Example:

The following command can be run with the server on or offline with the addition of the `--task` and connection options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index vlv.givenName
```

Rebuilding a VLV index

When rebuilding specific non-attribute indexes, it is important to include any appropriate prefixes or postfixes with the index name to avoid errors.

Steps

- When rebuilding a VLV index with the **rebuild-index** tool, the index name must be preceded by `vlv.`

```
bin/rebuild-index --index vlv.thisIndexName
```

 **Note:**

For the exact name to use in rebuilding the index, run the **dbtest** tool with the `list-database-containers` option and `--backendID` property.

```
bin/dbtest list-database-containers --backendID {backendID}
```

Deleting a VLV index

About this task

Delete a VLV index using the **dsconfig** tool. Before deleting it, check that the index is not being used in any plugin applications.

Steps

1. To remove a VLV index from the database, use **dsconfig** with the `delete-local-db-ylv-index` option.

Example:

```
$ bin/dsconfig delete-local-db-ylv-index --index-name givenName \
  --backend-name userRoot
```

2. To verify the deletion, try to view the VLV index.

Example:

```
$ bin/dsconfig get-local-db-ylv-index-prop --index-name givenName \
  --backend-name userRoot
```

Working with filtered indexes

The PingDirectory Server filtered index is useful when client search requests consisting of a compound & filter with individual components matching a large number of entries, potentially greater than the index entry limit, have an intersection of a relatively small number of entries.

About this task

Filtered indexing is primarily useful for cases in which clients frequently issue searches with & filters that meet the following criteria:

- The & filter itself matches a small number of entries, but each of the individual components can match a large number of entries.
- The filter has a dynamic component that does change, and that dynamic component always uses the same attribute.
- The filter has a static component that does not change.
- The filter must be narrowed to a base distinguished name (DN) for data structures with many branches or if indexed attribute values appear in a large number of entries.

For an example, consider the following use case process. A database contains several thousand company profiles and each company profile is represented by many entries. The `(objectClass=company)` filter matches a small set of entries per company and can exceed the index entry limit because there are many companies. Also, the `(companyDomain=example.com)` filter matches many of the entries for the company with domain `example.com` and can also result in an unindexed search. The more narrow filter `(&(objectClass=company)(companyDomain=example.com))` also results in an unindexed search but only matches a small number of entries. The filtered index makes it possible to index this compound filter by defining an equality index on the `companyDomain` attribute with a static filter of `(objectClass=company)` in the `equality-index-filter` property of the index.

When configuring a filtered index, define the following properties.

Filtered Index Properties and their descriptions

Filtered Index Properties	Description
<code>equality-index-filter</code>	Specifies a search filter that can be used in conjunction with an equality component for the associated attribute type. If an equality index filter is defined, then an additional equality index is maintained for the associated attribute, but only for entries that match the provided filter. The index is used only for searches containing an equality component with the associated attribute type used with this filter.
<code>maintain-equality-index-without-filter</code>	Specifies whether to maintain a separate equality index for the associated attribute without any filter, in addition to maintaining an index for each equality index filter that is defined. If this is false, then the attribute does not indexed for equality by itself but only in conjunction with the defined equality index filters.

Steps

- Define the `equality-index-filter` filter index property.
- Define the `maintain-equality-index-without-filter` filter index property.

Note:

Maintain the filtered index independently from the equality filter for that attribute. Use the filtered index only for searches containing the equality component with the associated attribute type used with this

filter. When configuring a filtered index, be aware of the **equality-index-filter** and **maintain-equality-index-without-filter** properties of the index.

Result:

The searches are configured and built with the **rebuild-index** tool or **import-ldif** tool.

This example shows the result of searches built with filters based on the use case process described above with the following index.

```
(&(objectClass=company)(companyDomain=example.com))
(&(objectClass=company)(|(companyDomain=example.com)
(companyDomain=example.org)))
(&(companyDomain=example.com)(objectClass=company))
(&(companyDomain=example.com)(&(objectClass=company)))
(&(companyDomain=example.com)(objectClass=company)(something=else))
(&(companyDomain=example.com)(&(objectClass=company)(something=else)))
(|(&(objectClass=company)(companyDomain=example.com))
(&(objectClass=company)(companyDomain=example.org)))
```

Creating a filtered index

Steps

1. To create a filtered index, use the **dsconfig** tool.

The following command creates an equality index on the `companyDomain` attribute and maintains an index for the equality filter defined `"(objectclass=company)"`.

Example:

```
$ bin/dsconfig create-local-db-index --backend-name "userRoot" \
  --index-name companyDomain --set maintain-equality-index-without-
  filter:true \
  --set index-type:equality --set equality-index-
  filter:"(objectclass=company)"
```

2. After you have created the index, rebuild the indexes.
 - a. Stop the Directory Server using **bin/stop-server**.
 - b. Run the **rebuild-index** tool.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index companyDomain
```

3. Start the Directory Server using **bin/start-server**.

Tuning indexes

The PingDirectory Server provides several tools to help you optimize your indexes and improve the overall read and write performance for your system.

To process high write load operations, the server supports an optional expanded index database using an exploded format. To view the current state of the server's indexes and make adjustments to the index databases, the Directory Server automatically generates an Index Summary Statistics table after each LDIF import or index rebuild. To determine the key data size for the indexes, the **dbtest** tool includes an index histogram. This section describes each of these tools.

About the exploded index format

The `index-entry-limit` backend configuration property specifies the maximum number of entries kept in an index record before the server stops maintaining that record, begins scanning the whole database, and runs an expensive unindexed search.

Note:

Because composite indexes are much more efficient than exploded indexes when dealing with large numbers of identical keys, use composite indexes for data sets where large numbers of entries (several thousand or more) share the same value for an indexed attribute.

If any index keys have already reached this limit, you must rebuild these indexes before they can use a new limit. If you configure `index-entry-limit` to be greater than 50000, any keys with more than 50000 entries are stored in a separate database in an expanded, or exploded, format.

All keys with less than 50000 entries continue to be stored in one database in a consolidated format so that changes to the key require rewriting all the entry IDs matching the key. All keys with more than 50000 entries and less than the `index-entry-limit` are stored in a separate database in an exploded format so that changes to the key require writing to the updated entry ID only.

If you increase the `index-entry-limit` to 100000, any key with an entry count less than 50000 continues to be stored in consolidated format. If a key has an entry count greater than 50000, it is stored in a separate database where each key is stored with its entry ID individually. The consolidated format is efficient for read operations because the server can retrieve a row of entry IDs at once, while the exploded format is efficient for high volumes of write operations because it avoids large on-disk growth.

About monitoring index entry limits

Index keys that have reached their limit require indexes to be rebuilt before they can use a new limit. To avoid a potentially costly rebuild, there are several ways to monitor index limits.

In certain cases, it's acceptable for index keys to exceed the index entry limit. For example, the `objectClass` attribute type should be indexed for equality because the server needs to use it to find all group entries when bringing a backend online, and applications frequently need to find entries of a specific type. However, the top `objectClass` key doesn't need to be indexed because it appears in every entry in the server.

Select an index entry limit value that is high enough to ensure that all of the right keys are indexed, but keys that occur too frequently are not. The `--listKeysNearestIndexEntryLimit` argument of the `verify-index` tool lists a specified number of keys that are closest to the limit without having exceeded it. Make the index entry limit larger than the number of entries matching the largest key to remain indexed, with enough overhead to account for future growth. Use this command regularly to determine if you need to adjust the index entry limit needs to be adjusted.

The `--listKeysExceedingIndexEntryLimit` argument of the `verify-index` tool lists all keys for which the value has exceeded the index entry limit and the number of entries in which they appear. If there are keys for which the limit has been exceeded that need to be maintained, adjust the index entry limit to be higher than the number of entries that contain that key, with additional room for future growth. Then, run the `rebuild-index` tool or export to LDIF and re-import.

The server provides other methods for determining if index keys have exceeded or are close to exceeding the index entry limit, including:

- When performing an LDIF import, the tool includes an Index Summary Statistics section that provides usage information for each index, including:
 - The number of keys for which the index entry limit has been exceeded.
 - The number of keys for which the number of matching entries falls within a number of predefined buckets, such as 1–4 entries, 5–9 entries, 10–99 entries, and 100–999 entries.

and

- During a search operation, if the server accesses one or more index keys whose values have exceeded the index entry limit, the access log message for that operation includes an `indexesWithKeysAccessedExceedingEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field can appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to, or tried to write to, at least one index key whose value exceeded the index entry limit.
- During a search operation, if the server accesses one or more index keys whose values have not yet exceeded the index entry limit but are greater than 80 percent of it, the access log message for that operation includes an `indexesWithKeysAccessedNearEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field can appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to at least one index key whose value was within 80% of the index entry limit.
- If a search operation request includes either the `debugsearchindex` attribute or the matching entry count request control with debugging enabled, the debug information includes any indexes accessed that have exceeded the index entry limit or that are within 80% of the configured index entry limit.
- The monitor entry for each configured index includes attributes that provide information about the number of index keys that have been encountered since the backend was brought online, or since the index entry limit was changed in a number of different categories. These monitor attributes include:

`ds-index-exceeded-entry-limit-count-since-db-open`

The number of index keys for which the number of matching entries has crossed the index entry limit due to a write operation.

`ds-index-unique-keys-near-entry-limit-accessed-by-search-since-db-open`

The number of unique index keys that have been accessed by a search operation for which the number of matching entries is within 80% of the index entry limit.

`ds-index-unique-keys-exceeding-entry-limit-accessed-by-search-since-db-open`

The number of unique index keys that have been accessed by a search operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.

`ds-index-unique-keys-near-entry-limit-accessed-by-write-since-db-open`

The number of unique index keys that have been accessed by a write operation for which the number of matching entries is within 80% of the index entry limit.

`ds-index-unique-keys-exceeding-entry-limit-accessed-by-write-since-db-open`

The number of unique index keys that have been accessed by a write operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.

About the `dbtest` Index Status table

The `dbtest` tool has a `list-all --analyze` option that generates the current status of all of the databases on your system, including all index databases.

The table shows the following information:

- Type
- Entry count (the number of records in the database)
- Index status
 - `TRUSTED` indicates the indexes are up-to-date.
 - `UNTRUSTED` indicates the index needs rebuilding.
- Each key's total data size
- Each key's average data size

- Each key's maximum data size

Note:

Any indexes that are in exploded format are also listed in this table.

Index Name	Index Type	JE Database Name	Index Status
id2children	Index	dc_example_dc_com_id2children	TRUSTED
id2subtree	Index	dc_example_dc_com_id2subtree	TRUSTED
uid.equality	Index	dc_example_dc_com_uid.equality	TRUSTED
aci.presence	Index	dc_example_dc_com_aci.presence	TRUSTED
ds-soft-delete-timestamp.ordering	Index	dc_example_dc_com_ds-soft-delete-timestamp.ordering	TRUSTED
ds-soft-delete-from-dn.equality	Index	dc_example_dc_com_ds-soft-delete-from-dn.equality	TRUSTED
givenName.equality	Index	dc_example_dc_com_givenName.equality	TRUSTED
givenName.substring	Index	dc_example_dc_com_givenName.substring	TRUSTED
objectClass.equality	Index	dc_example_dc_com_objectClass.equality	TRUSTED
member.equality	Index	dc_example_dc_com_member.equality	TRUSTED
uniqueMember.equality	Index	dc_example_dc_com_uniqueMember.equality	TRUSTED
cn.equality	Index	dc_example_dc_com_cn.equality	TRUSTED
cn.substring	Index	dc_example_dc_com_cn.substring	TRUSTED
sn.equality	Index	dc_example_dc_com_sn.equality	TRUSTED
sn.substring	Index	dc_example_dc_com_sn.substring	TRUSTED
telephoneNumber.equality	Index	dc_example_dc_com_telephoneNumber.equality	TRUSTED
mail.equality	Index	dc_example_dc_com_mail.equality	TRUSTED
ds-entry-unique-id.equality	Index	dc_example_dc_com_ds-entry-unique-id.equality	TRUSTED

dbtest output including index databases

Configuring the index properties

By default, the `index-entry-limit` value is 4000, meaning the server stops maintaining index values for keys that match more than 4000 entries. You can change the value with the `dsconfig` tool.

About this task

Before running the following commands, be aware that you must do an index rebuild on the system, which requires a system shutdown unless the command is run as a task.

To configure the index properties:

Steps

1. Run `dsconfig` with the `set-backend-prop` subcommand.
2. Set the `index-entry-limit` to 5000. Confirm that you want to apply the changes.

By default, this value is set to 4000.

Note:

Remember to include the bind parameters for your system.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set index-entry-limit:5000 \
  One or more configuration property changes require administrative action
  or confirmation/notification. Those properties include:
  * index-entry-limit: If any index keys have already reached this limit,
  indexes must be rebuilt before they will be allowed to use the new limit.
  Setting a large limit (greater than 10,000) could have a big impact on
```

```
write performance and database growth on disk.
Continue? Choose 'no' to return to the previous step (yes / no) [yes]:
yes
```

3. Stop the server.

Example:

```
$ bin/stop-server
```

4. Rebuild the index.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com \
  --index cn --index givenName --index objectClass \
  --index sn --maxThreads 10
```

5. View the Index Summary Statistics table, which automatically displays to system out after running the `rebuild-index` command.

You can also access the table at `logs/tools/rebuild-index-summary.txt`.

Example:

```
--- Index Summary Statistics ---
Index : Limit : >Limit : Max : 1-9 : 10-99 : 100-999 : 1000-9999 : 10000-99999 : 100000-999999
-----
dc_example_dc_com_cn.equality : 5000 : 9 : 1 : 100001 : : : : : :
dc_example_dc_com_cn.substring : 5000 : 9 : 15401 : 131746 : 22372 : 545 : 39 : 3 : :
dc_example_dc_com_givenName.equality : 5000 : 16 : 3788 : 4817 : : : : : : :
dc_example_dc_com_givenName.substring : 5000 : 8 : 23809 : 7039 : 12062 : 483 : 42 : 3 : :
dc_example_dc_com_objectClass.equality : 5000 : 4 : 100003 : 3 : : : : : : : 4
dc_example_dc_com_sn.equality : 5000 : 8 : 13419 : : : : : : : :
dc_example_dc_com_sn.substring : 5000 : 9 : 15401 : 33967 : 7055 : 459 : 39 : 3 : :

The first three columns of numbers provide (1) "Limit" - the index entry limit (or blank if there is no limit),
(2) ">Limit" - the number of keys whose entry count exceeds the entry limit, and (3) "Max" - the
maximum entry count for any key in the index. The remaining columns provide the number of keys
whose entry count falls in the range indicated in the column heading
```

6. Repeat steps 1-4 to make more adjustments to your indexes.

7. Restart the server.

Example:

```
$ bin/start-server
```

About the Index Summary Statistics table

The Directory Server automatically generates an Index Summary Statistics table, which you can use to determine the optimal configuration for your system's indexes.

The table only generates when you run the `rebuild-index` tool in offline mode. The table generates after any LDIF import or an index rebuild. It is written to system out and to `logs/tools/rebuild-index-summary.txt`.

The table displays the following information:

- The current index entry limit set by the `index-entry-limit` property on the local database configuration
- The number of keys whose entry count exceeds this limit, if any
- The maximum entry count for any key in the index
- A histogram of the number of keys whose entry falls within a range of values

The following image is an example of the Index Summary Statistics table for the `sn.equality` and the `sn.substring` indexes.

In this figure, there are seven substrings whose entry counts exceed the `index-entry-limit` of 4000. Six of the substrings are in the 10000-99999 range with the maximum entry count being 13419. By deduction, one more substring must be present in the 1000-9999 range that exceeds the `index-entry-limit` of 4000. These substrings could be expensive for search operations.

```

--- Index Summary Statistics ---
Index      : Limit : >Limit : Max   : 1-9   : 10-99  : 100-999 : 1000-9999 : 10000-99999
-----
dc_example_dc_com_sn.equality : 4000 : 7       : 2     : 100000 : 13419  : 150814  : 7109   : 407   : 36   : 6
dc_example_dc_com_sn.substring : 4000 : 7       : 13419 : 150814 : 7109   : 407     : 36     : 6

```

Example of an Index Summary Statistics Table

Managing Entries

The Directory Server is a fully LDAPv3-compliant server that comes with a comprehensive set of LDAP command-line tools to search, add, modify, and delete entries.

Searching entries

The Directory Server provides an `ldapsearch` tool to search for entries or attributes within your server.

The `ldapsearch` tool requires the LDAP connection parameters to bind to the server, including the `baseDN` option to specify the starting point of the search within the server, and the search scope. The `searchScope` option determines the depth of the search.

`base`

Searches only for the specified entry.

`one`

Searches only the children of the entry and not the entry itself.

`sub`

Searches the entry and its descendants.

The `ldapsearch` tool provides basic functionality specified by the RFC 2254 and provides additional features that use the Directory Server's control mechanisms.

Note:

For more information, run the `ldapsearch --help` function.

Searching the root DSE

The root DSA-specific entry (DSE) is a special entry that resides at the root of the directory information tree (DIT). The entry holds operational information about the server and its supported controls.

About this task

Specifically, the root DSE entry provides information about the supported LDAP3 controls, Simple Authentication and Security Layer (SASL) mechanisms, password authentication schemes, supported LDAP protocols, additional features, naming contexts, extended operations, and server information.

The Directory Server provides an option to retrieve the Root DSE's operational attributes and add them to the user attribute map of the generated entry. This feature allows client applications that have difficulty handling operational attributes to access the root DSE using the `show-all-attributes` configuration property. After you set this property, the associated attribute types are recreated and re-registered as user attributes in the schema (in memory, not on disk). After you set the property, you can use `ldapsearch` without "+" to view the root DSE.

Steps

1. To set the `show-all-attributes` property to `TRUE`, run the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-root-dse-backend-prop --set show-all-attributes:true
```

2. Run the `ldapsearch` tool to view the root DSE entry on the Directory Server.

Note:

To display the operational attributes in the entry, use `+`.

Example:

```
$ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" "+"
```

Searching all entries in the Directory Server

Steps

- To search all entries in the Directory Server, run the `ldapsearch` tool.

Note:

The filter `"(objectclass=*)"` matches all entries. If you do not specify the `--searchScope` subcommand, it defaults to a search scope of `sub`.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --searchScope sub "(objectclass=*)" "
```

Searching for an access control instruction

Steps

- To search the `dc=example,dc=com` base distinguished name (DN) entry, run the `ldapsearch` tool.

Note:

The filter `"(aci=*)"` matches all `aci` attributes under the base DN, and the `aci` attribute is specified so that only it is returned. The `cn=Directory Manager` bind DN has the privileges to view an access control instruction (ACI).

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(aci=*)" aci
```

Result:

The system displays the following ACI information.

```
dn: dc=example,dc=com
aci: (targetattr!="userPassword")
      (version 3.0; aci "Allow anonymous read access for anyone";
        allow (read,search,compare) userdn="ldap:///anyone";)
```

```
aci: (targetattr="*")
  (version 3.0; acl "Allow users to update their own entries";
   allow (write) userdn="ldap:///self");
aci: (targetattr="*")
  (version 3.0; acl "Grant full access for the admin user";
   allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

Searching for the schema

Steps

- To search the `cn=schema` entry, run the `ldapsearch` tool.

Note:

The base distinguished name (DN) is specified as `cn=schema`, and the filter `"(objectclass=*)"` matches all entries. The command uses a special attribute `+` to return all operational attributes.

Example:

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base "(objectclass=*)" "+"
```

Searching for a single entry using base scope and base DN

Steps

- To search for a single entry, run the `ldapsearch` tool and specify the base scope and DN.

Example:

```
$ bin/ldapsearch --baseDN uid=user.14,ou=People,dc=example,dc=com \
  --searchScope base "(objectclass=*)" "
```

Searching for a single entry using the search filter

Steps

- To search for a single entry, specify the `sub` scope and a search filter that describes a single entry.

Example:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub "(uid=user.14) "
```

Searching for all immediate children for restricted return values

Steps

- To search for all immediate children of restricted return values, run the `ldapsearch` tool.

Note:

The special attribute "+" returns all operational attributes.

Example:

In this sample, the immediate children are `ou=People,dc=example,dc=com`, and the restricted returned values are `sn` and `givenName`.

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope one '(objectclass=*)' sn givenName "+"
```

Searching for all children of an entry in sorted order

Steps

- To search for all children of an entry in the appropriate subtree, run the `ldapsearch` command. Choose from:
 - To sort the resulting entries by the server in ascending order, use `sn`.
 - To sort the orders in descending order, use `givenName`.

Example:

For this example, the `ldapsearch` command searches for children in the `ou=People,dc=example,dc=com` subtree.

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub --sortOrder sn,-givenName '(objectclass=*)'
```

Limiting the number of returned search entries and search time

Steps

- To search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree, specify a compound filter.

Example:

In the following example, no more than 200 entries will be returned and the server will spend no more than 5 seconds processing the request. Returned attributes are restricted to a few operational attributes.

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub --sizeLimit 200 --timeLimit 5 \
  "(&(sn<=Doe)(employeeNumber<=1000))" ds-entry-unique-id entryUUID
```

Getting information about how indexes are used in a search operation

Before you begin

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT).

Steps

- To search for how indexes are used in a search operation, you can either:
Choose from:
 - Issue a search request with the desired base distinguished name (DN), scope, and filter, and request that the server return the special `debugsearchindex` attribute using the `ldapsearch` command.

```
$ bin/ldapsearch --hostname ds.example.com \
--port 389 --bindDN uid=admin,dc=example,dc=com \
--bindPassword password \
--baseDN dc=example,dc=com \
--searchScope sub "(&(givenName=John)(sn=Doe))" debugsearchindex
dn: cn=debugsearch
debugsearchindex: 0.040 ms - Beginning index processing for search
    request with base DN 'dc=example,dc=com', scope wholeSubtree,
    and filter (&(givenName=John)(sn=Doe)).
debugsearchindex: 0.067 ms - Unable to optimize the AND filter
    beyond what the client already provided.
debugsearchindex: 0.834 ms - Candidate set obtained for single-key
    filter (givenName=John) from index
    dc_example_dc_com_givenName.equality.
    Candidate set: CandidateSet(isDefined=true, isExploded=false,
    isResolved=true, size=2, originalFilter=(givenName=John),
    remainingFilter=null, matchingEntryCountType=UNEXAMINED_COUNT)
debugsearchindex: 0.030 ms - Final candidate set for filter
    (givenName=John)
    obtained from an unexploded index key in
    dc_example_dc_com_givenName.equality.
    Since the scope of the search includes the entire entry
    container, there is
    no need to attempt to further pare down the results based on the
    search scope.
    Candidate set: CandidateSet(isDefined=true, isExploded=false,
    isResolved=true,
    size=2, originalFilter=(givenName=John), remainingFilter=null,
    matchingEntryCountType=UNEXAMINED_COUNT)
debugsearchindex: 0.020 ms - Short-circuiting index processing for
    AND filter
    (&(givenName=John)(sn=Doe)) after evaluating single-key component
    (givenName=John) because the current ID set size of 2 is within
    the
    short-circuit threshold of 5.
debugsearchindex: 0.030 ms - Obtained a candidate set of size 2 for
    AND filter
    (&(givenName=John)(sn=Doe)) with remaining filter (sn=Doe). Even
    though
    there is still more of the filter to evaluate, the current
    candidate set is
    within the short-circuit threshold of 5, so no additional index
    processing will
    be performed to try to pare down the results based on the
    remaining filter or the
    search scope. Candidate set: CandidateSet(isDefined=true,
    isExploded=false,
    isResolved=true, size=2, originalFilter=(&(givenName=John)
    (sn=Doe)),
    remainingFilter=(sn=Doe), matchingEntryCountType=UPPER_BOUND)
debugsearchindex: 0.016 ms - Completed all index processing.
Candidate set:
    CandidateSet(isDefined=true, isExploded=false, isResolved=true,
    size=2,
```

```
originalFilter=(&(givenName=John)(sn=Doe)),
remainingFilter=(sn=Doe),
matchingEntryCountType=UPPER_BOUND)
```

 **Note:**

Users must have access to the **debugsearchindex** operational attribute and the **cn=debugsearch** portion of the DIT with the following command.

```
$ bin/dsconfig set-access-control-handler-prop \
--add "global-aci:(targetattr=\"debugsearchindex\") (target=\"ldap:///
cn=debugsearch\")
(version 3.0; acl \"Allow members of the Index Debugging Users
group
to request the debugsearchindex operational attribute \"; allow
(read,search,compare) groupdn=\"ldap:///cn=Index Debugging
Users,ou=Groups,dc=example,dc=com\");"
```

- Issue a search request with the desired base DN, scope, and filter, and include the matching entry count request control with the debug option set to **true** using **ldapsearch**.

```
$ bin/ldapsearch --hostname ds.example.com --port 389 \
--bindDN uid=admin,dc=example,dc=com --bindPassword password \
--baseDN dc=example,dc=com \
--searchScope sub --matchingEntryCountControl examineCount=0:debug
"(&(givenName=John)(sn=Doe))"
Upper Bound on Matching Entry Count: 2
Matching Entry Count Debug Messages:
* naw-desktop:1389 - 0.104 ms - Beginning index processing for search
request with
base DN 'dc=example,dc=com', scope wholeSubtree, and filter
(&(givenName=John)(sn=Doe)).
* naw-desktop:1389 - 0.105 ms - Unable to optimize the AND filter
beyond what the client already provided.
* naw-desktop:1389 - 0.614 ms - Candidate set obtained for single-key
filter (givenName=John) from index
dc_example_dc_com_givenName.equality. Candidate set:
CandidateSet(isDefined=true, isExploded=false, isResolved=true,
size=2, originalFilter=(givenName=John), remainingFilter=null,
matchingEntryCountType=UNEXAMINED_COUNT)
* naw-desktop:1389 - 0.090 ms - Final candidate set for filter
(givenName=John) obtained from an unexploded index key in
dc_example_dc_com_givenName.equality. Since the scope of the
search
includes the entire entry container, there is no need
to attempt to further pare down the results based on the search
scope.

(candidatesAreInScope=true,
unindexedFilterPortion=(sn=Doe))
* naw-desktop:1389 - Constructing an UPPER_BOUND response with a
count of 2

```

Working with the matching entry count control

You can use the `ldapsearch` command with the `--matchingEntryCountControl` option to determine the count of entries that match a search filter.

Users must be granted access to this control by its OID `1.3.6.1.4.1.30221.2.5.36` with the following command.

```

$ bin/dsconfig set-access-control-handler-prop \
--add "global-aci:(targetcontrol=\"1.3.6.1.4.1.30221.2.5.36\")
(version 3.0; acl \"Allow members of the Index Debugging Users group to
use the matching entry count request control \"; allow (read)
groupdn=\"ldap:///cn=Index Debugging Users,ou=Groups,dc=example,dc=com
\");)"

```

You can use an `examineCount` control for searches that are at least partially indexed to determine whether to return an examined count, an unexamined count, or an upper bound count. The following factors determine what is returned:

- A search is fully indexed if indexes can be used to identify the entry IDs for all entries that match the filter without ambiguity. You can also use indexes to make sure that all of those candidates are within the scope of the search.
- A search is partially indexed if you can use indexes to identify the entry IDs for all entries that match the search criteria.

Note:

The candidate list might also include entries that either don't match the filter or are outside the scope of the search.

- A search is unindexed if it's not possible to retrieve a candidate list based on either the filter or the search scope.
- An unexamined count is a count of the exact number of entries that match the search criteria, only through the use of index processing.
- An examined count is the same as an unexamined count except that all of the candidate entries are examined to determine whether they would have been returned to the client. An examined count might

be less than an unexamined count if the set of matching entries includes those that would be removed by access control evaluation or special entries, such as LDAP sub-entries, replication conflict entries, or soft-deleted entries.

- An upper bound count is the maximum number of entries that match the criteria, but indicates that the server could not determine exactly how many matching entries there were without examining each candidate, which it doesn't do.
- If a search is fully indexed, the result is an examined count or an unexamined count. If **alwaysExamine** is true and **examineCount** is greater than or equal to the number of candidates, the result is an examined count. If **alwaysExamine** is false, or if the number of candidates exceeds **examineCount**, the result is an unexamined count.
- If a search is partially indexed, the result is either an examined count or an upper bound count. The **alwaysExamine** flag isn't relevant in this case. If **examineCount** is greater than or equal to the number of candidates, the result is an examined count. If not, the result is an upper bound count.
- If a search is unindexed, the result is either an examined count or an unknown count. If **allowUnindexed** is true, the unindexed search is processed, which can be very expensive. Instead of getting the matching entries back, the examined count is returned. If **allowUnindexed** is false, an unknown count is returned. If **allowUnindexed** is true, the requester needs to have the **unindexed-search** privilege to get the exact count.

Example

The following example is a `ldapsearch` with the `--matchingEntryCountControl` option.

```
$. /ldapsearch \
  --bindDN "cn=directory manager" \
  --bindPassword password \
  --baseDN dc=example,dc=com \
  --matchingEntryCountControl
examineCount=100:alwaysExamine:allowUnindexed:debug \
  "(objectclass=*)" "
```

Adding entries

Depending on the number of entries that you want to add to your Directory Server, you can use the `ldapmodify` tool for small additions.

The `ldapmodify` tool provides two methods for adding a single entry:

- Using an LDIF file
- Using the command line

The attributes must conform to your schema and contain the required object classes.

Adding requests with the **ignore-no-user-modification** control enables a client to include attributes that are not normally allowed from external sources, such as the **userPassword** attribute, which is a user-modifiable attribute. An add request with the **ignore-no-user-modification** control allows a one-time exception to the password policy, even if the requesting client does not have the **bypass-pw-policy** privilege. This exception enables specifying pre-encoded passwords.

Note:

When adding an entry, the server can ensure that the entry's relative distinguished name (RDN) is unique and does not contain any sensitive information by replacing the provided entry's RDN with the server-generated `entryUUID` value. An LDAP client written with the LDAP SDK for Java can use the **NameWithEntryUUIDRequestControl** to explicitly indicate which add requests should be named in this way or the `ldapmodify` tool with the `--nameWithEntryUUID` argument.

The `auto-name-with-entry-uuid-connection-criteria` and `auto-name-with-entry-uuid-request-criteria` global configuration properties can be used to identify which add requests should be automatically named this way.

You can also use the uniqueness request control with `ldapmodify` for enforcing uniqueness on a per-request basis. Provide at least one of the `uniquenessAttribute` or `uniquenessFilter` arguments with the request. For more information about this control, see the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control.

Adding an entry using an LDIF file

Use the `ldapmodify` tool to add an entry from an LDIF file.

Steps

1. Open a text editor and create an entry that conforms with your schema.

Note:

The Directory Server encrypts the password and stores its encrypted value in the server. Make sure that the LDIF file has limited read permissions for only authorized administrators.

Example:

The following example adds the entry in the file and saves the file as `add-user.ldif`. For the `userPassword` attribute, enter the cleartext password.

```
dn: uid=user.2000,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Toby Hall$73600 Mash Street$Cincinnati, OH 50563
  postalCode: 50563
description: This is the description for Toby Hall.
uid: user.2000
userPassword: wordsmith employeeNumber: 2000
initials: TBH
givenName: Toby
pager: +1 596 232 3321
mobile: +1 039 311 9878
cn: Toby Hall
sn: Hall
telephoneNumber: +1 097 678 9688
street: 73600 Mash Street
homePhone: +1 214 233 8484
l: Cincinnati
mail: user.2000@maildomain.net
st: OH
```

2. To add the entry specified in the LDIF file, run the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --defaultAdd --filename add-user.ldif
```

Result:

A confirmation message of the new addition appears. If the command is successful, you'll see generated success messages with the `#` symbol.

```
# Processing ADD request for uid=user.2000,ou=People,dc=example,dc=com
# ADD operation successful for DN
uid=user.2000,ou=People,dc=example,dc=com
```

Adding an entry using the `changetype` LDIF directive

About this task

RFC 2849 specifies LDIF directives that you can use within your LDIF files. The most commonly used directive is `changetype`, which follows the `dn:` directive and defines the operation on the entry. The main advantage of using this method in an LDIF file is that you can combine `add` and `modify` in one file.

Steps

1. Open a text editor and create an entry that conforms with your schema.

Example:

This example uses `changetype: add` to add the following entry in the file and saves the file as `add-user2.ldif`.

```
dn: uid=user.2001,ou=People,dc=example,dc=com
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Seely Dorm$100 Apple Street$Cincinnati, OH 50563
postalCode: 50563
description: This is the description for Seely Dorm.
uid: user.2001
userPassword: pleasantry
employeeNumber: 2001
initials: SPD
givenName: Seely pager: +1 596 665 3344
mobile: +1 039 686 4949
cn: Seely Dorm
sn: Dorm
telephoneNumber: +1 097 257 7542
street: 100 Apple Street
homePhone: +1 214 521 4883
l: Cincinnati
mail: user.2001@maildomain.net
st: OH
```

2. To add the entry specified in the LDIF file, run the `ldapmodify` tool.

Example:

In this example, you do not need to use the `--defaultAdd` or its shortform `-a` option with the command.

```
$ bin/ldapmodify --filename add-user2.ldif
```

Result: A confirmation message displays confirming the addition.

Adding multiple entries in a single file

About this task

Add multiple entries in your LDIF file by separating each distinguished name (DN) and its entry with a blank line from the next entry.

Steps

1. Open a text editor and create some entries that conform to your schema.

Example:

For example, add the following entries in the file and save the file as `add-user3.ldif`. Separate each entry with a blank line.

```
dn: uid=user.2003,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass:
organizationalPerson
objectClass: inetOrgPerson
...(similar attributes to previous examples)...

dn: uid=user.2004,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
...(similar attributes to previous examples)...
```

2. To add the entries specified in the LDIF file, run the `ldapmodify` tool.

Example:

This example uses the short form arguments for the `ldapmodify` tool.

```
$ bin/ldapmodify -h server.example.com -p 389 \
-D "cn=admin,dc=example,dc=com" -w password -a -f add-user3.ldif
```

The `-h` option specifies the host name, the `-p` option specifies the LDAP listener port, `-D` specifies the bind DN, `-w` specifies the bind DN password, `-a` specifies that entries that omit a changetype are treated as add operations, and `-f` specifies the path to the input file. If the operation is successful, you will see commented messages (those beginning with "#") for each addition.

Result:

```
# Processing ADD request for uid=user.2003,ou=People,dc=example,dc=com
# ADD operation successful for DN
uid=user.2003,ou=People,dc=example,dc=com
# Processing ADD request for uid=user.2004,ou=People,dc=example,dc=com
```

```
# ADD operation successful for DN
uid=user.2004,ou=People,dc=example,dc=com
```

Deleting entries using `ldapdelete`

You can delete an entry using the `ldapdelete` tool.

Note:

Ensure that there are no child entries below the entry because that can create an orphaned entry.

Back up your system prior to removing any entries.

Deleting an entry using `ldapdelete`

Steps

To delete an entry, run the `ldapdelete` command.

Example:

The following example deletes the `uid=user.14` entry.

```
$ bin/ldapdelete uid=user.14,ou=People,dc=example,dc=com
```

Deleting multiple entries using an LDIF file

About this task

To generate a file of distinguished names (DNs) to delete from the Directory Server:

Steps

1. To search for all entries in a branch and return the DN of the subentries, run the following command.

Example:

For this example, the search is for all entries in the `ou=Accounting` branch.

```
$ bin/dump-dns -D "cn=admin,dc=example,dc=com" -w password --baseDN \
    "ou=Accounting,ou=People,dc=example,dc=com" --
outputFile /usr/local/entry_dns.txt
```

2. Run the `ldapdelete` command with the file to delete the entries.

Example:

The following command uses the `--continueError` option, which continues deleting through the whole list even if an error is encountered for a DN entry.

```
$ bin/ldapdelete --filename /usr/local/entry_dns.txt --continueError
```

Deleting entries using `ldapmodify`

About this task

You can use the LDIF `changetype` directive to delete an entry from the Directory Server using the `ldapmodify` tool.

Note:

You can only delete leaf entries.

Steps

Delete an entry using the `ldapmodify` tool.

- a. From the command line run the `ldapmodify` tool with the `changetype:delete` option.
- b. Enter the distinguished name (DN) and press `Enter` to go to the next line.
- c. Enter the `changetype` directive.
- d. Press `Ctrl+D` twice to enter the end-of-file (EOF) sequence (UNIX) or `Ctrl+Z` (Windows).

Example:

```
$ bin/ldapmodify --hostname server1.example.com -port 389 --bindDN
"uid=admin,dc=example,dc=com" --bindPassword password
dn:uid=user.14,ou=People,dc=example,dc=com
changetype: delete
```

Modifying entries using `ldapmodify`

You can use the `ldapmodify` tool to modify entries from the command line or by using an LDIF file that has the `changetype:modify` directive and value.

If you have more than one change, you can separate them using the `-` (dash) symbol.

Modifying an attribute from the command line

Steps

1. To locate a specific entry, run the `ldapsearch` tool.

Example:

```
$ bin/ldapsearch -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password -b dc=example,dc=com "(uid=user.2004)"
```

2. To change attributes from the command line, run the `ldapmodify` command.
 - a. Specify the modification using the `changetype:modify` directive and then specify which attributes are to be changed using the `replace` directive.

Example:

In this example, we change the telephone number of a specific user entry.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

3. Process the request:

Choose from:

- For Unix EOF escape sequence, enter `ctrl+d` twice.
- For Windows, enter `ctrl+z`.

Modifying multiple attributes in an entry from the command line

Steps

1. To locate a specific entry, run the `ldapsearch` tool.

Example:

```
$ bin/ldapsearch -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password -b dc=example,dc=com "(uid=user.2004) "
```

2. To change attributes from the command line, use the `ldapmodify` command.
 - a. Specify the modification using the `changetype:modify` subcommand.
 - b. Specify the attributes to change using the `add` and `replace` subcommand.

Example:

In this example, we add the `postOfficeBox` attribute and change the mobile and telephone numbers of a specific user entry. The `postOfficeBox` attribute must be present in your schema to allow the addition. The three changes are separated by a dash ("-").

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postOfficeBox
postOfficeBox: 111
-
replace: mobile
mobile: +1 039 831 3737
-
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

3. Process the request.

Choose from:

- For Unix, enter `ctrl+d` twice.
This is the Unix EOF escape sequence.
- For Windows, enter `ctrl+z`.

Adding an attribute from the command line

Steps

1. Run the `ldapmodify` tool from the command line interface.
2. Specify the modification using the `changetype:modify` subcommand.
3. Specify which attributes to add using the `add` option.

Example:

In this example, we add another value for the `cn` attribute, which is multi-valued.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: cn
cn: Sally Tea Tree
```

- To process the request, enter `ctrl+d` twice.

This is the UNIX EOF escape sequence.

Note:

An error might occur if the attribute is single-valued, if the value already exists, if the value does not meet the proper syntax, or if the value does not meet the entry's `objectclass` requirements.

Remove any trailing spaces after the attribute value.

Adding an attribute using the language subtype

About this task

The Directory Server provides support for attributes using language subtypes. The operation must specifically match the subtype for successful operation. Any non-ASCII characters must be in UTF-8 format.

Steps

- Run the `ldapmodify` tool from the command line interface.
- Specify the modification using `changetype:modify`.
- Specify which attributes to add using the `add` option.

Example:

In this example, we add another value for the `lang` attribute.

```
$ bin/ldapmodify -h server.example.com -p 389 -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postalAddress; lang-ko
postalAddress; lang-ko:Byung-soon Kim$2020-14 Seoul
```

- To process the request, enter `ctrl+d` twice.

This is the UNIX EOF escape sequence.

Adding an attribute using the binary subtype

About this task

The Directory Server provides support for attributes using binary subtypes, which are typically used for certificates or JPEG images that you can store in an entry. The operation must specifically match the subtype for successful operation. You must use the version directive with a value of "1" for binary subtypes. Typical binary attribute types are `userCertificate` and `jpegPhoto`.

Steps

- To add an attribute with a binary subtype, run the `ldapmodify` tool from the command line interface.
- Specify the modification using `changetype:modify`.
- Specify which attributes to add using the `add` option.

Example:

The attribute in this example points to the filepath of the certificate.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
```

```
version: 1
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: userCertificate;binary
userCertificate;binary:<file:///path/to/cert
```

Deleting an attribute

Steps

To delete an attribute, run the `ldapmodify` tool with the LDIF `delete` subcommand.

Example:

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
delete: employeeNumber
```

Deleting one value from an attribute with multiple values

About this task

Use the LDIF `delete` subcommand to delete a specific attribute value from an attribute.

Steps

1. Run the `ldapmodify` tool from the command line.
2. Specify the modification using `changetype:modify`.
3. Specify the attribute pair that you want to delete using `delete`.

Example:

The following sample assumes you have multiple values of `cn` in an entry, such as `cn: Sally Tree, cn: Sally Tea Tree`. This sample keeps `cn:Sally Tree` and deletes the `cn: Sally Tea Tree`.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
delete: cn
cn: Sally Tea Tree
```

Renaming an entry

Rename an entry by changing the relative distinguished name (RDN) of an entry.

About this task

Note:

You cannot rename an RDN if it has children entries because this violates the LDAP protocol.

Steps

Run the **ldapmodify** tool to rename an entry.

- a. Run the `changetype`, `newrdn`, and `deleteoldrdn` directives.

Example:

The following command changes `uid=user.14` to `uid=user.2014` and uses the `changetype`, `newrdn`, and `deleteoldrdn` directives.

```
$ bin/ldapmodify
dn: uid=user.14,ou=People,dc=example,dc=com
changetype:moddn
newrdn: uid=user.2014
deleteoldrdn: 1
```

Moving an entry within a Directory Server

Run the **ldapmodify** tool to move an entry from one base distinguished name (DN) to another base DN.

Before you begin

- Assign access control instructions (ACIs) on the parent entries.
 - The source parent entry must have an ACI that allows export operations: `allow(export)`.
 - The target parent entry must have an ACI that allows import operations: `allow(import)`.

About this task

For more information on access control instructions, see [Working with Access Control](#).

Steps

1. To move an entry from one branch to another, run the **ldapmodify** tool.

Example:

In this example, an entry moves from the `ou=contractors` branch to the `ou=People` branch.

```
$ bin/ldapmodify
dn: uid=user.14,ou=contractors,dc=example,dc=com
changetype:moddn
newrdn: uid=user.2014
deleteoldrdn: 0
newsuperior: ou=People,dc=example,dc=com
```

2. Specify the modification using `changetype:moddn`.

Moving an entry from one machine to another

About this task

The Directory Server provides the **move-subtree** tool to move a subtree or one entry on one machine to another.

The **move-subtree** tool moves a subtree or multiple entries from one machine to another. The tool does not copy the entries. After the entries are moved, they are no longer present on the source server.

Note:

The subtree or entry must exist on the source server and cannot be present on the target server. The source server must also support the `real attributes only` request control. The target server must support the `Ignore NO-USER-MODIFICATION` request control.

Steps

- To move an entry, such as `uid=test.user,ou=People,dc=example,dc=com`, from the source host to the target host, run the **move-subtree** tool.

Example:

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
--sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword
password \
--targetHost target.example.com --targetPort 389 \
--targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword
password \
--entryDN uid=test.user,ou=People,dc=example,dc=com
```

Moving multiple entries from one machine to another

About this task

The **move-subtree** tool provides the ability to move multiple entries listed in a distinguished name (DN) file from one machine to another. Lines that begin with the octothorpe character (`#`) and empty lines will be ignored. You can prefix entry DNs with `dn:` , but long DNs can't be wrapped across multiple lines.

Steps

- In a text editor, create a new text file, enter a list of DNs, one DN per line, and then save the file.

You can also use the **ldapsearch** command with the special character `"1.1"` to create a file containing a list of DNs that you want to move.

Example:

The following example searches for all entries that match `"(department=Engineering)"` and returns only the DNs that match the criteria. The results are re-directed to an output file, `test-dns.ldif`.

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
--searchScope sub "(department=Engineering)" "1.1" > test-dns.ldif
```

- To specify the file of DNs to move from one machine to another, run the **move-subtree** tool with the `--entryDNFile` option.

Example:

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
--sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword
password \
--targetHost target.example.com --targetPort 389 \
--targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword
password \
```

```
--entryDNFile /path/to/file/test-dns.ldif
```

Note:

If an error occurs with one of the DNs in the file, the output message shows the error. The `move-subtree` tool keeps processing the remaining DNs in the file.

```
An error occurred while communicating with the target server: The entry
uid=user.2,ou=People,dc=example,dc=com cannot be added because an entry
with that name
already exists
Entry uid=user.3,ou=People,dc=example,dc=com was successfully moved from
source.example.com:389 to target.example.com:389
Entry uid=user.4,ou=People,dc=example,dc=com was successfully moved from
source.example.com:389 to target.example.com:389
```

Working with the parallel-update tool

The PingDirectory Server provides a **parallel-update** tool, which reads change information (`add`, `delete`, `modify`, and `modify DN`) from an LDIF file and applies the changes in parallel.

This tool is a multi-threaded version of the `ldapmodify` tool that is designed to process a large number of changes as quickly as possible.

The **parallel-update** tool provides logic to prevent conflicts resulting from concurrent operations targeting the same entry or concurrent operations involving hierarchically-dependent entries, such as modifying an entry after it has been added or adding a child after its parent.

The tool also has a retry capability that can help ensure that operations are ultimately successful even when interdependent operations are not present in the correct order in the LDIF file, such as if the change to add a parent entry is provided later in the LDIF file than a change to add a child entry.

After the tool applies the changes and reaches the end of the LDIF file, it automatically displays the update statistics described in the following table.

Processing Statistic	Description
Attempts	Number of update attempts
Successes	Number of successful update attempts
Rejects	Number of rejected updates
ToRetry	Number of updates that will be retried
AvgOps/S	Average operations per second
RctOps/S	Recent operations per second Total number of operations from the last interval of change updates
AvgDurMS	Average duration in milliseconds
RctDurMS	Recent duration in milliseconds Total duration from the last interval of change updates

Running the parallel-update tool

Steps

1. Create an LDIF file with your changes.

Example:

The third change in this example generates a rejected entry because its `userPassword` attribute contains an encoded value, which is not allowed.

```
dn:uid=user.2,ou=People,dc=example,dc=com
changetype: delete

dn:uid=user.99,ou=People,dc=example,dc=com
changetype: moddn
newrdn: uid=user.100
deleteoldrdn: 1

dn:uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==

dn:uid=user.100,ou=People,dc=example,dc=com
changetype: modify
replace: st
st: TX
-
replace: employeeNumber
employeeNumber: 100
```

2. To apply the changes in the LDIF file to a target server, run `parallel-update` with the `--ldifFile` and `--rejectFile` options.

Note:

The `--ldifFile` and `--rejectFile` options are required.

Example:

In this example, there are ten concurrent threads. The optimal number of threads depends on your underlying system.

```
$ bin/parallel-update --hostname 127.0.0.1 \
  --ldifFile changes.ldif --rejectFile reject.ldif --numThreads 10
```

Result:

```
Reached the end of the LDIF file
Attempts Successes Rejects ToRetry AvgOps/S RctOps/S AvgDurMS RctDurMS
-----
          4           3           1           0           3           3          26          26
All processing complete Attempted 4 operations in 1 seconds
```

3. View the rejects files for any failed updates.

Result:

The following sample elaborates on the rejected file.

```
# ResultCode=53, Diagnostic Message=Pre-encoded passwords are not allowed
for
# the password attribute userPassword
dn: uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==
```

Working with the watch-entry Tool

The PingDirectory Server provides a **watch-entry** tool that demonstrates replication or synchronization latency by watching an LDAP entry for changes.

About this task

You can directly modify attributes with the `watch-entry` tool.

Note:

If the LDAP entry changes, the background of modified attributes will briefly be red.

Steps

- Run the **watch-entry** tool.

Example:

This example connects to `server.example.com` as `uid=admin,dc=example,dc=com` and watches entry `uid=kate,ou=people,dc=example,dc=com` for changes.

```
$ bin/watch-entry --hostname server.example.com --port 389 \
--bindDN uid=admin,dc=example,dc=com --bindPassword password \
--entryDN uid=user,ou=people,dc=example,dc=com
```

Working with LDAP transactions

The PingDirectory Server provides support for batched transactions, which are processed together at commit time.

Applications developed to perform batched transactions should include as few operations in the transaction as possible. The changes aren't actually processed until the commit request is received. Therefore, the client can't know whether the changes are successful until commit time. If any of the operations fail, then the entire set of operations fails.

Batched transactions are write operations that are processed as a single atomic unit when the commit request is received. The write operations include the following:

- add
- delete

- modify
- modify DN
- password modify

If an abort request is received or an error occurs during the commit request, the changes are rolled back. The batched transaction mechanism supports the standard LDAP transaction implementation based on RFC 5805. It's not currently possible to process a transaction that requires changes to be processed across multiple servers or multiple Directory Server backends.

Directory servers can limit the set of controls that are available for use in requests that are part of a transaction. RFC 5805 section 4 indicates that you can use the following controls in conjunction with the transaction specification request control:

- Assertion request control
- manageDsaIT request control
- Pre-read request control
- Post-read request control

The proxied authorization v1 and v2 controls can't be included in requests that are part of a transaction, but they can be included in the start transaction request to indicate that all operations within the transaction should be processed with the specified authorization identity.

The PingDirectory Server supports the following additional controls in conjunction with operations included in a transaction:

- Account usable request control
- Hard delete request control
- Intermediate client request control
- Password policy request control
- Replication repair request control
- Soft delete request control
- Soft-deleted entry access request control
- Subtree delete request control, and undelete request control

Requesting a batched transaction using `ldapmodify`

About this task

You can run the `ldapmodify` tool's `--useTransaction` option to process multiple operations as part of a single batched transaction.

Steps

1. Create a batch text file with the changes that you want to apply as a single atomic unit.

Example:

```
dn:uid=user.3,ou=People,dc=example,dc=com
changetype: delete
dn:uid=user.1,ou=People,dc=example,dc=com
changetype: modify
replace: pager
pager: +1 383 288 1090
```

- To run the batched transaction, run the `ldapmodify` tool with the `--useTransaction` and `--filename` options.

Example:

```
$ bin/ldapmodify --useTransaction --filename test.ldif
```

Result:

```
#Successfully created a transaction with transaction ID 400
#Processing DELETE request for uid=user.3,ou=People,dc=example,dc=com
#DELETE operation successful for DN
uid=user.3,ou=People,dc=example,dc=com
#This operation will be processed as part of transaction 400
#Processing MODIFY request for uid=user.1,ou=People,dc=example,dc=com
#MODIFY operation successful for DN
uid=user.1,ou=People,dc=example,dc=com
#This operation will be processed as part of transaction 400
#Successfully committed transaction 400
```

Working with Virtual Attributes

PingDirectory Server supports virtual attributes.

Virtual attributes are abstract, dynamically generated attributes that are invoked through an LDAP operation, such as `ldapsearch`, but are not stored in the Directory Server backend.

Most virtual attributes are operational attributes, providing processing-related information that the server requires. The directory server virtual attribute subsystem allows you to create user-defined virtual attributes to suit your requirements.

Viewing the list of default virtual attributes

Use the `dsconfig` tool to view the list of Directory Server virtual attributes.

Some virtual attributes are enabled by default and are useful for most applications.

The default set of virtual attributes is described in the table below. You can enable or disable these attributes using the `dsconfig` tool.

Virtual Attributes

Virtual Attributes	Description
<code>ds-entry-checksum</code>	Generates a simple checksum of an entry's contents, which can be used with an LDAP assertion control to ensure that the entry has not been modified since it was last retrieved.
<code>ds-instance-name</code>	Generates the name of the Directory Server instance from which the associated entry was read. This virtual attribute can be useful in load-balancing environments to determine the instance from which an entry was retrieved.
<code>ds-pwp-state-json</code>	Generates an operational attribute whose values is a JSON object with information about a user's current password policy state.
<code>entryDN</code>	Generates an <code>entryDN</code> operational attribute in an entry that holds a normalized copy of the entry's current distinguished name (DN). Clients can use this attribute in search filters.

Virtual Attributes	Description
hasSubordinates	Creates an operational attribute that has a value of <code>TRUE</code> if the entry has subordinate entries.
isDirectMemberOf	<p>Generates an <code>isDirectMemberOf</code> operational attribute that contains the DNs of the groups in which the user is a member.</p> <p><code>isDirectMemberOf</code> includes only static groups in which the user is explicitly named as a member.</p> <p>Compare to <code>isMemberOf</code>.</p>
isMemberOf	<p>Generates an <code>isMemberOf</code> operational attribute that contains the DNs of the groups in which the user is a member.</p> <p><code>isMemberOf</code> includes all of the following:</p> <ul style="list-style-type: none"> ▪ Static groups in which the user is explicitly named as a member ▪ Dynamic groups in which the user is a member because of the criteria for that group ▪ Static groups in which the user is a member because they are a member of a nested group that is listed as a member of the static group <p>Compare to <code>isDirectMemberOf</code>.</p>
numSubordinates	<p>Generates an operational attribute that returns the number of child entries. While there is no cost if this operational attribute is enabled, there could be a performance cost if it is requested.</p> <div data-bbox="537 1031 1471 1209" style="border: 1px solid black; padding: 5px;"> <p> Note: This operational attribute only returns the number of immediate children of the node.</p> </div>
subschemaSubentry	<p>A special entry that provides information in the form of operational attributes about the schema elements defined in the server. It identifies the location of the schema for that part of the tree.</p> <ul style="list-style-type: none"> ▪ <code>ldapSyntaxes</code> - set of attribute syntaxes ▪ <code>matchingRules</code> - set of matching rules ▪ <code>matchingRuleUse</code> - set of matching rule uses ▪ <code>attributeTypes</code> - set of attribute types ▪ <code>objectClasses</code> - set of object classes ▪ <code>nameForms</code> - set of name forms ▪ <code>dITContentRules</code> - set of DIT content rules ▪ <code>dITStructureRules</code> - set of DIT structure rules
User Defined Virtual Attribute	Generates virtual attributes with user-defined values in entries that match the criteria defined in the plugin's configuration. User-defined virtual attributes are intended to specify a hard-coded value for entries matching a given set of criteria.

Virtual Attributes	Description
Virtual Static Member	<p>Generates a member attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group.</p> <p>Do not modify the filter in the <code>Virtual Static Member</code> attribute as it is an advanced property and modifying it can lead to undesirable side effects.</p>
Virtual Static Uniquemember	<p>Generates a <code>uniqueMember</code> attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group.</p> <p>Do not modify the filter in the <code>Virtual Static Uniquemember</code> attribute because it is an advanced property, and modifying it can lead to undesirable side effects.</p>

Viewing the list of default virtual attributes using dsconfig non-interactive mode

Steps

- To list the virtual attributes, use `dsconfig`.

```
$ bin/dsconfig list-virtual-attributes
```

Viewing virtual attribute properties

View the basic properties of each virtual attribute using the `dsconfig` tool.

About this task

For a complete list of properties, see [General Consent Service configuration](#) on page 1251. The following table shows some basic properties.

To view virtual attribute properties:

Property	Description
<code>description</code>	A description of the virtual attribute.
<code>enabled</code>	Specifies whether the virtual attribute is enabled for use.
<code>base-DN</code>	<p>Specifies the base DNs for the branches containing entries that are eligible to use this virtual attribute.</p> <p>If no values are given, the server generates virtual attributes anywhere in the server.</p>

Property	Description
group-DN	<p>Specifies the DNs of the groups whose members can use this virtual attribute.</p> <p>If no values are given, the group membership is not taken into account when generating the virtual attribute.</p> <p>If one or more group DNs are specified, then only members of those groups are allowed to have the virtual attribute.</p>
filter	<p>Specifies the filters that the server applies to entries to determine if they require virtual attributes</p> <p>If no values are given, then any entry is eligible to have a virtual attribute value generated.</p>

Steps

- To view the properties of a virtual attribute, use **dsconfig**.

Example:

```
$ bin/dsconfig get-virtual-attribute-prop --name isMemberOf
```

Enabling a virtual attribute

You can enable a virtual attribute using the **dsconfig** tool.

If you are using **dsconfig** in interactive command-line mode, you can access the virtual attribute menu from the `Standard object` menu.

Enabling a virtual attribute using dsconfig interactive mode

Steps

- To enable a virtual attribute, use **dsconfig**.
 - Specify the connection port, bind DN, password, and host information.
 - Enter the LDAP connection parameter for your Directory Server:
 - For LDAP, enter 1.
 - For SSL, enter 2.
 - For StartTLS, enter 3.

Example:

```
bin/dsconfig
```

- On the Directory Server main menu, enter `o` to change the object menu, and then enter the number corresponding to `Standard`.
 - On the Directory Server main menu, enter the number corresponding to virtual attributes.
 - On the `Virtual Attribute management` menu, enter the number to view and edit an existing virtual attribute.
 - From the list of existing virtual attributes on the system, select the virtual attribute.
- For this example, enter the number corresponding to the `numSubordinates` virtual attribute.

6. On the `numSubordinates` Virtual Attribute Properties menu, enter the number to enable the virtual attribute.
7. On the Enabled Property menu for the `numSubordinates` virtual attribute, enter the number to change the value to `TRUE`.
8. On the `numSubordinates` Virtual Attribute Properties menu, enter `f` to apply the changes.
9. Verify that the virtual attribute is enabled.

Example:

Note:

This example assumes you have configured the group entries.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(ou=People)" numSubordinates
```

Result: The system returns the following.

```
dn: ou=People,dc=example,dc=com
numSubordinates: 1000
```

Enabling a virtual attribute using dsconfig non-interactive mode

Steps

- To enable a virtual attribute, such as `numSubordinates`, use `dsconfig`.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop \
  --name numSubordinates --set enabled:true
```

Creating user-defined virtual attributes

User-defined virtual attributes allow you to specify an explicit value to use for the virtual attribute.

There are no restrictions on the length of the value for a user-defined virtual attribute. You must only ensure that the new virtual attribute conforms to your schema, or you will see an error message when you configure it.

You can define your virtual attributes using the `dsconfig` tool from the `Standard object` menu. Only the `value` property is specific to the user-defined virtual attribute. All the other properties are common across all kinds of virtual attributes, which include the following.

Property	Description
<code>enabled</code>	Indicates whether the virtual attribute should be used.
<code>attribute-type</code>	The attribute type for the virtual attribute that is generated.
<code>base-dn</code> <code>group-dn</code> <code>filter</code>	Can be used to select which entries are eligible to contain the virtual attribute.

Property	Description
<code>client-connection-policy</code>	Can be used to select which entries are eligible to contain the virtual attribute.
<code>conflict-behavior</code>	Used to indicate how the server should behave if there are one or more real values for the same attribute type in the same entry. The server can either return only the real values, only the virtual values, or merge both real and virtual values.
<code>require-explicit-request-by-name</code>	Used to indicate whether the server should only generate values for the virtual attribute if it was included in the list of requested attributes.
<code>multiple-virtual-attribute-evaluation-order-index</code> <code>multiple-virtual-attribute-merge-behavior</code>	Used to control the behavior of the server if multiple virtual attributes can be used to contribute values to the same attribute.

Creating a user-defined virtual attribute in interactive mode

About this task

The following example shows how to create a user-defined virtual attribute that assigns an Employee Password Policy to any entry that matches the filter "`(employeeType=employee)`".

Steps

1. To configure the user-defined virtual attribute:
 - a. Run `dsconfig`.
 - b. Specify the connection port, bind DN, password, and host information.
 - c. Type the LDAP connection parameter for your Directory Server:
 - For LDAP, enter 1.
 - For SSL, enter 2.
 - For StartTLS, enter 3.
2. To change the object menu, in the Directory Server main menu, type `o`, and then type the number to select `Standard`.
3. In the Directory Server main menu, type the number corresponding to virtual attributes.
4. To create a new virtual attribute, in the `Virtual Attribute management` menu, type the number.
5. Use an existing virtual attribute as a template for your new attribute, or create a new attribute from scratch.

In this example, type `n` to create a new Virtual Attribute from scratch.
6. In the `Virtual Attribute Type` menu, enter a number corresponding to the type of virtual attribute that you want to create.

In this example, type the number corresponding to User Defined Virtual Attribute.
7. Enter a name for the new virtual attribute.

In this example, enter `Employee Password Policy Assignment`.
8. In the `Enabled Property` menu, enter the number to set the property to `TRUE` (enable).

9. In the `Attribute-Type Property` menu, type the **attribute-type** property for the new virtual attribute.

You can enter the OID number or attribute name. The **attribute-type** property must conform to your schema. For this example, type `ds-pwp-password-policy-dn`.

10. Enter the value for the virtual attribute, and then press `Enter` or `Return` to continue.

In this example, enter `cn=Employee Password Policy,cn=Password Policies,cn=config`, and then type `Enter` or `Return` to continue.

11. In the `User Defined Virtual Attributes` menu, enter a description for the virtual attribute.

Though optional, this step is useful if you plan to create multiple virtual attributes. Enter the option to change the value, and then type a description of the virtual attribute. In this example, type `Virtual attribute that assigns the Employee Password Policy to all entries that match (employeeType=employee)`.

12. In the `User Defined Virtual Attribute` menu, type the number corresponding to the filter.

13. In the `Filter Property` menu, enter the option to add one or more filter properties, type the filter, and then press `Enter` to continue.

In this example, type `(employeeType=employee)`. Press the number to use the filter value entered.

14. In the `User Defined Virtual Attribute` menu, type `f` to finish creating the virtual attribute.

15. Verify that the attribute was created successfully.

- a. Add the `employeeType=employee` attribute to an entry, such as `uid=user.0`, using

ldapmodify.

- b. Add the `employeeType=contractor` attribute to another entry, such as `uid=user.1`.

16. To search for the user with the `employeeType=employee` attribute, such as `uid=user.0`, use **ldapsearch**.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
ds-pwp-password-policy-dn
```

Result: The `ds-pwp-password-policy-dn` attribute has the assigned password policy as its value.

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Employee Password Policy,cn=Password
Policies,cn=config
```

17. Run **ldapsearch** again using the filter `(uid=user.1)`.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.1)" \
ds-pwp-password-policy-dn
```

Result: The `ds-pwp-password-policy-dn` attribute is not present in the entry because the entry has the attribute `employeeType=contractor`.

```
dn: uid=user.1,ou=People,dc=example,dc=com
```

Creating a user-defined virtual attribute using `dsconfig` in non-interactive mode

About this task

You can create a virtual attribute in non-interactive command-line mode using `dsconfig`.

Steps

- To set up the Employee Password Policy Assignment virtual attribute introduced in the previous section, run the following command.

Example:

```
$ bin/dsconfig create-virtual-attribute \
  --name "Employee Password Policy Assignment" \
  --type user-defined \
  --set enabled:true \
  --set attribute-type:ds-pwp-password-policy-dn \
  --set "filter:(employeeType=employee)" \
  --set "value:cn=Employee Password Policy,cn>Password Policies,cn=config"
```

Creating mirror virtual attributes

PingDirectory Server provides a feature to mirror the value of another attribute in the same entry or mirror the value of the same or a different attribute in an entry referenced by the original entry.

For example, consider a directory information tree (DIT) where users have a `manager` attribute with a value of the DN of the employee as follows.

```
dn: uid=apeters,ou=people,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
uid: apeters
... (more attributes) ...
```

You can set up a mirror virtual attribute so that the returned value for the `managerName` virtual attribute can be the `cn` value of the entry referenced by the `manager` attribute.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)" \
dn: uid=apeters,ou=people,dc=example,dc=com

objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
managerName: John Doe
uid: apeters
... (more attributes not shown) ...
```

Creating a mirror virtual attribute using dsconfig in non-interactive mode

Create a mirror virtual attribute using `dsconfig` in non-interactive command-line mode.

About this task

The following example sets up the `managerName` virtual attribute introduced in the previous section:

Steps

1. Update the schema to define the `managerName` attribute.

You can optionally add the attribute to an object class.

- a. In a text editor, create a file with the following schema definition for the attribute.

```
dn: cn=schema
```

```
objectClass: top
objectClass: ldapSubentry
objectClass: subschema attributeTypes: ( 1.3.6.1.4.1.32473.3.1.9.4
  NAME 'managerName'
  EQUALITY caseIgnoreMatch SUBSTR caseIgnoreSubstringsMatch SYNTAX
  1.3.6.1.4.1.1466.115.121.1.44{256}
  X-ORIGIN 'Directory Server Example' )
```

b. Save the file as `98-myschema.ldif` in the `<server-root>/config/schema` folder.

2. Restart the Directory Server.

```
$ bin/stop-server --restart
```

3. To create the virtual attribute, use `dsconfig`.

```
$ bin/dsconfig create-virtual-attribute \
  --name "managerName" \
  --type mirror \
  --set "description:managerName from manager cn" \
  --set enabled:true \
  --set attribute-type:managerName \
  --set source-attribute:cn \
  --set source-entry-dn-attribute:manager
```

4. To verify the mirror virtual attribute, search for an entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)"
```

Result: Your search results in the following.

```
dn: uid=apeters,ou=People,dc=example,dc=com
... (attributes) ...
manager: uid=jdoe,ou=People,dc=example,dc=com
managerName: John Doe
```

Editing a virtual attribute

You can edit virtual attributes with the `dsconfig` tool.

Make sure that the virtual attribute conforms to your plugin schema. Otherwise, an error message appears when you attempt to edit the virtual attribute.

If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu from the Standard object menu.

Editing a virtual attribute using `dsconfig` in non-interactive mode

Steps

- To change a property value, use `dsconfig`.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name dept-number \
  --set "value:111"
```

Deleting a virtual attribute

Delete virtual attributes using the `dsconfig` tool.

About this task

If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu from the `Standard object` menu.

Steps

- To delete the `dept-number` virtual attribute, use `dsconfig`.

```
$ bin/dsconfig delete-virtual-attribute --name dept-number
```

Working with Composed Attributes

This section provides information on composed attributes, which dynamically generate attribute values to complement virtual attributes.

PingDirectory Server's support for virtual attributes is a useful facility that dynamically generates values in entries for a wide range of use cases. These values are used to generate key operational attributes such as:

- `entryDN`
- `subschemaSubentry`
- `isMemberOf`
- `numSubordinates`
- `hasSubordinates`
- `ds-entry-checksum`

The values of other attributes in the same or different entries can be mirrored, and values can be constructed from other attributes in the same entry. Items such as password policies and privileges can be dynamically generated, and you can create custom virtual attribute providers with the Server SDK using a wide variety of logic.

Virtual attributes should not be used for all use cases. Composed attributes, which complement virtual attributes, are more suited for scenarios that virtual attributes do not support.

Virtual attribute limitations

This section describes the limitations of virtual attributes, such as performance, indexing, and consistency limitations.

Performance limitations

The performance impact of virtual attribute generation is limited by computing these values only if they are returned to the client. However, performance can still be impacted because of other factors. Virtual attributes might be included or excluded based on a range of criteria and the evaluation of this criteria (for example, based on group membership) can impact performance.

Indexing limitations

You cannot index the values of a virtual attribute because the values can change from one invocation to the next.

Some virtual attributes implement support for an index-like functionality by offering logic that can quickly identify entries with specified virtual attribute values. These include the following:

- When mirroring values from another attribute in the same entry, and when that source attribute type is indexed, the mirror virtual attribute provider can use an internal search to identify matching entries.
- The `entryDN` virtual attribute provider retrieves the entry with the specified distinguished name (DN).
- The `isMemberOf` virtual attribute provider uses the server's group manager to identify the members of a targeted group.

Note:

This is not an option for all types of virtual attributes.

Index-like functionality is not available for the following virtual attribute types:

- User-defined virtual attributes that have a static value
- Constructed virtual attributes whose values are composed from multiple other attributes in the same entry
- Mirror virtual attributes whose values come from other entries
- Any custom virtual attribute types implemented using the Server SDK

If you want to have a mix of standard and virtual values for the same attribute type, whether in the same entry or in different entries, there is not a good solution. If you define an index for that attribute type, it only includes entries with standard values and entries with virtual values are overlooked. If there is no index but the virtual attribute provider supports some search functionality, only entries with virtual values are matched and entries with only standard values are excluded.

Unexpected behavior for write operations

A significant issue with virtual attributes is that they can result in unexpected behaviors when targeted by write operations.

These unexpected behaviors include the following:

- Attempting to delete a virtual value fails with a `no such attribute` result.
- If the virtual attribute provider is configured with a `conflict-behavior of real-overrides-virtual`, then attempting to add a value to an entry that only has virtual values causes the virtual values to disappear.
- If the virtual attribute provider is configured with a `conflict-behavior of real-overrides-virtual`, then attempting to remove all real values of an entry causes the virtual values to appear.
- If the virtual attribute provider is configured with a `conflict-behavior of virtual-overrides-real`, then attempting to add new values or replace the set of existing values yields a success result, but the operation has no visible effect on the entry.
- If the virtual attribute provider is configured with a `conflict-behavior of merge-real-and-virtual`, then attempting to replace the set of values for an entry yields a success result, but only the real values are replaced and the virtual values remain.

There is currently no method to prevent attempts to write to attributes with virtual values. The `NO-USER-MODIFICATION` constraint in attribute type definitions is honored, but this constraint only applies to operational attribute types. This is not an acceptable limitation in many cases. Access control restrictions could work for many clients, but do not have any effect for requesters with the `bypass-acl` privilege.

Overview of composed attributes

Composed attributes are generated when an entry is written.

This includes entries that are created by add operations and LDIF imports. These entries can be created, updated, or removed when processing `modify` and `modifyDN` operations. The server might optionally permit or reject attempts to alter the generated values.

Composed values are based on a combination of static text and the contents of the entry in which the value is being generated. You cannot construct values using content from other entries in the server because the necessary content might not be available at the time the value is being generated. An

example of this is if the referenced entry does not yet exist. It would also be difficult to ensure that the value is kept up to date whenever the referenced entry changes or is removed. Values are generated using the same logic that is available for constructed virtual attributes and constructed attribute mapping functionality in the Synchronization Server.

The composed attribute functionality is implemented using a plugin. The plugin is invoked during the pre-operation phases for `add`, `modify`, and `modifyDN` operations and also operates during LDIF import.

The server provides an administrative task that can be used to iterate through all entries in a backend and generate values. This is useful when a new composed attribute plugin instance is created after the backend has already been populated and you do not want to export the data to LDIF and re-import.

The server does not provide any first-class extensibility mechanisms for composed attributes. Unlike virtual attributes, which can be created through the Server SDK, composed attribute support is limited to what the server can provide. You can implement your own plugins to generate your own data.

Composed attribute plugin configuration properties

The composed attribute plugin provides the following configuration properties.

Configuration properties

plugin-type

The plugin type values for which the server is registered.

This is a mandatory multi-valued property with a default that includes all of the `ldifimport`, `preoperationadd`, `preoperationmodify`, and `preoperationmodifydn` values. In general, you should not override this default set, but this might be useful in some rare corner cases. The available options include:

ldifimport

Indicates that values should be generated for the target attribute in any appropriate entries created during LDIF import processing.

preoperationadd

Indicates that values should be generated for the target attribute in any appropriate entries created by add operations.

preoperationmodify

Indicates that values should be generated or altered for the target attribute in any appropriate entries updated by modify operations.

preoperationmodifydn

Indicates that values should be generated or altered for the target attribute in any appropriate entries updated by modify distinguished name (DN) operations.

attribute-type

The name or OID of the attribute type for which values are generated.

This attribute type must be defined in the schema. This is a mandatory, single-valued property with no default. To have multiple composed attribute types, configure a separate instance of the plugin for each attribute type. To compose multiple values for the same attribute type from different sets of source attributes, use a single instance of the plugin with multiple value patterns.

value-pattern

The value pattern that specifies the logic that should be used when constructing values.

This pattern must be compatible with the format expected by the `com.unboundid.directory.server.sync.mapping.ConstructedValue` class. This is a mandatory, multi-valued property in which the order of the values is preserved. If this is configured with multiple values, then the behavior the plugin should exhibit is controlled by the `multiple-value-pattern-behavior` property.

 **Note:**

A value pattern is only used for an entry if that entry contains all of the attributes referenced in the value pattern.

Virtual attributes are not considered when generating values.

`multiple-value-pattern-behavior`

The behavior that the server should exhibit if multiple value-pattern values are configured.

This is a single-valued property with a default value of `use-first-non-rejected-value-pattern-with-non-empty-values-but-might-reject`.

 **Note:**

The primary reason that a rejection might occur is as a result of multivalued source attributes, but it could also occur if an unexpected error occurs while trying to generate values.

The available options include:

`use-first-non-rejected-value-pattern-with-non-empty-values-but-might-reject`

Indicates that the server should only use values generated from the first value pattern that is not rejected and yields a non-empty result.

If all value patterns yield empty results, for example, if the entry is missing at least one source attribute for each of the value patterns, then no composed value is generated. If no value pattern yields a non-empty result but at least one is rejected, then the operation fails, or the entry is rejected if performing an LDIF import.

`use-first-non-rejected-value-pattern-with-non-empty-values-and-never-reject`

Indicates that the server should only use values generated from the first value pattern that is not rejected and yields a non-empty result.

If none of the value patterns yield non-empty results, regardless of whether any of them is rejected, then no composed value is generated.

`use-first-rejection-or-first-value-pattern-with-non-empty-values`

Indicates that the server should only use values generated from the first value pattern that yields non-empty results, but if a rejection is encountered before a non-empty result is obtained, then the operation or LDIF entry is rejected.

If none of the value patterns is not rejected and yields a non-empty result, then no composed value is generated.

`use-all-non-rejected-value-patterns-with-non-empty-values-but-might-reject`

Indicates that the server should use all values generated by all of the value patterns that were not rejected for the entry.

As long as at least one value pattern generated a non-empty result, then the entire set of values generated by all value patterns is used. If none of the value patterns yielded non-empty results but none were rejected, then no composed value is generated. If none of the value patterns yielded non-empty results and at least one was rejected, then the operation fails or the LDIF entry is rejected.

`use-all-non-rejected-value-patterns-with-non-empty-values-and-never-reject`

Indicates that the server should use all values generated by all of the value patterns that were not rejected for the entry.

As long as at least one value pattern generated a non-empty result, then the entire set of values generated by all value patterns is used. If none of the value patterns yielded non-empty results, regardless of whether any of them was rejected, then no composed value is generated.

`use-first-rejection-or-all-value-patterns-with-non-empty-values`

Indicates that the server should use all of the values generated by all of the value patterns as long as none of them is rejected.

If any value pattern is rejected, then the operation fails or the LDIF entry is rejected. If none of the value patterns is rejected but none of them generates any values, then no composed values are generated.

`multi-valued-attribute-behavior`

The behavior that the server should exhibit if any of the attributes used in the value pattern have multiple values.

Note:

No more than one source attribute should have multiple values. If multiple source attributes have multiple values, and if this property is configured to try to use all of them, then the attempt to generate composed values for the entry might fail.

This is a single-value property with a default value of `use-all-values-if-possible-but-reject-if-not`. Available options include:

`use-first-value`

Indicates that the server should only use the first value for each source attribute referenced in the value pattern.

With this value, entries should never be rejected for having multivalued attributes.

`reject-entries-with-any-multivalued-source-attribute`

Indicates that the server should reject any entry that has more than one value for any of the source attributes.

`use-all-values-if-possible-but-reject-if-not`

Indicates that the server should use all values for the source attributes as long as at most one of them has multiple values.

If multiple source attributes have multiple values, the entry is rejected.

`use-all-values-if-possible-but-only-first-value-if-not`

Indicates that the server should use all values for the source attributes as long as at most one of them has multiple values.

If multiple source attributes have multiple values, then only the first value from each source attribute is used so that the entry is not rejected.

target-attribute-exists-during-initial-population-behavior

The behavior that the server should exhibit for add operations and LDIF imports for entries that already contain one or more values for the target attribute.

This is a single-valued property with a default of **preserve-existing-values**. The available options include:

preserve-existing-values

Indicates that the server should preserve existing values in entries that are added or imported and should only construct values for entries that do not already contain the target attribute.

overwrite-existing-values

Indicates that the server should only use generated values for the target attribute and that any values provided during an add or LDIF import is discarded.

merge-existing-and-composed-values

Indicates that the server should preserve any existing values for the target attribute and should construct any additional values.

Note:

This option can only be used if the target attribute type allows multiple values.

reject-existing-values-in-add-but-preserve-in-ldif-import

Indicates that the server should reject any add operation that attempts to provide any values for the target attribute but should preserve any existing values when performing an LDIF import.

Note:

The server does not reject entries that already contain the target attribute when performing an LDIF import since this would interfere with the ability to export data to LDIF from a server that contains composed values and then re-import the LDIF file.

reject-existing-values-in-add-but-overwrite-in-ldif-import

Indicates that the server should reject any add operation that attempts to provide any values for the target attribute but should replace any existing values in an LDIF import with the values which would be composed for that entry.

reject-existing-values-in-add-but-merge-in-ldif-import

Indicates that the server should reject any add operation that attempts to provide any values for the target attribute but should preserve any existing values when performing an LDIF import and add any additional values that should be composed for the entry.

update-source-attribute-behavior

The behavior that the server should exhibit for entries that are updated by `modify` or `modifyDN` operations that alter values for one of the attributes used in the value pattern.

This is a single-valued property with a default of **replace-composed-values**. The available options include:

replace-composed-values

Indicates that the server should only update values for the target attribute that match those that would have been generated by the plugin.

Values that would not have been generated by the plugin are preserved.

replace-all-values

Indicates that the server should always replace the target attribute with new composed values even if the existing values were not generated by the plugin.

preserve-existing-values

Indicates that the server should always preserve the existing values for the target attribute even if they were generated by the plugin.

source-attribute-removal-behavior

The behavior that the server should exhibit when an entry is updated in a manner that removes one or more source attributes needed to compose values for the target attribute.

This is a single-valued property with a default of **preserve-non-composed-values**. The available options include:

preserve-non-composed-values

Indicates that the server attempts to remove any values for the target attribute that would have been generated for that entry by the associated value patterns but preserves any other values that might exist for the target attribute.

If the target attribute is required by any of the object classes in the entry and if that entry only contains composed values for the target attribute, then the composed values are preserved to avoid violating the schema.

preserve-all-values

Indicates that the server preserves any values that exist for the target attribute regardless of whether they would have been composed by any of the value patterns.

remove-all-values-but-preserve-all-if-required

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of **preserve-all-values** if the target attribute type is required by any of the entry's object classes.

remove-all-values-but-preserve-non-composed-values-if-required

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of **preserve-non-composed-values** if the target attribute type is required by any of the entry's object classes.

update-target-attribute-behavior

The behavior that the server should exhibit when a client attempts to alter the target attribute with a `modify` or `modifyDN` operation.

This is a single-valued property with a default of **always-allow**. The available options include:

always-allow

Indicates that the server always permits clients to alter the value of the target attribute regardless of whether these values were generated.

allow-only-for-non-composed-values

Indicates that the server only permits clients to alter values for the target attribute that were not generated by the plugin.

Attempts to alter composed values are rejected.

never-allow

Indicates that the server should reject any attempt to alter the target attribute regardless of the values it might have.

include-base-dn

A base DN that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

exclude-base-dn

A base DN that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

include-filter

A search filter that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

exclude-filter

A search filter that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

updated-entry-newly-matches-criteria-behavior

The behavior that the server should exhibit if an entry that previously did not satisfy either the base DN or filter criteria, but is updated so that it does match any configured base DN or filter criteria.

This is a single-valued property with a default value of **preserve-existing-values-and-compose-new-values**. The available options include:

preserve-existing-values-without-composing-new-values

Indicates that if the entry already had one or more values for the target attribute, those values are preserved and no additional composed values are added.

If the entry did not contain the target attribute, then no composed values are generated for the entry.

preserve-existing-values-or-compose-new-values

Indicates that if the entry already had one or more values for the target attribute, those values are preserved and no additional composed values are added.

If the entry did not contain the target attribute, then composed values are generated for the entry.

preserve-existing-values-and-compose-new-values

Indicates that if the entry already had one or more values for the target attribute, those values are preserved and any additional values that would be composed for that entry is also added.

If the entry did not contain the target attribute, then composed values are generated for the entry.

compose-new-values-without-preserving-existing-values

Indicates that if the entry already had one more composed values for the target attribute, then those values are removed and replaced with the composed values that would be generated for it

If the entry did not contain the target attribute, then composed values are generated for it. If no composed values would be generated for the entry, for example, if it was missing at least one source attribute for each value pattern, then the entry does not include the target attribute, regardless of whether it contained existing values for the attribute.

updated-entry-no-longer-matches-criteria-behavior

The behavior that the server should exhibit if an entry previously satisfied the configured base DN and filter criteria but has been updated so that it no longer matches that criteria.

This is a single-valued property with a default of **preserve-all-values**. The available options include:

preserve-all-values

Indicates that the server preserves any values that exist for the target attribute regardless of whether they would have been composed by any of the value patterns.

preserve-non-composed-values

Indicates that the server attempts to remove any values for the target attribute that would have been generated for that entry by the associated value patterns but preserves any other values that might exist for the target attribute.

However, if the target attribute is required by any of the object classes in the entry, and if that entry only contains composed values for the target attribute, then the composed values are preserved to avoid violating the schema.

remove-all-values-but-preserve-all-if-required

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of **preserve-all-values** if the target attribute type is required by any of the entry's object classes.

remove-all-values-but-preserve-non-composed-values-if-required

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of **preserve-non-composed-values** if the target attribute type is required by any of the entry's object classes.

Include and exclude criteria configuration

Attribute values are composed by default for every entry in any public backend that contains all of the source attributes used in the appropriate value patterns. To restrict composed values to a specific set of entries, use the **include-base-dn**, **exclude-base-dn**, **include-filter**, and **exclude-filter** properties.

If the `include-base-dn` property is provided, then values are composed for entries at or below one of those base DNs. If the `exclude-base-dn` property is provided, then values are not composed for any entries at or below one of those base DNs. If both properties are provided and a given entry follows both an include and an exclude base DN, then the exclude base DN takes precedence and values are not generated for that entry. If neither property is specified, then the naming contexts of all public backends are used as the default set of include base DNs.

If the `include-filter` property is provided, then values are composed for entries that match at least one of those filters. If the `exclude-filter` property is provided, then values are not composed for any entries that match at least one of those filters. If both properties are provided and a given entry matches both include and exclude filters, then the exclude filter takes precedence and values are not generated for that entry. If neither property is specified, then the server behaves as if an include filter of "&" had been specified.

Note:

No virtual attributes are considered when evaluating this filter although composed values might be taken into consideration. For more information about the order in which composed attribute definitions are evaluated, see [Composed attribute dependency considerations](#) on page 401.

Populate composed attribute values task

When a composed attribute plugin is created in the server, it takes effect immediately and starts creating values for any appropriate `add`, `modify`, and `modifyDN` operations.

Existing entries are not automatically populated with generated values. To populate existing entries with generated values, export the data to LDIF and then re-import it. This requires temporarily taking each instance out of service, since importing into a single instance has no effect on the data in other instances. The LDIF import option is only feasible when you are starting from scratch, not when you have existing data. To address this need, a “populate composed attribute values” task is provided. The populate composed attribute values task iterates through all entries in one or more backends and generates values as appropriate for any entries.

This task provides several number of configuration attributes, including the following:

`ds-task-populate-composed-attribute-plugin-config`

An optional, multi-valued attribute that can be used to specify the names or distinguished names (DNs) of the composed attribute plugin configuration entries for which values should be generated.

Note:

If this attribute is omitted, then values are generated for all defined and enabled composed attribute plugin instances.

`ds-task-populate-composed-attribute-backend-id`

An optional, multi-valued attribute that can be used to specify the backend IDs of the backends in which values should be generated.

Note:

If this attribute is omitted, then an appropriate set of backends is determined based on the include and exclude base DNs for the selected plugins.

`ds-task-populate-composed-attribute-max-rate-per-second`

An optional, single-valued integer attribute that can be used to specify the maximum number of entries to be updated per second.

 **Note:**

If this attribute is omitted, then no rate limit is imposed.

The task uses the same logic that the plugin uses for entries imported from LDIF when deciding what values to include in the entry, but it uses internal modify operations to make any updates to the entry. These changes are replicated to other servers in the topology, so the task only needs to be invoked on a single instance. However, you should only run it after the composed attribute plugins have been configured on all instances in the topology because this ensures that no entries, including those added or updated while the task is running, are overlooked.

To invoke the task and monitor its progress, use the `populate-composed-attribute-values` command-line tool. This processing is not expected to be needed on a regular basis, so it is not offered as a recurring task.

Composed attribute dependency considerations

Composed attributes must not have dependencies on virtual attributes.

The server does not use virtual attribute values when generating values from a value pattern, nor does it use virtual attribute values when determining if an entry matches an include or exclude filter.

In general, there is no need to have one composed attribute depend on another. If one composed attribute is constructed from other attributes in the entry, then a composed attribute that needs to use another composed attribute as its source can include the value pattern for the initial composed attribute as part of its own value pattern. However, this might not be sufficient if clients can override the composed values.

If there is a reason that one composed attribute needs to depend on another, then ensure that the following requirements are satisfied:

- Any composed attribute plugins that have dependencies should be configured so that they are invoked in the appropriate order.

 **Tip:**

To configure the order in which composed attribute plugins are invoked, use `plugin-order-ldif-import`.

- Run the populate composed attribute values task separately for each of the attributes to be generated.
- The first run should be to generate values for any composed attributes that are not dependent on any other composed attributes.
- The second run should generate values for any composed attributes that were created during the first run. If multiple levels of nesting are required, you must perform additional runs of the task.
- Enable the `plugin-order-pre-operation-add`, `plugin-order-pre-operation-modify`, and `plugin-order-pre-operation-modify-dn` properties in the plugin root configuration.

Schema validation considerations

The server only generates composed attributes for entries in which that attribute is allowed to be present.

For user attributes, the target attribute type must be permitted by at least one of the object classes associated with the entry. If an entry does not have any object class that permits the target attribute, then an attempt to generate composed values for the entry fails with an `objectClassViolation` (65) result. This restriction does not exist for operational attributes.

The server allows composed attributes to satisfy mandatory attribute requirements. If the target attribute is declared as a `MUST` type for any of the entry's object classes, then a client should be able to add an entry that does not include values for that attribute type as long as the server composes a value for that attribute.

The server enforces attribute syntax restrictions for composed attributes. If a composed attribute violates the syntax for the associated attribute type, then the operation resulting in that composed attribute value is rejected with an `INVALID_ATTRIBUTE_SYNTAX` result. This can be overridden on a per-attribute-type basis using the `permit-syntax-violations-for-attribute` property in the global configuration.

**Note:**

If this option is used to permit values that violate the associated syntax, then matching operations involving malformed values might not behave in a predictable manner.

The server should also enforce the `SINGLE-VALUE` constraint for the target attribute type. If an attribute type is defined with this constraint, you cannot configure the composed attribute plugin to generate multiple values for that attribute, and any operation that results in multiple values for the target attribute is rejected.

Composed attributes cannot set values for operational attributes that are defined with the `NO-USER-MODIFICATION` constraint.

Replication considerations

The composed attribute configuration should be identical for all servers in the replication topology. When a composed attribute plugin is configured for one instance, the same definition should be added to all other instances in the topology.

Composed attribute values should only be generated for the server that processes the request from the client. When that operation is replicated to other servers, the composed attribute changes should be included as part of that operation.

Replicated changes involving composed attributes should not be restricted in a way that prevents external clients from writing to those values. This includes composed values for operational attribute types with the `NO-USER-MODIFICATION` constraint as well as for cases in which the plugin forbids clients from modifying values.

**Note:**

The plugin rejects any `modifyDN` operation that alters source attributes in a way that results in composed attribute changes.

Synchronization Server considerations

Changes involving composed attributes should be synchronized from a PingDirectory Server instance to another endpoint type without issues. Changes that create or update composed attributes should be written to the LDAP changelog, just like changes to regular attributes.

Synchronization to PingDirectory Server configured with one or more composed attribute plugin instances might be more problematic. It might not be possible to synchronize a composed attribute type if the plugin that generates values for that attribute is configured to prohibit external clients from altering values of that attribute.

If PingDirectory Server is used as a sync destination in an environment in which some attribute values might need to be composed, then you should compose those values in the Synchronization Server using a constructed attribute mapping rather than attempt to generate them in the Directory Server with the composed attribute plugin.

Directory Proxy Server considerations

Using PingDirectoryProxy Server should not require any special consideration in an environment involving composed attributes. This should be true for both simple and entry-balanced proxy configurations.

Troubleshooting considerations

For operations that are rejected for reasons related to composed attribute processing, the diagnostic message is returned to the client and included in the access log.

Examples of rejected operations that result in a diagnostic message include:

- If an `add`, `modify`, or `modifyDN` operation is rejected because the composed value violated the syntax for the target attribute type.
- If an attempt was made to alter a composed attribute value in a way that is not permitted by the plugin.

The composed attribute plugin also contains detailed debug logging support. If you encounter unexpected behavior when using the composed attribute plugin, you should enable debugging for the plugin to provide information to help diagnose the problem.

Security considerations

The primary security consideration for composed attributes is that they can expose the values of other attributes.

For example, if the `cn` attribute is composed from the values of the `givenName` and `sn` attributes, then a user with permission to read the `cn` attribute could determine the values of the `givenName` and `sn` attributes even if they do not have permission to read these attributes directly.

This is not typically a significant concern, and you can address it by ensuring that the user's access-control configuration restricts access to source attributes used in a composed attribute value pattern and imposes similar restrictions to the composed attribute.

Limitations of composed attributes relative to virtual attributes

Composed attribute support provides an alternative to a specific set of use cases that might also be addressed by virtual attribute support. The composed attribute solution might improve performance, searchability, and write behavior, but it also has limitations relative to the virtual attribute subsystem.

Limitations of composed attributes relative to virtual attributes include:

- When creating a composed attribute plugin in the server, you must use manual action to populate composed values in existing entries. When enabling a virtual attribute, the attribute is immediately available to clients.
- When removing a virtual attribute from the server, values that would have been generated for the attribute are no longer present. When removing or disabling a composed attribute plugin, previously generated composed values remain.
- Virtual attributes can be configured so that the values are only generated under certain conditions, such as only for certain clients, and to enable different values being generated for different clients. Composed attributes are the same for all clients although access controls can be used to restrict which clients have access to them.
- Virtual attributes do not require any additional storage or memory usage. Composed attributes exist in the database, so they require additional disk space and memory for caching.
- The composed attribute plugin can only generate values from a combination of static text and values from other attributes in the same entry. Virtual attributes can use a much wider range of logic when generating values, including custom logic implemented using the Server SDK.

Encrypting Sensitive Data

This section covers how to configure the Directory Server to protect sensitive information in the server.

Some of the ways to protect sensitive data covered in this section are enabling on-disk encryption for data in backends, the changelog, and the replication databases. You can protect sensitive attributes by limiting the ways that clients can interact with them.

For more information, see the following topics:

- [About encrypting and protecting sensitive data](#) on page 404
- [About backing up and restoring the encryption-settings definitions](#) on page 412
- [Configuring sensitive attributes](#) on page 418
- [Configuring global sensitive attributes](#) on page 422
- [Excluding a global sensitive attribute on a client connection policy](#) on page 422

About encrypting and protecting sensitive data

The Directory Server provides an encryption-settings database that holds encryption and decryption definitions to protect sensitive data. You can enable on-disk encryption for data:

- in backends
- in the changelog
- in the replication databases

You can protect sensitive attributes by limiting the ways that clients can interact with them.

About the Encryption-Settings Database

The encryption-settings database is a repository that holds information for encrypting and decrypting data.

The database contains any number of encryption-settings definitions that specifies information about the cipher transformation and encapsulates the key used for encryption and decryption.

Before enabling data encryption, you must create an encryption-settings definition. An encryption-settings definition specifies the cipher transformation to use to encrypt the data and encapsulates the encryption key.

Use the `encryption-settings` command-line tool to manage the encryption settings database, including:

- Creating, deleting, exporting, and importing encryption-settings definitions
- Listing the available definitions
- Indicating which definition to use for subsequent encryption operations

Implementing encryption-settings definitions

Although the encryption-settings database can have multiple encryption-settings definitions, designate only one of them as the preferred definition. The preferred encryption-settings definition is the one used for any subsequent encryption operations. Any existing data that has not yet been encrypted remains unencrypted until it is rewritten, such as a result of a `modify` or `modifyDN` operation or if the data is exported to LDIF and re-imported. Similarly, if you introduce a new preferred encryption-settings definition, then any existing encrypted data continues to use the previous definition until it is rewritten. If you do change the preferred encryption-settings definition for the server, retain the previous definitions until you are confident that no remaining data uses those older keys.

Supported encryption ciphers and transformations

This topic covers implementing encryption ciphers, cipher algorithms, and Cipher Stream Providers in Directory Server.

Cipher algorithms

The Directory Server supports encryption cipher suites that are compliant with the [MISSING glossAcronymn or glossSurfaceform for gJVM] in which the server is running. When configuring encryption, you must specify the cipher using a key length in bits and either a cipher algorithm name, such as AES, or a full cipher transformation that explicitly specifies the mode and padding to use for the encryption, such as AES/CBC/ PKCS5Padding. If only a cipher algorithm is given, then the default mode and padding for that algorithm is automatically selected.

The following cipher algorithms and key lengths have been tested using the Oracle JVM.

Cipher algorithms and key length

Cipher Algorithm	Key Length (bits)
AES	128, 192, or 256
Blowfish	128
DES	64
DESede	192
RC4	128

For specific reference information about the algorithms and transformations available in all compliant JVM implementations, see the [Java Cryptography Architecture Reference Guide](#) and [Java Cryptography Architecture Standard Algorithm Name Documentation](#) documentation.

Cipher stream providers

By default, setup generates a strong, random passphrase and writes it to a file. The server then uses a file-based cipher stream provider to read the passphrase and generate a key for encrypting the contents of the encryption settings database. However, the server supports additional cipher stream providers that use alternative means for unlocking the encryption settings database. Options include:

- Require a passphrase to be interactively provided when the server is started, or any time an external process needs access to the encryption settings database.
- Use a key stored in the Amazon Key Management Service (KMS).
- Use a key stored in a HashiCorp Vault instance.
- Use a key generated from a passphrase stored in the Amazon Secrets Manager service.
- Use a key generated from a passphrase stored in the Azure Key Vault service.
- Use a key generated from a passphrase stored in a CyberArk Conjur instance.
- Use a key generated from a certificate stored in a PKCS #11 token.

For more information, see [Configuring cipher stream providers](#) on page 1751.

Using the encryption-settings Tool

The **encryption-settings** tool provides a mechanism for interacting with the server's encryption-settings database.

About this task

Use the **encryption-settings** tool to:

- List the available definitions.
- Create new definitions.
- Delete existing definitions.
- Indicate which definition is the preferred definition.
- Export definitions to a file for backup purposes and to allow them to be imported for use in other Directory Server instances.

To list the available encryption definitions:

Steps

- To display the set of available encryption settings definitions, use the **encryption-settings** tool with the **list** subcommand.

Note:

This subcommand does not take any arguments.

Example:

```
$ bin/encryption-settings list
```

Result:

For each definition, the result includes the unique identifier for the definition as well as the cipher transformation and key length that is used for encryption and whether it is the preferred definition. See the following example.

```
Encryption Settings Definition ID:
 4D86C7922F71BB57B8B5695D2993059A26B8FC01
Preferred for New Encryption: false
Cipher Transformation: DESede
Key Length (bits): 192

Encryption Settings Definition ID:
 F635E109A8549651025D01D9A6A90F7C9017C66D
Preferred for New Encryption: true
Cipher Transformation: AES
Key Length (bits): 128
```

Creating encryption-settings definitions

The **create** subcommand provides a mechanism for creating a new encryption-settings definition.

About this task

To create an encryption-settings definition:

Steps

- To specify the definition, use the **encryption-settings** tool with the `create` subcommand. This subcommand takes the following arguments.

The `create` subcommand accepted arguments

Argument	Description
<code>--cipher-algorithm <algorithm></code> (required)	Specifies the base cipher algorithm to use. Make sure the <code><algorithm></code> input is the name of the algorithm, such as AES, DES, DESede, Blowfish, RC4.
<code>--cipher-transformation <transformation></code> (optional)	Specifies the full cipher transformation to use including the cipher mode and padding algorithms, such as AES/CBC/ PKCS5Padding. If you do not provide this argument, the JVM-default transformation is used for the specified cipher algorithm.
<code>--key-length-bits <length></code> (required)	Specifies the length of the encryption key in bits, such as 128.
<code>--set-preferred</code>	Indicates that the new encryption-settings definition is made the preferred definition and used for subsequent encryption operations in the server. By default, the first definition you create in the encryption-settings database is the preferred definition.

Example:

```
$ bin/encryption-settings create --cipher-algorithm AES \
  --key-length-bits 128 --set-preferred
```

Result:

```
Successfully created a new encryption settings definition with ID
F635E109A8549651025D01D9A6A90F7C9017C66D
```

Changing the preferred encryption-settings definition

The **encryption-settings** tool with the `set-preferred` subcommand provides a mechanism for changing the preferred encryption-settings definition.

About this task

To change a definition to a preferred definition:

Steps

- To change a definition, use the **encryption-settings** tool with the `set-preferred` subcommand to change a definition to a preferred definition.

This subcommand takes the following argument.

The `set-preferred` subcommand accepted argument

Argument	Description
<code>--id <id>(required)</code>	Specifies the ID to export for the encryption-settings definition.

Example:

```
$ bin/encryption-settings set-preferred --id
4D86C7922F71BB57B8B5695D2993059A26B8FC01
```

Result:

```
Encryption settings definition 4D86C7922F71BB57B8B5695D2993059A26B8FC01
was
successfully set as the preferred definition for subsequent encryption
operations
```

Deleting an encryption-settings definition

The **encryption-settings** tool with the `delete` subcommand provides a mechanism for deleting an encryption-settings definition.

About this task

If data in the server is encrypted using the settings contained in that definition, never delete an encryption-settings definition. Any data encrypted with a definition that has been removed from the database is inaccessible to the server and causes errors for any attempt to access it. This includes the `replicationChanges` and Changelog Databases in which the **re-encode-entries** tool does not re-encode with the new encryption-settings definition. Before removing previous encryption-settings definitions, wait for the amount of time defined in the **replication-purge-delay** of the Replication Server and **changelog-maximum-age** of the Changelog Backend, if enabled. To safely delete a compromised encryption-settings definition, see [Dealing with a Compromised Encryption Key](#).

To stop using a definition for encryption and use a different definition, make sure that the desired definition exists in the encryption-settings database and set it as the preferred definition. As long as the encryption key is not compromised, there is no harm in having old encryption-settings definitions available to the server. Retain the old encryption-settings definitions in case they are referenced by something.

Note:

The preferred encryption-settings definition cannot be deleted unless it is the only one left. To delete the currently-preferred definition when one or more other definitions are available, make one of the other definitions preferred as described in the previous section.

To delete an encryption-settings definition:

Steps

- To delete an encryption-settings definition, use the **encryption-settings** command with the **delete** subcommand.

Remember:

Make sure to include the `--id` argument to specify the definition.

The `delete` subcommand accepted argument

Argument	Description
<code>--id <id>(required)</code>	Specifies the ID to export for the encryption-settings definition.

Example:

```
$ bin/encryption-settings delete --id
F635E109A8549651025D01D9A6A90F7C9017C66D
```

Result:

```
Successfully deleted encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D
```

Configuring the encryption-settings database

Configure the encryption-settings database to protect server data.

About this task

The encryption-settings database contains encryption keys to protect server data, which automatically encrypts the contents of the encryption-settings database. By default, the server derives a key to use for this purpose. Because of this, customize the logic used to access the encryption-settings database with a cipher stream provider. To create custom cipher stream provider implementations, the Server SDK provides an API. The server contains an API you can use to obtain the key from a PIN file that you create. See the following example procedure.

Steps

- To configure the server so that the encryption-settings database is encrypted with a PIN contained in the file `config/encryption-settings.pin`, use the **dsconfig** tool.

Example:

```
$ bin/dsconfig create-cipher-stream-provider \
  --provider-name "Encryption Settings PIN File" \
  --type file-based \
  --set enabled:true \
  --set password-file:config/encryption-settings.pin
```

- To set the global configuration property and the on-disk encryption for the cipher stream provider, use the **dsconfig** tool.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
```

```
--set "encryption-settings-cipher-stream-provider:Encryption Settings
PIN File"
```

- To create a new encryption-settings definition, use the `encryption-settings` tool.

Note:

This command fails if you do not have the unlimited encryption strength policy installed as described in the previous section. Without this policy installed, you are restricted to a 128-bit key for AES encryption.

Example:

```
$ bin/encryption-settings create \
  --cipher-algorithm AES \
  --key-length-bits 256 \
  --set-preferred
```

Result: This command automatically generates a new 256-bit encryption key for use with AES encryption and marks it as the preferred definition for future encryption operations in the server.

- To obtain a list of the definitions in the encryption-settings database, use the `encryption-settings` tool with the `list` subcommand.

Example:

```
$ bin/encryption-settings list
```

- Export an encryption-settings definition from the database using the `encryption-settings` tool with the `export` subcommand.

Note:

Change the encryption-settings ID as necessary to suit your deployment.

Example:

```
$ bin/encryption-settings export \
  --id DA39A3EE5E6B4B0D3255BF95601890AFD80709 \
  --output-file /tmp/exported-key \
  --pin-file /tmp/exported-key.pin
```

- To import an encryption-settings definition into the database on another server, use the `encryption-settings` tool with the `import` subcommand.

If you do not specify a PIN file, the tool interactively prompts you to provide it.

Example:

```
$ bin/encryption-settings import \
  --input-file /tmp/exported-key \
  --pin-file /tmp/exported-key.pin \
  --set-preferred
```

Encrypting passphrase files

Use an encrypted passphrase or a `tools.properties` file to enable the server and command-line tools to use credentials available but not store them in the clear.

About this task

Encrypt these files with the following considerations:

- If the file is encrypted with a key obtained from the server's encryption settings database, the server and associated command-line tools retrieve the appropriate key from the encryption settings database, so the clear-text contents of the file are accessed without any interaction. However, if the cipher stream provider configured to protect the contents of the encryption settings database requires interaction, such as the wait for passphrase cipher stream provider, then command-line tools might require interaction to unlock the encryption settings database.
- If the file is encrypted with a passphrase that the user specifies rather than one obtained from the encryption settings database, the user is interactively prompted for that passphrase when running the tool.

Note:

Do not use this option for key store and trust store PIN files that need to be accessed by the server.

You can encrypt these files using the `encrypt-file` tool and the following tools:

Certificate keystore and truststore PIN files

When setting up an instance with encryption and either SSL or StartTLS enabled, the installer automatically encrypts the PIN files for the `config/keystore`, `config/truststore`, and `config/ads-truststore` certificate databases.

Command-line arguments

Specify passphrase files using command-line arguments. Most LDAP tools offer `--bindPasswordFile`, `--keystorePasswordFile`, and `--truststorePasswordFile` arguments.

The `config/tools.properties` file

Use the `config/tools.properties` file to obtain a default set of arguments for most command-line tools. Alternately, you can use the `--propertiesFilePath` argument to specify an alternate properties file.

Steps

1. Encrypt a file with the server's preferred encryption settings definition.

Example:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted
```

- To use a key from an encryption settings definition that isn't the default and specify the ID of the desired encryption settings definition, use the `--encryption-settings-id` argument.

**Note:**

You can obtain the `--encryption-settings-id` with `encryption-settings list`.

Example:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted \
  --encryption-settings-id 4B6899D6716FC3AFFD71F7B447EB135063A0E724
```

- To encrypt the file with a passphrase rather than a key from an encryption settings definition, choose one of the following options:

Choose from:

- Use the `--prompt-for-passphrase` argument to interactively prompt for the passphrase.
- Use the `--passphrase-file` argument to specify the path to a file containing the clear-text passphrase.

Example:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted \
  --prompt-for-passphrase
```

About backing up and restoring the encryption-settings definitions

The Directory Server provides two different mechanisms for backing up and restoring encryption-settings definitions.

The two ways you can backup and restore encryption-settings definitions:

- Export and import one or more encryption-settings definitions using the `encryption-settings` tool.
- Backup and restore the entire encryption-settings database using the `backup` and `restore` tools.

If a PIN file is used to define a passphrase to the encryption-settings database, you must backup the passphrase and secure it independently of the userRoot and encryption-settings database backups. If the encryption-settings database is restored into a different server root, the passphrase in the PIN file is required.

**Attention:**

Make sure the encryption-settings definitions are backed up regularly so you don't lose the encryption-settings definitions used to encrypt data in the server. If an encryption-settings definition is lost, any data encrypted with that definition is completely inaccessible.

Exporting encryption-settings definitions

The `encryption-settings` tool with the `export` subcommand provides a mechanism for exporting encryption-settings definitions.

About this task

Use the `export` subcommand with the `encryption-settings` command for the following scenarios:

- To back up an individual definition
- To export an individual definition from one server and import it into another

Steps

- To export the definition to a file, use the **encryption-settings** tool with the **export** subcommand. The subcommand takes the following arguments.

<code>--id <id></code>	Specifies the ID to export for the encryption-settings definition. You can specify this argument multiple times. If it's omitted, all definitions are exported.
<code>--output-file <path>(required)</code>	Specifies the path to the output file to write the encryption-settings definition.
<code>--pin-file <path></code>	Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition. If this argument isn't provided, then the PIN is interactively requested from the server.

Example:

```
$ bin/encryption-settings export --id
F635E109A8549651025D01D9A6A90F7C9017C66D \
  --output-file /tmp/exported-key
Enter the PIN to use to encrypt the definition:
Re-enter the encryption PIN:
```

Result:

```
Successfully exported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D to file /tmp/exported-key
```

Importing encryption-settings definitions

About this task

To import an encryption-settings definition that has been previously exported, use the **encryption-settings** tool with the **import** subcommand. The subcommand takes the following arguments:

`--input-file {path}`

Specifies the path to the file containing the exported encryption-settings definition. This argument is required.

`--pin-file {path}`

Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition. If this argument isn't provided, then the PIN is interactively requested from the server.

`--set-preferred`

Specifies that the newly-imported encryption-settings definition should be made for the preferred definition for subsequent encryption-settings.

Steps

- Use the **encryption-settings** tool with the **import** subcommand to import the definition to a file.

Example:

```
$ bin/encryption-settings import --input-file /tmp/exported-key --set-preferred
Enter the PIN used to encrypt the definition:
```

Result:

```
Successfully imported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D from file /tmp/exported-key
```

Enabling data encryption in the server

Enable data encryption during server setup or after server setup.

About this task

When enabling data encryption in the server, configure for backups and LDIF exports with the following global properties.

Global property	Configuration description
automatically-compress-encrypted-ldif-exports	<p>Indicates whether to automatically compress LDIF exports that are also encrypted.</p> <ul style="list-style-type: none"> If set to <code>true</code>, any LDIF export that is encrypted, either explicitly with <code>--encryptLDIF</code> or implicitly with the <code>encrypt-ldif-exports-by-default</code> configuration property, is gzip-compressed. If set to <code>false</code>, manually compress encrypted LDIF exports using the <code>--compress</code> command-line argument.

Global property	Configuration description
<code>backup-encryption-settings-definition-id</code>	<p>The unique identifier for the encryption settings definition to use to generate the encryption key for encrypted backups by default.</p> <ul style="list-style-type: none"> ▪ If this property is given a value, then a definition with that ID must exist in the server's encryption settings database. ▪ If this property is not given a value, but the server is configured with at least one encryption settings definition, then the preferred definition is used. ▪ If no encryption settings definitions are available, the server will use an internal key shared among servers in the topology. Regardless of this property's value, it can be overridden with the <code>backup</code> command-line tool. Providing one of the <code>--promptForEncryptionPassphrase</code> or <code>--encryptionPassphraseFile</code> arguments will generate the encryption key from the provided passphrase. Or, the <code>--encryptionSettingsDefinitionID</code> argument can be used to generate the key from the specified encryption settings definition.
<code>encrypt-backups-by-default</code>	<p>Indicates whether the server should encrypt backups by default.</p> <ul style="list-style-type: none"> ▪ If set to true, a defined <code>backup-encryption-settings-definition-id</code> value is used to generate the encryption key for the backup. ▪ If this property is true, and if a <code>backup-encryption-settings-definition-id</code> value is not specified, the server tries to use the preferred encryption settings definition to generate the encryption key. ▪ If the server is not configured with any encryption settings definitions, an internal key that is shared among instances in the topology is used. <p> Note:</p> <p>Regardless of this property's value, even if this property is set to <code>false</code>, you can overwrite it with the <code>backup</code> command-line tool's <code>--encrypt</code> argument.</p> <p>Even if this property has a value of <code>true</code>, the <code>--doNotEncrypt</code> argument always causes the backup to be unencrypted.</p>

Global property	Configuration description
<p><code>encrypt-ldif-exports-by-default</code></p>	<p>Indicates whether the server should encrypt LDIF exports by default.</p> <ul style="list-style-type: none"> ▪ If set to <code>true</code>, and an <code>ldif-export-encryption-settings-definition-id</code> value is specified, then that encryption settings definition is used to generate the encryption key for the export. ▪ If this property is <code>true</code>, and an <code>ldif-export-encryption-settings-definition-id</code> value is not specified, the server first tries to use the preferred encryption settings definition to generate the encryption key. ▪ If the server is not configured with any encryption settings definitions, an internal key that is shared among instances in the topology is used. <p> Note:</p> <p>Regardless of this property's value, you can overwrite the default behavior with the <code>export-ldif</code> command-line tool.</p> <p>The tool's <code>--encryptLDIF</code> argument always encrypts the export, and the <code>--doNotEncryptLDIF</code> argument always creates an unencrypted export.</p>

Perform the following steps to enable data encryption:

Steps

1. To enable encryption, choose from one of the following setups:
Choose from:
 - During server setup, define an encryption key and passphrase.
 - On legacy systems or post setup, configure data encryption by having at least one encryption-settings definition available for use.
2. Set the value of the `encrypt-data` global configuration property to `true` using the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-global-configuration-prop --set encrypt-data:true
```

Result:

Setting the global configuration property automatically enables data encryption for all types of backends that support it, including the changelog backend and indexes, as well as for the replication server database. All subsequent write operations cause the corresponding records that are written into any of these locations to be encrypted. Any existing data remains unencrypted until it is rewritten by a write operation.

Next steps

To have existing data encrypted, export that data to LDIF and re-import it. This works for both the data backends, the changelog, and indexes.

Note:

This does not work for the replication database, so existing change records remain unencrypted until they are purged. To purge a compromised encryption settings definition, safely purge the replication database by following the steps in [Dealing with a Compromised Encryption Key](#).

Using data encryption in a replicated environment

Use data encryption for on-disk storage for data within the server.

Whenever clients access stored data in the server, it's presented in unencrypted form although the communication with those clients can itself be encrypted using SSL or StartTLS. Replication, the communication of updates between replication servers, is always encrypted using SSL. Each server can apply data encryption in an independent manner and have different sets of encryption-settings definitions. It's possible to have a replication topology containing some servers that have data encryption enabled and others with it disabled.

When initializing the backend of one server from another server with data encryption enabled, the server being initialized must have access to all encryption-settings definitions that might have been used for data contained in that backend.

To do this, perform an export of the encryption-settings database on the source server using `bin/encryption-settings export` and import it on the target server using `bin/encryption-settings import`.

Dealing with a compromised encryption key

When an encryption-settings definition is compromised, all data encrypted with that definition is vulnerable, and you must stop using the definition immediately.

About this task

If an encryption-settings definition becomes compromised, such as an unauthorized individual obtaining access to the encryption key, then any data encrypted with that definition is vulnerable because it can be decrypted using that key. It's important that the encryption-settings database is protected to ensure that its contents remain secure. For example, using file permissions or file system access control lists (ACLs).

In the event that an encryption-settings definition is compromised, stop using the definition immediately. You must re-encrypt any data encrypted with the compromised key with a new definition or purged from the server. Do this on one server at a time to avoid an environment-wide downtime and complete it as quickly as possible on all servers that used this definition at any point in the past to minimize the risk of data exposure.

To respond to a compromised encryption settings definition:

Steps

1. Create a new encryption-settings definition and make it the preferred definition for new writes.
2. Ensure that client traffic is routed away from the server instance to be updated.

If the Directory Server is accessed through a Directory Proxy Server, then you can set the `health-check-state` configuration property for any LDAP external server definitions that reference that server to have a value of `unavailable`.

3. To ensure that external clients are not allowed to write operations in the directory server instance, set the `writability-mode` global configuration property to have a value of `internal-only`.

4. Look at the monitor entries with the `ds-replication-server-handler-monitor-entry` object class to ensure that the value of the `update-sent` attribute is no longer increasing.

This signals that all outstanding local changes are replicated out to other servers.

5. Stop the directory server instance.
6. Delete the replication server database by removing all files in the `changeLogDb` directory below the server root.

Important:

As long as all local changes have been replicated out to other servers, this does not result in any data loss in the replication environment.

7. Export the contents of all local DB and changelog backends to LDIF.
8. Re-import the data from LDIF.

This causes the data to be encrypted using the new preferred encryption settings definition.

9. Export the compromised key from the encryption settings database.

Note:

For precautionary measures, do this to back up the key in case you need it in the future, such as if some remaining data was later found to have been encrypted with the key contained in that definition.

10. To no longer allow the directory server instance to use the key, delete the key from the encryption settings database.
11. Start the directory server instance.
12. Allow replication to bring the server back up-to-date with any changes processed while it was offline.
13. To re-allow externally-initiated write operations, change the value of the global `writability-mode` configuration property to `enable`.
14. To allow client traffic to be routed again to that server instance, reconfigure the environment.

An example is changing the value of the `health-check-state` property in the corresponding LDAP external instance definitions in the Directory Proxy Server instances back to `dynamically-determined`.

Configuring sensitive attributes

Use and configure sensitive attribute definitions to customize the level of client data access and encryption protection needed.

For a Directory Server instance, data encryption only applies to the on-disk storage. Although it doesn't automatically protect information accessed or replicated between servers, the server offers mechanisms to provide that protection, such as SSL, StartTLS, and SASL.

All client communication using either SSL or StartTLS encryption and all replication traffic using SSL encryption helps ensure that the data is protected from unauthorized individuals who might eavesdrop on network communication. You can enable this communication security independently of data encryption.

Note:

If data encryption is enabled, you should use secure communication to protect network access to that data.

Protecting client data access isn't as simple as enabling secure communication. In some cases, you might want to allow insecure access to some data. In other cases, you might need to have additional levels of

protection in place to ensure that some attributes are more carefully protected. To achieve varying levels of protection, use sensitive attribute definitions.

The following table explains the sensitive attribute definitions and their configuration properties.

Sensitive attribute	Configuration details
attribute-type	<p>Specifies the set of attribute types whose values might be considered sensitive.</p> <p>You must provide at least one attribute type and define all specified attribute types in the server schema.</p>
include-default-sensitive-operational-attributes	<p>Indicates whether the set of sensitive attributes that might contain sensitive information should automatically be updated to include any operational attributes maintained by the Directory Server itself.</p> <p>This includes the <code>ds-sync-hist</code> operation attribute, which is used for data required for replication conflict resolution and can contain values from other attributes in the entry.</p>
allow-in-filter	<p>Indicates whether sensitive attributes can be used in filters.</p> <p>This applies not only to the filter used in search requests, but also to filters that can be used in other places, such as the assertion and join request controls.</p> <p>The value of this property must be one of the following:</p> <ul style="list-style-type: none"> ▪ <code>Allow</code>: allows sensitive attributes to be used in filters over both secure and insecure connections. ▪ <code>Reject</code>: rejects any request that includes a filter targeting one or more sensitive attributes over both secure and insecure connections. ▪ <code>Secure-only</code>: allows sensitive attributes to be used in filters over secure connections but rejects any such requests over insecure connections.

Sensitive attribute	Configuration details
allow-in-add	<p>Indicates whether sensitive attributes can be included in entries created by <code>ldapadd</code> operations.</p> <p>The value of this property must be one of the following:</p> <ul style="list-style-type: none"> ▪ <code>Allow</code>: allows sensitive attributes included in add requests over both secure and insecure connections. ▪ <code>Reject</code>: rejects any add request containing sensitive attributes over both secure and insecure connections. ▪ <code>Secure-only</code>: allows sensitive attributes included in add requests received over secure connections but rejects any such requests over insecure connections.
allow-in-compare	<p>Indicates whether sensitive attributes can be targeted by the assertion used in a compare operation.</p> <p>The value of this property must be one of the following:</p> <ul style="list-style-type: none"> ▪ <code>Allow</code>: allows sensitive attributes to be targeted by requests over both secure and insecure connections. ▪ <code>Reject</code>: rejects compare requests targeting a sensitive attribute over both secure and insecure connections. ▪ <code>Secure-only</code>: allows compare requests targeting sensitive attributes over secure connections but rejects compare requests over insecure connections.
allow-in-modify	<p>Indicates whether sensitive attributes can be updated using modify operations.</p> <p>The value of this property must be one of following:</p> <ul style="list-style-type: none"> ▪ <code>Allow</code>: allows sensitive attribute to be modified by requests over both secure and insecure connections. ▪ <code>Reject</code>: rejects any modify request updating a sensitive attribute over both secure and insecure connections. ▪ <code>Secure-only</code>: allows only modify requests updating sensitive attributes over secure connections but rejects modify requests over insecure connections.

Note:

By default, `allow-in-returned-entries`, `allow-in-filter`, `allow-in-add`, `allow-in-compare`, and `allow-in-modify` properties have values of `secure-only` only. This prevents the possibility of exposing sensitive data in the clear to anyone able to observe network communication.

Sensitive attributes and client connection policies

If a client connection policy references a sensitive attribute definition, any restrictions imposed by that definition are enforced for clients associated with this client connection policy. If multiple sensitive attribute definitions are associated with a client connection policy, the server uses the most restrictive combination of all of those sets.

Sensitive attributes and other security mechanisms

The sensitive attribute definitions work in conjunction with other security mechanisms defined in the server and can only be used to enforce additional restrictions on clients.

Never use sensitive attribute definitions to grant a client additional access to information that it didn't have already through other means. For example, if the `employeeSSN` attribute is declared a sensitive attribute and the `allow-in-returned-entries` property has a value of `Secure-only`, then the `employeeSSN` attribute is only returned to those clients that have both permissions granted by the access control rules defined in the server and are communicating with the server over a secure connection.

The `employeeSSN` attribute is stripped out of entries returned to clients normally authorized to see it if they are using insecure connections. It is also stripped out of entries for clients normally not authorized to see it even if they have established secure connections.

Creating a sensitive attribute

Creating sensitive attributes involves creating and associating definitions to set configuration properties and policies according to your business needs.

About this task

To create a sensitive attribute:

Steps

1. Create one or more sensitive attribute definitions using `dsconfig create-sensitive-attribute`.

Example:

For example, to create a sensitive attribute definition that only allows access to the `employeeSSN` attribute by clients using secure connections, make the following configuration changes.

```
$ bin/dsconfig create-sensitive-attribute \
  --attribute-name "Employee Social Security Numbers" \
  --set attribute-type:employeeSSN \
  --set include-default-sensitive-operational-attributes:true \
  --set allow-in-returned-entries:secure-only \
  --set allow-in-filter:secure-only \
  --set allow-in-add:secure-only \
  --set allow-in-compare:secure-only \
  --set allow-in-modify:secure-only
```

2. Associate the sensitive attribute definitions with the client connection policies that you want to enforce using `dsconfig set-client-connection-policy-prop`.

Example:

```
$ bin/dsconfig set-client-connection-policy-prop --policy-name default \
```

```
--set "sensitive-attribute:Employee Social Security Numbers"
```

Configuring global sensitive attributes

The Directory Server supports the ability to define sensitive attributes as a global configuration option so that they're automatically used across all client connection policies.

About this task

Administrators can assign one or more sensitive attribute definitions to a client connection policy.

Note:

When working in an environment with multiple client connection policies, it can be easy to add a sensitive attribute definition to one policy but overlook it in another.

Steps

- To add a global sensitive attribute across all client connection policies, run the `dsconfig` tool.

Example:

The following command adds the `employeeSSN` as a global sensitive attribute, which is applied across all client connection policies.

```
$ bin/dsconfig set-global-configuration-prop --add "sensitive-attribute:employeeSSN"
```

Excluding a global sensitive attribute on a client connection policy

Administrators can exclude a global sensitive attribute on a client connection policy when it's not needed for client connection requests.

About this task

Administrators can set a global sensitive attribute across all client connection policies. However, there can be cases when a specific directory server must exclude the sensitive attribute because it's not needed for client connection requests.

For example, in most environments, it's good to declare the `userPassword` attribute to be a sensitive attribute that prevents external clients reading it. This solution is more secure than protecting the `password` attribute using the server's default global access control instruction (ACI), which only exists for backwards compatibility purposes. If the Data Sync Server is installed, then it does need to access passwords for synchronization purposes. In this case, the administrator can set `userPassword` to be a sensitive attribute in all client connection policies, but exclude it in a policy specifically created for use by the Data Sync Server. The Directory Server provides an `exclude-global-sensitive-attribute` property for this purpose.

Steps

1. To remove the global ACI that limits access to the `userPassword` or `authPassword` attribute, run the `dsconfig` tool.

Note:

The global ACI is present for backwards compatibility.

Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --remove 'global-aci:(targetattr="userPassword || authPassword")
  (version 3.0; acl "Prevent clients from retrieving passwords from the
  server";
  deny (read,search,compare) userdn="ldap:///anyone");'
```

2. To add the `userPassword` attribute as a global sensitive attribute, run the `dsconfig` tool and add the built-in "sensitive-attribute:Sensitive Password Attributes" definition to the global configuration.

This applies to all client connection policies.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --add "sensitive-attribute:Sensitive Password Attributes"
```

3. If the server is designated to synchronize passwords with a Sync Server, configure a client connection policy for the Sync User to exclude the global sensitive attribute.

Example:

The following example shows how to create a new policy if the Data Sync Server binds with the default distinguished name (DN) of `cn=Sync User,cn=Root DNs,cn=config`.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Requests by Sync Users" \
  --type simple \
  --set user-auth-type:internal \
  --set user-auth-type:sasl \
  --set user-auth-type:simple \
  --set "included-user-base-dn:cn=Sync User,cn=Root DNs,cn=config"

$ bin/dsconfig create-client-connection-policy \
  --policy-name "Data Sync Server Connection Policy" \
  --set enabled:true \
  --set evaluation-order-index:9998 \
  --set "connection-criteria:Requests by Sync Users" \
  --set "exclude-global-sensitive-attribute:Sensitive Password
  Attributes"
```

Working with the LDAP Changelog

The Directory Server provides a client-accessible LDAP changelog, based on the Changelog Internet Draft Specification, for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format. The LDAP changelog is typically used by external software to maintain application compatibility between client services.

Overview of the LDAP changelog

The Directory Server provides a client-accessible LDAP changelog, based on the Changelog Internet Draft Specification, for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format.

The LDAP changelog is used by external software to maintain application compatibility between client services. For example, you can install the Data Sync Server that monitors the LDAP changelog for any updates that occur on a source directory server and synchronizes these changes to a target directory information tree (DIT) or database server.

The Directory Server provides an additional feature in that the LDAP changelog supports virtual attributes.

Note:

The LDAP changelog should not be confused with the Replication changelog. The main distinction is as follows:

- The LDAP changelog (the external changelog that clients can access) physically resides at `<server-root>/db/changelog`.
- The Replication changelog backend (the changelog that replication servers use) physically resides at `<server-root>/changelogDB`.

Key changelog features

As of 3.2, the Directory Server supports two new changelog backend properties that allow access control filtering and sensitive attribute evaluation for targeted entries.

External client applications can change the contents of attributes seen in the targeted entry based on the access control rules applied to the associated base DN.

Attribute	Description
<code>apply-access-controls-to-changelog-entry-contents</code>	Indicates whether the contents of changelog entry attributes, such as <code>changes</code> , <code>deletedEntryAttrs</code> , <code>ds-changelog-entry-key-attr-values</code> , <code>ds-changelog-before-values</code> , and <code>ds-changelog-after-values</code> , are subject to access control and sensitive attribute evaluation to limit data that LDAP clients can see. The client must have the access control permissions to read changelog entries to retrieve them in any form. If this feature is enabled and the client does not have permission to read an entry at all, or if that client does not have permission to see any attributes that were targeted by the change, then the associated changelog entries targeted by those operations are suppressed. If a client does not have permission to see certain attributes within the target entry, then references to those attributes in the changelog entry are also suppressed. This property only applies to standard LDAP searches of the <code>cn=changelog</code> branch.

Attribute	Description
<p>report-excluded-changelog-attributes</p>	<p>Indicates whether to include additional information about any attributes that might have been removed due to access control filtering. This property only applies to content removed as a result of processing performed by the <code>apply-access-controls-to-changelog-entry-contents</code> property. Possible values are:</p> <p><code>none</code></p> <p>Indicates that changelog entries should not include any information about attributes that have been removed.</p> <p><code>attribute-counts</code></p> <p>Indicates that changelog entries should include a count of user and operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, the number of the excluded user attributes are reported in the <code>ds-changelog-num-excluded-user-attributes</code> attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the number of the excluded operational attributes are reported in the <code>ds-changelog-num-excluded-operational-attributes</code> attribute of the changelog entry. Both the <code>ds-changelog-num-excluded-user-attributes</code> and <code>ds-changelog-num-excluded-operational-attributes</code> are operational and must be explicitly requested by clients or all operational attributes requested using <code>+</code> to be returned.</p> <p><code>attribute-names</code></p> <p>Indicates that changelog entries should include the names of user and operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, then the names of the excluded user attributes are reported in the <code>ds-changelog-excluded-user-attributes</code> attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the names of the excluded operational attributes are reported in the <code>ds-change-log-excluded-operational-attribute</code> attribute of the changelog entry. Both the <code>ds-changelog-excluded-user-attribute</code> and <code>ds-changelog-excluded-operational-attribute</code> attributes are operational and must be explicitly requested by clients or all operational attributes requested using <code>+</code> to be returned.</p>

Enabling access control filtering in the LDAP changelog

Use the `dsconfig` tool to enable the properties to the changelog backend to set up access control to the LDAP changelog.

About this task

Only admin users with the `bypass-acl` privilege can read the changelog.

Steps

1. To allow LDAP clients to undergo access control filtering using standard LDAP searches of the `cn=changelog` backend, enable the `apply-access-control-to-changelog-entry-contents` property.

Access control filtering is applied regardless of the value of the `apply-access-controls-to-changelog-entry-contents` setting when the changelog backend is servicing requests from an PingDataSync Server that has the `filter-changes-by-user` Sync Pipe property set.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
  --set "apply-access-controls-to-changelog-entry-contents:true"
```

2. To include a count of users that have been removed through access control filtering, set the `report-excluded-changelog-attributes` property.

The count appears in the `ds-changelog-num-excluded-user-attributes` attribute for users and in the `ds-changelog-num-excluded-operational-attributes` attribute for operational attributes.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
  --set "report-excluded-changelog-attributes:attribute-counts"
```

Useful changelog features

The Directory Server provides two changelog configuration properties: `changelog-max-before-after-values` and `changelog-include-key-attribute`.

`changelog-max-before-after-values`

Setting this property to a non-zero value causes all of the old values and all of the new values, up to the specified maximum, for each changed attribute to be stored in the changelog entry. The values are stored in the `ds-change-log-before-values` and `ds-changelog-after-values` attributes on the changelog entry. These attributes are not present by default.

Note:

The `changelog-max-before-after-values` property can be expensive for attributes with hundreds or thousands of values, such as a group entry.

If any attribute has more than the maximum number of values, their names and number of before and after values are stored in the `ds-changelog-attr-exceeded-max-values-count` attribute on the changelog entry. This is a multi-valued attribute with the following format.:

```
attr=attributeName,beforeCount=100,afterCount=101
```

`attributeName` is the name of the attribute, and the `beforeCount` and `afterCount` are the total number of values for that attribute before and after the change, respectively. This attribute indicates that

you must reset the `changelog-max-before-after-values` property to a higher value. When this attribute is set, an alert is generated.

Note:

If the number of values for an attribute exceeds the maximum value set by the `changelog-max-before-after-values` property, then those values are not stored.

changelog-include-key-attribute

This property is used for correlation attributes that need to be synchronized across servers, such as `uid`. It causes the current (after-change) value of the specified attributes to be recorded in the `ds-changelog-entry-key-attr-values` attribute on the changelog entry. This applies for all change types. On a `DELETE` operation, the values are from the entry before they were deleted.

The key values are recorded on every change and override the settings configured in `changelog-include-attribute`, `changelog-exclude-attribute`, `changelog-deleted-entry-include-attribute`, or `changelog-deleted-entry-exclude-attribute`.

Example of the changelog features

After the `changelog-max-before-after-values` property is set, the before and after values of any change attribute are recorded in the LDAP changelog.

For example, consider a simple entry with two multi-valued mail attributes.

```
dn: uid=test,dc=example,dc=com
objectclass: inetorgperson
cn: test user
sn: user
description: oldDescription
mail: test@yahoo.com
mail: test@gmail.com
```

Then, apply the following changes to the entry.

```
dn: uid=test,dc=example,dc=com
changetype: modify
add: mail
mail: test@hotmail.com
-
delete: mail
mail: test@yahoo.com
-
replace: description
description: newDescription
```

The resulting changelog would record the following attribute values.

```
dn: changeNumber=1,cn=changelog
objectClass: top
objectClass: changeLogEntry
targetDN: uid=test,dc=example,dc=com
changeType: modify
changes::

ds-changelog-entry-key-attr-values:: dWlkOiB0ZXN0Cg==
changenumber: 1

```

Run the `bin/base64 decode -d` command line tool to view the decoded value for the `changes`, `ds-changelog-before-values`, and `ds-changelog-after-values` attributes.

After base64 decoding, the `changes` attribute displays the following.

```

add: mail
mail: test@hotmail.com
-
delete: mail
mail: test@yahoo.com
-
replace: description
description: newDescription
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z
-

```

After base64 decoding, the `ds-changelog-before-values` attribute displays the following.

```

description: oldDescription
mail: test@yahoo.com
mail: test@gmail.com
modifyTimestamp: 20131010020345.546Z
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config

```

After base64 decoding, the `ds-changelog-after-values` attribute displays the following.

```

description: newDescription
mail: test@gmail.com
mail: test@hotmail.com
modifyTimestamp: 20131010020345.546Z
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config

```

Viewing the LDAP changelog properties

To view the LDAP changelog properties, run the `dsconfig get-backend-prop` command and specify the changelog backend.

Viewing the LDAP changelog properties using dsconfig non-interactive mode

Steps

- To view the changelog properties on the Directory Server, use `dsconfig`.

Tip:

To view "advanced" properties that are normally hidden, add the `--advanced` option when running the command. For a specific description of each property, see the PingDirectory Server [Configuration Reference](#).

Example:

```
$ bin/dsconfig get-backend-prop --backend-name changelog
```

Result:

```
Property                               : Value(s)
-----
backend-id                             : changelog
description                             : -
enabled                                 : false
writability-mode                       : disabled
base-dn                                 : cn=changelog
set-degraded-alert-when-disabled       : false
return-unavailable-when-disabled       : false
db-directory                           : db
db-directory-permissions                : 700
changelog-maximum-age                  : 2 d
db-cache-percent                        : 1
changelog-include-attribute            : -
changelog-exclude-attribute            : -
changelog-deleted-entry-include-attribute : -
changelog-deleted-entry-exclude-attribute : -
changelog-include-key-attribute        : -
changelog-max-before-after-values     : 0
changelog-write-batch-size             : 100
changelog-purge-batch-size             : 1000
changelog-write-queue-capacity         : 100
write-lastmod-attributes                : true
use-reversible-form                    : false
je-property                             : -
```

Enabling the LDAP changelog

Enable the LDAP changelog to maintain application compatibility between client services.

The LDAP changelog is disabled by default on the Directory Server. If you are using the `dsconfig` tool in interactive mode, the changelog appears in the backend configuration as a Standard object menu item.

Note:

Enable the feature using the `dsconfig` tool only if required because it can affect LDAP update performance.

Enabling the LDAP changelog using dsconfig non-interactive mode

Steps

- Use `dsconfig` to enable the changelog property on the Directory Server.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name changelog --set enabled:true
```

Enabling the LDAP changelog using interactive mode

Steps

- Use `dsconfig` to enable the changelog on each server in the network.
- Authenticate to the server by entering the host name, LDAP connection, port, bindDN, and bind password.
- In the `Directory Server` main menu, enter `o` to change from the Basic object level to the Standard object level.
- Enter the option to select the `Standard object level`.
- In the `Directory Server` main menu, enter the number corresponding to `backend`.
- In the `Backend Management` menu, enter the option to view and edit an existing backend.
Result: The system displays a list of the accessible backends. For example, you see options for the `changelog` and `userRoot` backends.
- Enter the option to work with the changelog backend.
- In the `Changelog Backend properties` menu, enter the number corresponding to the `Enabled` property.
- In the `Enabled Property` menu, enter the number to change the `Enabled` property to `TRUE`.
- In the `Backend Properties` menu, enter `f` to apply the change.
If you set up the server in a server group, enter `g` to update all of the servers in the group. Otherwise, repeat steps 1-10 on the other servers.
- Verify that changes made to the data are recorded in the changelog.

Changing the LDAP changelog database location

If you have disk space issues, you can change the on-disk location of the LDAP changelog database.

The changelog backend supports a `db-directory` property that specifies the absolute or relative path (relative to the local server root) to the file system directory that is used to hold the Oracle Berkeley DB Java Edition database files containing the data for this backend.

If you change the changelog database location, you must stop and restart the Directory Server for the change to take effect. If the changelog backend is already enabled, then the database files must be manually moved or copied to the new location while the server is stopped.

Changing the LDAP changelog location using dsconfig non-interactive mode

Steps

1. Use **dsconfig** to change the database location for the LDAP changelog, which by default is at `<server-root>/db`.

Example:

The following command sets the LDAP changelog backend to `<server-root>/db2`.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set "db-directory:db2" --set "enabled:true"
```

Note:

Remember to include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

The database files are stored under `<server-root>/db2/changelog`. The files for this backend are stored in a sub-directory named after the `backend-id` property.

2. Stop and restart the server.

Because the LDAP changelog backend was previous disabled, you do not need to manually relocate any existing database files.

Example:

```
$ bin/stop-server
$ bin/start-server
```

Resetting the LDAP changelog location using dsconfig non-interactive mode

Steps

1. If you have changed the LDAP changelog location, to reset it to its original location, use **dsconfig**.

Example:

The following command resets the LDAP changelog backend to `<server-root>/db` location.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --reset "db-directory"
```

Note:

Remember to include the LDAP connection parameters such as host name, port, bindDN, and bindPassword.

2. If the LDAP changelog backend at the previous location is enabled:
 - a. Stop the server.
 - b. Copy the database files to the new LDAP changelog location.
 - c. Restart the server.

**Note:**

The server attempts to use whatever it finds in the configured location when it starts. If there is nothing there, it creates an empty database.

Viewing the LDAP changelog parameters in the Root DSE

The Root DSE is a special entry that holds operational information about the server.

About this task

The entry provides information about the LDAP controls, extended operations, and Simple Authentication and Security Layer (SASL) mechanisms available in the server as well as the state of the data within the changelog. For changelog parameters, the attributes of interest include:

`firstChangeNumber`

Change number for the first (oldest) change record contained in the LDAP changelog.

`lastChangeNumber`

Change number for the last (most recent) change record contained in the LDAP changelog.

`lastPurgedChangeNumber`

Change number for the last change that was purged from the LDAP changelog. It can be 0 if no changes have yet been purged.

`firstReplicaChange`

Information about the first (oldest) change record for a change received from the specified replica. This is a multi-valued attribute and should include a value for each server in the replication topology.

`lastReplicaChange`

Information about the last (most recent) change record for a change received from the specified replica.

The `firstReplicaChange` and `lastReplicaChange` attributes use the following syntax.

```
serverID:CSN:changeNumber
```

Where:

`serverID`

Specifies the unique identifier for the server updating the change log.

`CSN`

Specifies the Change Sequence Number, which is the time when the update was made to the given replica.

`changeNumber`

Specifies the order of the change that is logged to the LDAP changelog.

The `firstReplicaChange` and `lastReplicaChange` attributes can be used to correlate information in the local LDAP changelog with data in the LDAP changelog of other servers in the replication topology.

The order of the individual changes in the LDAP changelog can vary between servers based on the order in which they were received from a replica.

Steps

- Use `ldapsearch` to view the Root DSE.

Example:

```
$ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" ""
```

Viewing the LDAP changelog using `ldapsearch`

View changelog entries using `ldapsearch`.

All records in the changelog are immediate children of the `cn=changelog` entry and are named with the `changeNumber` attribute. Changes are represented in the form documented in the `draft-good-ldap-changelog` specification with the `targetDN` attribute providing the distinguished name (DN) of the updated entry, the `changeType` attribute providing the type of operation (`add`, `delete`, `modify`, or `modDN`), and the `changes` attribute providing a base64-encoded representation of the attributes included in the entry (for `add` operations) or the changes made (for `modify` operations) in LDIF form. View the changes by decoding the encoded value using the `base64 decode` utility. The LDAP SDK for Java also provides support for parsing changelog entries.

Viewing the LDAP changelog using `ldapsearch`

Steps

1. Grant access to the `cn=changelog` backend to the `uid=admin` account using access control rules.

By default, only the root user has access to this backend.

Example:

```
$ bin/ldapmodify
dn: cn=changelog
changetype: modify
add: aci
aci: (targetattr="*|+")
  (version 3.0; acl "Access to the changelog backend for the admin
  account";
  allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

2. Use `ldapsearch` to view the changelog.

Example:

```
$ bin/ldapsearch --baseDN cn=changelog --dontWrap "(objectclass=*)" "
```

Result:

```
dn: cn=changelog
objectClass: top
objectClass: untypedObject
cn: changelog

dn: changeNumber=1,cn=changelog
objectClass: changeLogEntry
objectClass: top
targetDN: uid=user.0,ou=People,dc=example,dc=com
changeType: modify
changes::
  cmVwbGFjZTogbW9iaWxlCm1vYmlsZTogKzEgMDIwIDE1NCA5Mzk4Ci0KcmVwbGFjZToga
```

changenumber: 2
```

Viewing the LDAP change sequence numbers

About this task

The changelog displays the server state information, which is important for failover between servers during synchronization operations. The server state information is exchanged between the servers in the network (LDAP servers and replication servers) as part of the protocol start message. It also helps the client application determine which server is most up-to-date.

Steps

- Make sure the `uid=admin` account has the necessary access rights to the `cn=changelog` backend.

Example:

```
$ bin/ldapsearch --baseDN cn=changelog --dontWrap "(objectclass=*)" "+"
```

Result:

```
dn: cn=changelog

dn: changeNumber=1,cn=changelog
entry-size-bytes: 182
targetUniqueId: 68147342-1f61-3465-8489-3de58c532130
changeTime: 20111023002624Z
lastReplicaCSN: 0000011D27184D9E303000000001
replicationCSN: 0000011D27184D9E303000000001
replicaIdentifier: 12336

dn: changeNumber=2,cn=changelog
entry-size-bytes: 263
targetUniqueId: 4e9b7847-edcb-3791-b11b-7505f4a55af4
changeTime: 20111023002624Z
lastReplicaCSN: 0000011D27184F2E303000000002
replicationCSN: 0000011D27184F2E303000000002
replicaIdentifier: 12336
```

Viewing LDAP changelog monitoring information

About this task

The changelog contains a monitor entry accessed over LDAP, JConsole, the Administrative Console, or SNMP. Make sure the `uid=admin` account has the necessary access rights to the `cn=changelog` backend.

Steps

- Use `ldapsearch` to view the changelog monitor entry.

Example:

```
$ bin/ldapsearch --baseDN cn=changelog,cn=monitor "(objectclass=*)"
```

Result:

```
dn: cn=changelog,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: extensibleObject
cn: changelog
changelog: cn=changelog
firstchangenumber: 1
lastchangenumber: 8
lastpurgedchangenumber: 0
firstReplicaChange: 16225:0000011D0205237F3F6100000001:5
firstReplicaChange: 16531:0000011CFF334C60409300000002:1
lastReplicaChange: 16225:0000011D02054E8B3F6100000002:7
lastReplicaChange: 16531:0000011CFF334C60409300000002:1
oldest-change-time: 20081015063104Z
... (more data) ...
```

Indexing the LDAP changelog

The Directory Server supports attribute indexing in the Changelog Backend to allow Get Changelog Batch requests to filter results that include only changes involving specific attributes.

Normally, the directory server that receives a request must iterate over the whole range of changelog entries and then match entries based on search criteria for inclusion in the batch. The majority of this processing also involves determining whether or not the changelog entry includes changes to a particular attribute or set of attributes. Using changelog indexing, client applications can dramatically speed up throughput when targeting the specific attributes.

You can configure attribute indexing using the `index-include-attribute` and `index-exclude-attribute` properties on the Changelog Backend. The properties can accept the specific attribute name or special LDAP values `*` to specify all user attributes or `+` to specify all operational attributes.

To determine if the directory server supports this feature, view the Root DSE for the following entry.

```
supportedFeatures: 1.3.6.1.4.1.30221.2.12.3
```

Indexing a changelog attribute

Steps

- Use `dsconfig` to set attribute indexing on an attribute in the changelog backend.

Example:

Index different attributes by adding specific properties. In the following example, the command enables the Changelog Backend and sets the backend to include all user attributes (`*`) for `ADD` or `MODIFY` operations using the `changelog-include-attribute` property. The `changelog-deleted-entry-include-attribute` property is set to all attributes (`*`) to specify a set of attribute types that should be included in a changelog entry for `DELETE` operations. Attributes specified in this list are recorded in the `deletedEntryAttrs` attribute on the changelog entry when an entry is deleted.

The attributes `displayName` and `employeeNumber` are indexed using the `index-include-attribute` property.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set "enabled:true" \
  --set "changelog-include-attribute:*" \
  --set "changelog-deleted-entry-include-attribute:*" \
  --set "index-include-attribute:displayName" \
  --set "index-include-attribute:employeeNumber"
```

2. To add another attribute to index, use the `dsconfig --add` option, which adds the attribute to an existing configuration setting.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --add "index-include-attribute:cn"
```

Excluding attributes from indexing

Steps

- Use `dsconfig` to set attribute indexing on all user attributes in the changelog backend.

Example:

The following command includes all user attributes except the description and location attributes.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set "index-include-attribute:*" \
  --set "index-exclude-attribute:description" \
  --set "index-exclude-attribute:location"
```

Tracking virtual attribute changes in the LDAP changelog

While the LDAP Changelog primarily tracks changes to real attributes, it can also provide information about virtual attributes included in created, updated, or deleted entries.

About this task

The `include-virtual-attributes` property controls the virtual attribute information to include in changelog entries, and this property might include any or all of the following values:

`add-attributes`

Indicates that changelog entries for `add` operations should include a `ds-changelog-virtual-attributes` attribute that lists the virtual attribute values generated for the entry at the time it was created.

`deleted-entry-attributes`

Indicates that changelog entries for `delete` operations should include a `ds-changelog-virtual-attributes` attribute that lists the virtual attribute values generated for the entry at the time it was deleted.

`before-and-after-values`

Indicates that changelog entries for `modify` and `modify DN` operations should include `ds-changelog-before-virtual-values` and `ds-changelog-after-virtual-values` attributes that contain the values of virtual attributes that have been updated.

`key-attribute-values`

Indicates that changelog entries should include a `ds-changelog-entry-key-virtual-values` attribute that holds the values for any virtual attributes included in the set of key attributes, as defined by the `changelog-include-key-attribute` property.

The `add-attributes` and `before-and-after-values` values are selected by default.

To enable virtual attribute change tracking in the LDAP Changelog:

Steps

- Use `dsconfig`.

Example:

Note:

The following command enables the LDAP changelog and sets `include-virtual-attributes` to `add-attributes`, which indicates that virtual attributes be included in the set of attributes listed for an add operation. The `delete-entry-attributes` value indicates that virtual attributes should be included in the set of deleted entry attributes listed for a delete operation. The `before-and-after-values` value indicates that virtual attributes should be included in the set of before and after values for attributes targeted by the changes. The `key-attribute-values` value indicates that virtual attributes should be included in the set of entry key attribute values.

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
  --set "enabled:true" \
  --set "include-virtual-attributes:add-attributes" \
  --set "include-virtual-attributes:deleted-entry-attributes" \
  --set "include-virtual-attributes: before-and-after-values" \
  --set "include-virtual-attributes: key-attribute-values"
```

Managing Access Control

The PingDirectory Server provides a fine-grained access control model to ensure that users are able to access the information they need but are prevented from accessing information that they shouldn't see.

The access control model includes a privilege subsystem that provides even greater flexibility and protection.

This section presents the access control model and provides examples that illustrate the use of key access control functionality.

Overview of access control

The access control model uses access control instructions (ACIs) to determine what a user or a group of users can do with a set of entries, down to the attribute level.

The ACIs are stored in the `aci` operational attribute. The operational attribute can appear on any entry and affects the entry or any subentries within that branch of the directory information tree (DIT).

Access control instructions specify four items:

Resources

Resources are the targeted items or objects that specifies the set of entries and operations to which the access control instruction applies. For example, you can specify access to certain attributes, such as the `cn` or `userPassword` password.

Name

Name is the descriptive label for each ACI. Typically, you have multiple ACIs for a given branch of your DIT. The access control name helps describe its purpose. For example, you can configure an ACI labeled "ACI to grant full access to administrators."

Clients

Clients are the users or entities to which you grant or deny access. You can specify individual users or groups of users using an LDAP URL. For example, you can specify a group of administrators using the LDAP URL: `groupdn="ldap:///cn=admin,ou=groups,dc=example,dc=com."`

Rights

Rights are permissions granted to users or client applications. You can grant or deny access to certain branches or operations. For example, you can grant `read` or `write` permission to a `telephoneNumber` attribute.

Key access control features

The Server provides important access control features that provide added security for the Directory Server's entries.

Improved validation and security

The Directory Server provides an access control model with strong validation to help ensure that invalid access control instructions (ACIs) are not allowed into the server.

The Directory Server ensures that all access control rules (ACRs) added over LDAP are valid and can be fully parsed. The Directory Server rejects any operation that attempts to store one or more invalid ACIs. It also validates ACIs contained in data imported from an LDIF file. The Directory Server rejects any entry containing a malformed `aci` value.

As an additional level of security, the Directory Server examines and validates all ACIs stored in the data whenever a backend is brought online. If the server finds any malformed ACIs in the backend, it generates an administrative alert to notify administrators of the problem and places itself in lockdown mode. While in lockdown mode, the server only allows requests from users who have the `lockdown-mode` privilege. This action allows administrators to correct the malformed ACI while ensuring that no sensitive data is inadvertently exposed because of an ACI not being enforced. When the problem has been corrected, the administrator can use the `leave-lockdown-mode` tool or restart the server to allow it to resume normal operation.

Global ACIs

Global ACIs are a set of ACIs that apply to entries anywhere in the server or scoped to only apply to a specific set of entries.

Global ACIs work in conjunction with ACRs stored in user data and provide a convenient way to define ACIs that span disparate portions of the directory information tree (DIT).

In the Server, global ACIs are defined within the server configuration, in the `global-aci` property of the configuration object for the access control handler. To view and manage global ACIs, use configuration tools like `dsconfig` and the administrative console.

The global ACIs available by default in the Server include:

- Allow anyone, including unauthenticated users, to access key attributes of the root DSA-specific entry (DSE), including:
 - `namingContexts`
 - `subschemaSubentry`
 - `supportedAuthPasswordSchemes`
 - `supportedControl`
 - `supportedExtension`
 - `supportedFeatures`
 - `supportedLDAPVersion`
 - `supportedSASLMechanisms`
 - `vendorName`
 - `vendorVersion`
- Allow anyone, including unauthenticated users, to access key attributes of the subschema subentry, including:
 - `attributeTypes`
 - `dITContentRules`
 - `dITStructureRules`
 - `ldapSyntaxes`
 - `matchingRules`
 - `matchingRuleUse`
 - `nameForms`
 - `objectClasses`
- Allow anyone, including unauthenticated users, to include the following controls in requests made to the server:
 - Authorization identity request
 - Manage DSA IT
 - Password policy
 - Real attributes only
 - Virtual attributes only
- Allow anyone, including unauthenticated users, to request the following extended operations:
 - Get symmetric key
 - Password modify request
 - Password policy state
 - StartTLS
 - Who Am I?

Access controls for public or private backends

Depending on their intended purpose, the Server classifies backends as either public or private.

A backend is private if one of the following applies:

- Its content is generated by the Directory Server itself, such as the root DSE, monitor, and backup backends.
- It is used in the operation of the server, such as the configuration, schema, task, and trust store backends.
- Its content is maintained by the server, such as the LDAP changelog backend.

A public backend is intended to hold user-defined content, such as user accounts, groups, application data, and device data.

The Server access control model also supports the distinction between public backends and private backends. Many private backends do not allow writes of any kind from clients, and some of the private backends that do allow writes only allow changes to a specific set of attributes. As a result, you should

define any ACI intended to permit or restrict access to information in private backends as global ACIs, rather than attempting to add those instructions to the data for that private backend.

General format of the access control rules

Access control instructions (ACIs) are represented as strings that are applied to one or more entries within the directory information tree (DIT).

Typically, an ACI is placed on a subtree, such as `dc=example,dc=com`, and applies to that base entry and all entries below it in the tree. The Directory Server iterates through the DIT to compile the access control rules into an internally-used list of denied and allowed targets and their permissible operations. When a client application, such as `ldapsearch`, enters a request, the Directory Server checks that the user who binds with the server has the necessary access rights to the requested search targets. ACIs are cumulatively applied so that a user who has an ACI at an entry can also have other access rights available if ACIs are defined higher in the DIT and are applicable to the user. In most environments, ACIs are defined at the root of a main branch or a subtree, and not on individual entries unless absolutely required.

ACI

An access control rule has the following basic syntax.

```
aci : (targets) (version 3.0; acl "name";
      permissions
      bind rules
      ;)
```

Access Control Components

Access Control Component	Description
targets	Specifies the set of entries and attributes to which an access control rule applies. Use the following syntax: <code>(target keyword = != expression)</code>
name	Specifies the name of the ACI
permissions	Specifies the type of operations to which an access control rule might apply. Use the following syntax: <code>allow deny (permission)</code>
bind rules	Specifies the criteria that indicate whether an access control rule should apply to a given requester. Use the following syntax: <code>bind rule keyword = != expression;</code>
	 Note: The bind rule syntax requires that it be terminated with a <code>;</code> .

Summary of access control keywords

This section provides an overview of the supported keywords in the Server access control implementation.

Targets

A target expression specifies the set of entries and attributes to which an access control rule applies.

A target expression has three components:

Keyword

The keyword specifies the type of target element.

Expression

The expression specifies the items that are targeted by the access control rule.

Operator

The operator is either equal, =, or not-equal, !=.

Note:

You cannot use the != operator with the `targetattrfilters` and `targetscope` keywords.

For specific examples of each target keyword, see [Working with Targets](#).

```
(keyword [=|!=]expression)
```

You can use the following keywords in the target portion of ACIs:

Summary of Access Control Target Keywords

Target Keyword	Description	Wildcards
<code>extop</code>	Specifies the OIDs for any extended operations to which the access control rule should apply.	No
<code>target</code>	Specifies the set of entries, identified using LDAP URLs, to which the access control rule applies.	Yes
<code>targetattrfilters</code>	Identifies specific attribute values based on filters that can be added to or removed from entries to which the access control rule applies.	Yes
<code>targetattr</code>	Specifies the set of attributes to which the access control rule should apply.	Yes
<code>targetcontrol</code>	Specifies the OIDs for any request controls to which the access control rule should apply.	No
<code>targetfilter</code>	Specifies one or more search filters that can be used to indicate the set of entries to which the access control should apply.	Yes
<code>targetscope</code>	Specifies the scope of entries, relative to the defined target entries or the entry containing the ACI if there is no target, to which the access control rule should apply.	No

Permissions

Permissions indicate the types of operations to which an access control rule could apply.

You can specify if the user or group of users are allowed or not allowed to carry out a specific operation. For example, you can grant read access to targeted entries using the `allow (read)` permission. You can also deny access to the target entries and attributes using the `deny (read)` permission. You can list multiple permissions as required in the ACI.

```
allow (permission1
    ...,
    permission2
    ,...permissionN)
```

```
deny (permission1
    ...,
    permission2
    ,...permissionN)
```

You can use the following keywords in the permissions portion of ACIs.

Keyword	Description
add	Indicates that the access control applies to <code>add</code> operations.
compare	Indicates that the access control applies to <code>compare</code> operations and to search operations with a base-level scope that targets a single entry.
delete	Indicates that the access control applies to <code>delete</code> operations.
export	Indicates that the access control applies only to <code>modify DN</code> operations in which an entry is moved below a different parent by specifying a new superior distinguished name (DN) in the <code>modify DN</code> request. The requestor must have the <code>export</code> permission for operations against the entry's original DN. The requestor must have the <code>import</code> permission for operations against the entry's new superior DN. For <code>modify DN</code> operations that alter the relative distinguished name (RDN) of an entry but keeps it below the same parent, such as renaming the entry, only the <code>write</code> permission is required. This is true regardless of whether the entry being renamed is a leaf entry or has subordinate entries.
import	See the description for the <code>export</code> permission.
proxy	Indicates that the access control rule applies to operations that attempt to use an alternate authorization identity, such as operations that include a proxied authorization request control, an intermediate client request control with an alternate authorization identity, or a client that has authenticated with a Simple Authentication and Security Layer (SASL) mechanism that allows an alternate authorization identity to be specified.
read	Indicates that the access control rule applies to search result entries returned by the server.
search	Indicates that the access control rule applies to <code>search</code> operations with a non-base scope.
selfwrite	Indicates that the access control rule applies to operations in which a user attempts to add or remove their own DN to the values for an attribute, such as users adding or removing themselves from groups.

Keyword	Description
write	Indicates that the access control rule applies to <code>modify</code> and <code>modify DN</code> operations.
all	An aggregate permission that includes all other permissions except <code>import</code> , <code>export</code> , and <code>proxy</code> . This is equivalent to providing a permission of <code>add</code> , <code>compare</code> , <code>delete</code> , <code>read</code> , <code>search</code> , <code>selfwrite</code> , and <code>write</code> .

Bind rules

The bind rules indicate whether an access control rule should apply to a given requester.

The syntax for the target keyword has three components:

Keyword

The keyword specifies the type of target element.

Expression

The expression specifies the items that are targeted by the access control rule.

Operator

The operator is either equal, `=`, or not-equal, `!=`.

You must use the semicolon delimiter symbol, `;`, after the end of the final bind rule.

```
keyword [=|!= ] expression;
```

For added access control precision, you can combine multiple bind rules using the Boolean operations `AND`, `OR`, and `NOT`. The standard Boolean rules for evaluation apply:

- Innermost to outer parentheses first
- Left to right expressions
- `NOT` before `AND` or `OR`

For example, an access control instruction (ACI) with the following bind rule targets all users who are not `uid=admin,dc=example,dc=com` and use simple authentication.

```
(userdn!="ldap:///uid=admin,dc=example,dc=com" and authmethod="simple");
```

The following bind rule targets users that are `uid=admin,dc=example,dc=com` and authenticate using Simple Authentication and Security Layer (SASL) `EXTERNAL` or access the server from a loopback interface.

```
(userdn="ldap:///uid=admin,dc=example,dc=com and (authmethod="SSL" or ip="127.0.0.1"));
```

You can use the following keywords in the bind rule portion of ACIs.

Bind Rule Keyword	Description
authmethod	<p>Indicates that the requester's authentication method is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.</p> <p>Use the syntax <code>authmethod = method</code> where <i>method</i> is one of the following representations:</p> <ul style="list-style-type: none"> ▪ <code>none</code> ▪ <code>simple</code> Indicates that the client is authenticated to the server using a bind DN and password. ▪ <code>ssl</code> Indicates that the client is authenticated with an SSL/TLS certificate (for example, via SASL EXTERNAL), and not just over a secure connection to the server. ▪ <code>sasl {sasl_mechanism}</code>. Indicates that the client is authenticated to the server using a specified SASL mechanism. <p>The following example allows users who authenticate with an SSL/TLS certificate (for example, using SASL EXTERNAL) to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (userdn="ldap:///self" and authmethod="ssl");)</pre>
dayofweek	<p>Indicates that the day of the week is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.</p> <p>You can separate multiple day of week values by commas. Use the following syntax.</p> <pre>dayofweek = day1, day2, ...</pre> <p><i>day</i> is one of the following:</p> <ul style="list-style-type: none"> ▪ <code>sun</code> ▪ <code>mon</code> ▪ <code>tues</code> ▪ <code>wed</code> ▪ <code>thu</code> ▪ <code>fri</code> ▪ <code>sat</code> <p>The following example allows users who authenticate on weekdays with an SSL/TLS certificate, such as SASL EXTERNAL, to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (dayofweek!="sun,sat" and userdn="ldap:/// self" and authmethod="ssl");)</pre>

Bind Rule Keyword	Description
dns	<p>Indicates that the requester's DNS-resolvable host name is taken into account when determining whether the access control rule should apply to an operation. You can use wildcards in this expression.</p> <p>You can separate multiple DNS patterns by commas. Use the following syntax.</p> <pre>dns = dns-host-name</pre> <p>The following example allows users on host name <code>server.example.com</code> to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (dns="server.example.com" and userdn="ldap:///self");)</pre>
groupdn	<p>Indicates that the requester's group membership is taken into account when determining whether the access control rule should apply to any operation. You cannot use wildcards in this expression.</p> <pre>groupdn [= !=] "ldap:///groupdn [ldap:///groupdn] ..."</pre> <p>The following example allows users in the managers group to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (groupdn="ldap:///cn=managers,ou=groups,dc=example,dc=com");)</pre>
ip	<p>Indicates that the requester's IP address is taken into account when determining whether the access control rule should apply to an operation. You can use wildcards in this expression.</p> <p>You can separate multiple IP address patterns by commas. Use the following syntax.</p> <pre>ip [= !=] <ipAddressList></pre> <p><i>ipAddressList</i> is one of the following:</p> <ul style="list-style-type: none"> ▪ A specific IPv4 address: 127.0.0.1 ▪ An IPv4 address with wildcards to specify a subnetwork: 127.0.0.* ▪ An IPv4 address or subnetwork with subnetwork mask: 123.4.5.0+255.255.255.0 ▪ An IPv4 address range using CIDR notation: 123.4.5.0/24 ▪ An IPv6 address as defined by RFC 2373. <p>The following example allows users on 10.130.10.2 and localhost to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (ip="10.130.10.2,127.0.0.1" and userdn="ldap:///self");)</pre>

Bind Rule Keyword	Description
oauthscope	<p>Indicates that the scopes associated with any OAuth 2.0 access token presented by a SCIMv2 client is taken into account when determining whether the access control rule applies to an operation.</p> <p>Use the following syntax.</p> <pre data-bbox="461 422 1130 453">oauthscope [= !=] "<scopeIdentifier>"</pre> <p><i>scopeIdentifier</i> is one of the following:</p> <ul data-bbox="461 533 1458 636" style="list-style-type: none"> ▪ The name of a single scope to match. The name will be treated as case-sensitive. ▪ A substring assertion that contains one or more asterisks as wildcards. ▪ A single asterisk by itself, which will match any scope. <p>The following example grants all rights to any client that presented an OAuth 2.0 token that is associated with the <code>scim_admin</code> scope.</p> <pre data-bbox="461 747 1419 858">aci: (targetattr="*") (version 3.0; acl "Full rights for users with the scim_admin OAuth 2.0 scope"; allow (all) oauthscope="scim_admin";)</pre>
timeofday	<p>Indicates that the time of day is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.</p> <p>Use the following syntax.</p> <pre data-bbox="461 1083 1260 1115">timeofday [= != >= > <= <] <time></pre> <p><i>time</i> is one of the following:</p> <ul data-bbox="461 1194 1446 1297" style="list-style-type: none"> ▪ 4-digit 24-hour time format (0000 to 2359, where the first two digits represent the hour of the day and the last two represent the minute of the hour) ▪ You cannot use wildcards in this expression <p>The following example allows users to update their own entries if the request is received before 12 noon.</p> <pre data-bbox="461 1404 1403 1541">aci: (targetattr="*") (version 3.0; acl "Allow users who authenticate before noon to update their own entries"; allow (write) (timeofday<1200 and userdn="ldap:///self" and authmethod="simple");)</pre>

Bind Rule Keyword	Description
oauthscope	<p>Indicates that the scopes associated with any OAuth 2.0 access token presented by a SCIMv2 client is taken into account when determining whether the access control rule should apply to an operation. The keyword's syntax is as follows:</p> <pre data-bbox="462 367 1128 409">oauthscope [= !=] "<scopeIdentifier>"</pre> <p><i>scopeIdentifier</i> is one of the following:</p> <ul data-bbox="462 483 1453 588" style="list-style-type: none"> ▪ The name of a single scope to match. The name will be treated as case-sensitive. ▪ A substring assertion that contains one or more asterisks as wildcards. ▪ A single asterisk by itself, which will match any scope. <p>The following example grants all rights to any client that presented an OAuth 2.0 token that is associated with the <code>scim_admin</code> scope:</p> <pre data-bbox="462 693 1421 819">aci: (targetattr="*") (version 3.0; acl "Full rights for users with the scim_admin OAuth 2.0 scope"; allow (all) oauthscope="scim_admin";)</pre>

Bind Rule Keyword	Description
userattr	<p>Indicates that the requester's relation to the value of the specified attribute is taken into account when determining whether the access control rule should apply to an operation.</p> <p>Use the following syntax.</p> <pre data-bbox="448 411 1459 470">userattr = <attrName># [<bindType> <attrValue>]</pre> <p>Where:</p> <ul data-bbox="467 533 1451 663" style="list-style-type: none"> ▪ <i>attrName</i> = name of the attribute for matching ▪ <i>bindType</i> = USERDN, GROUPDN, LDAPURL ▪ <i>attrValue</i> = an attribute value. The <i>attrVALUE</i> of the attribute must match on both the bind entry and the target of the ACI. <p>A <i>bindType</i> value of <code>USERDN</code> indicates that the target attribute should have a value which matches the DN of the authenticated user. A <i>bindType</i> value of <code>GROUPDN</code> indicates that the target attribute should have a value which matches the DN of a group in which the authenticated user is a member. A <i>bindType</i> value of <code>LDAPURL</code> indicates that the target attribute should have a value that is an LDAP URL whose criteria matches the entry for the authenticated user.</p> <p>Any value other than <code>USERDN</code>, <code>GROUPDN</code>, or <code>LDAPURL</code> is expected to be present in the target attribute of the authenticated user's entry.</p> <p>The following example allows a manager to change employee's entries. If the bind DN is specified in the manager attribute of the targeted entry, the bind rule is evaluated to <code>TRUE</code>.</p> <pre data-bbox="448 1094 1459 1224">aci: (targetattr="*") (version 3.0; acl "Allow a manager to change employee entries"; allow (write) userattr="manager#USERDN";)</pre> <p>The following example allows any member of a group to change employee's entries. If the bind DN is a member of the group specified in the <code>allowEditors</code> attribute of the targeted entry, the bind rule is evaluated to <code>TRUE</code>.</p> <pre data-bbox="448 1367 1459 1497">aci: (targetattr="*") (version 3.0; acl "Allow allowEditors to change employee entries"; allow (write) userattr="allowEditors#GROUPDN";)</pre> <p>The following example allows a user's manager to edit that user's entry and any entries below the user's entry up to two levels deep. You can specify up to five levels (0, 1, 2, 3, 4) below the targeted entry, with zero 0 indicating the targeted entry.</p> <pre data-bbox="448 1640 1459 1770">aci: (targetattr="*") (version 3.0; acl "Allow managers to change employees entries two levels below"; allow (write) userattr="parent[0,1,2].manager#USERDN";)</pre> <p>The following example allows any member of the engineering department to update any other member of the engineering department at or below the specified ACI.</p> <pre data-bbox="448 1881 1459 2011">aci: (targetattr="*") (version 3.0; acl "Allow any member of Eng Dept to update any other member of the engineering department at or below the ACI"; allow (write) userattr="department#ENGINEERING";)</pre> <p>The following example allows an entry to be updated by any user whose entry matches the criteria defined in the LDAP URL contained in the</p>

Bind Rule Keyword	Description
userdn	<p>Indicates that the user's DN is taken into account when determining whether the access control rule should apply to an operation.</p> <p>Use the following syntax.</p> <pre>. userdn [= !=] "ldap:///<value> ["ldap:///<value> ..."]</pre> <p>Where <i>value</i> is one of the following representations:</p> <ul style="list-style-type: none"> ▪ The DN of the target user ▪ A value of <i>anyone</i> to match any client, including unauthenticated clients. ▪ A value of <i>all</i> to match any authenticated client. ▪ A value of <i>parent</i> to match the client authenticated as the user defined in the immediate parent of the target entry. ▪ A value of <i>self</i> to match the client authenticated as the user defined in the target entry. <p>If the value provided is a DN, then that DN can include wildcard characters to define patterns. A single asterisk will match any content within the associated DN component, and two consecutive asterisks can be used to match zero or more DN components.</p> <p>The following example allows users to update their own entries.</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) userdn="ldap:///self";)</pre>

Access token validators

Access token validators verify the tokens that HTTP client applications submit when they request access to protected resources and associate each token with an identity stored in the directory server.

To authenticate to The Server's HTTP services, clients use OAuth 2 bearer token authentication to present an access token in the HTTP Authorization request header.

To process the incoming access tokens, The Server uses access token validators, which determine whether to accept an access token and translate it into a set of properties, called claims, which The Server's HTTP services use to make access control decisions.

Most access tokens identify a user as its subject using the `sub` claim. Access token validators can retrieve the token subject's attributes from the directory using an identity mapper, which correlates the access token subject to an LDAP entry.

Access token validators are used by the following services:

- Directory REST API
- SCIM 2
- Delegated Admin
- Consent API

You can configure The Server to accept access tokens provided by LDAP clients using the OAUTHBEARER Simple Authentication and Security Layer (SASL) authentication method.

About access token validator processing

You can configure any number of access token validators for The Server.

Each access token validator has an evaluation order index, which is an integer that determines the processing priority when multiple access token validators are configured. Lower values are processed before higher values.

**Note:**

Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by The Server.

Processing steps

1. If an incoming HTTP request contains an access token, the token is sent to the access token validator with the lowest evaluation order index.
2. The access token validator validates the access token. Validation logic varies by access token validator type, but the validator generally verifies the following information:
 - A trusted source issued the token.
 - The token is not expired.
3. If the access token contains a subject, the access token validator uses its identity mapper to find a matching LDAP entry.
4. If the access token validator is unable to validate the access token, it passes the token to the access token validator with the next lowest evaluation order index, and the previous two steps are repeated.
5. HTTP request processing continues, and the policy request is sent to the HTTP service, such as the Directory REST API, for further evaluation.
6. Using either the access token claims parsed by the access token validator or the LDAP entry found by the identity mapper, the HTTP service determines whether the request should be accepted and which access control rules should be applied. This access control behavior varies by each HTTP service.

Access token validator types

The Server works with a variety of access token validators.

Configuring a sample PingFederate access token validator

To verify the access tokens that a PingFederate authorization server issues, the PingFederate access token validator uses HTTP to submit the tokens to PingFederate Server's token introspection endpoint.

Before you begin

Before using a PingFederate access token validator, create a client that represents the access token validator in the PingFederate configuration. This client must use the Access Token Validation grant type.

About this task

This step allows the authorization server to determine whether a token is valid.

**Note:**

Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by The Server.

Because this step requires an outgoing HTTP request to the authorization server, the PingFederate access token validator might perform slower than other access token validator types. The validation result is guaranteed to be current, which is an important consideration if the authorization server permits the revocation of access tokens.

Steps

1. In PingFederate, create a client with the following properties:
 - Client ID: Ping Identity
 - Client authentication: Client Secret
 - Allowed grant types: Access Token Validation
2. Take note of the client secret and use the Server's `dsconfig` command to create an access token validator, as shown.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com
# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031
# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "PingFederate Access Token Validator" \
  --type ping-federate \
  --set enabled:true \
  --set "authorization-server:PingFederate External Server" \
  --set client-id:PingDataGovernance \
  --set "client-secret:<client secret>" \
  --set evaluation-order-index:2000 \
  --set "identity-mapper:User ID Identity Mapper"
```

3. Replace `<client secret>` with the client secret value generated by the PingFederate client.

JWT access token validator

The JWT access token validator verifies access tokens that are encoded in JSON Web Token (JWT) format, which can be signed in JSON web signature (JWS) format or signed and encrypted in JSON web encryption (JWE) format.

The JWT access token validator inspects the JWT token without presenting it to an authorization server for validation. Because the JWT access token validator does not make a token introspection request for every access token that it processes, it performs faster than the PingFederate access token validator. The access token is self-validated, so the JWT access token validator cannot determine whether the token has been revoked.

Supported JWS/JWE features

For signed tokens, the JWT access token validator supports the following JWT web algorithm (JWA) types:

- RS256
- RS384
- RS512
- ES256
- ES384
- ES512

For encrypted tokens, the JWT access token validator supports the following key-encryption algorithms:

- RSA-OAEP

- ECDH-ES
- ECDH-ES+A128KW
- ECDH-ES+A192KW
- ECDH-ES+A256KW

For encrypted tokens, the JWT access token validator supports the following content-encryption algorithms:

- A128CBC-HS256
- A192CBC-HS384
- A256CBC-HS512

The JWT access token validator configuration defines three allow lists for the JWS/JWE signing and encryption algorithms that it accepts. Customize these allow lists to reflect only the signing and encryption algorithms used by your access token issuer and no others. This minimizes the access token validator's security threat surface.

Configure these allow lists using the following configuration properties:

`allowed-signing-algorithm`

Specifies the signing algorithms that the access token validator accepts.

`allowed-key-encryption-algorithm`

Specifies the key-encryption algorithms that the access token validator accepts.

`allowed-content-encryption-algorithm`

Specifies the content-encryption algorithms that the access token validator accepts.

Handling signed tokens

The token issuer must cryptographically sign all access tokens that the JSON web token (JWT) access token validator handles. The JWT access token validator validates a token's signature using a public signing key provided by the issuer.

Steps

- Configure the JWT access token validator with the issuer's public signing key:
Choose from:
 - Store the public key as a trusted certificate in The Server's local configuration using the `trusted-certificate` property.
 - Provide the issuer's JSON Web Key Set (JWKS) endpoint using the `jwtks-endpoint-path` property.

Note:

The JWT access token validator then retrieves the issuer's public keys when it initializes. This method ensures that the JWT access token validator uses updated copies of the issuer's public keys.

Example: Use a locally configured trusted certificate

The following example configures a JWT access token validator to use a locally stored public signing certificate to validate access token signatures. The signing certificate is assumed to have been obtained out-of-band and must be a PEM-encoded X.509v3 certificate.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
```

```

--type exact-match \
--set enabled:true \
--set match-attribute:uid \
--set match-base-dn:ou=people,dc=example,dc=com

# Add the public signing certificate to the server configuration
dsconfig create-trusted-certificate \
  --certificate-name "JWT Signing Certificate" \
  --set "certificate</path/to/signing-certificate.pem"

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "JWT Access Token Validator" \
  --type jwt \
  --set enabled:true \
  --set evaluation-order-index:1000 \
  --set allowed-signing-algorithm:RS256 \
  --set "trusted-certificate:JWT Signing Certificate"
  --set "identity-mapper:User ID Identity Mapper"

```

Example: Use the issuer's JWKS endpoint

The following example configures a JWT access token validator to retrieve public keys from a PingFederate authorization server's JWKS endpoint.

```

# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "JWT Access Token Validator" \
  --type jwt \
  --set enabled:true \
  --set evaluation-order-index:1000 \
  --set allowed-signing-algorithm:RS256 \
  --set "authorization-server:PingFederate External Server" \
  --set jwks-endpoint-path:/ext/oauth/jwks
  --set "identity-mapper:User ID Identity Mapper"

```

Handling encrypted tokens

Configure the JSON web token (JWT) access token validator to accept encrypted access tokens. You must configure the access token validator with a private and public key pair and provide the public key to the token issuer.

Steps

1. Create an encryption key pair.
2. Create the JWT access token validator.

- Export the public encryption key from PingDataGovernance Server and provide it to your token issuer. Choose from:
 - To copy the public key to a file, run **dsconfig**.
 - Copy the value of the key pair's `certificate-chain` property in the administrative console.

**Note:**

Without this public encryption key, the issuer cannot encrypt tokens that can be decrypted by the JWT access token validator.

Example

The following example configures a JWT access token validator to handle access tokens signed and encrypted using elliptic curve algorithms.

For RSA signing and encryption algorithms, the configuration is similar, but you choose different values for the `allowed-signing-algorithm` and `allowed-encryption-algorithm` properties.

- Create an encryption key pair.

```
# Create an encryption key pair
dsconfig create-key-pair \
  --pair-name "JWT Elliptic Curve Encryption Key Pair" \
  --set key-algorithm:EC_256
```

- Create the JWT access token validator.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "JWT Access Token Validator" \
  --type jwt \
  --set enabled:true \
  --set evaluation-order-index:1000 \
  --set allowed-signing-algorithm:ES256 \
  --set "authorization-server:PingFederate External Server" \
  --set jwks-endpoint-path:/ext/oauth/jwks \
  --set "encryption-key-pair:JWT Elliptic Curve Encryption Key Pair" \
  --set allowed-key-encryption-algorithm:ECDH_ES
  --set "identity-mapper:User ID Identity Mapper"
```

- Export the public encryption key from PingDataGovernance Server and provide it to your token issuer.

The following command copies the key to a file.

```
dsconfig get-key-pair-prop \
  --pair-name "JWT Elliptic Curve Encryption Key Pair" \
  --property certificate-chain \
```

```
--no-prompt \  
--script-friendly > jwt-public-encryption-key.pem
```

Mock access token validator

A mock access token validator is a special access token validator type for development or testing purposes.

A mock access token validator accepts arbitrary tokens without validating whether a trusted source issued them. This allows you to make bearer token-authenticated requests without first setting up an authorization server.

Mock access tokens are formatted as plain-text JSON objects using standard JSON web token (JWT) claims.

Always provide the boolean `active` claim when creating a mock token. If this value is `true`, the token is accepted. If this value is `false`, the token is rejected.

If the `sub` claim is provided, a token owner lookup populates the `TokenOwner` policy request attribute as with the other access token validator types.

The following example cURL command shows a mock access token in an HTTP request.

```
curl -k -X GET https://localhost:8443/scim/v2/Me -H 'Authorization:  
Bearer {"active": true, "sub":"user.3", "scope":"email profile",  
"client":"client1"}'
```

Important:

Never use mock access token validators in a production environment because they do not verify whether a trusted source issued an access token.

Example

Sample configuration

The configuration for a mock access token validator resembles the configuration for a JWT access token validator. However, the JSON web signature (JWS) signatures require no configuration because mock tokens are not authenticated.

```
# Create an identity mapper that expects the token subject to be a uid  
dsconfig create-identity-mapper \  
  --type exact-match \  
  --set enabled:true \  
  --set match-attribute:uid \  
  --set match-base-dn:ou=people,dc=example,dc=com  
  
# Create the Access Token Validator  
dsconfig create-access-token-validator \  
  --validator-name "Mock Access Token Validator" \  
  --type mock --set enabled:true \  
  --set evaluation-order-index:9999  
  --set "identity-mapper:User ID Identity Mapper"
```

Third-party access token validator

To create custom access token validators, use the Server SDK.

Working with targets

The following section presents a detailed look and examples of the target access control instruction (ACI) keywords:

- `target`
- `targetattr`
- `targetfilter`
- `targattrfilters`
- `targetscope`
- `targetcontrol`
- `extop`

target

The `target` keyword indicates that the ACI should apply to one or more entries at or below the specified distinguished name (DN).

The target DN must be equal or subordinate to the DN of the entry in which the ACI is placed. For example, if you place the ACI at the root of `ou=People,dc=example,dc=com`, you can target the DN, `uid=user.1,ou=People,dc=example,dc=com`, within your ACI rule. The DN must meet the string representation specification of distinguished names, outlined in RFC 4514, and requires that special characters be properly escaped.

The `target` clause has the following format, where *DN* is the distinguished name of the entry or branch:

```
(target = ldap:///<DN>)
```

For example, to target a specific entry, use a clause like the following.

```
(target = ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

Note:

In most cases, you should avoid specifying a target DN. Instead, define the ACI in that entry and omit the `target` element altogether.

For example, although you can have `(target="ldap:///uid=john.doe,ou=People,dc=example,dc=com)` in any of the `dc=example,dc=com` or `ou=People` entries, you should define it in the `uid=john.doe` entry and not explicitly include the `target` element.

The expression allows for the not equal operator (`!=`) to indicate that all entries within the scope of the given branch that do not match the expression be targeted for the ACI. The following expression targets all entries within the subtree that do not match `uid=john.doe`.

```
(target != ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

The `target` keyword also supports the use of asterisk (`*`) characters as wildcards to match elements within the distinguished name.

- The following target expression matches all entries that contain and begin with `john.d`.

```
(target = ldap:///uid=john.d*,ou=People,dc=example,dc=com)
```

Entries such as `john.doe,ou=People,dc=example,dc=com` and `john.davies,ou=People,dc=example,dc=com` would match the target expression.

- The following target expression matches all entries whose DN begins with `john.d` and matches the `ou` attribute.

```
(target = ldap:///uid=john.d*,ou=*,dc=example,dc=com)
```

Entries such as `john.doe,ou=People,dc=example,dc=com` and `john.davies,ou=asia-branch,dc=example,dc=com` would match the target expression.

Another example of a complete ACL targets the entries in the `ou=People,dc=example,dc=com` branch and the entries below it and grants the users the privilege to modify all of their user attributes within their own entries.

```
aci: (target="ldap:///ou=People,dc=example,dc=com")
(targetattr="*")
(version 3.0; acl "Allow all the ou=People branch to modify their own
entries";
allow (write) userdn="ldap:///self";)
```

targetattr

The `targetattr` keyword targets the attributes for which the access control instruction should apply.

There are four general forms that it can take in the Server:

```
(targetattr="*")
```

Indicates that the access control rule applies to all user attributes. Operational attributes are not automatically included in this set.

```
(targetattr="+")
```

Indicates that the access control rule applies to all operational attributes. User attributes are not automatically included in this set.

```
(targetattr="<attr1>||<attr2>||<attr3>||...||<attrN>")
```

Indicates that the access control rule applies only to the named set of attributes.

```
(targetattr!="attr1||attr2||attr3||...||attrN")
```

Indicates that the access control rule applies to all user attributes except the named set of attributes. It does not apply to any operational attributes.

The targeted attributes can be classified as user attributes and operational attributes. User attributes define the actual data for that entry while operational attributes provide additional metadata about the entry that can be used for informational purposes, such as when the entry was created, last modified and by whom. Metadata can also include attributes specifying which password policy applies to the user, or overridden default constraints like size limit, time limit, or look-through limit for that user.

The Server distinguishes between these two types of attributes in its access control implementation. The Directory Server does not automatically grant any access at all to operational attributes. For example, the following clause applies only to user attributes and not to operational attributes.

```
(targetattr="*")
```

You can also target multiple attributes in the entry. The following clause targets the common name (`cn`), surname (`sn`) and state (`st`) attribute.

```
(targetattr="cn||sn||st")
```

You can use the `+` symbol to indicate that the rule should apply to all operational attributes.

```
(targetattr="+")
```

To include all user and all operational attributes, use both symbols.

```
(targetattr="*||+")
```

If you need to target a specific operational attribute rather than all operational attributes, include it in the values of the `targetattr` clause.

```
(targetattr="ds-rlim-size-limit")
```

If you want to target all user attributes and a specific operational attribute, use them in the `targetattr` clause.

```
(targetattr="*||ds-rlim-size-limit")
```

The following sample ACIs are placed on the `dc=example,dc=com` tree. The first ACI allows any user anonymous read access to all entries except the `userPassword` attribute. The second ACI allows users to update their own contact information. The third ACI allows the `uid=admin` user full access privileges to all user attributes in the `dc=example,dc=com` subtree.

```
aci: (targetattr!="userPassword") (version 3.0; acl "Allow anonymous
  read access for anyone"; allow (read,search,compare) userdn="ldap:///
  anyone");
aci: (targetattr="telephonenumber||street||homePhone||l||st")
  (version 3.0; acl "Allow users to update their own contact info";
  allow (write) userdn="ldap:///self");
aci: (targetattr="*") (version 3.0; acl "Grant full access for the admin
  user";
  allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

When assigning access to user and operational attributes, it is easy to inadvertently create an access control instruction that grants far more capabilities to a user than originally intended. The following example shows the implications of the Directory Server not distinguishing between these attributes.

```
aci: (targetattr!="uid||employeeNumber")
  (version 3.0; acl "Allow users to update their own entries";
  allow (write) userdn="ldap:///self");
```

This instruction is intended to allow a user to update any attribute in his or her own entry with the exception of `uid` and `employeeNumber`. This ACI is a common rule and seems harmless, but has serious consequences for a Directory Server that does not distinguish between user attributes and operational attributes. It allows users to update operational attributes in their own entries, and could be used for a number of malicious purposes, including:

- A user could alter password policy state attributes to become exempt from password policy restrictions.
- A user could alter resource limit attributes and bypass size limit, time limit, and look-through-limit constraints.
- A user could add access control rules to his or her own entry, which could allow them to make their entry completely invisible to all other users, including administrators granted full rights by access

control rules, but excluding users with the `bypass-acl` privilege allows them to edit any other attributes in their own entry, including those excluded by rules like `uid` and `employeeNumber` in the previous example, or add, modify, or delete any entries below his or her own entry.

Because the Server does not automatically include operational attributes in the target attribute list, these types of ACIs do not present a security risk for it. Users cannot add ACIs to any entries unless they have the `modify-acl` privilege.

Another danger in using the `(targetattr!="x")` pattern is that two ACIs within the same scope could have two different `targetattr` policies that cancel each other out. For example, if one ACI has `(targetattr!="cn|sn")` and a second ACI has `(targetattr!="userPassword")`, then the net effect is `(targetattr="*")`, because the first ACI inherently allows `userPassword` and the second allows `cn` and `sn`.

targetfilter

The `targetfilter` keyword targets all attributes that match results returned from a filter.

The `targetfilter` clause has the following syntax.

```
(targetfilter = <ldap_filter>)
```

For example, the following clause targets all entries that contain the `ou=engineering` attribute.

```
(targetfilter = "(ou=engineering)")
```

You can only specify a single filter, but that filter can contain multiple elements combined with the `OR` operator. The following clause targets all entries that contain `ou=engineering`, `ou=accounting`, and `ou=marketing`.

```
(targetfilter = "(|(ou=engineering)(ou=accounting)(ou=marketing)")
```

The following example allows the user, `uid=eng-mgr`, to modify the `departmentNumber`, `cn`, and `sn` attributes for all entries that match the filter `ou=engineering`.

```
aci:(targetfilter="(ou=engineering)")
(targetattr="departmentNumber|cn|sn")
(version 3.0; acl "example"; allow (write)
 userdn="ldap:///uid=eng-mgr,dc=example,dc=com";)
```

targattrfilters

The `targattrfilters` keyword targets specific attribute values that match a filtered search criteria.

This keyword allows you to set up an ACI that grants or denies permissions on an attribute value if that value meets the filter criteria. The `targattrfilters` keyword applies to individual values of an attribute, not to the whole attribute. The keyword also allows the use of wildcards in the filters.

The keyword clause has the following format.

```
(target = "add=attr1:Filter1 && attr2:Filter2... && attrN:FilterN,
del=attr1:Filter1 && attr2:Filter2 ... && attrN:FilterN" )
```

Where:

`add`

Represents the operation of adding an attribute value to the entry.

`del`

Represents the operation of removing an attribute value from the entry.

`<attr1>, <attr2> ... <attrN>`

Represents the targeted attributes.

`<filter1>, <filter2> ... <filterN>`

Represents filters that identify matching attribute values.

The following conditions determine when the attribute must satisfy the filter:

- When adding or deleting an entry containing an attribute targeted a `targattrfilters` element, each value of that attribute must satisfy the corresponding filter.
- When modifying an entry, if the operation adds one or more values for an attribute targeted by a `targattrfilters` element, each value must satisfy the corresponding filter. If the operation deletes one or more values for a targeted attribute, each value must satisfy the corresponding filter.
- When replacing the set of values for an attribute targeted by a `targattrfilters` element, each value removed must satisfy the delete filters and each value added must satisfy the add filters.

The following example allows any user who is part of the `cn=directory server admins` group to add the `soft-delete-read` privilege.

```
aci: (targattrfilter="add=ds-privilege-name:(ds-privilege-name=soft-delete-read) ")
  (version 3.0; acl "Allow members of the directory server admins group to grant the
  soft-delete-read privilege"; allow (write)
  groupdn="ldap:///cn=directory server admins,ou=group,dc=example,dc=com";)
```

targetscope

Use the `targetscope` keyword to restrict the scope of an access control rule (ACR).

ACIs use a subtree scope by default, meaning they are applied to the target entry and all entries below it, either as defined by the target clause of the ACI or the entry in which the ACI is defined if it does not include a target. However, you can add the `targetscope` element into an ACR to restrict the set of entries to which it applies.

The following `targetscope` keyword values are allowed:

`base`

Indicates that the ACR applies only to the target entry and not to any of its subordinates.

`onelevel`

Indicates that the ACR applies only to entries that are immediate children of the target entry and not to the target entry itself nor to any subordinates of the immediate children of the target entry.

`subtree`

Indicates that the ACR applies to the target entry and all of its subordinates. This is the default behavior if no `targetscope` is specified.

`subordinate`

Indicates that the ACR applies to all entries below the target entry but not the target entry itself.

The following ACI targets all users to view the operational attributes present in the root DSA-specific entry (DSE):

- `supportedControl`
- `supportedExtension`
- `supportedFeatures`
- `supportedSASLMechanisms`
- `vendorName`

- `vendorVersion`

In the following example, `targetscope` is set to `base` to limit users to view only those attributes in the root DSE.

```
aci: (target="ldap:///") (targetscope="base")
    (targetattr="supportedControl||supportedExtension||
    supportedFeatures||supportedSASLMechanisms||vendorName||vendorVersion")
    (version 3.0; acl "Allow users to view Root DSE Operational Attributes";
    allow (read,search,compare) userdn="ldap:///anyone")
```

targetcontrol

Use the `targetcontrol` keyword to indicate whether a given request control can be used by users targeted in the ACI.

You can provide multiple OIDs by separating them with two pipe characters, optionally surrounded by spaces. When specifying control OIDs, wildcards are not allowed.

The following ACI example shows the controls required to allow an administrator to use and manage the soft delete feature. The soft delete request control allows the user to soft-delete an entry, so that it could be undeleted at a later time. The hard delete request control allows the user to permanently remove an entry or soft-deleted entry. The undelete request control allows the user to undelete a currently soft-deleted entry. The soft-deleted entry access request control allows the user to search for any soft-deleted entries in the server.

```
aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.22||
    1.3.6.1.4.1.30221.2.5.23||1.3.6.1.4.1.30221.2.5.24")
    (version 3.0; acl "Allow admins to use the Soft Delete Request Control,
    Hard Delete Request Control, Undelete Request Control, and
    Soft-deleted entry access request control";
    allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

extOp

Use the `extop` keyword to indicate whether a given extended request operation can be used.

You can provide multiple OIDs by separating them with two pipe characters, optionally surrounded by spaces. When specifying extended request OIDs, wildcards are not allowed.

The following ACI example allows the `uid=user-mgr` to use the password modify request, `OID=1.3.6.1.4.1.4203.1.11.1`, and the `StartTLS`, `OID=1.3.6.1.4.1.1466.20037`, which are extended request OIDs.

```
aci: (extop="1.3.6.1.4.1.4203.1.11.1 || 1.3.6.1.4.1.1466.20037")
    (version 3.0; acl "Allows the mgr to use the Password Modify Request and
    StartTLS;
    allow(read) userdn="ldap:///uid=user-mgr,ou=people,dc=example,dc=com";)
```

Examples of common access control rules

This section demonstrates access controls that are commonly used in your environment.

To modify access control definitions in the server, a user must have the `modify-acl` privilege.

Administrator access

The following access control instructions (ACIs) grant members of the `cn=admins,ou=groups,dc=example,dc=com` group the following permissions:

- Add, modify, and delete entries
- Reset passwords

- Read operational attributes, such as `isMemberOf` and password policy state

```
aci: (targetattr="+") (version 3.0; acl "Administrators can read, search or
  compare operational attributes";
  allow (read,search,compare) groupdn="ldap:///
  cn=admins,ou=groups,dc=example,dc=com");
aci: (targetattr="*") (version 3.0; acl "Administrators can add, modify and
  delete entries";
  allow (all) groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com");
```

Anonymous and authenticated access

The following ACIs allow anonymous read, search, and compare on select attributes of `inetOrgPerson` entries while authenticated users can access several more. An authenticated user inherits the privileges of the anonymous ACI and can also change `userPassword`.

```
aci: (targetattr="objectclass || uid || cn || mail || sn || givenName")
  (targetfilter="(objectClass=inetorgperson)")
  (version 3.0; acl "Anyone can access names and email addresses of entries
  representing people";
  allow (read,search,compare) userdn="ldap:///anyone");
aci: (targetattr="departmentNumber || manager || isMemberOf")
  (targetfilter="(objectClass=inetorgperson)")
  (version 3.0; acl "Authenticated users can access these fields for entries
  representing people";
  allow (read,search,compare) userdn="ldap:///all");
aci: (targetattr="userPassword") (version 3.0; acl "Authenticated users can
  change password";
  allow (write) userdn="ldap:///all");
```

To prevent anonymous access to the Directory Server, set the global configuration property `reject-unauthenticated-requests` to `true`.

Delegated access to a manager

The following ACI allows an employee's manager to edit the value of the employee's `telephoneNumber` attribute. This ACI uses the `userattr` keyword with a bind type of `USERDN`, which indicates that the target entry's manager attribute must have a value equal to the distinguished name (DN) of the authenticated user.

```
aci: (targetattr="telephoneNumber")
  (version 3.0; acl "A manager can update telephone numbers of her direct
  reports";
  allow (read,search,compare,write) userattr="manager#USERDN");
```

Proxy authorization

The following ACI allows the application `cn=OnBehalf,ou=applications,dc=example,dc=com` to use the proxied authorization V2 control to request that operations be performed using an alternate authorization identity.

```
aci: (version 3.0;acl "Application OnBehalf can proxy as another entry";
  allow (proxy) userdn="ldap:///
  cn=OnBehalf,ou=applications,dc=example,dc=com");
```

Note:

The application user must have the `proxied-auth` privilege.

Validating ACIs before migrating data

Identify any access control instruction (ACI) syntax problems before migrating data.

Many directory servers allow for a less restrictive application of their access control instructions so that they accept invalid ACIs. For example, if an Oracle directory server encounters an access control rule that it can't parse, it ignores the rule without providing a warning, and the server might not offer the intended access protection. The Server rejects any ACIs that it can't interpret, which ensures that data access is limited as intended. However, this can cause problems when migrating data with existing access control rules to a The Server.

To validate an ACI, the Server provides a `validate-aci` tool in the `bin` directory on UNIX or Linux systems or in the `bat` directory on Windows systems.

The `validate-aci` tool identifies any ACI syntax problems before you migrate data. The tool can examine access control rules contained in either an LDIF file or an LDAP directory and write its result in LDIF with comments providing information about any problems that were identified.

Each entry in the output contains a single ACI. If an entry in the input contains multiple ACIs, then it can be present multiple times in the output, each time with a different ACI value. The entries contained in the output contains only ACI values. All other attributes are ignored.

Validating ACIs from a file

Use the `validate-aci` tool to process data contained in an LDIF file.

About this task

Note:

The `validate-aci` tool ignores all attributes except `aci` and ignores all entries that do not contain the `aci` attribute. You can use any existing LDIF file that contains access control rules.

Steps

1. Run the `validate-aci` tool and specify the input file and output file.

Choose from:

- UNIX or Linux: `bin/validate-aci`
- Windows: `bat\validate-aci`

If the output file already exists, the existing file contents are re-written. If no output file is specified, the results are written to standard output.

Example:

```
$ bin/validate-aci --ldifFile test-aci.ldif --outputFile validated-aci.ldif
```

Result:

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

2. Open the output file and review the results.

Example:

For example, the `validated-acis.ldif` file generated in the previous step reads as follows.

```
# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr!="userPassword")
    (version 3.0; acl "Allow anonymous read access for anyone";
      allow (read,search,compare) userdn="ldap:///anyone");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
    (version 3.0; acl "Allow users to update their own entries";
      allow (write) userdn="ldap:///self");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
    (version 3.0; acl "Grant full access for the admin user";
      allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

Example:

If the input file has any malformed access control instructions (ACIs), then the generated output file will show what was incorrectly entered. For example, if `userPassword` in the `test-acis.ldif` file does not have quotation marks around it, the output file reports an error. The following command uses the `--onlyReportErrors` option to write any error messages to the output file only if a malformed ACI syntax is encountered.

```
$ bin/validate-acis --ldifFile test-acis.ldif --outputFile validated-
acis.ldif \
  --onlyReportErrors
```

Result:

```
# Processing complete
# Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 1
# Other processing errors encountered: 0
```

The output file shows the following message.

```
# The following access control rule is malformed or contains an
  unsupported
# syntax: The provided string '(targetattr!=userPassword)(version 3.0;
  acl
# "Allow anonymous read access for anyone"; allow (read,search,compare)
# userdn="ldap:///anyone");' could not be parsed as a valid Access
  Control
# Instruction (ACI) because it failed general ACI syntax evaluation
dn: dc=example,dc=com
aci: (targetattr!=userPassword)
    (version 3.0; acl "Allow anonymous read access for anyone";
      allow (read,search,compare) userdn="ldap:///anyone");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
```

```
(version 3.0; acl "Allow users to update their own entries";
  allow (write) userdn="ldap:///self");

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

Validating ACIs in another Directory Server

Use the `validate-acis` tool to examine access control instructions (ACIs) in data that exists in another Directory Server that you are planning to migrate to the Server.

About this task

The tool helps to determine whether the Ping Identity Server accepts those ACIs.

Steps

- Run the `validate-acis` tool.
Choose from:
 - UNIX or Linux: `bin/validate-acis`
 - Windows: `bat\validate-acis`

Provide arguments that specify:

- The address and port of the target Directory Server
- Credentials to use to bind
- The base DN of the subtree containing the ACIs to validate

Example:

```
$ bin/validate-acis
```

Result:

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

Migrating ACIs from Oracle to the Server

This section describes the most important differences in access control evaluation between Oracle and the Server.

Support for macro ACIs

Oracle supports macro access control instructions (ACIs), making it possible to define a single ACI that you can use to apply the same access restrictions to multiple branches in the same basic structure.

Macro ACIs are infrequently used and can cause severe performance degradation, so the The Server does not support them. However, you can achieve the same result by creating the same ACIs in each branch.

Support for the roleDN bind rule

Oracle roles are a proprietary, non-standard grouping mechanism that provide little value over standard grouping mechanisms.

The Server does not support Oracle Directory Server Enterprise Edition roles and does not support the use of the `roleDN` ACI bind rule. However, you can achieve the same behavior by converting the Oracle Directory Server Enterprise Edition roles to standard groups and using the `groupDN` ACI bind rule.

Targeting operational attributes

The Oracle access control model doesn't differentiate between user attributes and operational attributes.

In the Oracle access control model, using `targetattr="*"` automatically targets both user and operational attributes. Using an exclusion list like `targetattr!="userPassword"` automatically targets all operational attributes in addition to all user attributes except `userPassword`. This presents several significant security holes here users are unintentionally given access to operational attributes. In some cases, it could allow users to exempt themselves from password policy restrictions.

The Server treats operational attributes differently from user attributes and never automatically includes operational attributes. For example, `targetattr="*" targets all user attributes but no operational attributes, and targetattr!="userPassword" targets all user attributes except userPassword but no operational attributes.`

You can target specific operational attributes by including the names in the list, such as `targetattr="creatorsName|modifiersName"`. You can target all operational attributes by using the "+" character. For example, `targetattr="+" targets all operational attributes but no user attributes, and targetattr="*|+" targets all user and operational attributes.`

Example

The following example searches for all immediate children of `ou=People,dc=example,dc=com`. The attributes returned are restricted to `sn`, `givenName`, and all operational attributes.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --baseDN ou=People,dc=example,dc=com --searchScope one
  '(objectclass=*)' \
  sn givenName "+"
```

Example

You can use compound filters to search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree. The following example limits the returned entry amount to 200, and the server will spend no more than 5 seconds processing the request.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --baseDN ou=People,dc=example,dc=com --searchScope sub --sizeLimit 200
  \
  --timeLimit 5 "(&(sn<=Doe) (employeeNumber<=1000))" ds-entry-unique-id \
  entryUUID
```

Specification of global ACIs

Both Oracle Directory Server Enterprise Edition and the Server support global ACIs, which you can use to define ACIs that apply throughout the server.

In servers with multiple naming contexts, this feature allows you to define a rule once as a global ACI rather than maintaining an identical rule in each naming context.

In Oracle Directory Server Enterprise Edition, global ACIs are created by modifying the root DSA-specific entry (DSE) to add values of the `aci` attribute. In the Server, you manage global ACIs with `dsconfig` referenced in the `global-aci` property of the access control handler.

Defining ACIs for non-user content

In DSEE, you can write to the following backends to define ACIs:

- Configuration
- Monitor
- Changelog
- Tasks

In the Server, you should define access control for private backends as global ACIs, such as the following backends:

- Configuration
- Monitor
- Schema
- Changelog
- Tasks
- Encryption settings
- Backups
- Alerts

Limiting access to controls and extended operations

DSEE provides limited support for restricting access to controls and extended operations.

To the extent that you can control access to controls and extended operations with access control instructions (ACIs), DSEE defines entries with a distinguished name (DN), such as `oid={oid},cn=features,cn=config`, where `{oid}` is the OID of the associated control or extended operation. For example, the following DSEE entry defines ACIs for the persistent search control.

```
oid=2.16.840.1.113730.3.4.3,cn=features,cn=config
```

In the Server, you can use the `targetcontrol` keyword to define ACIs that grant or deny access to controls. You can use the `extop` keyword to define ACIs that grant or deny access to extended operation requests.

Tolerance for malformed ACI values

If the server is running with less than the intended set of access control instructions (ACIs), it might prevent access to data that should be allowed or grant access to data that should be restricted. In DSEE, if the server encounters a malformed access control rule (ACR), it ignores the rule. This can cause the server to run with less than the intended set of ACIs. To guard against this, the Server is more strict about the ACRs that it accepts.

When performing an LDIF import, the Server rejects any entry containing a malformed or unsupported ACR. The Server also rejects any `add` or `modify` request that attempts to create an invalid ACI.

In the unlikely event that a malformed ACI is accepted into the data, the server immediately places itself in lockdown mode. In lockdown mode, the server terminates connections and rejects requests from users without the `lockdown-mode` privilege. Lockdown mode allows an administrator to correct the problem without risking exposure to user data.

Note:

To review any rejected ACIs, run the `import-ldif` tool with the `--rejectFile` option.

About the privilege subsystem

In DSEE, only the root user is exempt from access control evaluation.

While administrators can create access control instructions (ACIs) that give normal users full access to any content, they can also create ACIs that would make a portion of the data inaccessible to those users. Additionally, some tasks can only be accomplished by the root user and the capabilities assigned to the root user can't be restricted.

The Server uses a privilege subsystem to control the capabilities available to various users. Non-root users can be granted limited access to certain administrative capabilities, and restrictions can be enforced on root users. Additionally, certain risky actions require that the requester have certain privileges in addition to the sufficient access control rights to process the operation.

These risky actions include:

- Interacting with the server configuration
- Changing another user's password
- Impersonating another user
- Shutting down and restarting the server

Identifying unsupported ACIs

To determine whether access control instructions (ACIs) are suitable for use, the the Server provides a `validate-acis` tool that you can use to examine content in an LDIF file or data in another directory server, such as a DSEE instance.

When migrating data from a DSEE deployment into a The Server instance, use the `validate-acis` tool to determine whether ACIs contained in the data are acceptable. If any problems exist, update the data to redefine the ACIs so they are suitable for use in the Server.

For more information, see [Validating ACIs Before Migrating Data](#).

Working with privileges

In addition to the access control implementation, the Server includes a privilege subsystem that you can use to control what users are allowed to do.

The privilege subsystem works in conjunction with the access control subsystem to only allow privileged operations that are permitted by the access control configuration. The user must also have all of the necessary privileges.

You can use privileges to grant normal users the ability to perform certain tasks that, in most other directories, would only be allowed for the root user. The capabilities given to root users in the Server are all granted through privileges, so you can create a normal user account with the ability to perform the same actions as root users.

Administrators can also remove privileges from root users so that they are unable to perform certain types of operations. To restrict root users to only the tasks that they must perform, define multiple root users in the server with different sets of privileges.

Available privileges

The following privileges are defined in the Server.

Summary of Privileges

Privilege	Description
<code>audit-data-security</code>	This privilege is required to initiate a data security audit on the server, which is invoked by the <code>audit-data-security</code> tool.

Privilege	Description
<code>backend-backup</code>	This privilege is required to initiate an online backup through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
<code>backend-restore</code>	This privilege is required to initiate an online restore through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
<code>bypass-acl</code>	<p>This privilege allows a user to bypass access control evaluation. For a user with this privilege, any access control determination made by the server immediately returns that the operation is allowed.</p> <p> Note:</p> <p>This does not bypass privilege evaluation, so the user must have the appropriate set of additional privileges to be able to perform any privileged operation. For example, a user with the <code>bypass-acl</code> privilege but without the <code>config-read</code> privilege is not allowed to access the server configuration.</p>
<code>bypass-pw-policy</code>	This privilege allows a user entry to bypass password policy evaluation. This privilege is intended for cases where external synchronization might require passwords that violate the password validation rules. The privilege is also evaluated for bind operations, meaning password restrictions are also bypassed when binding as a user who has this privilege.
<code>bypass-read-acl</code>	This privilege allows the associated user to bypass access control checks performed by the server for bind, search, and compare operations. Access control evaluation may still be enforced for other types of operations.
<code>config-read</code>	This privilege is required for a user to access the server configuration. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to see.
<code>config-write</code>	This privilege is required for a user to alter the server configuration. The user must also have the <code>config-read</code> privilege. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to alter.
<code>disconnect-client</code>	This privilege is required for a user to request that an existing client connection be terminated. The connection is terminated through the disconnect client task. The server's access control configuration must also allow the user to add the corresponding entry to the tasks backend.
<code>jmx-notify</code>	This privilege is required for a user to subscribe to Java Management Extensions (JMX) notifications generated by the Directory Server. The user is also required to have the <code>jmx-read</code> privilege.
<code>jmx-read</code>	This privilege is required for a user to access any information provided by the Directory Server through the JMX.

Privilege	Description
jmx-write	<p>This privilege is required for a user to update any information exposed by the Directory Server through the JMX. The user is also required to have the <code>jmx-read</code> privilege.</p> <p> Note: Currently, all of the information exposed by the server over JMX is read-only.</p>
ldif-export	This privilege is required to initiate an online LDIF export through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, you can set up a global access control instruction (ACI) that allows access to members of an Administrators group.
ldif-import	This privilege is required to initiate an online LDIF import through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, configure the global ACI as described in the previous description of the <code>ldif-export</code> privilege.
lockdown-mode	This privilege allows the associated user to request that the server enter or leave lockdown mode, or to perform operations while the server is in lockdown mode.
modify-acl	This privilege is required for a user to add, modify, or remove access control rules defined in the server. The server's access control configuration must also allow the user to make the corresponding change to the <code>aci</code> operational attribute.
password-reset	This privilege is required for one user to be allowed to change another user's password. This privilege is not required for a user to be allowed to change his or her own password. The user must also have the access control instruction privilege to write the <code>userPassword</code> attribute to the target entry.
privilege-change	This privilege is required for a user to change the set of privileges assigned to a user, including the set of privileges, which are automatically granted to root users. The server's access control configuration must also allow the user to make the corresponding change to the <code>ds-privilege-name</code> operational attribute.
proxied-auth	This privilege is required for a user to request that an operation be performed with an alternate authorization identity. This privilege bears some security risk, because it allows users to inherit the level of access of any user, including root users and administrators. Consider restricting proxy users as described in the section Restricting proxy users on page 475.
server-restart	This privilege is required to initiate a server restart through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.

Privilege	Description
<code>server-shutdown</code>	This privilege is required to initiate a server shutdown through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
<code>soft-delete-read</code>	This privilege is required for a user to access a soft-deleted-entry.
<code>stream-values</code>	This privilege is required for a user to perform a stream values extended operation, which obtains all entry distinguished names (DNs) and all values for one or more attributes for a specified portion of the directory information tree (DIT).
<code>unindexed-search</code>	This privilege is required for a user to be able to perform a search operation in which a reasonable set of candidate entries cannot be determined using the defined index and instead, a significant portion of the database needs to be traversed to identify matching entries. The server's access control configuration must also allow the user to request the search.
<code>update-schema</code>	This privilege is required for a user to modify the server schema. The server's access control configuration must allow the user to update the operational attributes that contain the schema elements.

Privileges automatically granted to root users

The special abilities that root users have are granted through privileges.

You can assign privileges to root users in two ways:

- By default, root users can be granted a specified set of privileges.

Note:

You can create root users which are not automatically granted these privileges by including the `ds-cfg-inherit-default-root-privileges` attribute with a value of `FALSE` in the entries for those root users.

- You can grant additional privileges to individual root users and remove some automatically-granted privileges from individual root users.

The `default-root-privilege-name` property of the root distinguished name (DN) configuration object controls the set of privileges that are automatically granted to root users. By default, these privileges include:

- `audit-data-security`
- `backend-backup`
- `backend-restore`
- `bypass-acl`
- `config-read`
- `config-write`
- `disconnect-client`
- `ldif-export`
- `lockdown-mode`
- `manage-topology`
- `metrics-read`
- `modify-acl`
- `password-reset`

- `permit-get-password-policy-state-issues`
- `privilege-change`
- `server-restart`
- `server-shutdown`
- `soft-delete-read`
- `stream-values`
- `unindexed-search`
- `update-schema`

The privileges not granted to root users by default include:

- `bypass-pw-policy`
- `bypass-read-acl`
- `jmx-read`
- `jmx-write`
- `jmx-notify`
- `permit-externally-processed-authentication`
- `permit-proxied-mschapv2-details`
- `proxied-auth`

You can change the set of default root privileges to add or remove values as necessary. This requires the `config-read`, `config-write`, and `privilege-change` privileges, and either the `bypass-acl` privilege or sufficient permission granted by the access control configuration to change the server's configuration.

Assigning additional privileges for administrators

Steps

- To allow access to the Tasks backend, set up a global access control instruction (ACI) using `dsconfig` that allows access to members of an Administrators group.

Example:

```
$ dsconfig set-access-control-handler-prop \
  --add 'global-aci:(target="ldap:///cn=tasks") (targetattr="*|+")(
    version 3.0; acl "Access to the tasks backend for
administrators";
    allow (all) groupdn="ldap:///
cn=admin,ou=groups,dc=example,dc=com";) '
```

Assigning privileges to normal users and individual root users

You can grant privileges to normal users on an individual basis.

Add the `ds-privilege-name` operational attribute to the user's entry with the names of the desired privileges. For example, the following change grants the `proxied-auth` privilege to the `uid=proxy,dc=example,dc=com` account.

```
dn: uid=proxy,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: proxied-auth
```

The user making this change must have the `privilege-change` privilege, and the server's access control configuration must also allow the requester to write to the `ds-privilege-name` attribute in the target user's entry.

You can use the same method to grant root users privileges that aren't included in the set of default root privileges. You can also remove default root privileges from root users by prefixing the name of the

privilege to remove with a minus sign. For example, the following change grants a root user the `jmx-read` privilege in addition to the set of default root privileges and removes the `server-restart` and `server-shutdown` privileges.

```
dn: cn=Sync Root User,cn=Root DNs,cn=config
changetype: modify
add: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: -server-restart
ds-privilege-name: -server-shutdown
```

Note:

Because root user entries exist in the configuration, this update requires the `config-read` and `config-write` privileges in addition to the `privilege-change` privilege.

Disabling privileges

Although the privilege subsystem in the Server is a powerful feature, it might break some applications if they expect to perform an operation requiring a privilege that they do not have.

In the majority of these cases, you can assign the necessary privilege manually to the account used by that application. However, if this workaround isn't sufficient, or if you need to remove a particular privilege, such as allowing anyone to access information through Java Management Extensions (JMX) without requiring the `jmx-read` privilege, then you can disable privileges on an individual basis.

The `disabled-privilege` property in the global configuration object controls the set of disabled privileges. By default, no privileges are disabled. If a privilege is disabled, then the server behaves as if all users have that privilege.

Working with proxied authorization

The Directory Server supports the Proxied Authorization Control (RFC 4370) to allow an authorized LDAP client to authenticate to the server as another user.

Typically, LDAP servers are deployed as backend authentication systems that store user credentials and authorization privileges necessary to carry out an operation. Single sign-on (SSO) systems can retrieve user credentials from the Directory Server and then issue permissions that allow the LDAP client to request operations under the identity as another user. The proxied authorization control allows client applications to securely process requests without binding or re-authenticating to the server for every operation.

The Directory Server supports the proxied authorization v1 and v2 request controls. The proxied authorization v1 request control is based on early versions of the `draft-weltman-ldapv3-proxy` Internet draft and is available primarily for legacy systems. You should use the proxied authorization v2 request control based on RFC 4370.

The proxied authorization v2 control requests that the associated operation is performed as if it had been requested by another user. You can use this control in conjunction with `add`, `delete`, `compare`, `extended`, `modify`, `modify DN`, and `search` requests. In such case, the associated operation processes under the authority of the specified authorization identity rather than the identity associated with the client connection, such as the user as whom that connection is bound. Specify the target authorization identity for this control as an `authzid` value, either with `dn:`, followed by the distinguished name of the target user or `u:`, followed by the user name.

Note:

Because of the security risks when using the proxied authorization control, most directory servers enforce strict restrictions on users that can request this control. If a user attempts to use the proxied

authorization v2 request control without the sufficient permission, the server returns a failure response with the `AUTHORIZATION_DENIED` result code.

Configuring proxied authorization

About this task

Configuring proxied authorization requires a combination of access control instructions (ACIs) and the `proxied-auth` privilege to the entry that will perform operations as another user.

Note:

You cannot use the `cn=Directory Manager` root DN as a proxying DN.

Note:

Unless your use case requires proxying root users and administrators, consider restricting proxy users as described in [Restricting proxy users](#) on page 475.

Steps

1. Open a text editor and create a user entry that will request operations as another user. Include the `proxied-auth` privilege. Save the file as `add-user.ldif`.

Example:

In this example, the user entry `uid=clientApp` will request operations as `uid=admin,dc=example,dc=com`.

```
dn: ou=Applications,dc=example,dc=com
objectClass: top
objectClass: organizationalUnit
objectClass: extensibleObject
ou: Admins
ou: Applications

dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
givenName: Client
uid: clientApp
cn: Client App
sn: App
userPassword: password
ds-privilege-name: proxied-auth
```

2. Add the file using `ldapmodify`.

Example:

```
$ bin/ldapmodify --defaultAdd --filename add-user.ldif
```

- To allow the target, open a text editor and create an LDIF file to assign an ACI to that branch so that the client app user can access it as a proxy auth user. Add the file using the `ldapmodify`.

The client application targets a specific subtree in the Directory Information Tree (DIT) for its operations. For example, a client might need access to an accounts subtree to retrieve customer information while another client might need access to another subtree, such as a subscriber subtree.

Example:

In this example, the client application targets the `ou=People,dc=example,dc=com` subtree.

Note:

The ACI should be on a single line of text. The example shows the ACI over multiple lines for readability.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
    userdn="ldap:///uid=clientApp,ou=Applications,dc=example,dc=com");
```

- Run a search to test the configuration using the bind DN `uid=clientApp` and the `proxyAs` option.

Prefix `dn:` to the proxying entry or `u:` to the user name.

Example:

The `uid=clientApp` binds to the server and proxies as `uid=admin` to access the `ou=People,dc=example,dc=com` subtree.

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)" "
```

Restricting proxy users

The Directory Server provides a set of operational attributes that restrict the proxied authorization capabilities of a client application and its proxyable target entry.

When present in an entry, the Directory Server evaluates each operational attribute together to form a whitelist of potential users that can be proxied. If none of those attributes are present, the user can potentially proxy as anyone.

The Directory Server supports a two-tier provision system that can restrict specific users for proxied authorization:

- The first tier is a set of `ds-auth-may-proxy-as-*` operational attributes on the client entry that binds to the server and carries out operations under the identity of another user.
- The second tier is a set of `ds-auth-is-proxyable-*` operational attributes on the user entry that defines whether access is allowed, prohibited, or required through proxied authorization. If proxied authorization is allowed or required, the attributes define which client entries can proxy as the user.

Proxying operational attributes

For example, the following command demonstrates the client application `uid=clientApp` requesting to search the `ou=People,dc=example,dc=com` branch as the user `uid=admin`.

```
ldapsearch --bindDN uid=clientApp,dc=example,dc=com \
--bindPassword password \
--proxyAs uid=admin,dc=example,dc=com \
--baseDN ou=People,dc=example,dc=com \
"(object-class=*)
```

At bind, the Directory Server evaluates the list of users in the `uid=clientApp` entry based on the presence of any `ds-auth-may-proxy-as-*` attributes.

In the previous figure, the `uid=clientApp` entry has a `ds-auth-may-proxy-as` attribute with a value of `uid=admin`, meaning the client app user can proxy only as the `uid=admin` account.

Next, the server confirms that `uid=admin` is in the list of proxyable users and then evaluates the `ds-auth-is-proxyable-*` attributes present in the `uid=admin` entry. These attributes determine the list of restricted users that either are allowed, prohibited, or required to proxy as the `uid=admin` entry. In this case, the `uid=admin` entry has the `ds-auth-is-proxyable` attribute with a value of `required`, meaning the entry can only be accessed by means of proxied authorization.

The `uid=admin` entry also has the `ds-auth-is-proxyable-by` attribute with a value of `uid=clientApp`, meaning it can only be requested by the `uid=clientApp` entry. When both sets of attributes have been satisfied, the `uid=clientApp` can bind to the server as the authenticated user.

Next, the Directory Server performs access control instruction (ACI) evaluation on the branch and determines if the requested user has access rights to the branch. If the `uid=clientApp` entry can access the branch, the search request is processed.

About the `ds-auth-may-proxy-as-*` operational attributes

The Directory Server first evaluates the list of potential users that can be proxied for the authenticated user depending on the presence of the `ds-auth-may-*` operational attributes in the entry.

These operational attributes are multi-valued and are evaluated together if all are present in an entry:

`ds-auth-may-proxy-as`

Specifies the user distinguished names (DNs) that the associated user can proxy as. For example, you can specify in the `uid=clientApp` entry that it can proxy operations as `uid=admin` and `uid=agent1`.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as: uid=admin,dc=example,dc=com
ds-auth-may-proxy-as: uid=agent1,ou=admins,dc=example,dc=com
```

`ds-auth-may-proxy-as-group`

Specifies the group DNs and its group members that the associated user can proxy as. For example, you can specify that the potential users that the `uid=clientApp` entry can proxy as are those members who are present in the group `cn=Agents,ou=Groups,dc=example,dc=com`. This attribute is multi-valued, so you can specify more than one group. Nested static and dynamic groups are also supported.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as-group: cn=Agents,ou=Groups,dc=example,dc=com
```

`ds-auth-may-proxy-as-url`

Specifies the DNs that are returned based on the criteria defined in an LDAP URL that the associated user can proxy as. For example, the attribute specifies that the client can proxy as those entries that match the criteria in the LDAP URL. This attribute is multi-valued, so you can specify more than one LDAP URL.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as-url: ldap:///ou=People,dc=example,dc=com??sub?
(l=austin)
```

About the `ds-auth-is-proxyable-*` operational attributes

After the Directory Server evaluates the list of users that the authenticated user can proxy as, the server checks to see if the requested authorized user is in the list.

If the requested authorized user is present in the list, then the server continues processing the proxable attributes in the entry. If the requested authorized user is not present in the list, the bind fails.

The operational attributes on the proxying entry are as follows:

`ds-auth-is-proxyable`

Specifies whether the entry is proxyable or not. Possible values are:

`allowed`

Operations can be proxied as this user.

`prohibited`

Operations can't be proxied as this user.

`required`

The account cannot authenticate directly but can only be accessed by some form of proxied authorization.

`ds-auth-is-proxyable-as`

Specifies any users allowed to use this entry as a target of proxied authorization.

`ds-auth-is-proxyable-as-group`

Specifies any groups allowed to use this entry as a target of proxied authorization. Nested static and dynamic groups are also supported.

`ds-auth-is-proxyable-as-url`

Specifies the LDAP URLs that are used to determine any users that are allowed to use this entry as a target of proxied authorization.

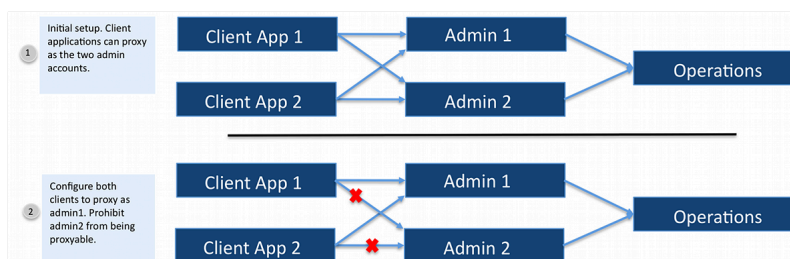

Restricting proxied authorization for specific users

Use the following example scenario with proxied users to restrict proxied authorization.

About this task

To illustrate how the proxied authorization operational attributes work, set up a simple example where two LDAP clients, `uid=clientApp1` and `uid=clientApp2` and `uid=admin1` and `uid=admin2`. Add the , can freely proxy two administrator accounts, `ds-auth-may-proxy-as-*` and `ds-auth-is-proxyable-*` attributes to these entries to restrict how each account can use proxied authorization.

For example, the two client applications can continue to proxy the `uid=admin1` account but the `uid=admin2` account are no longer able to be used as a proxied entry.

Proxy Users Example Scenario

Steps

1. Set up two user entries, `uid=clientApp1`, can freely proxy two administrator accounts, and `uid=clientApp2`, with the `proxied-auth` privilege assigned to them.

The user entries will proxy as the `uid=admin1` and `uid=admin2` accounts to access the `ou=People,dc=example,dc=com` subtree.

- a. Open a text editor and create an LDIF file.
- b. Add the file using the `ldapmodify` tool.

Example:

Note:

In this example, ... indicates that other attributes present in the entry are not included for readability purposes.

```
dn: uid=clientApp1,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth

dn: uid=clientApp2,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
```

2. Assign the access control instruction (ACI) for each client application to the subtree, `ou=People,dc=example,dc=com`.

Note:

ACIs should be on one line of text. The following example displays ACIs over multiple lines for readability.

Example:

```
dn: ou=People,dc=example,dc=com
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
    userdn="ldap:///
uid=clientApp1,ou=Applications,dc=example,dc=com");
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
```

```
userdn="ldap:///
uid=clientApp2,ou=Applications,dc=example,dc=com");)
```

3. Run a search for each entry.

Example:

In this example, assume that there are two admin accounts, `admin1` and `admin2`, that have full access rights to user attributes. You should be able to proxy as the `uid=admin1` and `uid=admin2` entries to access the subtree for both clients.

```
$ bin/ldapsearch --port 1389 \
--bindDN "uid=clientApp1,ou=Applications,dc=example,dc=com" \
--bindPassword password \
--proxyAs "dn:uid=admin1,dc=example,dc=com" \
--baseDN ou=People,dc=example,dc=com \
"(objectclass=*)"

$ bin/ldapsearch --port 1389 \
--bindDN "uid=clientApp2,ou=Applications,dc=example,dc=com" \
--bindPassword password \
--proxyAs "dn:uid=admin2,dc=example,dc=com" \
--baseDN ou=People,dc=example,dc=com \
"(objectclass=*)"
```

4. Limit the proxied authorization capabilities for each client application.

In the following example, the `ds-auth-may-proxy-as` attribute specifies that `uid=clientApp1` can proxy as the `uid=admin1` entry.

- a. Open a text editor and create the following LDIF file.
- b. Update the `uid=clientApp1` entry to add the `ds-auth-may-proxy-as` attribute.

Note:

`ds-auth-may-proxy-as` is multi-valued.

- c. Save the file and add it using `ldapmodify`.

Example:

```
dn: uid=clientApp1,ou=Applications,dc=example,dc=com
changetype: modify
add: ds-auth-may-proxy-as
ds-auth-may-proxy-as: uid=admin1,dc=example,dc=com
```

5. Repeat the previous step for the `uid=clientApp2` entry, but specify the `ds-auth-may-proxy-as-url` attribute.

The client entry can proxy as any distinguished name (DN) that matches the LDAP URL.

Example:

```
dn: uid=clientApp2,ou=Applications,dc=example,dc=com
changetype: modify
add: ds-auth-may-proxy-as-url
ds-auth-may-proxy-as-url: ldap:///dc=example,dc=com??sub?(uid=admin*)
```

6. To illustrate the `ds-auth-proxyable-by-group` attribute, create a group of client applications that has `uid=clientApp1` and `uid=clientApp2` as its `uniquemembers`.

Example:

This example sets up a static group using the `groupOfUniqueNames` object class.

```
dn: ou=Groups,dc=example,dc=com
objectClass: top
objectClass: organizationalunit
ou: groups

dn: cn=Client Applications,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
cn: Client Applications
ou: groups
uniquemember: uid=clientApp1,ou=Applications,dc=example,dc=com
uniquemember: uid=clientApp2,ou=Applications,dc=example,dc=com
```

7. Update the `uid=admin1` entry to provide the DN that it can be proxied as.
 - a. Open a text editor and create the following LDIF file.
 - b. Use the `ds-auth-is-proxyable` to make the `uid=admin1` a required proxyable entry, meaning that it can only be accessed by some form of proxied authorization.
 - c. Use the `ds-auth-is-proxyable-by` attribute to specify each DN that can proxy as `uid=admin1`.
 - d. Save the LDIF file and add it using `ldapmodify`.

Example:

```
dn: uid=admin1,dc=example,dc=com
changetype: modify
add: ds-auth-is-proxyable
ds-auth-is-proxyable: required
-
add: ds-auth-is-proxyable-by
ds-auth-is-proxyable-by: ou=clientApp1,ou=Applications,dc=example,dc=com
ds-auth-is-proxyable-by: ou=clientApp2,ou=Applications,dc=example,dc=com
-
add: ds-auth-is-proxyable-by-group
ds-auth-is-proxyable-by-group: cn=Client
Applications,ou=Groups,dc=example,dc=com
-
add: ds-auth-is-proxyable-by-url
ds-auth-is-proxyable-by-url: ldap:///ou=Applications,dc=example,dc=com??
sub?(uid=clientApp*)
```

Note:

The example includes all three types of `ds-auth-is-proxyable-by-*` attributes as an illustration, but only one type of attribute is necessary if they all target the same entries.

8. Prohibit proxying for the `uid=admin2` entry.
 - a. Open a text editor and create the following LDIF file.
 - b. Set the `ds-auth-is-proxyable` attribute to prohibited.
 - c. Save the LDIF file and add it using `ldapmodify`.

Example:

```
dn: uid=admin2,dc=example,dc=com
changetype: modify
```

```
add: ds-auth-is-proxyable
ds-auth-is-proxyable: prohibited
```

9. Run a search using the proxied account.
 - a. To return a successful operation, run a search with `uid=clientApp1` or `uid=clientApp2` that proxies as `uid=admin1`.
 - b. To return an unsuccessful operation, run a search for `uid=clientApp1` that proxies as `uid=admin2`.

Example:

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp1,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin2,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)" "
```

Result:

The operation is unsuccessful because `uid=admin2` does not match the list of potential entries that can be proxied. The `ds-auth-may-proxy-as-*` attributes specify that the client can only proxy as `uid=admin1`.

```
One of the operational attributes (ds-auth-may-proxy-as,
ds-auth-may-proxy-as-group, ds-auth-may-proxy-as-url) in user entry
'uid=clientApp1,ou=Applications,dc=example,dc=com' does not allow
that user to be proxied as user 'uid=admin2,dc=example,dc=com'
```

```
Result Code: 123 (Authorization Denied)
```

```
Diagnostic Message: One of the operational attributes (ds-auth-may-proxy-
as,
ds-auth-may-proxy-as-group, ds-auth-may-proxy-as-url) in user entry
'uid=clientApp1,ou=Applications,dc=example,dc=com' does not allow that
user to be proxied as user 'uid=admin2,dc=example,dc=com'
```

10. Run another search using `uid=clientApp2`, which attempts to proxy as `uid=admin2`.

Example:

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp2,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin2,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)" "
```

Result:

The operation is unsuccessful because the `ds-auth-is-proxyable:prohibited` operational attribute states that `uid=admin2` is not available for proxied authorization.

```
The 'ds-auth-is-proxyable' operational attribute
in user entry 'uid=admin2,dc=example,dc=com' indicates that
user may not be accessed via proxied authorization
```

```
Result Code: 123 (Authorization Denied)
```

```
Diagnostic Message: The 'ds-auth-is-proxyable' operational
attribute in user entry 'uid=admin2,dc=example,dc=com' indicates
that user may not be accessed via proxied authorization
```

Working with parameterized ACIs

The Directory Server supports the use of parameterized access control instructions (ACIs) to control access to subtrees with homogenous administrative group or user patterns, which can be used in multi-tenant deployments.

A single parameterized ACI can take the place of specifying identical ACIs on each tenant's subtree. For example, consider the following parameterized ACI.

```
(target="ldap:///o=($1),dc=example,dc=com") (version 3.0; acl \
"Subtree Admin Group members may search for and read entries in their
subtree."; allow \
(search, read) groupdn="ldap:///cn=Subtree Admin
Group,ou=groups,o=($1),dc=example,dc=com";)
```

This parameterized ACI enables:

- Members of a group with the distinguished name (DN) "cn=Subtree Admin Group,ou=groups,o=Customers, dc=example,dc=com" to search for and read entries in the "o=Customers, dc=example,dc=com" subtree.
- Members of a group with the DN "cn=Subtree Admin Group,ou=groups,o=Partners, dc=example,dc=com" to search for and read entries in the "o=Partners, dc=example,dc=com" subtree

The same access is granted for any substitution value for the (\$1) parameter variable. If an operation tries to read the uid=user.1,o=acme,dc=example,dc=com entry, this ACI is considered. This ACI would allow a read action if the operation's user is a member of the cn=Subtree Admin Group,ou=groups,o=acme,dc=example,dc=com group.

You can replace attribute values from the target DN with different variables, (\$#), and then reference those variables in the group DN or user DN. Construct the string representation of a parameter variable as follows:

1. An open parenthesis
2. A dollar sign
3. A positive integer
4. A closing parenthesis

Consider the following example.

```
"population=($2),ou=Populations,environment=($1),ou=Environments,o=Acme"
```

The (\$2) variable is the population ID in the DN of the target entry, and (\$1) is the environment ID in the DN of the target entry. Those values from the target entry's DN are substituted into the group DN or user DN value.

Parameter variables present in a parameterized ACI's target will be associated with the actual values from the resource DN. Each actual value will be substituted for its respective parameter variable in the ACI's target and group bind rule DN's when performing access control on the resource entry.

Parameter variables can be used in multiple relative distinguished names (RDNs) in a parameterized target. A given RDN can have at most one parameter variable as its attribute value. A given parameter variable can appear only once in the parameterized target.

The following values are examples of valid parameterized target DN's:

- ou=(\$1),dc=example,dc=com
- population=(\$2),ou=Populations,environment=(\$1),ou=Environments,o=Acme
- o=(\$1) (for a global ACI)

An ACI on an entry only applies to that entry's subtree. If an ACI with a parameterized target is stored on an entry, that entry's DN must appear in a non-parameterized form as the rightmost RDN of

the parameterized target's DN. For example, if an ACI with a parameterized target is stored on the `dc=example,dc=com` entry, that parameterized target must end in `dc=example,dc=com` in a non-parameterized form. Global ACIs do not have this restriction. Each global ACI can have parameter variables in any or all of its parameterized target's RDNs.

Additional restrictions for parameterized targets include:

- They cannot be pattern ACIs, meaning they cannot contain wildcards (*).
- RDNs that are parameterized must be single-valued. For example, a given parameterized RDN cannot consist of two or more type-value pairs joined by +.

\$attr.attrName macro

The `($attr.attrName)` macro extracts a value from a specified attribute in the target entry rather than extracting a value from a field with the same number in the target distinguished name (DN).

For example, `($attr.description)` is replaced with the value of the `description` attribute in the target entry. If there are multiple values for the specified attribute, then multiple actualized DN's are produced for the bind DN, and the first matching actualized DN is used.

The `($attr.attrName)` macro expands only the attribute's value so that you can extract values from the target DN and build relative distinguished names (RDNs) with different attribute names and types. Because the `($attr.attrName)` macro extracts only the attribute's value, you can combine it with a type other than what is in the target DN.

Managing the Schema

This section is a summary of the supported schema components on PingDirectory Server and procedures to extend the schema with new element definitions.

About the schema

A schema is the set of directory server rules that define the structures, contents, and constraints of a directory information tree (DIT).

The schema guarantees that any new data entries or modifications meet and conform to these predetermined set of definitions. It also reduces redundant data definitions and provides a uniform method for clients or applications to access its Directory Server objects.

PingDirectory Server includes a default set of read-only schema files that define the core properties for the Directory Server. The Administrative Console provides a Schema Editor to view existing schema definitions and add new custom schema elements to your DIT.

Note:

Any attempt to alter a schema element defined in a read-only file or add a new schema element to a read-only file results in an `Unwilling to Perform` result.

About the Schema Editor

The Administrative Console provides a user-friendly graphical editor with tabs to manage any existing schema components related to the directory information tree (DIT).

The list of existing schema components that can be managed includes:

- Object classes
- Attributes
- Matching rules
- Attribute syntaxes

- Schema utilities

The following list describes the tabs of the Schema Editor page:

- The **Object Classes** and **Attribute Types** tabs enable viewing existing definitions as well as adding, modifying, or removing custom schema elements.
- The **Matching Rules** and **Attribute Syntaxes** tabs are read-only and provide a comprehensive listing of all of the elements necessary to define new schema elements.
- The **Schema Utilities** tab provides a schema validator that allows you to load a schema file or perform a cut-and-paste operation on the schema definition to verify that it meets the proper schema and ASN.1 formatting rules.
- The **Utilities** tab supports schema file imports by first checking for proper syntax compliance and generating any error message if the definitions do not meet specification.

LDAP Schema ▾

The screenshot shows the 'LDAP Schema' page with tabs for 'Object Classes', 'Attribute Types', 'Matching Rules', 'Attribute Syntaxes', and 'Schema Utilities'. The 'Object Classes' tab is active, displaying a table of schema elements. The table has columns for Name, Type, Modifiable, Description, File, and Actions. The elements listed include account, alias, applicationEntity, applicationProcess, authPasswordObject, automount, automountMap, bootableDevice, cllDistributionPoint, callEntry, certificationAuthority, and certificationAuthority-V2.

Name	Type	Modifiable	Description	File	Actions
account	Structural	No	-	00-core.ldif	Actions ▾
alias	Structural	No	-	00-core.ldif	Actions ▾
applicationEntity	Structural	No	-	00-core.ldif	Actions ▾
applicationProcess	Structural	No	-	00-core.ldif	Actions ▾
authPasswordObject	Auxiliary	No	authentication password mix in class	03-rl3112.ldif	Actions ▾
automount	Structural	No	Automount information	04-rl2307bis.ldif	Actions ▾
automountMap	Structural	No	-	04-rl2307bis.ldif	Actions ▾
bootableDevice	Auxiliary	No	A device with boot parameters; device SI structural class	04-rl2307bis.ldif	Actions ▾
cllDistributionPoint	Structural	No	-	00-core.ldif	Actions ▾
callEntry	Auxiliary	No	-	03-rl2739.ldif	Actions ▾
certificationAuthority	Auxiliary	No	-	00-core.ldif	Actions ▾
certificationAuthority-V2	Auxiliary	No	-	00-core.ldif	Actions ▾

Example Schema Editor Page

The Schema Editor provides two views for each definition:

- The **Properties View** that breaks down the schema definition by its properties and shows any inheritance relationships among the attributes.
- The **LDIF View** that shows the equivalent schema definition in ASN.1 format, which includes the proper text spacing required for each schema element.

Default Directory Server schema files

PingDirectory Server stores its schema as a set of LDIF files for a Directory Server instance in the `<server-root>/config/schema` directory. Directory Server reads the schema files in alphanumeric order at startup in the following order:

1. The `00-core.ldif` file
2. The `01-pwpolicy.ldif` file
3. Remaining files

You should name custom schema files so that they are loaded in last. For example, custom schema elements could be saved in a file labeled `99-user.ldif` that loads after the default schema files are read at startup.

The Directory Server then uses the schema definitions to determine any violations that might occur during **add**, **modify**, or **import** requests. Clients applications check the schema (matching rule definitions) to determine the assertion value algorithm used in comparison or search operations.

The default set of schema files are present at installation and should not be modified. Modifying the default schema files could result in an inoperable server.

The schema files have the following descriptions.

Default Schema Files

Schema Files	Description
00-core.ldif	Governs the Directory Server's core functions
01-pwpolicy.ldif	Governs password policies
02-config.ldif	Governs the Directory Server's configuration
03-changelog.ldif	Governs the Directory Server's change log
03-rfc2713.ldif	Governs Java objects
03-rfc2714.ldif	Governs Common Object Request Broker Architecture (CORBA) object references
03-rfc2739.ldif	Governs calendar attributes for vCard
03-rfc2926.ldif	Governs Server Location Protocol (SLP) mappings to and from LDAP schemas
03-rfc2985.ldif	Governs PKCS #9 public-key cryptography
03-rfc3112.ldif	Governs LDAP authentication passwords
03-rfc3712.ldif	Governs printer services
03-uddiv3.ldif	Governs web services registries of Service Oriented Architecture (SOA) components
04-rfc2307bis.ldif	Governs mapping entities from TCP/IP and UNIX into X.500 entries

Extending the Directory Server schema

PingDirectory Server stores its schema as LDIF files in the `<server-root>/config/schema` directory.

At startup, the Directory Server reads the schema files in alphanumeric order starting with `00-core.ldif` and ending with any custom schema definition files, such as `99-user.ldif`, if present.

You can extend the schema to include additional customizations necessary for your Directory Server data using one of the following methods:

- Using the Schema Editor

This method is the easiest and quickest way to set up a schema definition and have it validated for the correct ASN.1 formatting. The Editor lets you define your schema properties, load your custom file, or perform a cut-and-paste operation on a new schema element. If any errors exist in the file, the Schema Editor generates an error message if the schema definitions do not pass compliance.

- Using a custom schema file

You can create a custom schema file with your new definitions using a text editor, save it as `99-user.ldif`, and then import the file using the Schema Editor or the `ldapmodify` tool. You must

name the custom LDIF file with a high two-digit number prefix, so that the Directory Server reads the file after the core schema files are read at startup. For example, you can name the file `99-myschema.ldif`.

Note:

For more information on the requirements for naming each file, see the next section, [General tips on extending the schema](#) on page 486.

- Using the command line

If you have a small number of additions, you can extend the schema over LDAP and from the command line using the `ldapmodify` tool. The Directory Server writes the new schema changes to a file such as `99-user.ldif` in the `<server-root>/config/schema` directory. However, this method can be cumbersome because schema definitions require strict adherence to text spacing and white space characters.

General tips on extending the schema

Consider the following points when extending the schema:

- Never modify the default schema files because doing so could damage the Directory Server's processing capabilities.
- Define all attributes before they can be used in an object class. If you are using the Schema Editor to add new schema elements, use the `Quick Add Attributes` option when defining new object classes.
- Define the parent object class before creating object classes that inherit from the parent.
- You must name custom schema files according to the following syntax:
 1. Begin with exactly two digits.
 2. Follow the two digits with a non-digit character.
 3. Follow the non-digit character with a zero or more characters.
 4. End in `.ldif`.

Note:

The two digits don't need to be followed by a dash ("-").

Any files that do not meet this criteria are ignored and either a `NOTICE` or `SEVERE_WARNING` message is logged.

Any file in the `<server-root>/config/schema` directory with a name that starts with "." or ends with a tilde (~), `.swp`, or `.tmp` generates a `NOTICE` message indicating that temporary files will be ignored. Any other file that does not meet the naming criteria generates a `SEVERE_WARNING` message indicating that it will be ignored.

- Define custom attributes and object classes in one file. Typically, this file is the `99-user.ldif`. You can specify a different file name that the Directory Server writes to using the `X-SCHEMA-FILE` element and the file name in the definition, as in the following example.

```
add: attributeTypes attributeTypes: ( 1.3.6.1.4.1.32473.3.1.9.1
  NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'Directory Server Example'
  X-SCHEMA-FILE '99-custom.ldif' )
```

- In the white space characters in the schema definitions, `WSP` means zero or more space characters, and `SP` means one or more space characters. The LDIF specification states that LDIF parsers should ignore exactly one space at the beginning of each continuation line because continuation lines must begin with a space character.

If you define a new schema definition with each keyword on a separate continuation line, you should add two spaces before an element keyword to guarantee correct formatting. For example, the following attribute definition has two spaces before the keywords `NAME`, `SUP`, and `X-ORIGIN`.

```
attributeTypes: ( 2.5.4.32 NAME 'owner' SUP distinguishedName X-ORIGIN
  'RFC 4519' )
```

- In a replicated topology, any new schema additions are replicated to other replication servers to their respective Schema backend. The additions are written to the file specified by the `X-SCHEMA-FILE` extension or written to `99-user.ldif` if no file is specified.

About managing attribute types

An attribute type determines the important properties related to an attribute, such as specifying the matching and syntax rules used in value comparisons. An attribute description consists of an attribute type and a set of zero or more options.

Options are short, case-insensitive text strings that differentiate between attribute descriptions. For example, the LDAPv3 specification defines only one type of option, the tagging option, that can be used to tag language options, such as `cn;lang-de;lang-sp` or binary data, such as `userCertificate;binary`. You can also extend the schema by adding your own attribute definitions.

Attributes have the following properties:

- Attributes can be user attributes that hold information for client applications, or operational attributes used for administrative or server-related purposes.

Tip:

To specify the purpose of the attribute, use the `USAGE` element.

- Attributes are multi-valued by default. Multi-valued means that attributes can contain more than one value within an entry.

Tip:

If the attribute should contain at most one value within an entry, include the `SINGLE-VALUE` element.

- Attributes can inherit properties from a parent attribute as long as they both have the same `USAGE`, and the child attribute has the same `SYNTAX`, or its `SYNTAX` allows values that are a subset of the values allowed by the `SYNTAX` of the parent attribute. For example, the surname (`sn`) attribute is a child of the name attribute.

Attribute type definitions

New attribute types don't require server code extensions if the provided matching rules and attribute syntaxes are used in the definitions.

Administrators can create new attributes using the Schema Editor, which stores the definition in a file in the `<server-root>/config/schema` directory. For more information, see [Extending the Directory Server Schema](#).

The formal specification for attribute types is provided in RFC 4512, section 4.1.2 as follows.

```
AttributeTypeDescription = "(" wsp; Left parentheses followed by a white
  space
  numericoid
  ; Required numeric object identifier
```

```

[ sp "NAME" sp qdescrs ]           ; Short name descriptor as alias for the
  OID
[ sp "DESC" sp qdstring ]         ; Optional descriptive string
[ sp "OBSOLETE" ]                 ; Determines if the element is active
[ sp "SUP" sp oid ]               ; Specifies the supertype
[ sp "EQUALITY" sp oid ]          ; Specifies the equality matching rule
[ sp "ORDERING" sp oid ]          ; Specifies ordering matching rule
[ sp "SUBSTR" sp oid ]            ; Specifies substrings matching rule
[ sp "SYNTAX" sp oidlen ]         ; Numeric attribute syntax with minimum
  upper bound
                                   ; length expressed in {num}
[ sp "SINGLE-VALUE" ]              ; Specifies if the attribute is single
  valued in
                                   ; the entry
[ sp "COLLECTIVE" ]               ; Specifies if it is a collective
  attribute
[ sp "NO-USER-MODIFICATION" ]     ; Not modifiable by external clients
[ sp "USAGE" sp usage ]           ; Application usage
extensions wsp ")"                ; Extensions followed by a white space and
  ")"
usage = "userApplications" /      ; Stores user data
  "directoryOperation" /         ; Stores internal server data
  "distributedOperation" /       ; Stores operational data that must be
  synchronized
                                   ; across servers
  "dSAOperation"                 ; Stores operational data specific to a
  server and
                                   ; should not be synchronized across
  servers

```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512.

```

extensions = /
"X-ORIGIN" /                       ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /                   ; Specifies which schema file contains the
  definition
"X-APPROX" /                         ; Specifies the approximate matching rule
"X-ALLOWED-VALUE" /                 ; Explicitly specifies the set of allowed values
"X-VALUE-REGEX" /                   ; Specifies the set of regular expressions to
  compare against
                                   ; attribute values to determine acceptance
"X-MIN-VALUE-LENGTH" /              ; Specifies the minimum character length for
  attribute values
"X-MAX-VALUE-LENGTH" /              ; Specifies the maximum character length for
  attribute values
"X-MIN-INT-VALUE" /                 ; Specifies the minimum integer value for the
  attribute
"X-MAX-INT-VALUE" /                 ; Specifies the maximum integer value for the
  attribute
"X-MIN-VALUE-COUNT" /               ; Specifies the minimum number of allowable values
  for the
                                   ; attribute
"X-MAX-VALUE-COUNT" /               ; Specifies the maximum number of allowable values
  for the
                                   ; attribute
"X-READ-ONLY"                       ; True or False. Specifies if the file that
  contains the
                                   ; schema element is marked as read-only in the
  server
                                   ; configuration.

```

Basic properties of attributes

The following table details the standard elements in schema definition.

Basic Properties of Attributes

Attributes	Description
Name	The globally unique name
Description	An optional definition that describes the attribute and its contents The LDIF equivalent is <code>DESC</code> .
OID	The object identifier assigned to the schema definition You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
Syntax	The attribute syntax used For example, the <code>userPassword</code> attribute uses the User Password Syntax whereas the <code>authPassword</code> attribute uses the Authentication Password Syntax.
Parent	The schema definition's parent or supertype, if any The analogous LDIF equivalent is <code>SUP</code> .
Multivalued	Specifies if the attribute can appear more than once in its containing object class
Required By Class	Specifies any object classes that require the attribute
Allowed By Class	Specifies any object classes that can optionally use the attribute
Value Restrictions	Specifies any restriction on the value of the attribute

The Additional Properties table details auxiliary information associated with the attribute.

Attributes	Description
Aliases	Any shortform alias names, if any You can have any number of shortform names as long as they are all unique. The analogous LDIF equivalent appears as the secondary element with the <code>NAME</code> element. For example, <code>NAME, sn, surname</code> .
Origin	The origin of the schema definition Typically, it could refer to a specific RFC or company.
Stored in File	Specifies the schema file that stores the definition in the <code><server-root>/config/schema</code> folder

Attributes	Description
Usage	<p>The intended use of the attribute</p> <p>The choices are:</p> <ul style="list-style-type: none"> ▪ userApplications ▪ directoryOperation ▪ distributedOperation ▪ dSAOperation
User-Modifiable	Specifies if the attribute can be modified by an authorized user
Obsolete	Specifies if the schema definition is obsolete or not
Matching Rules	Specifies the associated matching rules for the attribute

Viewing attributes

The Schema Editor displays all of the attribute types on your directory server instance.

It shows the basic properties that are required elements in addition to the extra properties that are allowed within the attribute definition.

Viewing attribute types using the Schema Editor

Before you begin

Ensure that the Directory Server instance is running.

About this task

To view attribute types using the Schema Editor:

Steps

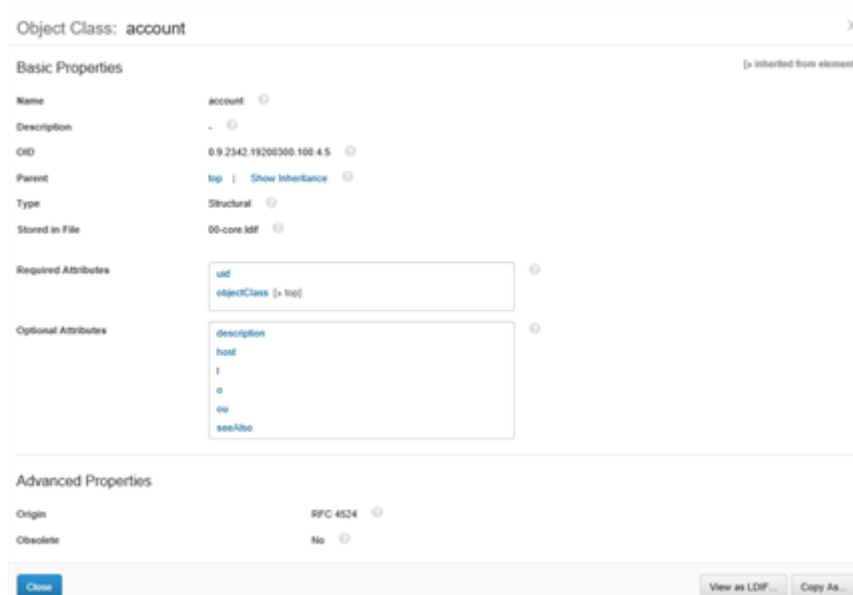

1. Start the Administrative Console.
2. In the main menu, select **Schema**.
3. In the **Schema Editor**, click the **Attribute Types** tab.

- Click a specific attribute to view its definition.

In the **Object Class** window, view the attribute properties.

Example:

To follow this example, click the `account` attribute.

- To see the equivalent attribute definition in ASN.1 format, click the **View as LDIF** button.

Viewing attribute types over LDAP

Steps

- To view an operational attribute, run `ldapsearch`.

Example:

This example uses `ldapsearch` to view the multi-valued operational attribute `attributeTypes`, which publishes the definitions on the Directory Server.

Note:

The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" attributeTypes
```

Viewing a specific attribute type over LDAP

Steps

- To search for a specific attribute, run `ldapsearch` with the `--dontWrap` option and use the `grep` command.

Example:

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base --dontWrap "(objectclass=*)" \
  attributeTypes | grep 'personalTitle'
```

Creating a new attribute over LDAP

The following sections demonstrate how to add a schema element over LDAP.

You can create your own schema file or type the schema from the command line.

Note:

Make sure you're aware of text spacing and ASN.1 formatting.

Adding a new attribute to the schema over LDAP

Steps

1. In a text editor, create an LDIF file with the new attribute definition.

Example:

In this example, the LDIF file is named `myschema.ldif`.

```
dn: cn=schema
changetype: modify
add: attributeTypes
attributeTypes: ( contractorStatus-OID NAME 'contractorStatus'
EQUALITY booleanMatch
SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
SINGLE-VALUE
USAGE userApplications
X-ALLOWED-VALUES ( 'Y' 'N' 'y' 'n' )
X-ORIGIN 'PingDirectory Server Example' )
```

2. To add the attribute, run `ldapmodify`.

Example:

```
$ bin/ldapmodify --filename myschema.ldif
```

3. To verify the addition, display the attribute using `ldapsearch`.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
--dontwrap "(objectclass=*)" attributeTypes | grep 'contractorStatus'
```

4. To view the custom schema file, go to `<server-root>/config/schema/99-user.ldif`.

Result:

For this example, you see the following details:

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( contractorStatus-OID
NAME 'contractorStatus'
EQUALITY booleanMatch
SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
SINGLE-VALUE
USAGE userApplications
X-ORIGIN 'PingDirectory Server Example' )
```

Adding constraints to attribute types

About this task

The Directory Server provides attribute type extensions that constrain the values for the associated attribute using the `DirectoryString` attribute syntax.

To constrain the values for an attribute:

Steps

- Use the `DirectoryString` attribute syntax.

Example:

The following example schema definition includes two `attributeType` definitions for `myAttr1` and `myAttr2`:

- The first definition constrains the values for the attribute `myAttr1` to `'foo'`, `'bar'`, and `'baz'`.
- The second definition constrains the minimum allowable length for `myAttr2` to 1 and the maximum allowable length to 5.

```
attributeTypes: (1.2.3.4
  NAME 'myAttr1'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  X-ALLOWED-VALUES ( 'foo' 'bar' 'baz' ))
attributeTypes: ( 1.2.3.5
  NAME 'myAttr2'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  X-MIN-VALUE-LENGTH '1'
  X-MAX-VALUE-LENGTH '5' )
```

Managing object classes

Object classes are sets of related information objects that form entries in a directory information tree (DIT).

The Directory Server uses the schema to do the following:

- Define the entries.
- Specify the position of the entries in a DIT.
- Control the operations of the server.

You can also extend the schema by adding your own schema definitions.

Object classes have the following general properties:

- Object classes must have a globally unique name or identifier.
- Object classes specify the required and allowed attributes in an entry.
- Object classes can inherit the properties and the set of allowed attributes from its parent object classes, which might also be part of a hierarchical chain derived from the top abstract object class.
- Object classes that are defined in PingDirectory Server can be searched using the `objectClasses` operational attribute.

Note:

The Directory Server also has a special entry called the subschema subentry, which provides information about the available schema elements on the server.

Object classes types

Based on [RFC 4512](#), object classes can be a combination of three different types:

Abstract object classes

Used as the base object class from which structural or auxiliary classes inherit its properties.

This inheritance is a one-way relationship because abstract object classes cannot be derived from structural or auxiliary classes. The most common abstract object class is `top`, which defines the highest level object class in a hierarchical chain of object classes.

Structural object classes

Define the basic attributes in an entry and define where an entry can be placed in a directory information tree (DIT).

All entries in a DIT belong to one structural object class. Structural object classes can inherit properties from other structural object classes and from abstract object classes to form a chain of inherited classes. For example, the `inetOrgPerson` structural object class inherits properties from the `organizationalPerson` structural class, which inherits from another object class, `person`.

Auxiliary object classes

Used together with structural object classes to define additional sets of attributes required in an entry.

The auxiliary object class cannot form an entry alone but must be present with a structural object class. Auxiliary object classes cannot derive from structural object classes or vice-versa. They can inherit properties from other auxiliary classes and from abstract classes.

Object class definition

You can specify new object classes with existing schema components that don't require additional server code extensions for their implementation. To create new object classes, use the Schema Editor, which manages schema in the `<server-root>/config/schema` directory. For more information, see [Extending the Directory Server Schema](#).

RFC 4512, section 4.1.1, defines the following object class definition.

```
ObjectClassDescription = "(" wsp; Left parenthesis followed by a white space
numericoid                ; Required numeric object identifier
[ sp "NAME" sp qdescrs ]  ; Short name descriptor as alias for the
OID
[ sp "DESC" sp qdstring ] ; Optional descriptive string
[ sp "OBSOLETE" ]         ; Determines if the element is inactive
[ sp "SUP" sp oid ]       ; Specifies the direct superior object
class
[ sp kind ]               ; abstract, structural (default),
auxiliary
[ sp "MUST" sp oids ]     ; Required attribute types
[ sp "MAY" sp oids ]      ; Allowed attribute type
extensions wsp ")"       ; Extensions followed by a white space and
")"

usage = "userApplications" / ; Stores user data
"directoryOperation" /     ; Stores internal server data
"distributedOperation" /   ; Stores operational data that must be
synchronized
"dsaOperation"            ; across servers
server and                ; Stores operational data specific to a
servers                    ; should not be synchronized across
```

The following extensions are specific to PingDirectory Server and aren't defined in RFC 4512.

```

extensions = /
"X-ORIGIN" /           ; Specifies where the object class is defined
"X-SCHEMA-FILE" /     ; Specifies which schema file contains the
  definition
"X-READ-ONLY"         ; True or False. Specifies if the file that
  contains
                       ;   the schema element is marked as read-only
                       ;   in the server configuration.

```

Note:

Although RFC 4512 allows multiple superior object classes, PingDirectory Server allows at most one superior object class, which is defined by the `SUP` element in the definition.

Basic object class properties

The Basic Properties table displays the standard elements in schema definition.

Attributes	Description
Name	The globally unique name.
Description	An optional definition that describes the object class and its contents. The analogous LDIF equivalent is <code>DESC</code> .
OID	The object identifier assigned to the schema definition. You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
Parent	The schema definition's hierarchical parent or superior object class, if any. An object class can have one parent.
Type	The type of schema definition, which can be abstract, structural, or auxiliary. The analogous LDIF equivalent is <code>ABSTRACT</code> , <code>STRUCTURAL</code> , or <code>AUX</code> .
Required Attributes	<p>Specifies required attributes with the object class. The analogous LDIF equivalent is <code>MUST</code>.</p> <p> Tip: The Schema Editor marks any inherited attributes from another object class. Double-click an attribute value to take you to the Properties View for that particular attribute.</p>

Attributes	Description
Optional Attributes	Specifies optional attributes that can be used with the object class. The analogous LDIF equivalent is <code>MAY</code> .
	 Tip: The Schema Editor marks any inherited attributes from another object class. Double-click an attribute value to take you to the properties view for that particular attribute.

The Additional Properties table provides auxiliary information associated with the object class.

Attributes	Description
Aliases	Specifies short-form alias names, if any. You could have any number of short-form names as long as they are all unique. The analogous LDIF equivalent appears as the secondary element with the <code>NAME</code> element although most object classes do not have aliases.
Origin	The origin of the schema definition. Typically, it could refer to a specific RFC or company.
Obsolete	Specifies if the schema definition is obsolete or not.
Stored in File	Specifies the schema file that stores the definition in the <code><server-root>/config/schema</code> folder.

Viewing object classes

About this task

To view the object classes on your Directory Server, use any of the following:

- The Administrative Console Schema Editor
- LDAP with the `ldapsearch` tool
- A third-party tool

Note:

The Schema Editor displays all of the object classes on the directory server instance. It shows the basic properties that are required elements and the extra properties that are allowed within the object class.

To view object classes over LDAP:

Steps

- To view an operational attribute, run `ldapsearch`.

Example:

This example uses `ldapsearch` to view the multi-valued operational attribute `objectClasses`, which publishes the object class definitions on the Directory Server.

Note:

The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
--dontWrap "(objectclass=*)" objectClasses
```

Result:

```
dn: cn=schema
objectClasses: ( 2.5.6.0 NAME 'top' ABSTRACT MUST objectClass X-ORIGIN
'RFC 4512' )
objectClasses: ( 2.5.6.1 NAME 'alias' SUP top STRUCTURAL MUST
aliasedObjectName
X-ORIGIN 'RFC 4512' )
objectClasses: ( 2.5.6.2 NAME 'country' SUP top STRUCTURAL MUST c
MAY ( searchGuide $ description ) X-ORIGIN 'RFC 4519' )
...(more output)...
```

Managing an object class over LDAP

Manage an object class schema element over LDAP by adding a new attribute element to an existing object class. You can create your own schema file or type the schema from the command line. In either case, you must pay special attention to text spacing and ASN.1 formatting.

Before you begin

Define the attribute you want to add to the custom schema file.

About this task

The following example procedure adds a predefined attribute, `contractorAddress`, to the custom schema file, then adds it to the `contractor` object class.

Steps

1. Create and save an LDIF file with the content in the following example.

Example:

In this example, the file is named `contractorAddress-attr.ldif`.

```
dn: cn=schema
changetype: modify

add: attributeTypes attributeTypes: ( contractor-OID NAME
'contractorAddress'
SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
SINGLE-VALUE
USAGE userApplications
X-ORIGIN 'user defined'
X-SCHEMA-FILE '98-custom-schema.ldif' )
X-ORIGINS 'user defined'
```

```
X-SCHEMA-FILE '98-custom-schema.ldif' )
```

2. To add the attribute you defined, run **ldapmodify**.

Example:

In this example, the `contractorAddress` attribute is being added.

```
$ bin/ldapmodify --filename contractorAddress-attr.ldif
```

3. To modify the contractor object class to allow this attribute, create an LDIF file.

When doing this, you are re-adding the updated `objectClass`. The Directory Server handles the proper replacement of the existing object class with the new one.

Note:

Ensure that the lines are not wrapped, the `objectClasses` line should be one continuous line.

Example:

In this example, the file is named `contractor-oc.ldif`.

```
dn:cn=schema
changetype: modify
add: objectClasses
objectClasses: ( contractor-OID NAME 'contractor'
DESC 'Contractor status information
SUP top
AUXILIARY MAY ( contractorStatus $ contractorAgency $
contractorAddress )
X-ORIGIN 'Directory Server Example'
X-SCHEMA-FILE '98-custom-schema.ldif' )
```

4. To update the `objectClass`, run **ldapmodify**.

Example:

```
$ bin/ldapmodify --filename contractor-oc.ldif
```

Result: These schema changes are replicated to all servers in the replication topology.

5. To verify the change, view the `config/schema/98-custom-schema.ldif` file on the other servers in the replication topology to ensure that the changes are present.
6. Optional: To add an index for this attribute, run **dsconfig** with the `create-local-db-index` option.

Note:

You must do this on each server in your topology unless you have server configuration groups set up.

For more information, see [Configuring Server Groups](#).

Example:

```
$ bin/dsconfig create-local-db-index --backend-name userRoot \
--index-name contractorAddress --set index-type:equality
```

7. Rebuild the index online.

Note:

This doesn't affect other indexes or entries because there is no existing data for this attribute on any entry.

Example:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index contractorAddress
```

Creating a new object class using the Schema Editor

The procedures to create a new object class are similar to that of creating a new attribute.

Before you begin

Ensure that any attributes that are part of the new object class are defined before defining the object class.

About this task

To create a new object class:

Steps

1. Start the Administrative Console.
2. From the main menu, select **LDAP Schema**.
3. On the **Schema Editor**, click the **Object Classes** tab, and then click **New**.
4. Enter the properties for the new object class.
5. In the **Attributes** box, filter the types of attributes required for the new object class. Click the right arrow to move it into the **Required** or the **Optional** box.

Note:

All custom attributes appear at the bottom of the list in the **Attributes** box.

Extending the schema using a custom schema file

To add new attributes and object classes to your Directory Server schema, create a custom schema file.

Steps

1. Create an LDIF file with the new attribute extensions using a text editor.

Example:

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
attributeTypes: ( contractorStatus-OID NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'Directory Server Example' )
attributeTypes: ( contractorAgency-OID NAME 'contractorAgency'
  EQUALITY caseIgnoreMatch
  SUBSTR caseIgnoreSubstringsMatch
```

```
SYNTAX 1.3.6.1.4.1.1466.115.121.1.44{256}
SINGLE-VALUE
USAGE userApplications
X-ORIGIN 'PingDirectory Server Example' )
```

2. In the LDIF file you created in step 1, add a new object class definition after the attribute types.

Example:

This example creates an auxiliary object class, `contractor`, that alone cannot be used as an entry.

The object class is used to add supplemental information to the `inetOrgPerson` structural object class. The attributes are all optional for the new object class.

```
objectClasses: ( contractor-OID
  NAME 'contractor'
  DESC 'Contractor status information'
  SUP top
  AUXILIARY
  MAY ( contractorStatus $ contractorAgency )
  X-ORIGIN 'PingDirectory Server Example' )
```

3. Save the file and place it in the `<server-root>/config/schema` directory.

In this example, the file is saved as `99-auxobjclass.ldif`.

4. Load the schema extensions into Directory Server. You have four options:

Choose from:

- Create a task that loads the new extensions into the schema.

The following example creates a task with the ID `add-schema-99-auxobjclass` and adds it using `ldapmodify`.

```
dn: ds-task-id=add-schema-99-auxobjclass,cn=Scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-add-schema-file
ds-task-id: add-schema-99-auxobjclass
ds-task-class-name:
  com.unboundid.directory.server.tasks.AddSchemaFileTask
```

```
ds-task-schema-file-name: 99-auxobjclass.ldif
```

 **Note:**

When using this method, you don't need to restart the server.

- Import the schema file using the Administrative Console Schema Editor.

 **Note:**

When using this method, you don't need to restart the server.

- a. Place the `99-auxobjclass.ldif` file in the `<server-root>/config/schema` directory.
- b. Restart PingDirectory Server.

 **Note:**

The schema file is read at startup.

- Add the schema file using `load-ldap-schema-file`.

```
$ bin/load-ldap-schema-file --schemaFile config/schema 99-
auxobjclass.ldif
```

 **Note:**

When using this method, you don't need to restart the server.

5. Add the new object class and attribute to an existing user entry.

Example:

```
$ bin/ldapmodify
dn: uid=user.9,ou=People,dc=example,dc=com
changetype: modify
add: objectClass
objectClass: contractor
-
add: contractorStatus
contractorStatus: TRUE
```

6. To verify the addition, run `ldapsearch` to display the attribute.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.9)"
contractorStatus
```

Result:

```
dn: uid=user.9,ou=People,dc=example,dc=com
contractorStatus: TRUE
```

About managing matching rules

Matching rules determine how clients and servers compare attribute values during LDAP requests or operations.

Matching rules are also used in evaluating search filter elements, including distinguished names (DNs) and attributes. They are defined for each attribute based on the following properties:

- **EQUALITY:** two attributes are equal based on case, exact match, and so forth
- **SUBSTR:** assertion value is a substring of an attribute
- **ORDERING:** greater than or equal, less than or equal, and so forth

Note:

PingDirectory Server supports an `APPROXIMATE` matching rule that compares similar attributes based on fuzzy logic. Attributes that are similar or sound alike are matched. For example, `petersen` would match `peterson`.

Matching rule definition

New matching rules require additional server code extensions to be implemented on PingDirectory Server.

If you need new matching rules, contact a Ping Identity support representative for assistance.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.3.

```
MatchingRuleDescription = "(" wsp           ; Left parentheses followed by a white
  space
  numericoid                       ; Required numeric object identifier
  identifying                        ; this matching rule

  [ sp "NAME" sp qdescrs            ; Short name descriptor
  [ sp "DESC" sp qdstring           ; Description
  [ sp "OBSOLETE" ]                 ; Specifies if the rule is inactive
  sp "SYNTAX" sp numericoid        ; Assertion syntax
  extensions wsp ")"               ; Extensions followed by a white space
  and ")"
```

Default matching rules

PingDirectory Server provides a large set of matching rules that support a variety of applications.

The default matching rules available for the Directory Server are listed in the table below for each matching rule type:

- Equality matches
- Substring matches
- Ordering matches
- Approximate matches

Default Matching Rules

Matching Rule/OID	Attribute Syntax/OID	Description
uuidMatch/ 1.3.6.1.1.16.2	UUID/ 1.3.6.1.1.16.1	Compares an asserted UUID with a stored UUID attribute value for equality RFC 4530

Matching Rule/OID	Attribute Syntax/OID	Description
uuidOrderingMatch/ 1.3.6.1.1.16.3	UUID/ 1.3.6.1.1.16.1	Compares the collation order of an asserted UUID with a stored UUID attribute value for ordering RFC 4530
caseExactIA5Match/ 1.3.6.1.4.1.1466.109.114.1	IA5 String/ 1.3.6.1.4.1.1466.115.121.1.2	Compares an asserted value with an attribute value of International Alphabet 5 (IA5) syntax RFC 4517
caseIgnoreIA5Match/ 1.3.6.1.4.1.1466.109.114.2	IA5 String/ 1.3.6.1.4.1.1466.115.121.1.2	Compares an asserted value with an attribute value of IA5 syntax Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
caseIgnoreIA5SubstringsMatch/ 1.3.6.1.4.1.1466.109.114.3	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.5	Compares an asserted substring with an attribute value of IA5 string syntax Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
authPasswordExactMatch/ 1.3.6.1.4.1.4203.1.2.2	Authentication Password Syntax/ 1.3.6.1.4.1.4203.1.1.2	Authentication password exact matching rule
authPasswordMatch/ 1.3.6.1.4.1.4203.1.2.3	Authentication Password Syntax/ 1.3.6.1.4.1.4203.1.1.2	Authentication password matching rule
ds-mr-double-metaphone-approx/ 1.3.6.1.4.1.30221.1.4.1	Directory String/ 1.3.6.1.4.1.1466.115.121.1.1	Syntax based on the phonetic Double Metaphone algorithm for approximate matching
ds-mr-user-password-exact/ 1.3.6.1.4.1.30221.1.4.2	User Password Syntax/ 1.3.6.1.4.1.30221.1.3.1	User password exact matching rule
ds-mr-user-password-equality/ 1.3.6.1.4.1.30221.1.4.3	User Password Syntax/ 1.3.6.1.4.1.30221.1.3.1	User password equality matching rule

Matching Rule/OID	Attribute Syntax/OID	Description
historicalCsnOrderingMatch/ 1.3.6.1.4.1.30221.1.4.4	1.3.6.1.4.1.30221.1.3.5	Compares the collation order of a historical change sequence number with a historical Change Sequence Number (CSN) attribute value
caseExactIA5SubstringsMatch/ 1.3.6.1.4.1.30221.1.4.902	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.5	Compares an asserted substring with an attribute value of IA5 string syntax RFC 4517
compactTimestampMatch/ 1.3.6.1.4.1.30221.2.4.1	Compact Timestamp/ 1.3.6.1.4.1.30221.2.3.1	Compact Timestamp matching rule
compactTimestampOrderingMatch/ 1.3.6.1.4.1.30221.2.4.2	Compact Timestamp/ 1.3.6.1.4.1.30221.2.3.1	Compares the collation order of a compact timestamp number with an attribute value of Compact Timestamp syntax
objectIdentifierMatch/ 2.5.13.0	OID/ 1.3.6.1.4.1.1466.115.121.1.3	Compares an asserted value with an attribute value of OID syntax RFC 4517
distinguishedNameMatch/ 2.5.13.1	DN/ 1.3.6.1.4.1.1466.115.121.1.1	Compares an asserted value with an attribute value of distinguished name (DN) syntax Spaces around commas and semicolons are ignored. Spaces around plus and equal signs around relative distinguished name (RDN) components are ignored. RFC 4517.
caseIgnoreMatch/ 2.5.13.2	Directory String/ 1.3.6.1.4.1.1466.115.121.1.1	Compares an asserted value with an attribute value Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517

Matching Rule/OID	Attribute Syntax/OID	Description
caseIgnoreOrderingMatch/ 2.5.13.3	Directory String/ 1.3.6.1.4.1.1466.115.121.1.10	Compares the collation order of the asserted string with an attribute value of Directory String syntax Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
caseIgnoreSubstringsMatch/ 2.5.13.4	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.5	Compares an asserted substring value with an attribute value of Directory String syntax Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
caseExactMatch/ 2.5.13.5	Directory String/ 1.3.6.1.4.1.1466.115.121.1.10	Compares an asserted value with an attribute value of Directory String syntax RFC 4517
caseExactOrderingMatch/ 2.5.13.6	Directory String 1.3.6.1.4.1.1466.115.121.1.10	Compares the collation order of the asserted string with an attribute value of Directory String syntax RFC 3698
caseExactSubstringsMatch/ 2.5.13.7	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.5	Compares an asserted substring with an attribute value of Directory String syntax RFC 3698
numericStringMatch/ 2.5.13.8	Numeric String/ 1.3.6.1.4.1.1466.115.121.1.3	Compares an asserted value with an attribute value of Numeric String syntax. Spaces are ignored when performing these comparisons RFC 4517.

Matching Rule/OID	Attribute Syntax/OID	Description
numericStringOrderingMatch/ 2.5.13.9	Numeric String/ 1.3.6.1.4.1.1466.115.121.1.30	Compares the collation order of the asserted string with an attribute value of Numeric String syntax Spaces are ignored when performing these comparisons. RFC 4517
numericStringSubstringsMatch/ 2.5.13.10	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.50	Compares an asserted substring with an attribute value of Numeric String syntax Spaces are ignored when performing these comparisons. RFC 4517
caseIgnoreListMatch/ 2.5.13.11	Postal Address/ 1.3.6.1.4.1.1466.115.121.1.40	Compares an asserted value with an attribute value, which is a sequence of Directory Strings Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
caseIgnoreListSubstringsMatch/ 2.5.13.12	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.50	Compares the asserted substring with an attribute value, which is a sequence of Directory Strings Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 3698
booleanMatch/ 2.5.13.13	Boolean/ 1.3.6.1.4.1.1466.115.121.1.70	Compares an asserted boolean value with an attribute value of BOOLEAN syntax Returns true if the values are both TRUE or both FALSE. RFC 3698

Matching Rule/OID	Attribute Syntax/OID	Description
integerMatch/ 2.5.13.14	Integer/ 1.3.6.1.4.1.1466.115.121.1.20	Compares an asserted value with an attribute value of INTEGER syntax RFC 4517
integerOrderingMatch/ 2.5.13.15	Integer/ 1.3.6.1.4.1.1466.115.121.1.20	Compares the collation order of the asserted integer with an attribute value of Integer syntax Returns true if the attribute value is less than the asserted value. RFC 3698
bitStringMatch/ 2.5.13.16	Bit String/ 1.3.6.1.4.1.1466.115.121.1.6	Compares an asserted Bit String value with an attribute value of Bit String syntax RFC 4517
octetStringMatch/ 2.5.13.17	Octet String/ 1.3.6.1.4.1.1466.115.121.1.40	Compares an asserted value with an attribute value of octet string syntax using a byte-for-byte comparison RFC 4517
octetStringOrderingMatch/ 2.5.13.18	Octet String/ 1.3.6.1.4.1.1466.115.121.1.40	Compares the collation order of the asserted octet string with an attribute value of Octet String syntax Zero precedes a one bit. Shorter strings precede longer strings. RFC 3698
octetStringSubstringsMatch/ 2.5.13.19	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58	Compares an asserted substring with an attribute value of octet string syntax using a byte-for-byte comparison RFC 4517
telephoneNumberMatch/ 2.5.13.20	Telephone Number/ 1.3.6.1.4.1.1466.115.121.1.50	Compares an asserted value with an attribute value of Telephone Number syntax RFC 4517

Matching Rule/OID	Attribute Syntax/OID	Description
telephoneNumberSubstringsMatch/ 2.5.13.21	Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.50	Compares an asserted value with the substrings of an attribute value of Telephone Number String syntax RFC 4517
presentationAddressMatch/ 2.5.13.22	Presentation Address/ 1.3.6.1.4.1.1466.115.121.1.40	Compares an asserted value with an attribute value of Presentation Address syntax RFC 4517
uniqueMemberMatch/ 2.5.13.23	Name and Optional UID/ 1.3.6.1.4.1.1466.115.121.1.30	Compares an asserted value with an attribute value of Unique Member syntax RFC 4517
protocolInformationMatch/ 2.5.13.24	Protocol Information/ 1.3.6.1.4.1.1466.115.121.1.40	Compares an asserted value with an attribute value of Protocol Information syntax RFC 4517
generalizedTimeMatch/ 2.5.13.27	Generalized Time/ 1.3.6.1.4.1.1466.115.121.1.20	Compares an asserted value with an attribute value of Generalized Time syntax RFC 4517
generalizedTimeOrderingMatch/ 2.5.13.28	Generalized Time 1.3.6.1.4.1.1466.115.121.1.20	Compares the collation order of the asserted string with an attribute value of Generalized Time String syntax and case is ignored RFC 4517
integerFirstComponentMatch/ 2.5.13.29	Integer/ 1.3.6.1.4.1.1466.115.121.1.20	Equality matching rules for subschema attributes between an Integer syntax and the value syntax RFC 4517
objectIdentifierFirstComponentMatch/ 2.5.13.30	OID/ 1.3.6.1.4.1.1466.115.121.1.30	Equality matching rules for subschema attributes between an OID syntax and the value syntax RFC 4517

Matching Rule/OID	Attribute Syntax/OID	Description
directoryStringFirstComponentMatch/ 2.5.13.31	Directory String/ 1.3.6.1.4.1.1466.115.121.1.1	Compares an asserted Directory String value with an attribute value of type SEQUENCE whose first component is mandatory and of type Directory String Returns true if the attribute value has a first component whose value matches the asserted Directory String using the rules of caseIgnoreMatch. RFC 3698 .
wordMatch/ 2.5.13.32	Directory String/ 1.3.6.1.4.1.1466.115.121.1.1	Compares an asserted word with any word in the attribute value for equality RFC 3698
keywordMatch/ 2.5.13.33	Directory String/ 1.3.6.1.4.1.1466.115.121.1.1	Compares an asserted value with any keyword in the attribute value for equality RFC 3698

Basic matching rule properties

The following table describes the standard elements in a matching rule schema definition.

Attributes	Description
Name	Specifies the descriptive and unique name of the element
Description	Specifies an optional definition that describes the matching rule The analogous LDIF equivalent is DESC.
OID	Specifies the globally unique object identifier assigned to the schema definition You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
Type	Specifies the type of matching rule: <ul style="list-style-type: none"> ▪ Equality ▪ Ordering ▪ Substring ▪ Approximate
Syntax	Specifies the matching rule syntax
Used by Attributes	Specifies any attributes that use the corresponding matching rule

Viewing matching rules

To view the matching rules on your Directory Server, use the Schema Editor, LDAP with `ldapsearch`, or a third-party tool.

About this task

To view matching rules over LDAP:

Steps

- To view the `matchingRules` attribute, run `ldapsearch`.

Example:

The following example uses `ldapsearch` to view a multi-valued operational attribute, `matchingRules`, which publishes the definitions on the Directory Server.

Note:

The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" matchingRules
```

About managing attribute syntaxes

The attribute type definition has a `SYNTAX` element, or attribute syntax, that specifies how the data values for the attribute are represented.

The syntax can be used to define a large range of data types necessary for client applications. An attribute syntax uses the Abstract Syntax Notation One (ASN.1) format for its definitions.

Attribute syntax definition

New attribute syntaxes require additional code to be implemented on PingDirectory Server.

If you need new syntax definitions, contact Ping Identity support for assistance.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.5.

```
SyntaxDescription = "(" wsp
  numericoid           ; Object identifier
  [ sp "DESC" sp qdstring ] ; Description
  extensions wsp ")"   ; Extensions followed by a white space and ")"
```

Default attribute syntaxes

PingDirectory Server supports a large set of Attribute Syntax rules for applications.

The default Attribute Syntax rules available for the directory server are listed in the following table.

LDAP Syntax	OID	Description
UUID	1.3.6.1.1.16.1	128-bit (16 octets) Universally Unique Identifier (UUID) used for Uniform Resource Names as defined in RFC 4122 For example, a4028c1a-f36e-11da-bala-04112154bd1e

LDAP Syntax	OID	Description
Attribute Type Description	1.3.6.1.4.1.1466.115.1	Syntax for the AttributeTypeDescription rule based on RFC 4517
Binary	1.3.6.1.4.1.1466.115.1	Strings based on Basic Encoding Rules (BER) or Distinguished Encoding rules (DER) For example, an X.509 digital certificate or LDAP messages are BER encoded
Bit String	1.3.6.1.4.1.1466.115.1	Sequence of binary digits based on RFC 4517 For example, '0010111'B
Boolean	1.3.6.1.4.1.1466.115.1	TRUE or FALSE
Certificate	1.3.6.1.4.1.1466.115.1	BER/DER-encoded octet strings based on an X.509 public key certificate as defined in RFC 4523
Certificate List	1.3.6.1.4.1.1466.115.1	BER/DER-encoded octet string based on an X.509 certificate revocation list as defined in RFC 4523
Certificate Pair	1.3.6.1.4.1.1466.115.1	BER/DER-encoded octet string based on an X.509 public key certificate pair as defined in RFC 4523
Country String	1.3.6.1.4.1.1466.115.1	Two character country code specified in ISO 3166 For example, US, CA, and so forth  Note: The current implementation for Country String: <ul style="list-style-type: none"> ▪ Only verifies that values are two printable characters, where the set of printable characters is defined in RFC 2252. ▪ Does not check that the value is a valid ISO 3166 country code.
DN	1.3.6.1.4.1.1466.115.1	Distinguished name of an entry as defined in RFC 4514

LDAP Syntax	OID	Description
Delivery Method	1.3.6.1.4.1.1466.115.1	Sequence of services in preference order by which an entity receives messages as defined in RFC 4517 For example, videotext \$ telephone
Directory String	1.3.6.1.4.1.1466.115.1	String of one or more characters from the Universal Character Set (UCS) using UCS Transformation Format 8 (UTF-8) encoding of the string
DIT Content Rule Description	1.3.6.1.4.1.1466.115.1	DITContentRuleDescription as defined in RFC 4517
DIT Structure Rule Description	1.3.6.1.4.1.1466.115.1	DITStructureRuleDescription as defined in RFC 4517
Enhanced Guide	1.3.6.1.4.1.1466.115.1	Combination of attribute types and filter operators to be used to construct search filters as defined in RFC 4517 For example, person#(sn\$EQ)#oneLevel
Facsimile Telephone Number	1.3.6.1.4.1.1466.115.1	Fax telephone number on the public switched telephone network as defined in RFC 4517
Fax	1.3.6.1.4.1.1466.115.1	Image generated using Group 3 fax process as defined in RFC 4517
Generalized Time	1.3.6.1.4.1.1466.115.1	String representing data and time as defined in RFC 4517 YYYYMMDDHHMMSS[.fraction][(+ -HHMM) Z] For example, 201103061032, 201103061032-0500, or 201103061032Z (Z indicates Coordinated Universal Time)
Guide	1.3.6.1.4.1.1466.115.1	Attribute types and filter operators as defined in RFC 4517
IA5 String	1.3.6.1.4.1.1466.115.1	String of zero or more characters from the International Alphabet 5 (IA5) character set as defined in RFC 4517
Integer	1.3.6.1.4.1.1466.115.1	String representations of integer values For example, the character string 1234 represents the number 1234 as defined in RFC 4517
JPEG	1.3.6.1.4.1.1466.115.1	Image in JPEG File Interchange Format (JFIF) as defined in RFC 4517

LDAP Syntax	OID	Description
Matching Rule Description	1.3.6.1.4.1.1466.115.1.1.30	MatchingRuleDescription as defined in RFC 4512
Matching Rule Use Description	1.3.6.1.4.1.1466.115.1.1.31	Attribute types to which a matching rule is applied in an extensibleMatch search filter RFC 4511
Name and Optional UID	1.3.6.1.4.1.1466.115.1.1.32	Distinguished name and an optional unique identifier that differentiates identical distinguished names (DNs) as defined in RFC 4517 For example, uid=jsmith,ou=People,dc=example,dc=com#'0111'B
Name Form Description	1.3.6.1.4.1.1466.115.1.1.35	NameFormDescription as defined in RFC 4512
Numeric String	1.3.6.1.4.1.1466.115.1.1.36	Sequence of one or more numerals and spaces as defined in RFC 4517 For example, 14 848 929 102
Object Class Description	1.3.6.1.4.1.1466.115.1.1.37	ObjectClassDescription as defined in RFC 4512
OID	1.3.6.1.4.1.1466.115.1.1.38	ObjectIdentifier as defined in RFC 4512
Other Mailbox	1.3.6.1.4.1.1466.115.1.1.39	Specifies an electronic mailbox as defined in RFC 4517 For example, otherMailbox = google \$user@gmail.com
Octet String	1.3.6.1.4.1.1466.115.1.1.40	Sequence of zero or more octets (8-bit bytes) as defined in RFC 4517
Postal Address	1.3.6.1.4.1.1466.115.1.1.41	Strings of characters that form a multi-line address in a physical mail system. Each component is separated by a \$ For example, 1234 Main St.\$Austin, TX 78744\$USA
Protocol Information	1.3.6.1.4.1.1466.115.1.1.42	Undefined
Presentation Address	1.3.6.1.4.1.1466.115.1.1.43	String encoded OSI presentation address as defined in RFC 1278 For example, TELEX+00728722+RFC-1006+03+10.0.0.6

LDAP Syntax	OID	Description
Printable String	1.3.6.1.4.1.1466.115.1	String of one or more printable ASCII alphabetic, numeric, and punctuation characters as defined in RFC 4517
RFC3672 Subtree Specification	1.3.6.1.4.1.1466.115.1	Syntax based on subtree specification as defined as RFC 3672
Supported Algorithm	1.3.6.1.4.1.1466.115.1	Octet string based on the LDAP-encoding for a supported algorithm value that results from the BER encoding of a SupportedAlgorithm ASN.1 value
Telephone Number	1.3.6.1.4.1.1466.115.1	String of printable international telephone number representations in E.123 format as defined in RFC 4517 For example, +1 512 904 5525
Teletex Terminal Identifier	1.3.6.1.4.1.1466.115.1	Identifier and telex terminal as defined in RFC 4517
Telex Number	1.3.6.1.4.1.1466.115.1	String representing the telex number, country code, and answerback code as defined in RFC 4517 For example, 812374, ch, ehhg
UTC Time	1.3.6.1.4.1.1466.115.1	Character string representing the data and time in UTC Time format as defined as RFC 4517 : YMMDDHHMM[SS] [(+ -)HHMM] Z], where Z is the coordinated universal time. For example, 0903051035Z, 0903051035-0500
LDAP Syntax Description	1.3.6.1.4.1.1466.115.1	Syntax Description as defined in RFC 4512
Substring Assertion	1.3.6.1.4.1.1466.115.1	Syntax for assertion values in an extensible match as defined in RFC 4517
Authentication Password Syntax	1.3.6.1.4.1.4203.1.1.2	Encoded password storage syntax as defined in RFC 3112 For example, the syntax specifies the storage scheme in brackets: <storage-scheme>\$<auth component>\$<auth value> For example, SSHA\$xdezWRqgyJk=\$egDEFDXvdeeEnXUEIDPnd39dkpe=

LDAP Syntax	OID	Description
User Password Syntax	1.3.6.1.4.1.30221.1.3	Encoded password storage syntax as defined in RFC 2307 For example, the syntax specifies the storage scheme in brackets: {SSHA}XaljOF0ii3fOwCrU1klgBpWFayqSYs+5W1pMnw==
Relative Subtree Specification	1.3.6.1.4.1.30221.1.3	Similar to the RFC 3672 subtree specification except it uses an LDAP search filter as the specification filter
Absolute Subtree Specification	1.3.6.1.4.1.30221.1.3	Syntax for a subset of entries in a subtree based on RFC 3672
Sun-defined Access Control Information	1.3.6.1.4.1.30221.1.3	Syntax for access control instructions used in Sun Directory Servers
Compact Timestamp	1.3.6.1.4.1.30221.2.3	Syntax based on Compact Timestamp ISO 8601 format For example, 20110306T102532

Basic attribute syntax properties

The following table provides a description of the standard elements in an attribute syntax.

Attributes	Description
Name	Specifies the descriptive and unique name of the element
Description	Indicates an optional definition that describes the attribute syntax The analogous LDIF equivalent is <code>DESC</code> .
OID	Specifies the globally unique object identifier assigned to the schema definition
Used by Attributes	Indicates any attributes that use the corresponding attribute syntax

Viewing attribute syntaxes

To view the attribute syntaxes on your Directory Server, use the Schema Editor, LDAP with `ldapsearch`, or a third-party tool.

About this task

To view attribute syntaxes over LDAP:

Steps

- To view the Directory Server's published list of attribute syntaxes, run **ldapsearch** using the `ldapSyntaxes` attribute.

Example:

The following example uses **ldapsearch** to view the Directory Server's published list of attribute syntaxes using the multi-valued operational attribute, `ldapSyntaxes`, which publishes the definitions on the Directory Server.

Note:

The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base "(objectclass=*)" ldapSyntaxes
```

Using the Schema Editor utilities

The Schema Editor provides a **Schema Utilities** tab that enables importing new schema elements from a file and checking schema compliance.

About this task

If you are importing a schema file, the system automatically checks for compliance before the import. If the definition doesn't meet schema compliance, the system displays an error message. However, you should check if your file is compliant with your schema prior to importing it.

To check schema compliance using the Schema Editor:

Steps

1. Start the Administrative Console.
2. In the main menu, click **LDAP Schema**.
3. In the Schema Editor, click the **Schema Utilities** tab.
4. Add your schema definition using one of two methods:
Choose from:
 - To have the system check an LDIF file, click **Import Schema Elements** and select a file to upload.
 - Copy and paste a new schema definition into the field.
5. Click **Validate Entries**.

Result: If there is a problem with your definition, an error message is generated.

Modifying a schema definition

You can only edit schema definitions in Directory Server that are read-write. The schema elements indicated by the **Modifiable** column in the Schema Editor's tables can be modified.

Before you begin

Ensure that your Directory Server instance is running.

About this task

To modify a schema definition:

Steps

1. Start the Administrative Console.
2. In the main menu, click **Schema**.
3. On the Schema Editor, click the **Object Classes** tab.
4. Select the object class that you want to modify, and then click **Actions # Edit**.
Result: The **Edit** dialog box appears.
5. Make your changes and click **OK**.

Deleting a schema definition

You can only delete schema definitions in Directory Server that are read-write. In general, you can only remove schema definitions in the **Custom** folder of the Schema Editor.

Before you begin

Ensure that your Directory Server instance is running.

About this task

Ensure that the schema element you are deleting is not currently in use.

To delete a schema definition:

Steps

1. Start the Administrative Console.
2. In the main menu, click **Schema**.
3. On the **Schema Editor**, click the **Object Classes** tab.
4. Select the object class that you want to remove, and then click **Actions # Delete**.
Result: The **Confirmation** dialog box opens.
5. To delete the schema element, click **Yes**.

Managing schema checking

PingDirectory Server provides full support for parsing all schema elements and provides access to all of its components.

By default, the Directory Server enables schema checking for all operations, especially when importing data to the server or when modifying entries using the `ldapmodify` tool. Any schema violations generate an error message to standard output.

Viewing the schema checking properties

Steps

- To view the schema checking property, run `dsconfig` with the `get-global-configuration-prop` option.

Example:

```
$ bin/dsconfig get-global-configuration-prop \
  --property check-schema
```

Disabling schema checking

Although you can use the `dsconfig` tool to disable the schema checking, it's not recommended.

About this task

This feature only applies to public backends. Schema checking is enforced on private backends, such as changes to the configuration, schema, task, and others. An admin action alert is generated if you attempt to disable schema checking using `dsconfig` in interactive or non-interactive mode. The alert provides alternatives to disabling schema checking.

Steps

1. To disable the `check-schema` property, run `dsconfig` with the `set-global-configuration-prop` option.

Example:

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
  --set check-schema:false
```

Result:

The system generates an admin action alert that provides alternate options to disabling schema checking.

```
One or more configuration property changes require administrative action
or
confirmation/notification.
```

Those properties include:

- * `check-schema`: Schema checking should only be disabled as a last resort since disabling schema checking harms performance and can lead to unexpected behavior in the server as well as the applications that access it. There are less severe options for addressing schema issues:
 1. Update the data to conform to the server schema.
 2. Modify the server schema to conform to the data. Contact support before modifying the server's default schema.
 3. Change the `single-structural-objectclass-behavior` property to allow entries to have no structural object class or multiple structural object classes.
 4. Change the `invalid-attribute-syntax-behavior` property to allow attribute values to violate their attribute syntax.
 5. Change the `allow-zero-length-values` property of the Directory String Attribute Syntax configuration to allow attributes with this syntax to have a zero length value.

```
Continue? Choose 'no' to return to the previous step (yes / no) [yes]:
```

2. To continue the process of disabling the schema checking instead of following one of the alternate options, press Enter.

Managing matching rule uses

Matching rule use definitions map certain attribute types with a matching rule definition for extensible match filters.

Extensible match filters allow clients to search using distinguished name (DN) components, such as (`ou:dn:=engineering`), or using an OID number, such as (`cn:1.2.3.4:=Sam Carter`). The matching rule use attribute publishes those attribute types and matching rule combinations, which can be used in extensible match assertions.

Typically, you define a matching rule use that isn't normally specified in the attribute type definition. You can create new matching rule uses from the existing schema definitions by adding a custom schema file in the `<server-root>/config/schema` directory.

Matching rule use definitions

Matching rule uses can be specified with existing schema components and don't require additional code for implementation.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.4.

```
MatchingRuleUseDescription = "(" wsp
numericoid                 ; Object identifier
[ sp "NAME" sp qdescrs ]   ; Short name descriptor
[ sp "DESC" sp qdstring ]  ; Description
[ sp "OBSOLETE" ]         ; Specifies if the rule use is inactive
sp "APPLIES" sp oid       ; Attribute types
extensions wsp ")"        ; Extensions followed by a white space and ")"
```

The following extensions are specific to PingDirectory Server and aren't defined in RFC 4512.

```
extensions = /
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the
  definition
"X-READ-ONLY"           ; True or False. Specifies if the file that
  contains
  the                    ; the schema element is marked as read-only in
                        ; server configuration.
```

Viewing matching rule uses

About this task

A matching rule use lists the attribute types that are suitable for use with an `extensibleMatch` search filter.

Steps

- To view the Directory Server's published list of matching rule uses that use the operational attribute `matchingRuleUse`, run `ldapsearch`.

Note:

The multi-valued operational attribute `matchingRuleUse` publishes the definitions on the Directory Server, if any. The attribute is stored in the subschema subentry.

Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" matchingRuleUse
```

Managing DIT content rules

Directory information tree (DIT) content rules provide a way to precisely define what attributes might be present in an entry based on its structural object class without specifically creating a new object class definition.

The DIT content rules can define the following:

- Mandatory and optional attributes that entries contain
- The set of auxiliary object classes that entries can be part of
- Any optional attributes from the structural and auxiliary object classes that are prohibited from being present in the entries

DIT content rule definitions

DIT content rules can be specified with existing schema components and don't require additional code for implementation.

On PingDirectory Server, only one DIT content rule can be defined for an entry in the structural object class.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.6.

```
DITContentRuleDescription = "(" wsp
numericoid                 ; Object identifier of the structural object
  class the rule applies to
[ sp "NAME" sp qdescrs ]   ; Short name descriptor
[ sp "DESC" sp qdstring ]  ; Description
[ sp "OBSOLETE" ]         ; Specifies if the rule is inactive
[ sp "AUX" sp oids ]      ; List of allowed auxiliary object classes
[ sp "MUST" sp oids ]     ; List of required attributes
[ sp "MAY" sp oids ]      ; List of allowed attributes in the entry
[ sp "NOT" sp oids ]      ; List of prohibited attributes in the entry
extensions wsp ")"        ; Extensions followed by a white space and ")"
```

The following extensions are specific to PingDirectory Server and aren't defined in RFC 4512.

```
extensions = /
"X-ORIGIN" /              ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the
  definition
"X-READ-ONLY"            ; True or False. Specifies if the file that
  contains
                          ; the schema element is marked as read-only in
                          ; the server configuration.
```

Viewing DIT content rules

Steps

- To view the `dITContentRules` attribute, run `ldapsearch`.

Note:

`dITContentRules` is a multi-valued operational attribute that publishes the definitions on the Directory Server, if any. The attribute is stored in the subschema subentry.

Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" dITContentRules
```

Managing name forms

Name forms define how entries can be named based on their structural object class.

Specifically, name forms specify the structural object class you are naming as well as the mutually-exclusive set of required and allowed attributes to form the relative distinguished names (RDNs) of the entries. Each structural object class can be associated with at most one name form definition.

Name form definitions

Name forms can be specified with existing schema components and don't require additional code for implementation.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.7.2.

```
NameFormDescription = "(" wsp
numericoid           ; object identifier
[ sp "NAME" sp qdescrs ] ; short name descriptor
[ sp "DESC" sp qdstring ] ; description
[ sp "OBSOLETE" ]    ; not active
sp "OC" sp oid       ; structural object class
sp "MUST" SP oids    ; attribute types
[ sp "MAY" sp oids ] ; attribute types
extensions wsp ")"   ; extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory Server and aren't defined in RFC 4512.

```
extensions = /
"X-ORIGIN" /           ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /     ; Specifies which schema file contains the
  definition
"X-READ-ONLY"         ; True or False. Specifies if the file that
  contains
                       ; the schema element is marked as read-only in
                       ; the server configuration.
```

Viewing name forms

Steps

- To view the `nameForms` attribute, run `ldapsearch`.

Note:

`nameForms` is a multi-valued operational attribute that publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
"(objectclass=*)" nameForms
```

Managing DIT structure rules

Directory information tree (DIT) structure rules define which entries might be superior or subordinate to other entries in the DIT.

Together with name forms, DIT structure rules determine how relative distinguished names (RDNs) are added together to make up distinguished names (DNs). Because DITs don't have a global standard and are specific to a company's implementation, each DIT structure rule associates a name form with an object class and specifies each structure rule with an integer rule identifier, instead of an OID number. The identifier defines its relationship, either superior or subordinate, to another object class. If no superior rules are specified, the DIT structure rule applies to the root of the subtree.

DIT structure rule definition

DIT structure rules can be specified with existing schema components and don't require additional code for implementation.

The following formal specification for attribute types is provided in [RFC 4512](#), section 4.1.7.1.

```
DITStructureRuleDescription = "(" wsp
ruleid                       ; object identifier
[ sp "NAME" sp qdescrs ]     ; short name descriptor
[ sp "DESC" sp qdstring ]    ; description
[ sp "OBSOLETE" ]           ; specifies if the rule is inactive
sp "FORM" sp oid             ; OID or name form with which the rule is
associated
[ sp "SUP" ruleids ]         ; Superior rule IDs
extensions wsp ")"          ; extensions followed by a white space and ")"
```

The following extensions are specific to PingDirectory Server and are not defined in RFC 4512.

```
extensions = /
"X-ORIGIN" /                 ; Specifies where the rule is defined
"X-SCHEMA-FILE" /           ; Specifies which schema file contains the
definition
"X-READ-ONLY"                ; True or False. Specifies if the file that
contains
                               ; the schema element is marked as read-only in
                               ; the server configuration.
```

Viewing DIT structure rules

Steps

- To view the `dITStructureRules` attribute, run `ldapsearch`.

Note:

`dITStructureRules` is a multi-valued operational attribute that publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" dITStructureRules
```

About managing JSON attribute values

PingDirectory Server supports a JSON object attribute syntax that can be used for attribute types whose values are JSON objects. The syntax requires that each value of this type is a valid JSON object.

The following is an example schema definition.

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( jsonAttr1-OID NAME 'jsonAttr1' DESC 'test json attribute
  support' EQUALITY jsonObjectExactMatch SYNTAX 1.3.6.1.4.1.30221.2.3.4 USAGE
  userApplications )
objectClasses: ( jsonObjectClass-OID NAME 'jsonObjectClass' AUXILIARY MAY
  jsonAttr1 )
```

Note:

You should always specify the `EQUALITY` matching rule as `jsonObjectExactMatch` in the schema definition. Using the `jsonObjectFilterExtensibleMatch` isn't valid in this case.

The `jsonObjectExactMatch` and `jsonObjectFilterExtensibleMatch` matching rules are provided to filter equality matching rule JSON object syntax. The following three additional matching rules are used in conjunction with `jsonObjectExactMatch` and provide support for customizing the way that the server treats case sensitivity in JSON field names and in string values:

- `jsonObjectCaseSensitiveNamesCaseSensitiveValues`
- `jsonObjectCaseInsensitiveNamesCaseInsensitiveValues`
- `jsonObjectCaseInsensitiveNamesCaseSensitiveValues`

The `jsonObjectExactMatch` equality matching rule is used in evaluating equality filters in **search** operations, and for matching performed against JSON object attributes for **add**, **compare**, and **modify** operations. It determines whether two values are logically-equivalent JSON objects. The field names used in both objects must match exactly, although fields may appear in different orders. The values of each field must have the same data types. The order of elements in arrays is considered significant. Substring or approximate matching isn't supported.

The `jsonObjectFilterExtensibleMatch` matching rule can perform more powerful matching against JSON objects. The assertion values for these extensible matching filters should be JSON objects that

express the constraints for the matching. These JSON object filters are described in detail in the Javadoc documentation for the LDAP SDK for Java. Although the LDAP SDK can facilitate searches with this matching rule, these searches can be issued through any LDAP client API that supports extensible matching.

The following are example searches using the `jsonObjectFilterExtensibleMatch` rule with available filter types:

"equals" filter type

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com
-D "cn=Directory Manager" -w password
'(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
"equals", "field" : ["stuff", "onetype", "name"], "value" : "John
Doe" })'
```

"containsField" filter type

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com
-D "cn=Directory Manager" -w password
'(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
"containsField", "field" : "age", "expectedType" : "number" })'
```

"greaterThan" filter type

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com
-D "cn=Directory Manager" -w password
'(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
"greaterThan", "field" : "age", "value" : 26, "allowEquals" : true})'
```

Configuring JSON attribute constraints

PingDirectory Server can define a number of constraints for the fields included in JSON objects stored in values of a specified attribute type.

Defining constraints on JSON object fields allows administrators to set requirements on what values a JSON field may take to ensure consistency across entries.

Constraints that can be placed on a JSON field include:

- Requiring values of the field to have a specified data type.
- Indicating whether the field is required or optional.
- Indicating whether the field can have multiple values in an array. If a field is permitted to have array values, restrictions can also be placed on the number of elements that can be present in the array.
- Indicating whether the field can have a value that is the null primitive as an alternative to values of the indicated data type.
- Restricting values of string fields to a predefined set of values that match a given regular expression or to a length specified by the user.
- Restricting values of numeric fields with upper and lower bounds.

Note:

Only new entries are subject to the new constraints. Existing data that doesn't match newly-defined JSON constraints can still be decoded and managed by the server. Attempts to alter existing entries with non-compliant JSON objects might require fixing those objects to conform to the new constraints.

The global configuration properties that define schema constraints for JSON objects are `create-json-attribute-constraints` and `create-json-field-constraints` in **dsconfig**. In **dsconfig** interactive, under advanced settings, the menu options are `JSON Attribute Constraints` and `JSON Field Constraints`.

Configuration properties for each include:

attribute-type

The name or object identifier of the attribute type with which the definition is associated. This attribute type must have the JSON object syntax. **attribute-type** is the naming attribute for the configuration entry.

allow-unnamed-fields

A Boolean value that indicates whether JSON objects, used as the values of attributes of the associated type, can include fields that are not referenced in the `attribute-value-constraints` object. The default value is `true`.

If **allow-unnamed-fields** is `true` JSON objects can have fields that are not referenced, and no constraints are imposed on those fields. If **allow-unnamed-fields** is `false`, JSON objects can only have the defined fields.

Note:

Unless a schema definition is configured with `allow-unnamed-fields` set to `false`, only information about fields whose values should be indexed or tokenized is required. To ensure that clients cannot store invalid values, you should define any other expected fields. .

As with the standard LDAP schema, JSON schema constraints are enforced for any changes made after the constraints are defined. If there are already JSON values in the data before a JSON schema is defined for that attribute type, or before changes are made, values that already exist might violate those constraints. JSON schema constraints are also enforced for data provided in an LDIF import, and entries containing JSON objects that violate these constraints are rejected.

JSON Field Constraints

Property	Description
<code>field</code>	Specifies the path to the target field as a string with periods to separate levels of hierarchy. If any field name in the hierarchy includes a period, then that period must be escaped with a backslash.

Property	Description
value-type	<p>Specifies the expected data type for the target field.</p> <p>The available values are:</p> <p>any</p> <p>The target field can have any value.</p> <p>boolean</p> <p>The target field must have a value of <code>true</code> or <code>false</code>.</p> <p>integer</p> <p>The target field must have a number that can be exactly represented as an integer.</p> <p>null</p> <p>The target field must have a value of <code>null</code>.</p> <p>number</p> <p>The target field must have a value that represents a valid JSON number.</p> <p>object</p> <p>The target field must have a value that represents a valid JSON object. The <code>allowed-fields</code> array can contain additional elements that define constraints for the fields.</p> <p>string</p> <p>The target field must have a value that represents a valid JSON string.</p>
is-required	<p>Specifies whether the target field is required to be present.</p> <p>If the target field is present, its value must be either <code>true</code> or <code>false</code>. If it is absent, a default of <code>false</code> is assumed.</p>
is-array	<p>Indicates whether the target field can be an array.</p> <p>If the value can be an array, all of the elements of the array must be of the type specified in the <code>value-type</code> field. The field constraint can be present with a value of one of the single strings listed below. If the constraint is absent, a value of <code>prohibited</code> is assumed.</p> <p>Values are:</p> <p>required</p> <p>The target field must be an array with zero or more values of the specified type and must not be a single value of the specified type.</p> <p>optional</p> <p>The target field can be an array with zero or more values of the specified type, or it can be a single value of the specified type.</p> <p>prohibited</p> <p>The target field must not be an array and can only be a single value of the specified type.</p>

Property	Description
<code>allow-null-value</code>	<p>Specifies whether the target field can have a value of <code>null</code> as an alternative to the specified <code>value-type</code>.</p> <p>If the field constraint is present, <code>allows-null-value</code>'s value must be either <code>true</code> or <code>false</code>. If the constraint is absent, a default of <code>false</code> is assumed. <code>allow-null-value</code> has no effect if the <code>value-type</code> is <code>null</code>.</p>
<code>allow-empty-object</code>	<p>Specifies whether empty objects are permitted if the value of the target field is a JSON object or an array of JSON objects.</p> <p>If the field constraint is present, the value must be either <code>true</code>, where the object can have zero or more fields, or <code>false</code>, where the object can have one or more fields. If the constraint is absent, a default of <code>false</code> is assumed.</p>
<code>index-values</code>	<p>Specifies whether values of the target field should be indexed in backends.</p> <p>If the field constraint is present, the value must be either <code>true</code> (the field should be indexed) or <code>false</code> (the field should not be indexed). If the constraint is absent, a default of <code>false</code> is assumed. If <code>true</code>, the <code>value-type</code> must be <code>boolean</code>, <code>integer</code>, <code>null</code>, or <code>string</code>.</p>
<code>index-entry-limit</code>	<p>Specifies the maximum number of entries in which a particular value can appear before the entry ID list for that value is no longer maintained.</p> <p>If the field constraint is present, the value must be an integer greater than or equal to 1. If the constraint is absent, the server uses the default index entry limit for the associated backend. This is only applicable if <code>index-values</code> is <code>true</code>.</p>
<code>prime-index</code>	<p>Specifies whether backends should prime the contents of the JSON index database into memory when they are opened.</p> <p>This is ignored if the backend's <code>prime-all-indexes</code> property has a value of <code>true</code>.</p>
<code>cache-mode</code>	<p>Specifies the cache mode to use for the contents of the JSON index database.</p> <p>If the value is not specified, the backend's default cache mode is used. If a cache mode of <code>cache-keys-only</code> is configured, priming only loads the internal nodes into memory for the index. If <code>no-caching</code> is configured, no priming is performed for the index.</p>
<code>tokenize-values</code>	<p>Specifies whether values of the target field should be tokenized in backends.</p> <p>If the field constraint is present, the value is either <code>true</code> (field values should be tokenized) or <code>false</code> (field values should not be tokenized). If the constraint is absent, a value of <code>false</code> is assumed. If <code>true</code>, the <code>value-type</code> must be <code>string</code>.</p>
<code>allowed-values</code>	<p>Specifies an explicit set of values allowed in the target field .</p> <p>If the field constraint is present, the value must be an array of strings. Any attempt to use a value not in this array for the associated field is rejected. <code>allowed-values</code> can only be used with a <code>value-type</code> of <code>string</code>. If the constraint is absent, any value can be used as long as it satisfies all other defined constraints.</p>

Property	Description
<code>allowed-value-regular-expression</code>	<p>Specifies a regular expression that the target field must match</p> <p>If the field constraint is present, the value must be a single string or an array of strings representing valid regular expressions (which might require escaping to represent in JSON). Any attempt to use a value that does not match one of the provided regular expressions is rejected. <code>allowed-value-regular-expression</code> can only be used with a <code>value-type</code> of <code>string</code>. If the constraint is absent, values are not required to match any regular expression.</p>
<code>minimum-numeric-value</code>	<p>Specifies the lower bound for values of the target field</p> <p>If the field constraint is present, the value must be a single number and can be an integer. Any attempt to use a value that is less than this number is rejected. <code>minimum-numeric-value</code> can only be used with a <code>value-type</code> of <code>integer</code> or <code>number</code>. If the constraint is absent, no minimum numeric value applies.</p>
<code>maximum-numeric-value</code>	<p>Specifies the upper bound for values of the target field</p> <p>If the field constraint is present, the value must be a single number and can be an integer. Any attempt to use a value that is greater than this number is rejected. <code>maximum-numeric-value</code> can only be used with a <code>value-type</code> of <code>integer</code> or <code>number</code>. If the constraint is absent, no maximum numeric value applies.</p>
<code>minimum-value-length</code>	<p>Specifies the minimum number of characters allowed for values of the target field</p> <p>If the field constraint is present, the value must be an integer. Any attempt to use a value with fewer characters than this number is rejected. <code>minimum-value-length</code> can only be used with a <code>value-type</code> of <code>string</code>. If the constraint is absent, no minimum length applies.</p>
<code>maximum-value-length</code>	<p>Specifies the maximum number of characters allowed for values of the target field</p> <p>If the field constraint is present, the value must be an integer. Any attempt to use a value with more characters than this number is rejected. <code>maximum-value-length</code> can only be used with a <code>value-type</code> of <code>string</code>. If the constraint is absent, no maximum length applies.</p>
<code>minimum-value-count</code>	<p>Specifies the minimum number of elements that must be present in an array</p> <p>If the field constraint is present, the value must be an integer. Any attempt to use an array with fewer elements is rejected. <code>minimum-value-count</code> can only be used with an <code>is-array</code> value of <code>required</code> or <code>optional</code>. If the constraint is absent, no minimum array value count applies.</p>
<code>maximum-value-count</code>	<p>Specifies the maximum number of elements that must be present in an array</p> <p>If the field constraint is present, the value must be an integer. Any attempt to use an array with more elements is rejected. <code>maximum-value-count</code> can only be used with an <code>is-array</code> value of <code>required</code> or <code>optional</code>. If the constraint is absent, no maximum array value count applies.</p>

When writing JSON objects in a local database backend, field names and JSON primitive values of `null`, `true`, and `false` are always tokenized. Integers are either tokenized or compacted using their two's

complement representation. Other numbers are stored using string representations. Array and object sizes are compacted, and their contents are compacted based on their data types.

String values are tokenized and match a recognizable format, including:

- Dates and times in common generalized time and ISO 8601 formats
- UUIDs in which the alphabetic characters are either all uppercase or all lowercase
- Strings of at least 12 bytes that are a valid base64 encoding
- Strings of at least 6 bytes that are a valid hexadecimal encoding, in which the alphabetic characters are either all uppercase or all lowercase

Adding constraints to JSON attributes

About this task

To create and configure JSON attribute constraints:

Steps

- Run `dsconfig` with the `create-json-attribute-constraints` option.

Example:

In this example, a JSON attribute constraint is defined on the `appjson` attribute type. This constrains values of the `appjson` attribute to be JSON objects. Because `allow-unnamed-fields` is set to `false`, those JSON objects can only have fields for which there is a corresponding JSON field constraints definition.

Note:

`appjson` is meant to be replaced by the name of the user's desired attribute type, as defined in the directory schema. For more information, see [About managing JSON attribute values](#) on page 523.

```
$ bin/dsconfig create-json-attribute-constraints \
  --attribute-type appjson \
  --set enabled:true \
  --set allow-unnamed-fields:false
```

Example:

In this example, a JSON field constraint object is defined for the `email.verified` field. The `email.verified` field must be present and must take a boolean value.

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type appjson \
  --json-field email.verified \
  --set value-type:boolean \
  --set is-required:true \
  --set index-values:false \
  --set tokenize-values:false \
  --set allow-null-value:true
```

Example:

In this example, a JSON field constraint object is defined for the `email.type` field. The `email.type` field must be present and must take a value of `home`, `work`, or `other`.

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type appjson \
  --json-field email.type \
```

```
--set value-type:string \
--set is-required:true \
--set index-values:false \
--set tokenize-values:true \
--set allowed-value:home \
--set allowed-value:other \
--set allowed-value:work \
--set allow-null-value:false
```

Example:

In this example, a JSON field constraint is defined for the `email.value` field. The `email.value` field must be present and must take a string value that matches the specified regular expression.

```
$ bin/dsconfig create-json-field-constraints \
--attribute-type appjson \
--json-field email.value \
--set value-type:string \
--set is-required:true \
--set index-values:true \
--set tokenize-values:false \
--set prime-index:true \
--set allow-null-value:true \
--set maximum-value-length:256 \
--set minimum-value-length:1 \
--set allowed-value-regular-expression:[-_]+\.\w\d]+@w+\.\w{2,5}
```

Managing password policies

The PingDirectory Server provides a flexible password policy system to assign, manage, or remove password policies for root and non-root users.

The password policy contains configurable properties for password expiration, failed sign-on attempts, account lockout, and other aspects of password and account maintenance on the Directory Server. The Directory Server also provides a global configuration option and a per-user privilege feature that disables parts of the password policy evaluation for production environments that don't require a password policy.

Viewing password policies

Password policies enforce rules that ensure that access to data is not compromised through negligent password practices.

The PingDirectory Server provides mechanisms to create and maintain password policies that determine:

- Whether passwords should expire
- Whether users are allowed to modify their own passwords
- Whether too many failed authentication attempts should result in an account lockout

Many other options are available to fully configure a password policy for your PingData Platform system.

The Directory Server provides three out-of-the-box password policies that you can apply to your entries or as templates for configuring customized policies:

Default password policy

The default password policy is automatically applied to all users although it is possible to use an alternate password policy on a per-user basis.

Root password policy

The root password policy is enforced for the default root user, which uses a stronger password storage scheme (PBKDF2 instead of the salted 256-bit SHA-2 scheme) and requires that a root user provide their current password to select a new password.

Secure password policy

The secure password policy provides a more secure option than the default policy that makes use of a number of features, including password expiration, account lockout, last sign-on time and last sign-on IP address tracking, password history, and a number of password validators.

CAUTION:

Using the Secure password policy as-is might notably increase write load in the server by requiring updates to password policy state attributes in user entries and by requiring users to change passwords more frequently. In environments where write throughput is a concern (including environments spread across multiple data centers requiring replication over a WAN), it might be useful to consider whether the policy should be updated to reduce the number of required entry updates.

Viewing password policies

About this task

To view the list of password policies configured on the Directory Server:

Steps

- Do one of the following:
Choose from:
 - Run the `dsconfig` tool in either interactive or non-interactive mode.
 - Use the Administrative Console.

Example:

The following example demonstrates the process for obtaining a list of defined password policies in non-interactive mode.

```
$ bin/dsconfig list-password-policies
```

Result:

```
Password Policy      : Type : password-attribute : default-password-
storage-scheme
-----:-----:-----:-----
Default Password Policy : generic : userpassword      : Salted 256-bit
SHA-2
Root Password Policy   : generic : userpassword      : PBKDF2
Secure Password Policy : generic : userpassword      : PBKDF2
```

Viewing a specific password policy

About this task

To view a specific password policy:

Steps

- Do one of the following:
Choose from:
 - Run the `dsconfig` tool.
 - Use the Administrative Console.

Example:

This example uses `dsconfig` to view the default password policy that applies to all uses for which no specific policy is configured.

```
$ bin/dsconfig get-password-policy-prop \
  --policy-name "Default Password Policy"
```

Result:

Property	: Value(s)
description	: -
password-attribute	: userpassword
default-password-storage-scheme	: Salted SHA-1
deprecated-password-storage-scheme	: -
password-validator	: -
account-status-notification-handler	: -
allow-user-password-changes	: true
password-change-requires-current-password	: false
force-change-on-add	: false
force-change-on-reset	: false
password-generator	: Random Password Generator
require-secure-authentication	: false
require-secure-password-changes	: false
min-password-age	: 0s
max-password-age	: 0s
max-password-reset-age	: 0s
password-expiration-warning-interval	: 5d
expire-passwords-without-warning	: false
allow-expired-password-changes	: false

last-login-time-format	: -
previous-last-login-time-format	: -
idle-lockout-interval	: 0s
password-history-count	: 0s
password-history-duration	: 0s

About the password policy properties

The Directory Server provides a number of configurable properties that you can use to control password policy behavior.

Note:

To view a description of each of the password policy properties, see the Ping Identity Directory Server Configuration Reference that is bundled with the PingDirectory Server.

Some of the most notable properties include:

`allow-user-password-changes`

Specifies whether users can change their own passwords. If a user attempts to change their own password, then the server consults this property for the user's password policy and ensures that the access control handler allows the user to modify the configured password attribute.

`default-password-storage-scheme`

Specifies the names of the password storage schemes that are used to encode clear-text passwords for this password policy.

`enable-debug`

When enabled, is used to debug password policy interaction. This property should be used in addition to the server's debug framework with a relevant debug target.

`force-change-on-add`

Specifies whether users are required to change their passwords upon first authenticating to the Directory Server after their account is created.

`force-change-on-reset`

Specifies whether users are required to change their passwords after they're reset by an administrator. An administrator is a user who has the `password-reset` privilege and the appropriate access control instruction to allow modification of other users' passwords.

`idle-lockout-interval`

Specifies the maximum length of time that an account can remain idle (the associated user does not authenticate to the server) before that user is locked out. For accounts that don't have a last sign-on time value, the password changed time or the account creation time is used. If that information is not available, then the user isn't allowed to authenticate.

Note:

The server should be allowed to run for a period of time with last sign-on time tracking enabled, such as values for both `last-login-time-attribute` and `last-login-time-format` properties to ensure that users have a last sign-on time before enabling idle account lockout.

`lockout-duration`

Specifies the length of time that an account is locked after too many authentication failures. The value of this attribute is an integer followed by a unit of seconds, minutes, hours, days, or weeks. A value of 0 seconds indicates that the account must remain locked until an administrator resets the password.

`lockout-failure-count`

Specifies the maximum number of times that a user can attempt to bind with the wrong password before that user's account becomes locked either temporarily (in which case the account is automatically unlocked after a configurable length of time) or permanently (in which case an administrator must reset the user's password before the account is used again). For example, if the value is set to 3, the user is locked out after three failed attempts, even if a fourth attempt is made with the correct password.

`max-password-age`

Specifies the maximum length of time that a user can continue to use the same password before they must choose a new one. The value can be expressed in seconds (s), minutes (m), hours (h),

days (d), or weeks (w). You can specify a minimum length of time before the user can change the password.

`password-change-requires-current-password`

Specifies whether users must include their current password when changing their password. This applies for both password changes made with the password modify extended operation as well as simple modify operations targeting the password attribute. In the latter case, if the current password is required then the password modification must remove the current value and add the desired new value (providing both the current and new passwords in the clear rather than using encoded representations).

`password-expiration-warning-interval`

Specifies the length of time before a user's password expires that they receive notification about the upcoming expiration (either through the password policy or password expiring response controls). The value can be expressed in seconds (s), minutes (m), hours (h), days (d), or weeks (w).

`password-retirement-behavior`

Specifies the behavior of a password that is allowed a retirement period before becoming invalid. You can use this setting by application service accounts that require a transition period while updating passwords. This is disabled by default.

`password-validator`

Specifies the names of the password validators that are used with the associated password storage scheme. The password validators are invoked when a user attempts to provide a new password to determine whether the new password is acceptable.

`require-secure-authentication`

Indicates whether users with the associated password policy are required to authenticate in a secure manner. This can mean either using a secure communication channel between the client and the server, or using a Simple Authentication and Security Layer (SASL) mechanism that doesn't expose the credentials.

`require-secure-password-changes`

Indicates whether users with the associated password policy are required to change their password in a secure manner that does not expose the credentials.

Note:

As an alternative to account lockout, you can set a **`failed-bind-response-delay`** configuration property on the LDAP connection handler to instruct the server to introduce a delay (such as one second) into the process of returning a response to an unsuccessful bind operation.

Delaying the response to a failed bind only affects the connection on which the bind was attempted, and still limits the rate at which a malicious client can try to guess a user's password. However, it won't affect other attempts to authenticate as that user on other connections, so the legitimate user can still authenticate with the correct password.

Access log

You can configure the server to maintain a recent sign-on history for both successful and failed sign-on attempts.

You can maintain this history by count or duration, and you can configure the history separately for successful and failed sign-on attempts. Each record in the sign-on history contains the following:

- The time of the sign-on attempt
- The client IP address

- The authentication method
- The reason for failure for failed attempts

You can collapse information about multiple similar attempts on the same date to avoid flooding the history for accounts that bind frequently. Records have an additional attempt count that tracks the number of attempts with the same client IP address, authentications method, and failure reason on the same date. You can configure the server to maintain each attempt separately, or to only update the history at most once per day.

Recent sign-on history is disabled by default. You can enable and configure the recent sign-on history in password policy. You can retrieve sign-on history with the `get recent login history` control, available in the LDAP SDK or with the `ldapsearch` and `ldapmodify` commands. The recent sign-on history is also available in the `ds-pwp-state-json` JSON attribute, the password policy state extended operation, and the `manage-account` command-line tool.

You can enable and configure the recent sign-on history with the following password policy configuration properties:

maximum-recent-login-history-successful-authentication-count

The maximum number of records that the server maintains about recent successful authentications.

maximum-recent-login-history-successful-authentication-duration

The maximum length of time for which the server maintains information about recent successful authentications.

maximum-recent-login-history-failed-authentication-count

The maximum number of records that the server maintains about recent failed authentication attempts.

maximum-recent-login-history-failed-authentication-duration

The maximum length of time for which the server maintains information about recent failed authentication attempts.

recent-login-history-similar-attempt-behavior

The behavior that the server exhibits for cases in which a user makes multiple authentication attempts on the same date in which all of the fields in the record other than the timestamp (`client-ip-address`, `authentication-method`, and potentially `failure-reason`) match.

Possible values for this property include the following:

collapse-similar-attempts-on-the-same-date

Indicates that the server only maintains one record for any given date with the same values for all non-timestamp fields, and it uses the `additional-attempt-count` field to keep track of the number of additional attempts that were collapsed into the same record. The timestamp field for that record reflects the most recent attempt on that date.

This is the default behavior.

maintain-every-attempt

Indicates that the server maintains a separate record for every attempt, regardless of how similar it is to a previous attempt although duplicate attempts within the same millisecond might not be preserved.

For more information, see [Replication considerations](#) on page 537.

update-at-most-once-per-day

Indicates that the server only maintains one record for any given date with the same values for all non-timestamp fields. This can help reduce the number of writes needed to maintain

a recent sign-on history, but the value of the timestamp field might not accurately reflect the timestamp of the most recent attempt.

None of these properties are defined by default. If at least one of these properties is defined, the server maintains a recent sign-on history within the specified constraints.

If both the `maximum-recent-login-history-successful-authentication-count` and `maximum-recent-login-history-successful-authentication-duration` properties are defined, the server uses the more-restrictive value that applies to a given user. This is also true for the `maximum-recent-login-history-failed-authentication-count` and `maximum-recent-login-history-failed-authentication-duration` properties. For example, if you configure the password policy to maintain a successful count of 10 and a successful duration of 30 days, then a user who successfully authenticates on more than 10 dates in a 30-day period would be capped at 10 records. A user who authenticates less frequently would only have records for however many attempts they made within those 30 days.

The server can collapse multiple authentication attempts from the same date into a single record if other fields in the record (`client-ip-address`, `authentication-method`, and potentially `failure-reason`) match. This caps the number of records that are maintained if you want to maintain records by duration rather than count. Because multiple records can be generated for the same user on the same date, if something is different (such as a different IP address or authentication method), there is technically no limit to the number of records that can be generated when using only a duration-based cap. To mitigate this, you can specify a maximum count to place an upper bound on what information the server maintains for a given user.

The password policy state for a given user is only updated when that user attempts to authenticate to the server. A user might have records in their entry for authentication attempts that occurred outside of the maximum duration if they have not made any authentication attempt within that duration.

If you configure the server to maintain recent sign-on history for successful authentication attempts, then it keeps a record of the most recent attempt even if the attempt occurs outside of the maximum duration.

Note:

If the `recent-login-history-similar-attempt-behavior` is set to `update-at-most-once-per-day`, it keeps an attempt from the same date as the most recent attempt.

If you configure the server to maintain a history of failed attempts, then it provides information about the most recent failed attempt even if it is older than the maximum duration.

If you configure the password policy to maintain a recent sign-on history, the `ds-pwp-state-json` virtual attribute includes a `recent-login-history` field whose value is a JSON object with the same representation used in the `get recent login history` response control. It can also include the following additional fields that provide information about related configuration in the password policy:

- `maximum-recent-login-history-successful-authentication-count`
- `maximum-recent-login-history-successful-authentication-duration-seconds`
- `maximum-recent-login-history-failed-authentication-count`
- `maximum-recent-login-history-failed-authentication-duration-seconds`

The password policy state extended operation provides support for two additional operations:

- An operation you can use to retrieve the recent sign-on history. The value returned in this operation is a JSON object in the same format as used in the `get recent login history` response control and the `ds-pwp-state-json` virtual attribute.
- An operation that you can use to clear the `get recent login history` for a user.

Replication considerations

Each sign-on attempt is maintained as a separate attribute value to avoid the potential for data loss as a result of replication propagation delay.

If a record of all sign-on attempts was maintained within a single JSON object, the object written on one server would not reflect concurrent attempts made on other servers, and replication would only use what it perceives to be the most recent value rather than attempting to merge the values.

It is possible that information about one or more attempts made around the same time could be lost. This includes the following cases:

- If the server is not configured to collapse information about multiple similar attempts, then it will not record information about multiple similar attempts made within the same millisecond because that would result in duplicate attribute values.
- If the server is configured to collapse information about multiple similar attempts, then concurrent modifications (especially on different servers) might cause the `additional-attempt-count` value to be incremented to the same value on each of those servers.

Note:

If the concurrent attempts occur within the same millisecond, then only one of them is preserved and any others are lost. If the attempts do not occur within the same millisecond, then you can infer the correct value during internal processing, but there might still be corner cases in which the server loses information about one or more attempts.

Get Recent Login History control

You can use a pair of request and response controls to obtain the recent sign-on history.

The request control, which has an OID of 1.3.6.1.4.1.30221.2.5.61 and no value, can be included in a bind request to indicate that the server should return the recent sign-on history in the bind response. This is provided in the response control, which has an OID of 1.3.6.1.4.1.30221.2.5.62 and a value containing only the string representation of a JSON object with the recent sign-on history.

The JSON object will have one or both of two top-level fields:

successful-attempts

This field is present if the server is configured to maintain a history of successful attempts, and its value is an array of JSON objects with information about those successful attempts.

In particular, each of those objects contains the following fields, as used in the `ds-pwp-recent-login-history-json` attribute:

- `timestamp`
- `client-ip-address`
- `authentication-method`
- `additional-attempt-count`

failed-attempts

This field is present if you configure the server to maintain a history of failed attempts, and its value is an array of JSON objects with information about these failed attempts.

In particular, each of those objects contains the following fields, as used in the `ds-pwp-recent-login-history-json` attribute:

- `timestamp`
- `client-ip-address`
- `authentication-method`
- `failure-reason`

- `additional-attempt-count`

The response control is only returned if the server is configured to maintain a recent sign-on history. When provided, the elements of the arrays are arranged in chronological order from most-recent to least-recent.

The UnboundID LDAP SDK for Java provides support for these controls, including enhanced support for retrieving information from the response control value. By ensuring that the request control does not have a value and that the response control value is a simple string, this information is readily accessible to applications using other APIs.

Modifying an existing password policy

Modify an existing password policy to meet your company's requirements.

About this task

Tip:

Keep your password policies synchronized across all PingDirectory Server and Directory Proxy Server instances.

To modify the configuration for any defined password policy:

Steps

- Choose one of the following methods:
Choose from:
 - Run the `dsconfig` tool in interactive or non-interactive mode.
 - Use the administrative console.

Example:

The following example sets some of the properties presented in the previous section for the default password policy using `dsconfig`.

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "max-password-age:90 days" \
  --set "password-expiration-warning-interval:14 days" \
  --set "lockout-failure-count:3" \
  --set "password-history-count:6"
```

Creating new password policies

You can create new password policies that meet your organization's requirements.

You can create any number of password policies in the Directory Server using either the `dsconfig` tool (in interactive or non-interactive mode) or the Administrative Console.

Creating a new password policy

Steps

- To create a new password policy:
Choose from:
 - Run **dsconfig** in interactive or non-interactive mode.
 - Use the administrative console.

Example:

This example demonstrates creating a new policy using **dsconfig** in non-interactive mode.

```
$ bin/dsconfig create-password-policy \
--policy-name "Demo Password Policy" \
--set "password-attribute:userpassword" \
--set "default-password-storage-scheme:Salted SHA-256" \
--set "force-change-on-add:true" \
--set "force-change-on-reset:true" \
--set "password-expiration-warning-interval:2 weeks" \
--set "max-password-age:90 days" \
--set "lockout-duration:24 hours" \
--set "lockout-failure-count:3" \
--set "password-change-requires-current-password:true"
```

Assigning a password policy to an individual account

About this task

Rather than a user automatically inheriting the default password policy, you can assign a user to a particular password policy by including the `ds-pwp-password-policy-dn` operational attribute in that user's entry with a value equal to the distinguished name (DN) of the desired password policy for that user. This operational attribute is explicitly included in a user's entry, or generated by a virtual attribute, which makes it easy to apply a custom password policy to a set of users based on a flexible set of criteria.

Steps

1. Create an LDIF file that adds the `ds-pwp-password-policy-dn` attribute with the password policy DN you want to assign to that user.

Example:

This example creates the file `assign.ldif` with the following contents.

```
dn: uid=user.1,ou=People,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Demo Password Policy,cn>Password
Policies,cn=config
```

2. To apply the modification to the user's entry, run **ldapmodify**.

Example:

For this example, the file used is `assign.ldif`.

```
$ bin/ldapmodify --filename assign.ldif
```

Assigning a password policy using a virtual attribute

About this task

You can automatically assign a custom password policy for a set of users using a virtual attribute. You can configure the virtual attribute so that it uses a range of criteria for selecting the entries for which the virtual attribute should appear.

Steps

1. Create an LDIF file, which you can use to add a group to the server.

Example:

```
dn: ou=Groups,dc=example,dc=com
objectClass: organizationalunit
objectClass: top
ou: Groups

dn: cn=Engineering Managers,ou=groups,dc=example,dc=com
objectClass: groupOfUniqueNames
objectClass: top
cn: Engineering Managers
uniqueMember: uid=user.0,ou=People,dc=example,dc=com ou: groups
```

2. To add the entries to the server, run the **ldapmodify** tool.

Example:

```
$ bin/ldapmodify --defaultAdd --filename groups.ldif
```

3. To create a virtual attribute, run **dsconfig**.

Example:

This virtual attribute adds the **ds-pwp-password-policy-dn** attribute with a value of **cn=Demo Password Policy,cn=Password Policies,cn=config** to the entries for all users that are members of the **cn=Engineering Managers,ou=Groups,dc=example,dc=com** group.

```
$ bin/dsconfig create-virtual-attribute \
  --name "Eng Mgrs Password Policy" \
  --type user-defined \
  --set "description:Eng Mgrs Grp PWPolicy" \
  --set enabled:true \
  --set attribute-type:ds-pwp-password-policy-dn \
  --set "value:cn=Demo Password Policy,cn=Password Policies,cn=config" \
  --set "group-dn:cn=Engineering Managers,ou=Groups,dc=example,dc=com"
```

4. To verify that a user in the group contains the assigned password policy distinguished name (DN), run the **ldapsearch** tool.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
  ds-pwp-password-policy-dn
```

Result:

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Demo Password Policy,cn=Password
Policies,cn=config
```

Deleting a password policy

You can delete a password policy with the `dsconfig` tool running in interactive or non-interactive mode.

About this task

Note:

You can also use the administrative console to delete a password policy.

Steps

- To delete a password policy, run the `dsconfig` command with the `delete-password-policy` subcommand.

Example:

```
$ bin/dsconfig delete-password-policy \
  --policy-name "Demo Password Policy"
```

Modifying a user's password

There are two primary ways to change user passwords in the Directory Server:

- Perform a modify operation which replaces the value of the password attribute (often `userPassword`).

Note:

In some configurations, when a user attempts to change their own password, it might be necessary to perform the modification by removing the password value and adding the desired new value to demonstrate that the user knows the current password value.

- Use the password modify extended operation to change the password.

Note:

If a user is changing their own password, it might be necessary to provide the current password value. If the new password is acceptable to all configured password validators, the server provides a new password, or it can automatically generate a new password for the user.

Note:

Regardless of the mechanism used to change the password, all password values should be provided in cleartext rather than pre-encoded, and the user must have sufficient access control rights to update the password attribute in the target user's entry.

When one user attempts to change the password for another user, the requester must have the `password-reset` privilege.

Validating a password

About this task

A new password is valid if it:

- Meets the server's password requirements

- Is assigned a password policy
- Passes user authentication

The server can display requirements for a password change to users. You can use the `get-password-quality-requirements` extended operation to retrieve information about the requirements, which you can forward to an end user before an attempted password change. You can also use these requirements to enable client-side validation so that any password problems can be identified before it is sent to the server. The password validation details request control can be included in an `add` or `modify` request, or a `password modify` extended request, to identify which validation requirements were not met by the password provided in the request.

You can configure password validators with user-friendly messages that describe the password requirements, and error messages that display if a proposed password does not satisfy those requirements. The server will automatically generate these messages if they are not provided in the configuration.

Password properties include the following:

`bind-password-validator`

Specifies which validators to invoke on bind.

`password-validator`

Specifies which validators to invoke during a password change.

`minimum-bind-password-validation-frequency`

Specifies how frequently the server should validate a user's password during bind. Although you can specify that the password should be validated during each bind, it's probably sufficient to only do so periodically (for example, once a week or once a month).

`bind-password-validation-failure-action`

Specifies the action the server should take if a user's password fails validation. By default, the account is placed in a "must change password" state where the user is allowed to bind, but any other operations the user attempts fail until the user changes their password. Alternatively, the account can be locked so that the password needs to be reset by an administrator, or the server can generate an account status notification to recommend that the user choose a new password.

Steps

1. Create a password validator.

Note:

Password validator properties include `validator-requirement-description` and `validator-failure-messages`.

Example:

The following is a simple password validator configuration that requires passwords to contain a minimum of five characters and lists custom validator messages.

```
$ dsconfig create-password-validator \
--validator-name "Minimum 5 Characters Password Validator" \
--type length-based --set enabled:true \
--set "validator-requirement-description:The password must contain
at least 5 characters." \
--set "validator-failure-message:The password did not contain
at least 5 characters." \
--set min-password-length:5
```

2. To make the newly created password validator take effect, assign it to a password policy.

Example:

```
$ dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Minimum 5 Characters Password Validator"
```

3. To validate the password, authenticate as a user.

Note:

When a user authenticates, password validation processing is performed so that the server has access to the user's clear-text password.

Retiring a password

About this task

An account password can be retired and rotated out of service instead of being invalidated. Retiring a password enables a new password to be assigned to an account while keeping the original password valid for a period of time to enable a transition. This is useful for application service accounts that require uninterrupted authentication with the server.

Steps

- To enable password retirement, set the `password-retirement-behavior` and `maximum-retired-password-age` properties in the password policy configuration.
- To manually retire an account password or purge a password that has been retired, run the `ldapmodify` and `ldappasswordmodify` tools with subcommands `-- retireCurrentPassword` and `--purgeCurrentPassword`.

Note:

To use these commands on an account, enable the `password-retirement-behavior` subcommand on the password policy that governs the account.

Changing a user's password using the Modify operation

Steps

- Use `ldapmodify` to change a user's password by replacing the `userPassword` attribute.

Example:

```
$ bin/ldapmodify
dn: uid=user.0,ou=People,dc=example,dc=com
changetype: modify
replace: userPassword
userPassword: newpw
```

Changing a user's password using the Password Modify extended operation

About this task

To request that the Password Modify extended operation be used to modify a user's password:

Steps

- Run the `ldappasswordmodify` tool.

Example:

```
$ bin/ldappasswordmodify --authzID
dn:uid=jdoe,ou=People,dc=example,dc=com \
--newPassword newpw
```

Using an automatically-generated password

Steps

- To automatically generate a new password for a user, run the `ldappasswordmodify` tool.

Example:

```
$ bin/ldappasswordmodify --authzID "u:user.1"
```

Result:

```
The LDAP password modify operation was successful
Generated Password: fbi27oqy
```

Enabling YubiKey authentication

Users can authenticate with YubiKey devices, which generate secure one-time passcodes (OTPs) with the `UNBOUNDEDID-YUBIKEY-OTP SASL` mechanism.

A YubiKey device generates a different password for every authentication attempt, and that OTP is sent to a validation service to ensure that it is genuine and has not been used in an earlier authentication attempt.

Note:

It is possible to use the OTP as the only proof of identity, but you should combine it with a static password as a form of two-factor authentication.

YubiKey authentication requires:

- Server configuration and the addition of this capability to a user entry
- Configuration of a client ID and API key to use when communicating with the validation service

Note:

The API key is a shared secret between the YubiKey validation service and the client that is interacting with it and is used when generating digital signatures so that both the server and the YubiKey validation service can ensure that the peer server is genuine.

All server and user entry configuration details are available in the [Security Guide](#).

Enabling social sign-on

You can enable authentication involving credentials that do not reside in, or cannot be forwarded to or validated by, the Directory Server (such as social sign-on through Facebook, Google, or Twitter) with the `UNBOUNDEDID-EXTERNALLY-PROCESSED-AUTHENTICATION SASL` mechanism.

The bind request does not include any credentials, and authentication with this mechanism does not actually change the state of the underlying client connection. The server behaves as if the bind request included the retain identity request control, whether or not that control was included.

Bind requests using this mechanism can include any request controls that are permitted with other bind requests. If the externally-processed authentication is successful, the client can include the `get password policy state issues request control` in the bind request to obtain information about any password policy state issues that might cause the Directory Server authentication attempt to fail. You can include the `password policy request control` to obtain certain password policy state warnings and errors or to look for the password expired or password expiring controls in the bind response.

Managing user accounts

Manage user accounts with the `manage-account` tool.

About this task

The Directory Server provides a user management utility, the `manage-account` tool, that provides a means to quickly view and manipulate a number of password and account policy properties for a user or group of users.

PingDirectory Server also hosts the Self Service Account Manager project at <https://github.com/pingidentity/ssam>, which is a customizable web application that allows users to perform their own account registration, profile updates, and password changes.

Note:

The project is for testing and development purposes and is not a supported PingDirectory Server application.

Steps

- Unlock a user account with the `manage-account` tool.
- To enable a disabled account, contact the administrator for assistance.

Note:

Password resets are not used.

Returning the password policy state information

Steps

- To get information about the account's password policy, run the `manage-account` tool.

Example:

```
$ bin/manage-account get-all \
  --targetDN uid=user.1,ou=People,dc=example,dc=com
```

Result:

```
Password Policy DN: cn=Demo Password Policy,cn>Password
Policies,cn=config
Account Is Disabled: false
Account Expiration Time:
Seconds Until Account Expiration:
Password Changed Time: 19700101000000.000Z
Password Expiration Warned Time:
Seconds Until Password Expiration: 1209600
Seconds Until Password Expiration Warning: 0
Authentication Failure Times:
```

```

Seconds Until Authentication Failure Unlock:
Remaining Authentication Failure Count: 3
Last Login Time:
Seconds Until Idle Account Lockout:
Password Is Reset: false
Seconds Until Password Reset Lockout:
Grace Login Use Times:
Remaining Grace Login Count: 0
Password Changed by Required Time:
Seconds Until Required Change Time:
Password History:

```

Determining whether an account is disabled

Steps

- To determine whether a user's account has been disabled, run the **manage-account** tool with the `get-account-is-disabled` subcommand.

Example:

```

$ bin/manage-account get-account-is-disabled \
  --targetDN uid=user.1,ou=People,dc=example,dc=com

```

Result:

If the account has been disabled, you receive the following message.

```
Account Is Disabled: true
```

Disabling an account

Steps

- To disable a user's account, run the **manage-account** tool.

Example:

```

$ bin/manage-account set-account-is-disabled \
  --operationValue true --targetDN uid=user.1,ou=People,dc=example,dc=com

```

Result:

You receive the following message.

```
Account Is Disabled: true
```

Enabling a disabled account

Steps

- To enable a user's account, run the **manage-account** tool with the `clear-account-is-disabled` subcommand.

Example:

```

$ bin/manage-account clear-account-is-disabled \
  --targetDN uid=user.1,ou=People,dc=example,dc=com

```

Result:

You receive the following message.

```
Account Is Disabled: false
```

Assigning the manage-account access privileges to non-root users

Assign access rights to the non-root admin user.

About this task

Non-root users, such as `uid=admin`, with admin right privileges require access control permission to interact with certain password policy operational attributes when using the `manage-account` tool.

For example, the presence of the `ds-pwp-account-disabled` operational attribute in an entry determines that the entry is disabled. If the non-root admin user does not have the access privilege to read or interact with the `ds-pwp-account-disabled` operational attribute, the `manage-account` tool might report that the account is active. An account is considered active if the `ds-pwp-account-disabled` operational attribute does not exist in the entry or if the admin user does not have permission to see it.

Steps

1. Create a non-root user admin account, such as `uid=admin,dc=example,dc=com`.
 - a. Grant the `password-reset` privilege to the account.

For more information, see steps 1 and 6 in the [Setting up a single administrator account](#) section in [Configuring Administrators](#).

2. To view the account status for an account, run the `manage-account` tool.

Example:

```
$ bin/manage-account get-all \
  --targetDN uid=user.0,ou=People,dc=example,dc=com
```

Result:

The system displays the following information for the account.

```
Password Policy DN:  cn=Default Password Policy,cn=Password
Policies,cn=config
Account Is Disabled:  false
Account Expiration Time:
Seconds Until Account Expiration:
Password Changed Time:  19700101000000.000Z
Password Expiration Warned Time:
Seconds Until Password Expiration:
Seconds Until Password Expiration Warning:
Authentication Failure Times:
Seconds Until Authentication Failure Unlock:
Remaining Authentication Failure Count:
Last Login Time:
Seconds Until Idle Account Lockout:
Password Is Reset:  false
Seconds Until Password Reset Lockout:
Grace Login Use Times:
Remaining Grace Login Count:  0
Password Changed by Required Time:
Seconds Until Required Change Time:
Password History:
```

3. Grant access control privileges to an account.

Example:

The following allows access to manage accounts to a helpdesk user. Depending on the configuration requirements, this user might also need the `permit-get-password-policy-state-issues` and `password-reset` privileges.

```
dn: dc=example,dc=com
```

```
changetype: modify
add: aci
aci: (targetattr="userPassword||ds-pwp-last-login-time||ds-pwp-password-
changed-by-required-time||ds-pwp-reset-time||ds-pwp-warned-time||
ds-pwp-account-disabled||ds-pwp-account-expiration-time||ds-pwp-
password-policy-dn||ds-pwp-auth-failure||ds-pwp-last-login-ip-address||
ds-pwp-retired-password||ds-pwp-account-activation-time||pwdReset||
pwdChangedTime||pwdAccountLockedTime")
(version 3.0; acl "Grant full access to PWP related attributes to
helpdesk"; allow (all) userdn="ldap:///uid=helpdesk,dc=example,dc=com";)
```

4. To disable an account, run the **manage-account** tool.

Example:

The following command sets the `account-is-disabled` property to true for the `uid=user.0,dc=example,dc=com`.

```
$ bin/manage-account set-account-is-disabled \
--targetDN uid=user.0,ou=People,dc=example,dc=com \
--operationValue true
```

Result:

You receive the following message.

```
Account Is Disabled: true
```

5. To view the presence of the `ds-pwp-account-disabled` operational attribute in the entry, run the **ldapsearch** tool.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" "+"
```

Result:

The system displays the following information.

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-account-disabled: true
```

Disabling password policy evaluation

You can disable and bypass password policy evaluations.

The Directory Server provides a global configuration property (`disable-password-policy-evaluation`) that can disable most password policy evaluation processing, which is convenient for those production environments that do not require password policy support. If the `disable-password-policy` property is set to true, passwords are still encoded and evaluated, but only account expiration and account disabling is in effect. All other password policy properties, such as password expiration, lockout, and force change on add or reset, are ignored.

The server also supports the use of a `bypass-pw-policy` privilege, which can skip password policy evaluation for operations on a per-user basis. If a user has this privilege, then they are allowed to perform operations on user entries that would normally be rejected by the password policy associated with the target entry.

Note:

This privilege does not have any effect for bind operations.

Globally disabling password policy evaluation

Steps

- To set the `disable-password-policy-evaluation` property globally for the Directory Server, run the `dsconfig` tool.

Example:

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
  --set "disable-password-policy-evaluation:false"
```

Exempting a user from password policy evaluation

Steps

- To add the `bypass-pw-policy` privilege to a user entry, run the `ldapmodify` tool with the `bypass-pw-policy` subcommand.

Example:

```
$ bin/ldapmodify
dn: uid=user.1,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: bypass-pw-policy
```

About managing password validators

A password validator is a password policy component you can use to determine if a new password is acceptable.

A password policy can be configured with any number of password validators. If a password policy is configured with multiple password validators, then they all must consider a proposed new password acceptable before it is allowed.

Password validators

The PingDirectory Server offers several types of password validators.

You can use the Server SDK to create custom password validators with the constraints necessary for your environment.

Password Validators

Password Validators	Description
Attribute Value	Ensures that the proposed password does not match the value of another attribute in the user's entry. You can configure the validator to look in all attributes or in a subset of attributes. It can perform forward and reverse mapping and reject values that are substrings of another attribute.
Character Set	Ensures that the proposed password contains a sufficient number of characters from one or more user-defined character sets. For example, the validator can ensure that passwords must have at least one lowercase letter, one uppercase letter, one digit, and one symbol.

Password Validators	Description
Commonly-Used Passwords Dictionary	Ensures that the proposed password is not one of 10,000 commonly used passwords. These are words that are common for attackers to use when trying to access user accounts. The Commonly-Used Passwords validator is invoked by the Secure Password Policy by default. The word list is located in <code><server-root>/config/commonly-used-passwords.txt</code> . While it can be used to create a custom validator, it should not be modified.
Dictionary	Ensures that the proposed password is not present in a specified dictionary file, optionally also testing the password with all characters in reverse order. A large dictionary file is provided with the server, but the administrator can supply an alternate dictionary. In this case, the dictionary must be a plain-text file with one word per line.
Haystack Password Validator	Ensures that the proposed password is secure based on a combination of its length and the types of characters that it contains. For example, a longer password containing only lowercase letters might be stronger than a shorter password containing a mix of uppercase and lowercase letters, numbers, and symbols. This is based on the Gibson Research Corporation Password Haystacks concept.
Length-Based Password Validator	Ensures that the number of characters in the proposed new password is within an acceptable range. Both a maximum and minimum number of characters can be specified.
Regular Expression Validator	Ensures that a proposed password either matches or does not match a given regular expression.
Repeated Characters	Ensures that a proposed password does not contain a substring in which the same character is repeated more than a specified number of times (for example, "aaaaa" or "aaabbb"). You can configure the validator to operate in a case-sensitive or case-insensitive manner, and you can also define custom sets of equivalent characters, such as defining all digits as equivalent so the proposed password could not contain more than a specified number of consecutive digits.
Similarity-Based Password Validator	<p>Ensures that the proposed new password is not too similar to the current password, using the Levenstein Distance algorithm, which calculates the number of characters that need to be inserted, removed, or replaced to transform one string into another.</p> <div data-bbox="626 1524 1468 1766" style="border: 1px solid black; padding: 5px;"> <p> Note:</p> <p>For this password validator to be effective, you must have access to the user's current password. If this password validator is enabled, the <code>password-change-requires-current-password</code> attribute in the password policy configuration must also be set to true.</p> </div>
Unique Characters	Ensures that the proposed password contains at least a specified minimum number of unique characters, optionally using case-insensitive validation.

Configuring password validators

You can use the `dsconfig` configuration tool or the administrative console to configure or modify any password validators.

After you define your password validators, you can add them to an existing password policy. The following example procedures show the `dsconfig` non-interactive commands necessary to carry out such tasks.

If you use `dsconfig` in interactive command-line mode, you can access the `Password Validator` menu in the `Basic Objects` menu. For more details on the password validator properties, see the [PingDirectory Server Configuration Reference](#).

Viewing the list of defined password validators

Steps

- To view the set of password validators defined in the Directory Server, run the `dsconfig` tool.

Configuring the Attribute Value Password Validator

Steps

- To edit the existing default configuration for the Attribute Value Password Validator, run the `dsconfig` tool.

Example:

In this example, the configuration change configures the validator to only examine a specified set of attributes.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Attribute Value" \
  --set match-attribute:cn \
  --set match-attribute:sn \
  --set match-attribute:telephonenumber \
  --set match-attribute:uid
```

- Update an existing password policy to use the Attribute Value Password Validator.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Attribute Value"
```

- Test the Attribute Value Password Validator by submitting a password that is identical to one of the configured attributes (`cn`, `sn`, `telephonenumber`, `uid`).

Example:

```
$ bin/ldappasswordmodify --authzID
"uid=user.0,ou=People,dc=example,dc=com" \
  --newPassword user.0
```

Result:

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
defined in the
server: The provided password was found in another attribute in the user
entry
```

Configuring the Character Set Password Validator

Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

Example:

This example changes the requirement for special characters by making them optional in a password and adds a requirement to include at least two digits in the password. In this example, all newly created passwords must have at least one lowercase letter, one uppercase letter, two digits, and optionally any special characters listed.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Character Set" \
  --remove character-set:1:0123456789 \
  --remove "character-set:1::~~\!@#\$\%^&*()-_+=[]{}|\|;:,.<>/?" \
  --add character-set:2:0123456789 \
  --add "character-set:0::~~\!@#\$\%^&*()-_+=[]{}|\|;:,.<>/?" \
  --set allow-unclassified-characters:false
```

2. Update an existing password policy to use the Character Set Password Validator.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Character Set"
```

3. Test the Character Set Password Validator by submitting a password that meets the requirements (one lowercase letter, one uppercase letter, two digits).

Example:

This example should reject the given password because it does not pass the Character Set Password Validator.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword abab1
```

Configuring the Length-Based Password Validator

Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

Example:

In this example, the required minimum number of characters in a password is set to five.

```
$ bin/dsconfig create-password-validator \
  --validator-name "Length-Based Password Validator" \
  --set max-password-length:5 --set min-password-length:5
```

2. Update an existing password policy to use the Length-Based Password Validator.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Length-Based Password Policy"
```

3. Test the Length-Based Password Validator by submitting a password that has fewer than the minimum number of required characters.

Example:

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword abcd
```

Result:

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
defined in
the server: The provided password is shorter than the minimum required
length of
5 characters
```

Configuring the Regular Expression Password Validator

About this task

Use the `dsconfig` tool to configure the Regular Expression Password Validator.

Steps

1. Use `dsconfig` to create a regular expression password validator.

Example:

The following password validator checks that the password contains at least one number, one lowercase letter, and one uppercase letter with no restrictions on password length. If the password matches the regular expression, then it is accepted. When using the following command, remember to include the LDAP/LDAPS connection parameters (host name and port), bind DN, and bind password.

```
$ bin/dsconfig create-password-validator \
  --validator-name "Regular Expression" \
  --type regular-expression --set enabled:true \
  --set "match-pattern:^\w*(?=\w*\d)(?=\w*[a-z])(?=\w*[A-Z])\w*$" \
  --set match-behavior:require-match
```

2. Update an existing password policy to use the regular expression password validator.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Regular Expression"
```

3. Test the regular expression password validator by submitting a password that meets the requirements.

Note:

To meet the password requirements, make sure your password contains one number, one lowercase letter, and one uppercase letter.

Example:

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword baaA1
```

Result: The LDAP password modify operation was successful

4. Test a password that does not meet the password requirements.

Example:

The following password should fail because no uppercase letter is present.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword baaa1
```

Result:

```
Error Message: The provided new password failed the validation checks
defined in the server: The provided password is not acceptable because it
does
not match regular expression pattern '^\\w*(?=\w*\d)(?=\w*[a-z])(?=\w*[A-
Z])\w*$'
```

Configuring the Repeated Character Password Validator

Configure the Repeated Character Password Validator with the `dsconfig` tool.

Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

Choose from:

- Set the maximum consecutive length of any character.

Note:

For the following example, the maximum consecutive length of any character is set to 3. The validator rejects any passwords with 4 or more consecutive characters, such as "baaaa1" or "4eeeeb", etc.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Repeated Characters" \
  --set max-consecutive-length:3
```

- Configure the validator to reject any character from a pre-defined character set that appears more than the specified number of times in a row (2).

Note:

You can specify more than one character set. For example, the following validator defines two characters sets: `abc` and `123`. It rejects any passwords with more than two consecutive characters from a character set, such as "aaa", "bbb", "ccc", "abc", or "123". However, a password, such as "12a3", is acceptable.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Repeated Characters" \
  --set character-set:123 --set character-set:abc
```

2. Update an existing password policy to use the Repeated Character Password Validator.

Example:

```
$ bin/dsconfig --no-prompt set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Repeated Characters"
```

3. To test the Repeated Character Validator, submit a password that has more than the maximum allowable length of consecutive characters.

Example:

For this example, the faulty password submitted is baaa1.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" \
  --newPassword baaa1
```

Result: The LDAP password modify operation failed with result code 53 Error Message: The provided new password failed the validation checks defined in the server: The provided password contained too many instances of the same character appearing consecutively. The maximum number of times the same character may appear consecutively in a password is 2

Configuring the Similarity-Based Password Validator

Use the `dsconfig` tool to configure the Similarity-Based Password Validator.

Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

Example:

In this example, we set the minimum number of differences to 2.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Similarity-Based Password Validator" \
  --set min-password-difference:2
```

2. Update an existing password policy to use the Similarity-Based Password Validator.

Note:

The `password-change-requires-current-password` property must be set to `true` so that the password policy will ensure that the user's current password is available when that user is choosing a new password.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Similarity-Based Password Validator" \
  --set password-change-requires-current-password:true
```

3. Test the Similarity-Based Password Validator by submitting a password that has fewer than the minimum number of changes, such as 2.

Note:

The `ldappasswordmodify` command requires the `--currentPassword` option when testing the Similarity-Based Password Validator.

Example:

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" \
```

```
--currentPassword abcde --newPassword abcdd
```

Result: The LDAP password modify operation failed with result code 49.

Configuring the Unique Characters Password Validator

Use the `dsconfig` tool to configure, update, and test the Unique Characters Password Validator.

Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

Example:

In this example, we set the minimum number of unique characters that a password is allowed to contain to 3.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Similarity-Based" --set min-unique-characters:3
```

2. Update an existing password policy to use the Unique Characters Password Validator.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Unique Characters"
```

3. Test the Unique Characters Password Validator by submitting a password that has fewer than the minimum number of unique characters, such as 3.

Example:

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" \
  --newPassword aaaaa
```

Result: The LDAP password modify operation failed with result code 53 Error Message: The provided new password failed the validation checks defined in the server: The provided password does not contain enough unique characters. The minimum number of unique characters that may appear in a user password is 3

Managing Replication

PingDirectory Server provides a robust replication system to ensure high availability and fast failover in production environments.

Every server in the topology can handle write requests, with the replication component performing immediate synchronization with other members. The replicated server environment ensures that LDAP clients can seamlessly fail over to another server instance.

Overview of replication

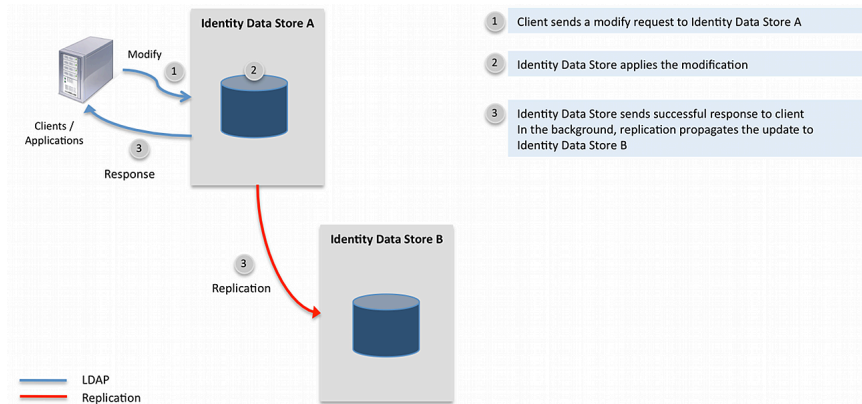

Replication is a data synchronization mechanism that ensures that updates made to a database are automatically duplicated to other servers.

Replication improves data availability when unforeseen or planned outages occur and improves search performance by allowing client requests to be distributed across multiple servers.

By default, all Directory Server instances participating in replication are writable so that LDAP clients can perform updates at any of these Directory Server instances. These updates are automatically propagated to the other servers in the background in the same order as the updates were entered. The replication

process flow is designed to immediately propagate changes to the other replicas in the topology with little or no latency.

The following figure demonstrates the basic flow of replication.

The benefits of replication can be summarized as follows:

High-Availability

Because the data is fully replicated on all other servers in the topology, replication allows participating servers to process all types of client requests. This mitigates any availability issues when a particular server is down due to a planned maintenance or unplanned outage. Servers that are temporarily unavailable receive updates when they become available again.

Improved Search Performance

Search requests can be directed to any Directory Server participating in replication, which improves search performance over systems that only access single servers.

Note:

Replication does not improve write throughput because updates need to be applied at all servers.

WAN Friendly Data Synchronization

The built-in compression feature in the replication protocol allows efficient propagation of updates over WAN links.

Replication versus synchronization

Replication and synchronization are distinct functions from one another and are not interchangeable.

Replication is not a general purpose synchronization function because it creates replicas with exact copies of the replicated data. By contrast, synchronization can:

- Transform data between two different directory information tree (DIT) structures
- Map attribute types
- Synchronize subsets of branches and specific object classes

The differences between replication and synchronization are as follows:

Replication cannot synchronize between different DIT structures

The distinguished name (DN) of replicated entries must be the same on all servers. In some situations, you might want to replicate entries with the help of DN mapping that are under different base DNs, but represent the same data, for example `uid=john.doe,ou=people,o=corp` on one server could represent the same user as `uid=john.doe,ou=people,dc=example,dc=com`.

This is not supported by replication. Synchronization fully supports this feature.

Replication cannot map attribute types or transform attribute values

Some situations might require you to map attribute types or transform attribute values when synchronizing data from one server to another. Replication does not support attribute type mappings or attribute value transformations.

Replication does not support fractional replication

Replication can't be configured to replicate a subset of the attribute types from the replicated data set. Synchronization fully supports this feature.

Replication does not support sparse replication

Replication can't be configured to replicate only entries with a particular object class. Synchronization fully supports this feature.

Replication requires full control of replicated data

When two servers participate in replication, both servers implicitly trust each other using public key cryptography and apply all received updates by replication, which is considered an internal operation. While trust between servers is established between two endpoint servers, synchronization doesn't require full control of the data. Disparate server system endpoints can be synchronized, such as a PingDirectory Server and a relational database management system (RDBMS) database endpoint with each fully in control of its own data.

If replication does not meet your data synchronization requirements, consider using PingDataSync Server instead, which provides the versatility and robust performance required for most production environments.

Replication terminology

The following terms have specific definitions as they apply to replication.

Replication Terminology

Term	Description
Assured Replication	Data is guaranteed to replicate before the response is returned to the client. This is useful for applications that require immediate access to replicated data or require data consistency over response time.
Change Number	A 64-bit number used to consistently order replication updates across the entire topology. It is composed of 3 fields: <ul style="list-style-type: none"> The timestamp of the update in milliseconds since 00:00:00 UTC, January 1, 1970 The replica ID The sequence number
Conflict	Client updates made at different replicas affecting the same entry may be found in conflict when the updates are replayed at another replica. The Change Number of each update allows most of these conflicts to be resolved automatically. Certain updates, such as adding an entry with different attribute values at two servers simultaneously, result in conflicts that are flagged for manual resolution.

Term	Description
Eventual Consistency	<p>When not using assured replication, recent updates from LDAP clients are not immediately present at all servers.</p> <p>Out-of-sync data will eventually be synchronized and will be consistent on all servers. The network latency typically controls how long a given update takes to replicate.</p>
Global Administrator	<p>The administrative user with full rights to manage the replication topology.</p> <p>The user is created at the time of replication enablement between two non-replicating servers and thereafter copied to newly-enabled servers. The replication command-line utility expects the user name of the Global Administrator (by default, admin).</p> <p>The user is stored in <code>cn=Topology Admin Users,cn=Topology,cn=config</code>.</p>
Historical Data	<p>Historical Data are records of attribute value changes as a result of an LDAP Modify operation.</p> <p>Historical data are stored in the <code>ds-sync-hist</code> attribute of the target entry. This information allows replication to resolve conflicts from simultaneous LDAP Modify operations automatically.</p>
Location	<p>The collection of servers that may have similar performance characteristics when accessed from this Directory Server or reside in the same data center or city.</p> <p>A separate location setting may be defined for each data center, such as Austin, London, Chicago, and so forth. Location settings are used in the selection of the WAN Gateway server.</p>
Modify Conflict	<p>A conflict between two LDAP Modify operations.</p> <p>Modify conflicts are automatically resolved.</p>
Naming Conflict	<p>Any conflict other than Modify Conflicts.</p> <p>Naming conflicts typically include an operation that changes the DN of the target entry, creates an entry, or deletes an entry at one replica.</p>
Replica	<p>The component in the Directory Server that handles interaction with a single replication domain.</p> <p>For example, the <code>dc=example,dc=com</code> replication domain within the <code>userRoot</code> backend is a replica.</p>
Replica ID	<p>The unique identifier of a replica.</p> <p>Replica ID is automatically set in the corresponding Replication Domain configuration entry at each participating server. The replica ID identifies the source of each update in the replication topology.</p>

Term	Description
Replica State	<p>A list of the most recent change numbers of replication updates that have been applied to a replica.</p> <p>Each replica in the state can have a maximum of one change number. The Replication Server component uses the replica state to determine which updates the Replica has not yet received.</p>
Replication	<p>An automated background process that pushes directory server data changes to all other replicas.</p>
Replication Changelog	<p>A backend maintained independently by each replication server that records updates from each replica.</p> <p>This backend is distinct from the LDAP Changelog, and the two should not be confused. The main distinction is as follows:</p> <ul style="list-style-type: none"> ▪ The LDAP Changelog is the external changelog that clients can access. It is located at <code><server-root>/db/changelog</code>. ▪ The Replication Changelog Backend is the changelog that replication servers use. It is located at <code><server-root>/changelogDB</code>, and is not accessible by clients or server extensions.
Replication Domain	<p>The data configured for replication as defined by the base DN.</p> <p>Updates to entries at and below the base DN will be replicated.</p>
Replication Replay	<p>When a replica locally applies the update received via a replication server.</p>
Replication Server	<p>A component within the Directory Server process that is responsible for propagating directory server data changes to and from replicas.</p> <p>Each Directory Server instance participating in replication is also running a replication server.</p>
Replication Server ID	<p>The unique identifier of a replication server.</p> <p>The replication server ID is set automatically in its configuration object at each server in the replication topology.</p> <p>This identifier is used in the connection management code of the replication servers.</p>
Replication Server State	<p>A list of the most recent change numbers of replication updates that have been processed by a replication server.</p> <p>Each replica in the topology can have a maximum of one change number.</p> <p>The Replication Server State is used to determine which updates need to be sent to other replication servers. Similarly, the replica can use the Replication Server State to identify the set of updates to send to the replication server.</p>
Sequence Number	<p>A field in the change number that indicates the sequence of the client updates at a particular replica.</p> <p>The sequence number increases incrementally for every update at the replica. The initial value of the sequence number is 1. The number is stored as a 32-bit integer, but only positive values are used. The sequence number can roll over.</p>

Term	Description
WAN Gateway	<p>The designated replication server that assumes the WAN Gateway role within a collection of servers that are defined with identical location settings.</p> <p>Replication update messages between servers at different locations are routed through WAN gateways.</p> <p>The WAN Gateway role is assigned automatically by the protocol based on the server's WAN Gateway Priority setting. If the WAN Gateway server is down for any reason, the server with the next highest WAN Gateway Priority will dynamically assume the WAN Gateway role.</p>
WAN Gateway Priority	<p>The configuration setting that determines which replication server assumes the WAN Gateway role.</p> <p>The replication server with the highest WAN Gateway Priority in a location assumes the role of the WAN Gateway.</p> <p>Servers can have a WAN Gateway Priority value from 1 to 10, with 1 being the highest priority. A server with a WAN Gateway priority value of 0 will never be a gateway.</p>

Replication architecture

This section introduces the major elements of replication in PingDirectory Server.

Eventual consistency

Replication is based on an eventual-consistency model where the updates propagated through a connected network of servers will eventually be consistent on all servers over a short period of time.

In a typical update operation, a client application updates an entry or group of entries on a PingDirectory Server with an **ADD**, **DELETE**, **MODIFY**, or **MODIFY DN** operation. After processing the operation, the Directory Server returns an LDAP response while simultaneously propagating the update to the other servers in the replicated topology. This simultaneous processing model allows the client to continue submitting update requests without waiting for a replication completion response from the server.

To support this processing model, replication never locks the targeted entries at the other Directory Server instances before an update can be made locally. This means that the replicated Directory Servers might have an inconsistent view of the targeted entry for a short period of time, but will catch up as the propagated changes are applied.

The eventual-consistency model also allows clients to complete update operations faster because clients can propagate a change without having to wait for replication. The rate of update operations remains the same no matter how many Directory Servers participate in replication.

Alternatively, you can configure assured replication for specific write requests to require local or global consistency, across data center locations, before a response is returned to the client. For more information, see [Configuring assured replication](#) on page 576.

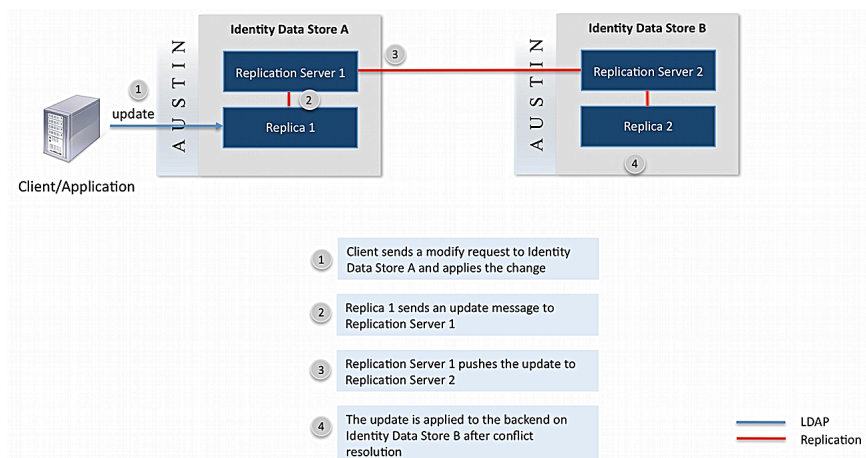

Replicas and replication servers

Each Directory Server has an embedded replication server that is responsible for transmitting updates to other replication servers. Each replicating base distinguished name (DN), such as `cn=schema,dc=example,dc=com`, has a separate component called a replica. Each replica connects to the embedded replication server running within the Directory Server Java virtual machine (JVM) process.

When a client application updates an entry on the Directory Server, the replica sends an update message to its embedded replication server. The replication server applies the change to the `replicationChangeLog` backend repository and then sends an update message to the connected

replication server on another directory server. The replication server on other directory servers then passes the change to the appropriate replica, which in turn applies the change to its backend after performing conflict resolution.

The following figure shows the standard setup.

Replicas and Replication Servers

1. The client or application sends a modification request to Identity Store A. The identity store applies the change.
2. The Replica backend in Identity Store A sends an update message to the Replication Server in Identity Store A.
3. The Replication Server in Identity Store A pushes the update to the Replication Server in Identity Store B.
4. The Replication Server in Identity Store B applies the update to the Replica backend in Identity Store B.

Authentication and authorization

Directory Server uses a simple authentication model to authorize replication servers.

After it is authenticated, the remote Directory Server is fully authorized to exchange replication messages with the local Directory Server. There is no other access control in place.

Authentication in the replication protocol is based on public key cryptography using TLS client certificate authentication. The certificate used for authentication is stored in the `ads-truststore` backend of the Directory Server.

During replication setup, the command-line utility distributes public keys to all directory servers to establish trust between the Directory Servers and to enable TLS client authentication.

Logging

The access log messages in the Directory Server indicate if the update was received by replication and includes the corresponding change number. This allows the administrator to track which Directory Server the update originated from.

Replication deployment planning

Consider the following factors before deploying replication in a production environment:

Minimizing Replication Conflicts

If two different clients attempt to create an entry with the same distinguished name (DN) at the same time against different servers, it's possible that both client requests will succeed. This triggers the server to send a conflict alert. You can minimize these conflicts by understanding the client traffic

pattern beforehand. PingDirectory's Assured Replication feature and the PingDirectoryProxy Server can both assist in minimizing conflicts.

For more information, see [Configuring assured replication](#) on page 576 and [PingDirectoryProxy](#) on page 564.

Replication Purge Delay

Adjust the default one-day replication purge delay to accommodate automatic catchup of changes when a server is offline for an extended period of time. The replication changes database, stored in `<server-root>/changelogDb`, grows larger with longer replication purge delays.

Define a minimum value for the replication purge delay. Make sure the value is consistent across all servers.

For more information, see [Modifying the replication purge delay](#) on page 588.

Domains

All servers in a replication topology must have the same domains.

Note:

Because the PingDirectory replication topology assumes that all domains are on all servers, it is not suitable for environments with an inconsistent presence of domains across the server topology.

Location

If your deployment incorporates multiple data regions, you should configure the directory servers with location information.

To set locations, use the `dsconfig create-location` and `dsconfig set-global-configuration-prop` commands.

The Directory Server cannot determine LAN boundaries automatically, so incorrect location settings can result in undesired WAN communication. By default, replication compresses all traffic between directory servers in different locations.

Set up the locations prior to enabling replication. The `dsreplication enable` command prompts for location information if you have forgotten to define the property.

User-defined LDAP

Directory Servers participating in replication must have a uniform user-defined schema.

The `dsreplication` command-line utility sets up replication for the schema backend the first time replication is enabled to ensure that future schema changes are propagated to all directory servers.

Disk space

Replication increases the disk space required for the Directory Server.

The Replication Changelog backend keeps changes from all directory servers for 24 hours by default. After this time period, also known as the purge delay, the backend is trimmed automatically.

In addition, within the `userRoot` and other local DN backends, attribute-level changes are recorded for a short period of time in the `ds-sync-hist` attribute of the entry targeted by an LDAP Modify operation. This attribute is used to resolve all conflicts resulting from LDAP Modify operations automatically.

The disk space impact of replication is dependent on the rate and size of changes in the replication topology and the Replication Changelog purge delay.

Memory

Replicated directory server instances require slightly more memory than a standalone directory server.

All of the items discussed in [Disk space](#) have an impact on the amount of memory the Directory Server is using. The additional replication overhead is typically less than 5%.

Time synchronization

Even though replication has a built-in mechanism to compensate for the potential clock skew between hosts, you should keep system clocks in sync within the deployment.

Communication ports

The replication server component in each directory server listens on a TCP/IP port for replication communication.

This replication server port, typically 8989, must be accessible from all directory servers participating in replication. The server-to-server communication channel is kept alive using a heartbeat, which occurs every 10 seconds. This traffic prevents firewalls from closing connections prematurely.

The replication command-line utility (`dsreplication`) requires access to all directory servers participating in replication. This includes the LDAP or LDAPS port of the directory servers.

Tip:

When configuring firewalls, keep these communication requirements in mind.

Hardware load balancers

Replication allows write operations to be directed to any directory server in the topology. Distributing write operations in a round-robin fashion could introduce conflicts. In particular, distributing a series of LDAP `add`, `delete`, and `modify` DN operations targeting the same distinguished name (DN) in quick succession can cause conflicts that require manual intervention.

The Assured Replication feature can help prevent conflicts created by the same client application. For more information, see [Configuring assured replication](#) on page 576.

Consider using server affinity with the load balancer that either associates a client IP address or a client connection with a single directory server instance at a time.

For load balancing LDAP traffic, consider using the PingDirectoryProxy Server. The Server Affinity feature in PingDirectoryProxy Server enables replication-friendly load balancing. For more information, see [Configuring server affinity](#) on page 994.

PingDirectoryProxy

To facilitate replication-friendly load balancing, consider using PingDirectoryProxy Server in every replication deployment.

Directory Proxy Server can automatically adapt to conditions in backend directory servers using health checks and route traffic accordingly.

For example, Directory Proxy Server can re-route traffic from directory servers with a large backlog of replication updates.

Displaying the server information for a replication deployment

Steps

- To display the server information for a replication deployment, run the **dsreplication status** command with the `--displayServerTable` option.

```
$ bin/dsreplication status --displayServerTable
```

Result:

```

--- Replication Status for dc=example,dc=com: ---
Server                : Location : Priority (1) : Status
-----:-----:-----:-----
austin-01.example.com:8989 : US      : 1 (*)       : Available
austin-02.example.com:8989 : US      : 2           : Available
london-01.example.com:8989 : UK      : 5           : Available
london-02.example.com:8989 : UK      : 5 (*)       : Available
sydney-01.example.com:8989 : AU      : 5 (*)       : Available
sydney-02.example.com:8989 : AU      : 5           : Available

[1] WAN Gateway Priority. WAN gateways are marked with a *. To minimize
WAN utilization, the server with the WAN Gateway role is the only server
in a location that exchanges updates with remote locations.

--- Replication Status for dc=example,dc=com: Enabled ---
Server                : Location : Entries : Conflict Entries :
Backlog : Recent Change Rate
-----:-----:-----:-----:-----:-----
austin-01.example.com:1389 : US      : 3478174 : 0                :
8      : 333
austin-02.example.com:1389 : US      : 3478174 : 0                :
5      : 345
london-01.example.com:1389 : UK      : 3478174 : 0                :
0      : 349
london-02.example.com:1389 : UK      : 3478174 : 0                :
0      : 5
sydney-01.example.com:1389 : AU      : 3478173 : 0                :
0      : 350
sydney-02.example.com:1389 : AU      : 3478270 : 0                :
30     : 332

```

Displaying all status information for a replication deployment

Steps

- To display the status information for a replication deployment, run the **dsreplication status** command with the `--showAll` option.

You can also use the `--showAll` option together with the `--displayServerTable` option to see the server table information for the replication topology.

Enabling replication

Enabling replication between multiple directory servers ensures that changes within the replicated base distinguished name (DN) are automatically propagated to all other directory servers in the topology.

Configuration changes are not replicated by default but can be through the use of server groups. Each directory server should be configured according to the deployment design.

Overview

To interface with the replication topology, Directory Server provides a command-line utility, **dsreplication**, that should be used to manage and monitor replication.

The cluster name for an instance should be set to a unique name during install. The cluster-name controls a handle of configuration settings that are used cluster-wide; any changes to the configuration will always get pushed out to other members of the topology. If the cluster-name is set to a unique name for each server, any change to the configuration via the **dsconfig** command or the console needs to be done on every server in the topology. In a devops model, it is recommended that the cluster name be unique so that everything can be managed with server profiles. If you are doing an on-premise install, you may want to use a common cluster-name across the topology.

Note:

You should set a cluster name for the topology if you want cluster-wide settings to propagate across the topology in a single action.

Replication setup involves the following basic steps:

- Set up the servers.

This is the basic installation step to set up a Directory Server instance.

- Import or restore data to one server.

After setting up the servers, at least one server should have the target data loaded through **import-ldif** or restore.

- Enable replication between the servers.

Using the **dsreplication** tool, enable replication for each server to be included in the replication topology. The **dsreplication enable** subcommand should be run N - 1 times for a topology of N servers. For more information, see [Command Line Interface](#).

- Initialize data from source server to all servers in the topology.

Run the **dsreplication initialize** subcommand for every target server that needs a copy of the data from the source server.

- Verify the replication topology.

Check the replication status after configuring the topology using the **dsreplication status** tool.

Command-line interface

Replication topologies are configured and maintained using the **dsreplication** command-line utility, which supports interactive and non-interactive modes. If you are running the server for the first time, use the **dsreplication** tool in interactive mode.

The **dsreplication** tool uses the following format, including some important subcommands listed in the section [The dsreplication Command-Line Utility](#).

```
dsreplication {subcommand} {connection parameters}
```

The **dsreplication** tool keeps a history of invocations in the `logs/tools/dsreplication.history` file and keeps a log of up to 10 **dsreplication** sessions in the `logs/tools` directory.

What happens when you enable replication

The **dsreplication enable** subcommand is used to set up replication. The **enable** subcommand carries out the following functions:

- If it does not already exist, the global administrator user is created. The global administrator user has all the rights and privileges to update replication-related configuration objects. Most **dsreplication** subcommands require the global administrator.

- The server instances are registered in the `cn=topology, cn=config` tree. The registration includes basic host name, port information, and the public key used during the replication authentication process.

If both servers are already participating in replication, the `cn=topology, cn=config` is merged to retain the server information from existing topologies.

- The embedded replication server is enabled. Servers already in replication see their replication server configuration updated with the information of the new replication server.
- A replication domain is created for the requested base distinguished names (DNs). If the first base DN is enabled, the replication domains for two additional base DNs are also enabled: `cn=topology, cn=config` and `cn=schema`.
- Initialization for the `cn=schema` base DN is executed. This ensures that a uniform schema is present in the replication topology.
- Initialization must be performed for the enabled base DNs.

Important:

The `dsreplication enable` subcommand removes all existing topology administrative users except for the default `uid=admin` that is provided to enable replication. Administrative users must be re-added after enabling replication.

Initialization

Replica initialization transfers a copy of the backend containing the replication domain to a target server. You should perform this after replication is enabled with the `dsreplication initialize` subcommand. There is no impact on the source server during this process.

Note:

When enabling or initializing servers, the `--topologyFilePath` option can be used with `dsreplication` to specify a file with a series of hosts and ports available in the topology that can be used as source servers.

This option is used in place of specifying `host 1, port 1`. When the `hosts` file is used for an `enable` or `initialize` action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available for replication. This file is generated with the `manage-topology export` command.

`dsreplication initialize`

The recommended approach for replica initialization. The `dsreplication initialize` subcommand performs the most efficient copy of data needed to initialize one or more replicas on a target server. Existing data on the target server replica is lost and the backend containing the base DN is taken offline on the target server during the initialization.

Binary copy

The database copy method involves copying database backup files from the source directory server to one or more target servers. The Directory Server provides tools necessary for backing up and restoring backends. Using `server-root/bin/backup`, create a backup of the backend containing the replicated base DN. The backup files must then be transferred to the target servers and restored individually with `server-root/bin/restore`. There are additional considerations when using database copy as the means to initialize a target replica:

- If encryption is enabled on the servers, then a database `bin/encryption-settings export` followed by `bin/encryption-settings import` must be performed on the `encryption-settings` backend.

- When using database copy to initialize a server that has been offline longer than the replication purge delay, the database copy of the `replicationChanges`, `schema`, and `adminRoot` backends are required.

Import/export LDIF

The import/export LDIF method is the most flexible approach, as it works well in environments where target replicas are configured differently than the backend containing the data (for example, the target replica has different indexes than the source server). The process involves exporting the backend data as LDIF from the source server and importing the LDIF into the target servers. Replicas can be initialized locally while the server is offline or online through remote access. For more information, see [Importing and exporting data](#) on page 288.

Replica generation ID

Each replica has a generation ID, which is an integer that summarizes the replica. It provides replication with a quick and simple means of determining if two replicas contain the same data. Two replicas containing the same data have the same generation ID.

When replication is operating correctly, all of the replicas for each replicated base DN have the same generation ID. The generation ID is stored on each replica as the operational attribute `ds-sync-generation-id`, as in the following example.

```
ldapsearch -b 'dc=example,dc=com' -s base '(&)' ds-sync-generation-id
dn: dc=example,dc=com
ds-sync-generation-id: 2058329333
```

When the server starts, or when replication is enabled, the generation ID is computed for each affected replica that does not already have a generation ID stored as `ds-sync-generation-id`. The following is used to calculate the generation ID:

- The total number of entries in the replica. This is referred to as the count.
- The first 1000 entries in the replica are converted to normalized LDIF, referred to as the LDIF. Normalized LDIF only includes attributes `objectclass`, `sn`, `cn`, and `ds-entry-unique-id` and uses OIDs in place of attribute names.
- The Adler-32 checksum is calculated with the string produced by concatenating the count and the LDIF as input. This Adler-32 checksum is the generation ID.
- The generation ID is stored on the base DN as `ds-sync-generation-id`. This ensures that the ID does not need to be computed the next time the replica is loaded.

Deploying a basic replication topology

Set up a two-server replication topology.

About this task

The example uses the LDAP and replication server ports 1389 and 8989, respectively.

Replica Ports

Host Name	LDAP Port	Replication Port
server1.example.com	1389	8989
server2.example.com	1389	8989

Steps

1. Install the first directory server with 2000 sample entries.

Example:

```
$ ./setup --acceptLicense --baseDN \
?oxy_insert_start author="jeffkilgore" \
timestamp="20220621T105332-0500"?>"dc=example,dc=com" \
--ldapPort 1389 \ --rootUserPassword pass --sampleData 2000 \
--no-prompt
```

2. Install the second directory server either on a separate host or the same host as the first, but with a different LDAP port.

Example:

```
$ ./setup --acceptLicense --baseDN \
"dc=example,dc=com" --ldapPort 1389 \
--rootUserPassword pass --no-prompt
```

3. To configure a replication topology, from the first server, run the `bin/dsreplication` command in interactive mode.

Example:

```
$ bin/dsreplication
```

4. From the Replication Main Menu, **select** Manage the topology.

Example:

```
>>>> Replication Main Menu

What do you want to do?

    1) Display replication status
    2) Manage the topology (add and remove servers)
    3) Initialize replica data over the network
    4) Initialize replica data manually
    5) Replace existing data on all servers

    q) quit

Enter choice: 2
```

5. From the Manage Replication Topology menu, **select** Enable Replication.

Example:

```
>>>> Manage Replication Topology

Select an operation for more information.

    1) Enable Replication -- add or re-attach a server to the topology
    2) Disable Replication -- permanently remove a running replica from the
       topology
    3) Remove Defunct Server -- permanently remove an unavailable server
       from the topology
    4) Cleanup Server -- remove replication artifacts from an offline, local
       server
       (allowing it to be re-added to a topology)

    b) back
    q) quit
```

```
Enter choice [b]: 1
```

6. From the `Enable Replication` menu, read the setup introduction. To continue the enable process, enter `c`.
7. Enter the LDAP connection parameters for the first of the two server replicas that you are configuring.
 - a. Enter the host name or IP address of the server.
 - b. Enter the type of LDAP connection to the server.

Choose from:

- LDAP
 - LDAP with SSL
 - LDAP with StartTLS
- c. Enter the LDAP listener port for the server.

 **Note:**

If you are a root user, you see port 389 as the default. Others see port 1389.

- d. Authenticate as a root distinguished name (DN), such as `cn=Directory Manager`.

 **Note:**

Later in the process, you are prompted to set up a global administrator and password. The global administrator is the user ID that manages the replication topology group.

8. Repeat steps 7a-7d for the second server replica.
9. When the `dsreplication` tool checks for the base DN on both servers, press enter to select the default base DN.

 **Note:**

To enable replication, data must be present on at least one of the servers.

Example:

```
Choose one or more available base DN's for which to enable replication:
```

```
1) dc=example,dc=com
```

```
c) cancel
```

```
Enter one or more choices separated by commas [1]:
```

 **Note:**

If you see the following message, in most cases, a base DN was not set up on one of the directory servers, or the backend is disabled.

```
There are no base DN's available to enable replication between the two servers.
```

- When you are prompted to set up entry balancing using the Directory Proxy Server, press enter to accept the default value.

**Note:**

For more information, see the PingDirectoryProxy Server Administration Guide.

Example:

```
Do you plan to configure entry balancing using the Directory Proxy
Server? (yes / no) [no]:
```

- Enter the replication port for the first replica.

**Note:**

The default replication port is 8989.

The port you enter must be free.

- If you are prompted to enter a location, press enter to accept the default and set up a location for the first server. Enter the name of the server's location.

**Note:**

You are prompted for the location if you did not pre-define a location setting for the server.

Example:

```
The first server has not been configured with a location.
Assigning a location to each server in the replication topology reduces
network traffic in multi-site deployments. Would you like to set the
location in the first server? (yes / no) [yes]
```

```
The location of the first server: Austin
```

- Repeat steps 9-12 for the second directory server.

**Note:**

If you did not pre-define a location setting for the second server, you are prompted to enter location information for the server.

- Set up the global administrator user ID and a password for this account.

**Note:**

The default global administrator user ID is `admin`.

The global administrator user ID manages the directory servers used in the replication topology.

Example:

```
Specify the user ID of the global administrator account
that will be used to manage the Ping Identity
Directory Server
instances to be replicated [admin]:
```

```
Password for the global administrator:
Confirm Password:
```

15. Return to the Replication Main Menu and enter the number corresponding to initializing data over the network.
16. To initialize data on a single server, from the Initialize Replica Data over the Network menu, select Initialize, and enter c to continue.
17. To specify a server in the replication topology, enter the following information for the first server:
 - Host name or IP address
 - LDAP connection type
 - LDAP port
 - Global admin user ID and password
18. Select the source server that is hosting the data to which the target server will be initialized. For this example, select the first server, since the sample dataset has been loaded onto this server.
19. Select the base DN to initialize.

**Note:**

In most cases, the base DN for the root suffix is replicated. In this example, `dc=example,dc=com`.

20. Select the second server to have its data initialized, and enter the global admin user ID and password for the target server.

**Note:**

Any data present on the target server is over-written.

21. To confirm that you want to initialize data on the target server, press enter.

Example:

```
Initializing the contents of a base DN removes all the existing contents
of
that base DN. Do you want to remove the contents of the selected base DN's
on server
server2.example.com:1389 and replace them with the contents of server
server1.example.com:1389? (yes / no) [yes]:
```

Result: The server displays a Base DN initialized successfully message.

22. On the Initialize Replica Data Over Network menu, enter b to back out one level to the main menu.
23. To view the replication status, on the Replication Main Menu, enter the host name or IP address. Example:

```
--- Replication Servers: dc=example,dc=com ---
Server                : Location : Conflict Entries : Backlog : Recent
Change Rate
-----:-----:-----:-----:-----
ds1 (example.com:1389) : austin : 0                : 0       : 0
ds2 (example.com:1389) : austin : 0                : 0       : 0
```

Example deployment with non-interactive dsreplication

The following example creates a 4-server topology spanning two data centers.

In the example, the four servers are already installed and have locations Austin and Budapest defined.

Note:

When enabling or initializing servers, the `--topologyFilePath` option can be used with `dsreplication` to specify a file with a series of hosts and ports available in the topology that can be used as source servers. This option is used in place of specifying `host 1, port 1`.

When the hosts file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available for replication. This file is generated with the `manage-topology export` command.

Deploying with non-interactive dsreplication

Steps

1. To generate the sample data on the first server, use the `make-ldif` tool.

Example:

```
$ bin/make-ldif --templateFile config/MakeLDIF/example-10K.template \
  --ldifFile ldif/10K.ldif
```

2. To import the data, select a server from which to import data and to be the source for future initialization to other servers, and then follow the import steps.
 - a. Stop the server.
 - b. To import the sample LDIF to the server, run `import-ldif`.
 - c. Start the server.

Example:

```
$ bin/stop-server
$ bin/import-ldif --backendID userRoot --ldifFile ldif/10K.ldif
$ bin/start-server
```

3. To enable replication, select a specific server and run `dsreplication enable` three times.

Note:

For the first invocation, create the replication topology administrator with the name `admin`.

Example:

```
$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 austin02.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt

$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 budapest01.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
```

```

--adminPassword password --no-prompt

$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 budapest02.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt

```

4. To initialize the other servers, the `dc=example,dc=com` replicas, from the server you imported the data into with `import-ldif`, run `dsreplication initialize`.

Example:

For this example, initialize `budapest02` from `budapest01` to minimize the WAN transfers.

```

$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
  --hostDestination austin02.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --
no-prompt

$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
  --hostDestination budapest01.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --
no-prompt

$ bin/dsreplication initialize --hostSource budapest01.example.com --
portSource 1389 \
  --hostDestination budapest02.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --
no-prompt

```

5. To view the replication state, run `dsreplication status`.

Example:

```

$ bin/dsreplication status --adminPassword password --no-prompt --
displayServerTable --showAll

```

Using dsreplication with SASL GSSAPI (Kerberos)

Before you begin

This example procedure assumes that you have configured SASL GSSAPI on all servers in the replication topology and that they are working properly.

About this task

Directory Server's utilities all support SASL GSSAPI options for systems using Kerberos as its main authentication mechanism. The following procedure shows how to use `dsreplication` with SASL GSSAPI to set up a new `replication.admin` identity while enabling replication on a server.

Note:

A separate Kerberos identity is required to manage replication. Existing Kerberos credentials can be used to interact with the server when enabling replication and creating the new identity.

The new identity, such as `replication.admin`, must not exist as the `cn` or `uid` value under any public base distinguished name (DN).

Steps

1. To set the LDAP Connection Handler to explicitly listen on the server's host name address, run **dsconfig** with the `set-connection-handler-prop` option.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --remove listen-address:0.0.0.0 --add listen-address:host.example.com
```

2. To update the identity mapper to have `cn=topology,cn=config` included in the list of base DNs and to add the `cn` attribute to match attributes, run **dsconfig** with the `set-identity-mapper-prop` option.

Note:

You must do this to map the admin account to the Kerberos realm.

Example:

```
$ bin/dsconfig set-identity-mapper-prop \
  --mapper-name "Regular Expression" \
  --add match-attribute:cn \
  --set "match-base-dn:cn=topology,cn=config" \
  --set match-base-dn:dc=example,dc=com
```

3. To invoke replication enable, authenticate as the existing Kerberos `authid`, and then run **dsreplication enable**.

Note:

No bind DNs and passwords are required to authenticate because you are using SASL binding. However, the new replication admin user requires a password at creation time, and you should use a strong random password. After SASL is working, you no longer have to provide this random password.

You must use the ticket cache, so make sure you have properly authenticated as `ds.admin` from your local host and the ticket is not expired in the cache.

Example:

```
$ kinit -p ds.admin
$ bin/dsreplication enable \
  --host1 server1.example.com --port1 1389 --replicationPort1 1989 \
  --host2 server2.example.com --port2 2389 --replicationPort2 2989 \
  --baseDN dc=example,dc=com \
  --adminUID replication.admin --adminPassword strongPassword \
  --saslOption1 mech=gssapi --saslOption1 authid=ds.admin@EXAMPLE.COM \
  --saslOption1 useTicketCache=true --saslOption1 requireCache=true \
  --saslOption2 mech=gssapi --saslOption2 authid=ds.admin@EXAMPLE.COM \
  --saslOption2 useTicketCache=true --saslOption2 requireCache=true
```

4. To initialize data on the remote server, run **dsreplication initialize**.

Example:

```
$ kinit -p replication.admin
$ bin/dsreplication initialize \
  --hostSource server1.example.com --portSource 1389 \
  --hostDestination server2.example.com --portDestination 2389 \
  --baseDN dc=example,dc=com \
```

```
--saslOption mech=GSSAPI \
--saslOption authID=replication.admin@EXAMPLE.COM \
--no-prompt
```

- To delete the temporary `userPassword` from the `replication.admin` entry, create an LDIF file.
Example:

In this example, the file is named `remove-password.ldif` and contains the following.

```
dn: cn=replication.admin,cn=Administrators,cn=topology,cn=config
changetype: modify
delete: userPassword
```

- To apply the modifications, use the `ldapmodify` tool.

Example:

```
$ ./ldapmodify --filename remove-password.ldif -o mech=GSSAPI
-o authid=replication.admin@example.com \
--saslOption useTicketCache=true \
--hostname host.example.com --port 1389 \
--noPropertiesFile
```

- To check the topology's status, run `dsreplication status`.

Note:

After the admin account and mappers are created, you can use the `--saslOption useTicketCache=true` and `--saslOption requireCache=true` properties instead of a password for all `dsreplication` commands.

Example:

```
$ bin/dsreplication status \
--saslOption mech=gssapi \
--saslOption authid=replication.admin@EXAMPLE.COM \
--saslOption useTicketCache=true --saslOption requireCache=true \
--hostname host.example.com --port 1389 \
--no-prompt
```

Configuring assured replication

PingDirectory Server's replication mechanism is based on the eventual-consistency model, which is a loosely-connected topology that propagates updates to other servers without waiting for their corresponding replication response messages.

There is a small window of time where updates are not all present on the replicas while the changes are replicating through the system. However, there are deployments that require immediate access to replicated data. In such cases, administrators can configure assured replication, which ensures that replication has completed before the update response is returned to the client.

From the LDAP client's perspective, assured replication has no bearing on the result code of the operation, just on the time in which it takes to receive the response for those requests in which replication assurance is applied. Detailed information regarding assurance processing is available to an LDAP client with awareness of the assured replication control.

The assured replication mechanism uses server location to distinguish between local and remote servers to allow different policies to apply. For example, a common assurance approach is to respond to a client update after all servers in the same location have applied the update and one or more servers in remote locations have received the update. The level of assurance applied to each operation can be explicitly

requested by the client, specified by the server configuration using the Replication Assurance Policy, or both.

Assured replication is supported by client requests directly to PingDirectory Server, through a PingDirectoryProxy Server, or both.

About the Replication Assurance Policy

Assured replication uses a Replication Assurance Policy to define the properties needed to ensure that replication has completed before the update response is returned to the client. Multiple policies can be defined, but only one policy is matched with a client update request. Each policy contains an evaluation order index that, together with an optional request and connection criteria, provides flexibility in matching a policy to request.

The Replication Assurance Policy defines local and remote assurance levels. A level defines how rigorous the policy should be when waiting for propagation of updates while local and remote distinguish servers in the same location versus servers in remote locations. Although optional, you should associate request or connection criteria with a policy to apply replication assurance appropriately.

Directory Server contains a default Replication Assurance Policy that is enabled with the local-level processed-all-servers assurance level. In addition to using the Default Replication Assurance Policy, any number of policies can be created and enabled. When a client request is received, the server iterates through the list of enabled policies according to each policy's `evaluation-order-index` property. A smaller `evaluation-order-index` value (such as 1) has precedence over policies with larger `evaluation-order-index` values (such as 2, 3, 4, and so forth). The `evaluation-order-index` values do not need to be contiguous. The first policy that matches a request is associated with the operation.

The Replication Assurance Policy, which is defined on the PingDirectory Server and not on the PingDirectoryProxy Server, has the following properties:

`evaluation-order-index`

Determines the evaluation order among multiple Replication Assurance Policies that match against an operation. The smaller value has precedence.

`local-level`

Specifies the assurance level used to replicate to local servers. A local server is defined as a server with the same `location` property value as set in the global configuration. The `local-level` property must be set to an assurance level as strict as the `remote-level` property. For example, if the `remote-level` is set to `processed-all-remote-locations`, then the `local-level` property must be `processed-all-servers`.

None

Replication to any local server is not assured.

`received-any-server`

At least one available local server must receive a replication update before a response is sent to the client.

`processed-all-servers`

All available local servers must complete replay of the replication update before the response is sent to the client. If a singular server is enabled, or only one server is available for a particular location, `processed-all-servers` returns a value of `false`.

`remote-level`

Specifies the assurance level used to replicate to remote servers. A remote server is defined as a server that has a different `location` property value as set in the global configuration.

None

Replication to any remote server is not assured.

received-any-remote-location

At least one server at any available remote location must receive a replication update before a response is sent to the client.

received-all-remote-locations

All available remote servers must receive a replication update before the response is sent to the client.

processed-all-remote-servers

All available servers at all locations must complete replay of the replication update before the response is sent to the client. If a single server is enabled, or only one server is available for a particular location, `processed-all-remote-servers` returns a value of `false`.

timeout

Specifies the maximum length of time to wait for the replication assurance requirements to be met before timeout and replying to the client.

connection-criteria

Specifies connection criteria used to indicate which operations from clients matching this criteria use this policy. If both connection criteria and request criteria are specified for a policy, then both must match an operation for the policy to be assigned.

request-criteria

Specifies request criteria used to indicate which operations from clients matching this criteria use this policy. If both connection criteria and a request criteria are specified for a policy, then both must match an operation for the policy to be assigned.

Servers in a replication topology are not required to share a homogeneous set of policies. You can configure the Replication Assurance Policies differently on the replicas in a topology. For example, if you configure server A to match add operations to a `processed-all-servers` assurance level, and server B to match add operations to a local `received-any-server` level, then add operations received on server A have the assurance level of `processed-all-servers` and add operations received on server B have the assurance level of `received-any-server`.

For more information, see the PingDirectory Server Configuration Reference Guide.

About assured replication

When implementing assured replication, make note of the following.

Item	Description
Client Controls	<p>The client can include an assured replication request control with each operation. This control allows the client to specify bounds on assurance levels, override the timeout assigned by the matching replication assurance policy for the associated operation, or both. The server always honors these request controls.</p> <p>For more information, see About the Assured Replication Controls.</p>

Item	Description
Directory Proxy Server	Replication assurance policies are not supported on PingDirectoryProxy Server. Replication client controls are passed through to the underlying Directory Server backend.
Schema backend Replication	The schema backend is not supported by assured replication. Replication assurance policies that include criteria to match this backend are rejected.
Backward Compatibility	Server versions that support assured replication are backwards-compatible with prior versions that do not support assured replication.
WAN-Friendly Replication	Assured replication functions independently from WAN-Friendly Replication and the notion of WAN Gateways.
Global Configuration Properties	<p>Directory Server provides two configurable global configuration properties that determine the timing of the assurance source and maximum number of replication backup updates recognized as an available source.</p> <p><code>replication-assurance-source-timeout-suspend-duration</code></p> <p>Specifies the amount of time a replication assurance source is suspended from assurance requirements if it experiences an assurance timeout. While suspended, the source is excluded from assurance requirements for all operations originating on this Directory Server. This avoids the situation of repeated timeouts caused by degraded or offline servers. The default time is 10 seconds.</p> <p><code>replication-assurance-source-backlog-fast-start-threshold</code></p> <p>Specifies the maximum number of replication backlog updates a replication assurance source can have and be immediately recognized as an available source. If a source connects to this server with more than the configured threshold backlog updates, it is excluded from assurance requirements for all operations originating from this Directory Server until it completes at least one assurance successfully, indicated by this Directory Server receiving an update acknowledgment message from it within the timeout window. The default maximum number of updates is 1000.</p>

Configuring assured replication

About this task

It is common for all servers to have the same policy. The following example, which demonstrates the configuration of various assured replication policies, assumes that three servers are configured on localhost, on ports 1389, 2389, and 3389.

Note:

In this example, each server has a default Replication Assurance Policy with no assurance levels set.

Steps

1. To create request criteria for add operations on server 1, run **dsconfig** with the `create-request-criteria` option.

Note:

This request criteria is used to match any add operation with the Replication Assurance Policy that is configured in the following step.

Example:

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Adds \
  --type simple \
  --set operation-type:add
```

2. To make all add operations assured with a level of `processed-all-servers` on server 1, set up the Replication Assurance Policy using **dsconfig** and specify the `Adds` request criteria configured in the previous step.

Note:

The `processed-all-servers` level indicates that all local servers in the topology must complete replay of the replication update before the response is sent to the client.

Example:

```
$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Adds Processed All Locally" \
  --set evaluation-order-index:1 \
  --set local-level:processed-all-servers \
  --set "timeout:500ms" \
  --set request-criteria:Adds
```

- On server 1, repeat steps 1-2 for `modify` operations.

Note:

The Replication Assurance Policy `Mods Received Any Locally` ensures that at least one available local server must receive a replication modify update before a response is sent to the client.

Example:

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Mods \
  --type simple \
  --set operation-type:modify

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Mods Received Any Locally" \
  --set evaluation-order-index:2 \
  --set local-level:received-any-server \
  --set "timeout:500ms" \
  --set request-criteria:Mods
```

- To set up the `Adds` and `Mods` request criteria and a Replication Assurance Policy on server 2, repeat steps 1-3.

Example:

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Adds \
  --type simple \
  --set operation-type:add

$ bin/dsconfig create-request-criteria \
  --criteria-name Mods \
  --type simple \
  --set operation-type:modify

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Adds Received Any Locally" \
  --set evaluation-order-index:1 \
  --set local-level:received-any-server \
  --set "timeout:500ms" \
  --set request-criteria:Adds

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Mods Processed All Locally" \
  --set evaluation-order-index:2 \
  --set local-level:processed-all-servers \
  --set "timeout:500ms" \
  --set request-criteria:Mods
```

Note:

Leave server 3 with the default Replication Assurance Policy configured with no assurance levels or criteria. In practice, it is common for all servers to have the same assurance levels or criteria.

- To list the policies on server 1 to confirm that they exist, run `dsconfig` with the `list-replication-assurance-policies` option.

Example:

```
$ bin/dsconfig list-replication-assurance-policies
```

- Repeat step 5 for server 2 and server 3.

Server 3 should only show the Default Replication Assurance Policy.

- To check the Replication Assurance counters on all servers before any `add` or `modify` operation, use `ldapsearch`.

Note:

The counters should be set to zero. These counters are on the replica server where the policy is matched and assigned.

Example:

For this example, on server 1, run the following command.

```
$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-local-completed-normally: 0
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

- To check the Replication Summary table on all of the servers, use `ldapsearch`.

Example:

For this example, on server 1, run the following command.

```
$ bin/ldapsearch --baseDN "cn=Replication Summary
dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 0
replication-assurance-local-completed-normally: 0
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

9. To add an entry to server 1 on Directory Server, use `ldapmodify`.

The counters should match the newly added entry to the `Adds Processed All Locally` policy and complete assured.

Example:

```
$ bin/ldapmodify --filename add-user.ldif --defaultAdd

$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 1
replication-assurance-local-completed-normally: 1
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
replication-assurance-policy-matches: Adds Processed All Locally: 1
replication-assurance-policy-matches: Default Replication Assurance
  Policy: 0
replication-assurance-policy-matches: Mods Received Any Locally: 0
replication-assurance-local-level-uses: processed-all-servers: 1
replication-assurance-remote-level-uses: none: 1

$ bin/ldapsearch --baseDN "cn=Replication Summary
  dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 1
replication-assurance-local-completed-normally: 1
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

10. Perform a modify of an entry under `dc=example,dc=com` on server 1.

The counters should match the `modify` operation to the `Mods Processed All Locally` policy and the operations should complete assured.

Example:

```
$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 2
replication-assurance-local-completed-normally: 2
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
```

```

replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
replication-assurance-policy-matches: Adds Processed All Locally: 1
replication-assurance-policy-matches: Default Replication Assurance
  Policy: 0
replication-assurance-policy-matches: Mods Received Any Locally: 1
replication-assurance-local-level-uses: processed-all-servers: 1
replication-assurance-local-level-uses: received-any-server: 1
replication-assurance-remote-level-uses: none: 2

$ bin/ldapsearch --baseDN "cn=Replication Summary
  dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 2
replication-assurance-local-completed-normally: 2
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0

```

Result: You have successfully configured Assured Replication.

About the assured replication controls

The LDAP SDK for Java provides an implementation of an LDAP control that can be included in `add`, `bind`, `modify`, `modifyDN`, and certain extended requests to indicate the optimal level of replication assurance for the associated operation. The OID for this control is 1.3.6.1.4.1.30221.2.5.28 and can have a criticality of either `TRUE` or `FALSE`.

For more information, see the LDAP SDK Javadoc for the `AssuredReplicationRequestControl` class.

Managing the topology

The following sections describe common topology management operations.

When enabling or disabling replication within a topology that contains multiple product versions, you must run the `dsreplication` tool from the server root location of a member of the topology that has the oldest product version.

Adding a server to the topology

Before you begin

You must:

- Have an existing directory server topology.
- Ensure that more than 50% of servers in the topology and the new server are online.

About this task

The commands are identical for initial enablement between two servers where one server contains data for the replication domain stored in the `userRoot` backend. If database encryption is being used on the servers in the topology, the server being initialized must have a copy of the `encryption-settings` backend from the source server.

Steps

1. To enable replication for the base distinguished name (DN), or base DNs, run **dsreplication enable** using an existing server as **host1** and the new server as **host2**.

Example:

```
$ bin/dsreplication enable \
  --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 austin03.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt
```

2. Optional: To compare the configurations between the two hosts used in the **dsreplication enable** command, run **config-diff**.

Note:

Ensure settings are consistent across the topology and are also consistent with the new system.

Example:

```
$ bin/config-diff --sourceLocal \
  --targetHost austin03.example.com \
  --targetBindDN "cn=directory manager" \
  --targetBindPassword pass --targetPort 1389
```

Disabling replication and removing a server from the topology

Before you begin

More than 50% of the servers not being removed from the topology must be online during the process.

About this task

When removing a server from the topology, the remaining servers need to be made aware of the change. If additional servers are offline and cannot be online while removing the server, you must distinguish between offline servers that are offline permanently and those that are offline temporarily.

Note:

If servers are offline permanently, use **remove-defunct-server** to remove them. If servers are offline temporarily, they update automatically after they are online.

Steps

1. To remove a server from the topology:

Choose from:

- To remove a server that is online, run **dsreplication disable** from any server.

```
$ bin/dsreplication disable --hostname austin03.example.com --port
1389 \
  --baseDN dc=example,dc=com --adminUID admin --adminPassword password \
```

```
--no-prompt
```

 **Note:**

If the server to remove is online, only one invocation of **dsreplication disable** is necessary.

- To remove a server that is offline, run **remove-defunct-server** in the following locations:
 - a. From any server not being removed from the topology
 - b. On the offline server to be removed

```
$ bin/remove-defunct-server --serverInstanceName austin01 \
--bindDN "cn=Directory Manager" --bindPassword password
```

 **Tip:**

To speed up the process of removing multiple servers, change the default 10-minute timeout for each server you are taking out of rotation by setting the Java virtual machine (JVM) property `com.unboundid.connectionutils.LdapResponseTimeoutMillis` before you run **remove-defunct-server**.

2. To remove any topology references, run the **remove-defunct-server** tool on each server that is removed from the topology.

Example:

```
$ bin/remove-defunct-server --performLocalCleanup --no-prompt
```

 **Warning:**

To remove the defunct server, you must include the `--no-prompt` parameter. If you exclude this parameter, the server won't be removed from the topology. Additionally, the server might attempt to contact additional hosts in the topology, which could result in an error. These are known issues that only apply to `--performLocalCleanup` and will be corrected in a future release.

 **Note:**

The `--ignore-online` option removes an online server cleanly from the topology.

Replacing the data for a replicating domain

About this task

In case the data for the entire replication domain, such as the backend, needs to be replaced, perform the following steps:

Steps

1. With all servers online, run **dsreplication pre-external-initialization** against any server in the topology.

Example:

```
$ bin/dsreplication pre-external-initialization --hostname
austin01.example.com \
```

```
--port 1389 --baseDN dc=example,dc=com --adminUID admin \  
--adminPassword password --no-prompt
```

Result: Replication is stopped for the domain. No writes are made by clients to any of the servers.

2. To replace the data for **dc=example,dc=com**, use **import-ldif**.
 - a. Optional: To overwrite the existing data for the domain, use the `--overwriteExistingEntries` option.
 - b. Optional: To ensure that the input LDIF is free of any replication attributes, use the `--excludeReplication` option.

Example:

In this example, you perform the **import-ldif** with the server offline using the `--excludeReplication` and `--overwriteExistingEntries` options.

```
$ bin/import-ldif --ldifFile new-data.ldif --backendID userRoot --  
excludeReplication --overwriteExistingEntries
```

3. To initialize the other servers in the topology, run **dsreplication initialize** using the server that has the new data as the source host.

Example:

```
$ bin/dsreplication initialize --hostSource austin01.example.com --  
portSource 1389 \  
--hostDestination budapest01.example.com --portDestination 1389 \  
--adminUID admin --adminPassword password --baseDN dc=example,dc=com \  
--no-prompt
```

4. From any server in the topology, run **dsreplication post-external-initialization** once.

Note:

All servers in the topology must be online.

Example:

```
$ bin/dsreplication post-external-initialization --hostname  
austin01.example.com \  
--port 1389 --baseDN dc=example,dc=com --adminUID admin \  
--adminPassword password --no-prompt
```

Advanced configuration

The following sections cover advanced configuration procedures for your company's deployment needs.

Changing the replicationChanges DB Location

About this task

If on-disk space issues arise, you can change the `replicationChanges` database (DB) location. The replication changelog database can live outside `<server-root>` and be placed in another location on the file system. To do this, specify the absolute path of the replication changelog directory.

Steps

1. To change the database location for the replication changelog, use the `dsconfig` tool.

Note:

By default, the database location is at `<server-root>/changelogDb`.

Example: The following command sets the replication Changelog Backend to `<server-root>/data/directory/changelogDB`.

Note:

Remember to include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set "replication-db-directory:/data/directory/changelogDb" \
  --bindDN "cn=Directory Manager" --bindPassword secret --no-prompt
```

2. Stop the server.

Example:

```
$ bin/stop-server
```

3. Move the DB files.

Example:

```
$ mv changelogDb /data/directory
```

4. Restart the server.

Example:

```
$ bin/start-server
```

Modifying the replication purge delay

The replication purge delay specifies the period after which the directory server purges replication server database changes. Any change that is older than the purge delay is removed from the replication server database regardless of whether the change has been applied.

About this task

Currently, PingDirectory Server sets the default purge delay to one day. Administrators can change the default purge delay using the `dsconfig` tool.

Note:

To ensure proper replication processing, you must have the same purge delay value set for all replication servers in the topology.

Steps

- To change the purge delay, choose from one of the following options:
Choose from:
 - Use the `dsconfig` tool.
 - Use the `dsconfig` tool in interactive mode:
 1. Open the **Advanced objects** menu.
 2. Select **Replication Server**.
 3. Select the replication synchronization provider.
 4. Select the option to change the replication purge delay.

The property accepts time units of seconds (s), minutes (m), hours (h), days (d), or weeks (w).

Example:

The following command changes the purge delay from the default of one day to two days.

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set "replication-purge-delay:2 d"
```

Configuring a single listener-address for the replication server

Configure a single listener-address for the replication server to change the default setting of listening on all addresses.

About this task

By default, the replication server binds the listening ports to all available interfaces of the machine. To bind the listener to a specific address, change the address to the host name provided when replication is enabled and set the `listen-on-all-addresses` property to `FALSE`.

The replication server's configuration entry stores a host name for itself so that it can resolve the address and specify it during the socket bind. If the server information is missing from the system, an error message generates with instructions on specific address binding. You can use the `dsconfig` tool to change the value of the `listen-on-all-addresses` property from `TRUE` (default) to `FALSE`.

To configure a replication server to listen on a single address:

Steps

1. Create a new directory server instance and enable replication on port 8989.
2. To see the ports bound for listening on port 8989, run `netstat`.

Note:

A port of `*.8989` means that it is listening on all addresses.

Example:

```
$ netstat -an | grep LISTEN | grep 8989
```

3. To disable listening on all addresses for the replication server, run the `dsconfig` tool.

Example:

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set listen-on-all-addresses:false
```

- To see the ports bound for listening on port 8989, run `netstat` again.

Note:

A port of `<address>.8989`, such as `10.8.1.211.8989`, means that it is listening on the one address.

Monitoring replication

This section covers how to use the PingDirectory Server to monitor replication.

The PingDirectory Server monitors replication in the following ways:

- Use the `dsreplication` tool with the `status` subcommand to display basic information about the replicated base distinguish names (DNs), the number of entries replicated, as well as the approximate size of replication backlogs at each Directory Server.
- Obtain more detailed information about the state of replication through the information exposed in its monitoring framework under `cn=monitor`.
- Use Periodic Stats Logger plugin, which allows collecting replication statistics for profiling server performance. For more information, see [Profiling Server Performance Using the Periodic Stats Logger](#).

Administrators can monitor their replication topologies using several tools and protocols:

- The PingDataMetrics Server
- SNMP
- LDAP
- JMX
- The Administrative Console. For more information, see [Managing Logging](#) and [Managing Monitoring](#).

Monitoring replication using `cn=monitor`

The `cn=monitor` branch has a number of entries that store the replication state of a topology.

`cn=monitor` branch entries and their descriptions

<code>cn=monitor</code> entries	Description
Direct LDAP Server <code><baseDN><host name:port><serverID></code>	<p>Defines an LDAP server that directly connects to the replication server you are querying. The information in this entry applies to the replication server local to the <code>cn=monitor</code> entry.</p> <p>For more information, see Summary of the Direct LDAP Monitor Information.</p>
Indirect LDAP Server <code><baseDN><serverID></code>	<p>Defines an LDAP server that connects to another replication server in the topology. While this server connects to the same topology, it does not connect to the replication server you are querying.</p> <p>For more information, see Summary of the Indirect LDAP Server Monitor Information.</p>
Remote Repl Server <code><baseDN><host name:port><serverID></code>	<p>Defines a remote replication server that connects to the local replication server. Information in this entry is in respect to the Replication Server local to the <code>cn=monitor</code> branch.</p> <p>For more information, see Summary of the Remote Replication Server Monitor Information.</p>

cn=monitor entries	Description
Replica <baseDN>	Stores information for an instance of the replicated naming context, also known as the replica, with respect to the Directory Server and its communication with a replication server. The replica information sends and receives changes from the replication servers. For more information, see Summary of the Replica Monitor Information .
Replication Server	Shows the information specific to the Replication Server running. For more information, see Summary of the Replication Server Monitor Information .
Replication Server Database <baseDN><serverID>	Shows information for the changelog table of replica (suffix) in the replication server. As the Replication Server receives updates from the Directory Server, it records those changes in the changelog table. For more information, see Summary of the Replication Server Database Monitor Information .
Replication Server Database Environment	Shows the information for the database environment for the replication server backend as well as the total number of records added to and deleted from the database. For more information, see Summary of the Replication Server Database Environment Monitor Information .
Replication Summary <baseDN>	Shows summary information on the replication topology and the state for a particular base distinguish name (DN). For more information, see Summary of the Replication Summary Monitor Information .
replicationChanges Backend	Shows the backend information for all replication changes. For more information, see Summary of the Replication Changes Backend Monitor Information .
Replication Protocol Buffer	Shows the state of the buffer (initially 4k) for protocol operations, which is stored in thread local storage. For more information, see Summary of the Replication Protocol Buffer Monitor Information .

Replication best practices

This section covers the best practices for replication based on our observations in production environments.

About the dsreplication command-line utility

The following points involve some security practices that apply to replication. For specific questions, contact your authorized support provider.

Developing Scripts

The **dsreplication** utility maintains the history of executed **dsreplication** commands with the full command-line arguments in the `logs/tools/dsreplication.history` file. Use the recorded commands to develop scripts to set up and configure replication.

Scripts invoking the **dsreplication** utility in non-interactive mode check the return code from the **dsreplication** process. A non-zero return code indicates a failure.

To exclude output messages from the **dsreplication** utility, use the `--quiet` option to suppress them.

By default, the utility fails if one or more warnings are issued during the command execution. To suppress warnings, use the `--ignoreWarnings` option.

Note:

This option is required when using **dsreplication** with non-fully-qualified host names, such as `localhost`. Otherwise **dsreplication** fails. However, you should avoid using this flag in production environments.

Concurrent Use

With the exception of using the **dsreplication** utility with the `status` subcommand, the **dsreplication** subcommands cannot execute concurrently. The command-line utility locks the replication topology at one or more servers to prevent accidental configuration changes caused by multiple **dsreplication** subcommands running at the same time. For best practices, avoid making concurrent configuration changes.

Status

Using the **dsreplication** utility with the `status` subcommand requires the Replication Servers to provide monitoring information. This can lead to a delay before the output of **dsreplication status** displays. By default, **dsreplication** displays the status for all replicated domains with the exception of the special domains of the schema and the server registry.

Select a particular base distinguished name (DN) for **dsreplication status** if multiple base DNs are configured for replication.

Avoid invoking **dsreplication status** too often, such as more than once every 15 seconds or from multiple locations at the same time. Some of the information displayed by **dsreplication status** is based on monitor information that does not refresh every time the monitor is queried.

Do not use the `status` subcommand for collecting performance metrics. It is best to use the Periodic Stats Logger plugin for replication-related information.

Topology Tasks

The **dsreplication** tool allows specifying more than one server in a topology to act as the host for other servers for the `enable` and `initialize` actions. Use the `--topologyFilePath` option to specify a file with a series of hosts and ports in the topology.

For example, when the hosts file is used for an `enable` or `initialize` action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available. This file generates with the `manage-topology export` command.

Replication conflicts

This section provides in-depth information about the mechanisms and possible scenarios behind replication conflicts.

Updates to the Directory Server entries in a replication topology can happen independently because replication guarantees only eventual consistency and not strong consistency. The eventual consistency model enables applying conflicting changes at different directory server instances. In most cases, the Directory Server can resolve these conflicts automatically and in a consistent manner: for example, all directory server instances in a replication topology resolving each and every conflict the same way. However, in some scenarios, manual administrative action is required. For any of these unresolved conflicts, the administrator receives notification through administrative alerts.

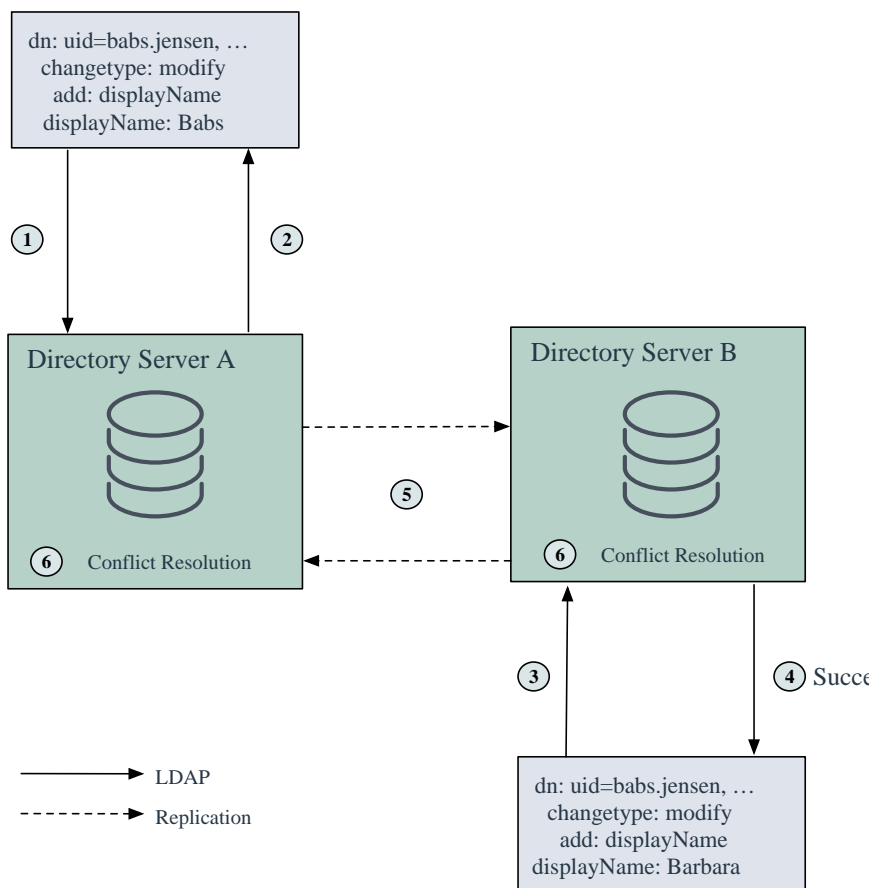

On a high level, the conflict resolution algorithm tries to resolve conflicts as if the operations causing the conflict in a distributed environment apply to a single directory server instance. For example, if the same entry is added to two different directory server instances at about the same time, after these operations are replicated, both directory servers keep only the first entry added.

The following image highlights the differences between standalone versus replicated environments.

Standalone

Replicated

Conflicting Operations in Standalone versus Replicated Environments

Processing steps

1. Client sends LDAP modify request to Directory Server and succeeds.
2. Client sends another LDAP modify request that conflicts with the first.

3. In the standalone case, the request is rejected. In the replicated case, the request succeeds.
4. Replication propagates the updates (replicated only).
5. Conflict resolution (replicated only): A ignores the update from B. B sets the attribute value to the value on A.

Types of replication conflicts

There are two types of replication conflicts:

Naming conflicts

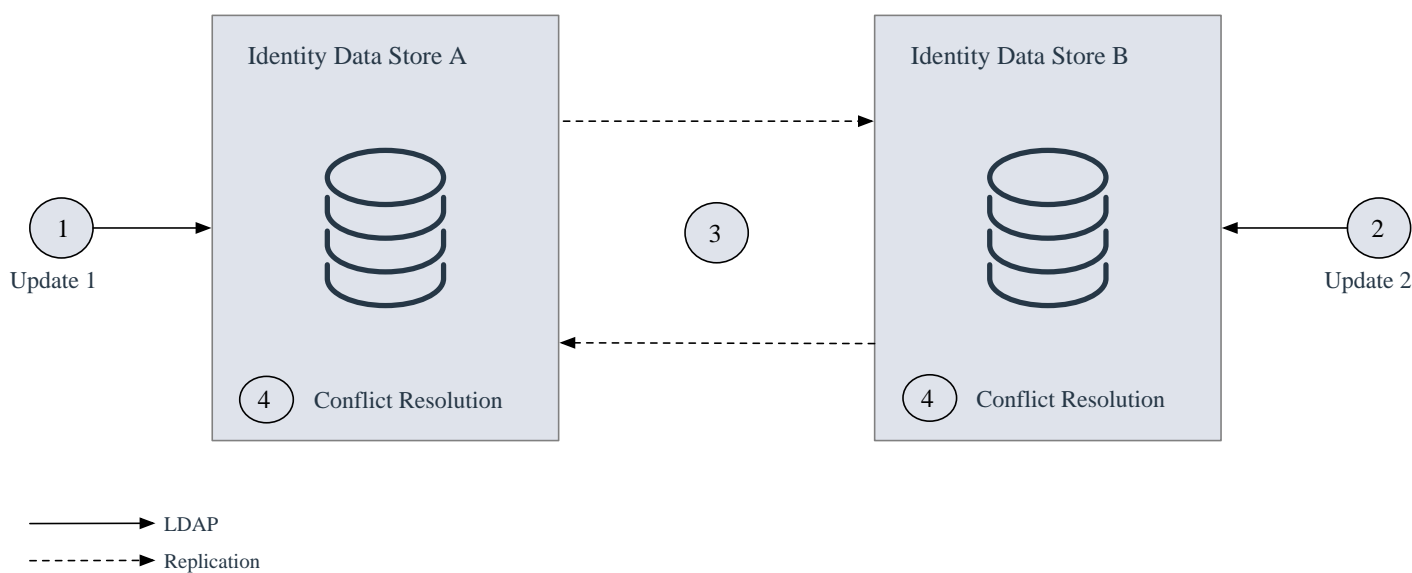

Naming conflicts include operations that cause conflicts with the naming of the distinguish name (DN) of the existing or new entries.

Modification conflicts

Modification conflicts include operations that result in conflicts in the modification of attributes.

Naming conflict scenarios

The following illustration depicts the naming conflict scenario.

Processing steps

1. The Client sends an update (Add, Delete, or Modify DN) request to server A.
2. The Client sends an update (Add, Delete, or Modify DN) request conflicting with the first request to server A.
3. Replication propagates the updates.
4. Conflict resolution takes place.

The following table shows the result of a modification conflict depending on the type of updates that occur. The code does not compare change sequence numbers (CSNs) but applies operations in the order they were received. This might lead to inconsistent replays.

For all of the naming conflict scenarios, assume the following:

- Update 1 was applied at Directory Server 1.
- Update 2 was applied at Directory Server 2.
- Update 1 occurred shortly before Update 2 so that Directory Server 2 received Update 1 after Update 2 was applied.

Naming Conflict Scenarios

Update 1	Update 2	Automatic Resolution?	Result of Conflict Resolution at Directory Server 2 When Update 1 is received
Modify	Delete	Yes	Modify is discarded.
Modify	Modify DN	Yes	New entry is located based on the entryUUID and Modify is applied to the renamed entry.
Delete	Delete	Yes	Delete operation is ignored.
Delete	Modify DN	Yes	Delete operation is applied to the renamed entry.
Delete of A	Add of B under A	Yes	Entry B is renamed and Entry A is deleted.
Modify DN	Delete of the same entry targeted by the Modify DN	Yes	Modify DN operation is ignored.
Modify DN with a new parent	Delete of parent	No	The entry targeted in the Modify DN operation is marked as a conflict entry.
Modify DN with a new parent	Modify DN of the parent	Yes	The entry is moved under the new DN of the parent.
Modify DN of A with new DN B	Modify DN of C with new DN B	No	A and B will be conflict entries.
Add A	Modify DN of the parent of A	Yes	The entry is added under the new DN of the parent.
Add A	Delete of the parent of A	No	The added entry is marked as a conflict entry.
Add A	Add A with same set of attributes	Yes	The entryUUID of the incoming Add operation applied to the existing entry.
Add A	Add A with different set of attributes (or values)	No	The existing entry is marked as a conflicting entry and the incoming Add is executed.

Modification conflict scenarios

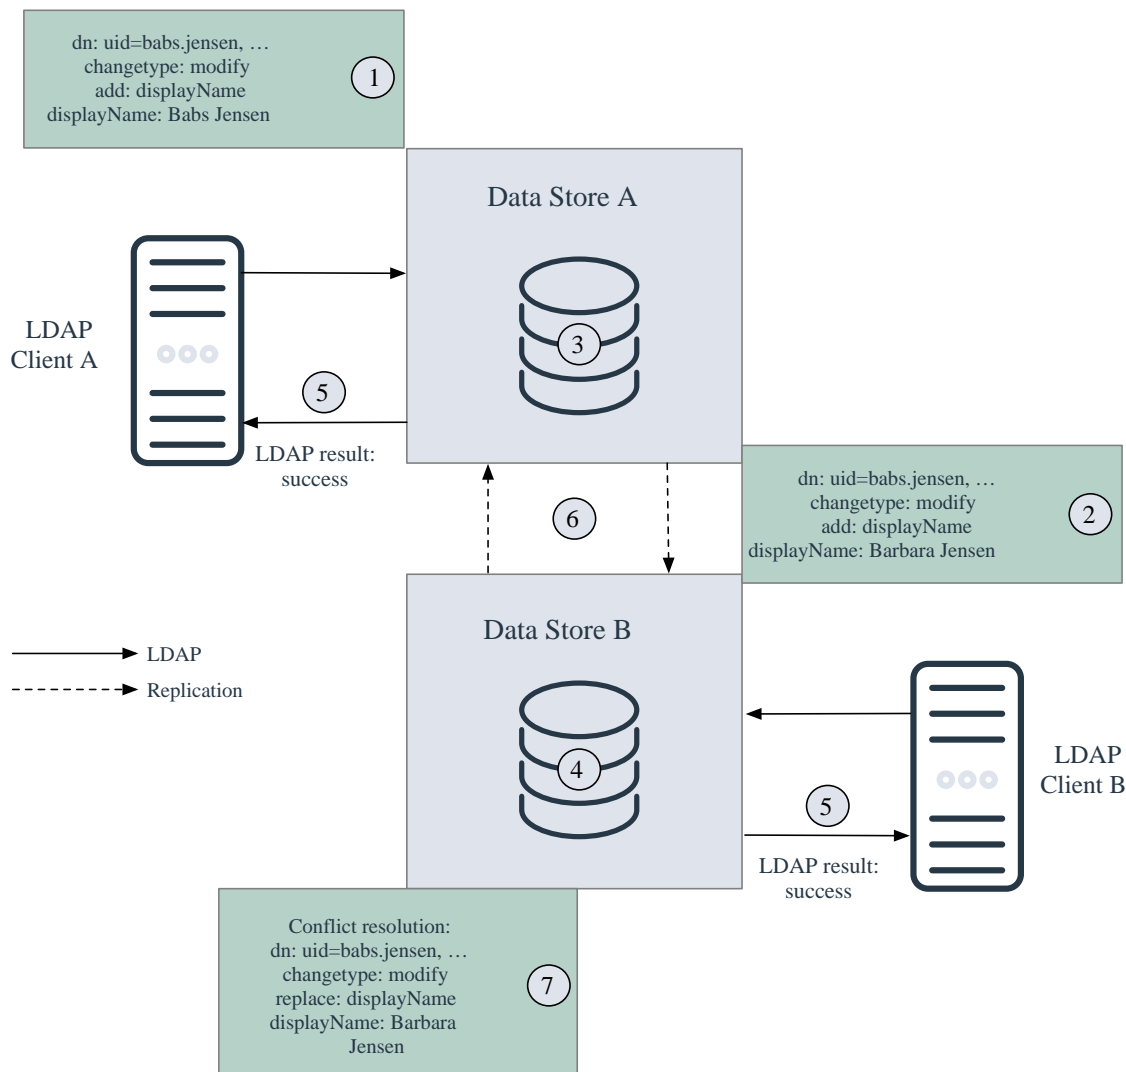

Modification conflicts resolve automatically and no manual action is required. The LDAPModify operation allows the following modification types:

- Add of one or more values
- Delete of one or more values or the entire attribute
- Replacement of all values

**Note:**

Replication does not currently support the increment LDAP modification type.

The following illustration presents a modification conflict scenario.

**Processing steps**

1. LDAP client A sends a `modify` request to Directory Server A.
2. LDAP client B sends a conflicting `modify` request to Directory Server B.
3. Directory Server A applies the modification.
4. Directory Server B applies the modification.
5. The LDAP clients receive successful responses.
6. Replication propagates the updates.
7. Conflict resolution on Directory Server A updates the entry to reflect the value on Directory Server B.

Conflict resolution on Directory Server B ignores the update received from Directory Server A.

The following table shows the result of a modification conflict depending on the type of updates that occur. For all of the operations in the table, assume the following:

- LDAP Modify 1 was applied at Directory Server 1.

- LDAP Modify 2 was applied at Directory Server 2.
- LDAP Modify 1 occurred shortly before LDAP Modify 2, so that Directory Server 2 received LDAP Modify 1 after LDAP Modify 2 was applied.

Modification Conflict Scenarios

Modify 1	Modify 2	Result of Conflict Resolution at Directory Server 2 When Modify 1 is received
Add of a single-value attribute	Add of the same attribute with a different value	Incoming <code>Modify</code> is ignored.
Delete of a single-valued attribute	Replacement of the value of the same attribute	Incoming <code>Delete</code> is ignored.
Replacement of a single-valued attribute	Delete of the same attribute	Incoming Replacement is ignored.
Delete some values from a multi-valued attribute	Delete some values from a multi-valued attribute	Incoming <code>Delete</code> is ignored.
Delete a multi-valued attribute	Delete of the same multi-valued attribute	Incoming <code>Delete</code> is ignored.
Delete a multi-valued attribute	Add the same multi-valued attribute	Incoming <code>Delete</code> is ignored.
Delete value X from a multi-valued attribute	Delete value X from the same multi-valued attribute	Incoming <code>Delete</code> is ignored.
Delete value X from a multi-valued attribute	Add value Y to the same multi-valued attribute	Delete of value X is applied.
Delete value X from a multi-valued attribute	Delete value Y from the same multi-valued attribute	Delete of value X is applied.
Delete value X from a multi-valued attribute	Replace all values of the same multi-valued attribute	Incoming <code>Delete</code> is ignored.
Add of values X and Y to a multi-valued attribute	Delete value X from the same multi-valued attribute	Only value Y is added.
Delete value X from a multi-valued attribute	Add of values X and Y to the same multi-valued attribute	Incoming <code>Delete</code> is ignored.

Troubleshooting replication

This section covers information on troubleshooting your replication deployment.

Recovering a replica with missed changes

If a server has been offline for a period of time longer than the replication purge delay, you must run the `dsreplication initialize` command to bring the replica into sync with the topology.

Any missed changes are detected at the time of server startup. A missed change is a change that the replica detects it needs, but the change is not found within any other replication server's replicationChanges backend stored in the `/changeLogDb` server root path.

If missed changes are detected, the server enters lockdown mode, where only privileged clients can make requests. Any other server that is not missing changes can be used as a source for `dsreplication initialize`.

If the server requires a manual backup and restore, perform the following steps, which are equivalent to `dsreplication initialize`.

Performing a manual initialization

About this task

To manually initialize a server when an online initialization isn't possible:

Steps

1. From another server in the replication topology, back up the `userRoot`, `schema`, and `replicationChanges` backends to the `<server-root>/bak` directory.

Tip:

If data encryption is enabled, export the `encryption-settings` backend because you might need to import one or more encryption settings IDs into the new replica.

Example:

```
$ source-server-root>/bin/backup --backendID userRoot --backupDirectory \
  bak/userRoot
$ <source-server-root>/bin/backup --backendID schema --backupDirectory \
  bak/schema
$ <source-server-root>/bin/backup --backendID replicationChanges \
  --backupDirectory bak/replicationChanges
$ <source-server-root>/bin/encryption-settings export --id <id> \
  --output-file bak/exported-key
```

2. Copy the `bak` directory to the new replica.

Example:

```
$ scp -r <source-server-root>/bak/* \
  <user>@<destination-server>:<destination-server-root>/bak
```

3. Stop the server.
4. Restore the `userRoot`, `schema`, `changelog`, and `replicationChanges` backends.

Important:

If the `encryption-settings` backend was exported, import it before restoring any of the backends.

Example:

```
$ <destination-server-root>bin/encryption-settings import --input-file \
  bak/exported-key --set-preferred
Enter the PIN used to encrypt the definition:
$ <destination-server-root>/bin/restore --backupDirectory bak/userRoot
$ <destination-server-root>/bin/restore --backupDirectory bak/schema
```

```
$ <destination-server-root>/bin/restore --backupDirectory \
    bak/replicationChanges
```

5. Start the server using `bin/start-server`.

Fixing replication conflicts

Replication conflicts occur when an incompatible change to an entry is made on two replicas at the same time. The change processes on one replica and then replicates to the other replica, which causes the conflict. While most conflicts resolve automatically, some require manual action.

To fix replication conflicts, initialize the replica containing the conflicts with the data from another replica that does not have conflicts. If the database is large and the number of conflicts is small, and the command includes the Replication Repair Control specified by OID value `1.3.6.1.4.1.30221.1.5.2`, run `ldapmodify` against the server with the conflict. The Replication Repair Control prevents the change from replicating and enables changing operational attribute values, which are not normally writable.

The following tasks use the Replication Repair Control to fix replication conflicts and apply change only to the server with the conflict. There are two examples provided to fix replication conflicts: one for fixing a modify conflict using the `ldap-diff` tool and the other for fixing a naming conflict.

Fixing a modify conflict

Steps

1. To isolate conflicting entries between two replicas, use the `bin/ldap-diff` tool.

Note:

Replace the `sourceHost` value with the server that needs the adjustment.

Example:

The following example uses the tool to search across the entire base distinguish name (DN) for any difference in user attributes and reports the difference in `difference.ldif`.

```
$ bin/ldap-diff --sourceHost austin02.example.com --sourcePort 1389 \
    --sourceBindDN "cn=Directory Manager" --
sourceBindPassword pass \
    --targetHost austin01.example.com --targetPort
1389 \
    --targetBindDN "cn=Directory Manager" --
targetBindPassword
difference.ldif \
    --baseDN "dc=example,dc=com" --outputLDIF
"*" pass \
    --searchFilter "(objectclass=*)" --numPasses 3
    "^userPassword"
```

2. To apply changes to the server that contains conflicts, use the `difference.ldif` file in a format compatible with `ldapmodify`.

Important:

Run `ldap-diff` command with the `sourceHost` value as the server with conflicts.

Example:

The following is an example of the contents of `difference.ldif` file.

```
dn: uid=user.1,ou=people,dc=example,dc=com
```

```
changetype: modify
add: mobile
mobile: +1 568 232 6789
-
delete: mobile
mobile: +1 568 591 7372
-
```

- To correct the entries on the sole server with conflicts, run `bin/ldapmodify`.

Example:

```
$ bin/ldapmodify --bindPassword password -J "1.3.6.1.4.1.30221.1.5.2" \
  --filename difference.ldif
```

Fixing a naming conflict

About this task

In this example, a naming conflict was encountered when the replica attempted to replay an `ADD` of `uid=user.200,ou=people,dc=example,dc=com`. Because of this conflict, the server returns a replication conflict message. See the following example message.

```
[18/Feb/2010:14:53:12 -0600] category=EXTENSIONS severity=SEVERE ERROR
msgID=1880359005 msg="Administrative alert type=replication-unresolved-
conflict
id=bbd2cbaf-90a4-42af-94a8-cla42df32fc6
class=com.unboundid.directory.server.replication.plugin.ReplicationDomain
msg='An unresolved conflict was detected for DN
uid=user.200,ou=People,dc=example,dc=com.
The conflicting entry has been renamed to
entryuuid=69807e3d-ab27-43a3-8759-
ec0d8d6b3107+uid=user.200,ou=People,dc=example,dc=com'"
```

The Directory Server prepends the entryUUID to the DN of the conflicting attribute and adds a `ds-sync-conflict-entry` auxiliary object class to the entry to aid in search.

To resolve the conflict:

Steps

- Search for any entry that has the `ds-sync-conflict-entry` objectclass and returns only the DNs that match the filter.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub \
  "(objectclass=ds-sync-conflict-entry)" "1.1"
```

Result: The search results display the conflicting entry for `uid=user.200`.

```
dn: entryuuid=69807e3d-ab27-43a3-8759-
ec0d8d6b3107+uid=user.200,ou=People,dc=example,dc=com
```

```
dn: entryuuid=523c430e-
a870-4ebe-90f8-9cd811946420+uid=user.200,ou=People,dc=example,dc=com
```

**Note:**

Conflict entries are not returned unless the `objectclass=ds-sync-conflict-entry` is present in the search filter.

2. Compare the conflict entry with the target entry.
3. Apply the difference in two ways:
Choose from:
 - Use the `ldapmodify` tool with the Replication Repair Control.

**Note:**

You can also delete the conflict entry using this command.

- Run `bin/ldapmodify` with the Replication Repair Control to make the fix.

**Note:**

When making changes using the Replication Repair Control, the updates are not propagated through replication. Examine each replica individually, and apply the necessary modifications using the request control.

Example:

```
$ bin/ldapmodify -J "1.3.6.1.4.1.30221.1.5.2" \
--filename difference.ldif
```

Fixing mismatched generation IDs

About this task

If you receive a warning message that multiple generation IDs were detected for a specific suffix, you must re-initialize one or more replicas. If the warning is presented from a server after an initialization, it could be that the `post-external-initialization` command was not run as part of a global change in data.

Try the following fixes as needed.

Steps

- To re-initialize replicas as part of a global change in data, run the `post-external-initialization` command.
- To fix mismatched generation IDs, run the `dsreplication` command.
- To warn when any generation IDs are different across the topology, run the `dsreplication` tool with the `status` command.

Replication reference

This section covers general reference information about replication.

Summary of the `dsreplication` Subcommands

Use this topic as a reference for `dsreplication` subcommands and functions and their descriptions.

The following table presents a summary of the `dsreplication` subcommands and functions.

**Tip:**

To see the available options for each subcommand, run `bin/dsreplication <subcommand> --help`.

Subcommand	Description
disable	Disables replication on the specified server for the provided base distinguish name (DN) and removes references to this server in the other servers with which it is replicating data.
enable	<p>Updates the configuration of the servers to replicate the data under the specified base DN.</p> <p>If one of the servers is already replicating the data under the base DN with other servers, executing this subcommand updates the configuration of all the servers. It is sufficient to execute the command line one time for each server you add to the replication topology.</p>
initialize	Initializes the data under the specified base DN on the destination server with the contents on the source server.
initialize-all	Initializes the data under the specified base DN on all servers in the replication topology with the contents on the specified server.
post-external-initialization	<p>Used with pre-external-initialization, the command resets the generation ID based on the newly-loaded data.</p> <p>Consider the following using this subcommand:</p> <ul style="list-style-type: none"> You must call this subcommand after initializing the contents of all the replicated servers using the import-ldif tool or dsreplication initialize. Specify the list of base DNs that have been initialized and provide the credentials of any of the servers that are being replicated. For more information, see the usage of the pre-external-initialization subcommand. This subcommand only needs to be run one time on one of the replicas.
pre-external-initialization	<p>Clears the existing generation ID and removes all accumulated changes of the replicated suffix from the Replication Changelog Database on every replication server.</p> <p>Consider the following using this subcommand:</p> <ul style="list-style-type: none"> Use this subcommand when globally restoring the replicas on all of the servers in a topology. You must specify the list of base DNs that will be initialized and provide the credentials of any of the servers that are being replicated. After calling this subcommand, initialize the contents of all the servers in the topology, then call the post-external-initialization subcommand. You only need to run this subcommand one time on one of the replicas.

Subcommand	Description
status	<p>Displays the status of replication domains. If no base DN's are specified as parameters, the information for all base DN's displays.</p> <p>Available options with the status subcommand are:</p> <ul style="list-style-type: none"> ▪ --showAll ▪ --displayServerTable ▪ --location

Summary of the Direct LDAP Monitor information

The following table provides a description of the attributes in the `cn=Direct LDAP Server` monitor entry.

The following is the distinguished name (DN) for the monitor entry.

```
dn: cn=Direct LDAP Server <baseDN> <host name:ldapPort>
    <serverID>,cn=monitor
```

Direct LDAP Monitor Information

Monitor Attribute	Description
<code>replica-id:<serverID></code>	Replica ID number.
<code>replication-backlog</code>	Number of changes that the replication server has not seen from the server.
<code>missing-changes</code>	Number of missing changes.
<code>approximate-delay</code>	Difference between the time of the last change that the replication server has seen from the LDAP server and the most current timestamp on the latest change on the server.
<code>base-dn</code>	Base DN
<code>ssl-encryption</code>	Flag to indicate if SSL encryption is in use.
<code>protocol-version</code>	Displays the replication protocol version.
<code>generation-id</code>	Generation ID for the base DN on the Directory Server.
<code>restricted</code>	Boolean that indicates whether the replication domain is restricted in an Entry Balancing Configuration with the Directory Proxy Server.
<code>ack-sent</code>	Number of acknowledgment messages sent to this replica not currently used.
<code>ack-received</code>	Number of acknowledgment messages received from this replica not currently used.
<code>add-sent</code>	Number of protocol messages with an LDAPAdd sent to this replica.
<code>add-received</code>	Number of protocol messages with an LDAPAdd received from this replica.

Monitor Attribute	Description
delete-sent	Number of protocol messages with an LDAPDelete sent to this replica.
delete-received	Number of protocol messages with an LDAPDelete received from this replica.
done-sent	Number of done messages sent to this replica. A done message indicates an end of an online initialization session. If the value is non-zero, then this replica has been initialized over the replication protocol.
done-received	Number of done messages received from this replica. A done message indicates an end of online initialization session. If the value is non-zero, then this replica has completed the initialization of other replicas over the replication protocol.
entry-sent	Number of entry messages sent to this replica. Entry messages carry replicated data to initialize replicas over the replication protocol.
entry-received	Number of entry messages received from this replica. Entry messages carry replicated data to initialize replicas over the replication protocol.
error-sent	Number of error messages sent to this replica.
error-received	Number of error messages received from this replica.
heartbeat-sent	Number of heartbeat messages sent to this replica.
heartbeat-received	Number of heartbeat messages received from this replica.  Note: The number of messages should always be 0 because the replica never sends a heartbeat message to the server.
initialize-request-sent	Number of initialize-request messages sent to this replica. This message is sent when another replica requested initialization of its data using the replication protocol.
initialize-request-received	Number of initialize-request messages received from this replica. This message is sent when this replica requested initialization of its data using the replication protocol from another replica.
initialize-target-sent	Number of initialize-target messages sent to this replica. This message is sent before another replica has started the initialization of this replica.
initialize-target-received	Number of initialize-target messages received from this replica. This message is sent before this replica starts the initialization of one or more replicas.

Monitor Attribute	Description
ldap-server: <hostname:ldapPort>	The host name and port of the local replication server.
modify-sent	Number of protocol messages with an LDAPModify sent to this replica.
modify-received	Number of protocol messages with an LDAPModify received from this replica.
modify-dn-sent	Number of protocol messages with an LDAPModify DN sent to this replica.
modify-dn-received	Number of protocol messages with an LDAPModify DN received from this replica.
repl-server-start-sent	<p>Number of replication-server-start messages sent to this replica. The Replication Server responds with this message to the start message received from the replica.</p> <p> Note: The number of messages should never be more than 1.</p>
repl-server-start-received	<p>Number of replication-server-start messages received from this replica.</p> <p> Note: The number of messages should always be 0.</p>
reset-generation-id-sent	Number of reset generation ID messages received from this replica.
reset-generation-id-received	<p>Number of reset generation ID messages sent to this replica.</p> <p> Note: The number of messages should always be 0.</p>
server-start-sent	<p>Number of server-start messages sent to this replica.</p> <p> Note: The number of messages should always be 0.</p>

Monitor Attribute	Description
server-start-received	<p>Number of server-start messages received from this replica. Server-start is the first message the replica sends after establishing a replication connection.</p> <p> Note: The number of messages should never be more than 1.</p>
window-sent	Number of window messages sent to this replica. Window messages are used for cumulative acknowledgment in the replication protocol.
window-received	Number of window messages received from this replica. Window messages are used for cumulative acknowledgment in the replication protocol.
window-probe-sent	<p>Number of window probe messages sent to this replica.</p> <p> Note: The number of messages should always be 0.</p>
window-probe-received	Number of window probe messages received from this replica. The replica sends a window probe message to the server if the send window in the replica is closed and the replica is unable to publish updates to the server.
update-sent	Number of changes sent to this server.
update-received	Number of changes received from this server.
internal-connection	Indicates if the replica is in the same process as the replication server.
server-state	Displays the state of the replica. Displays the latest change number that the replica has seen from all the other replicas including itself.
consumed-update-recent-rate	Rate that the connected Directory Server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last five seconds.
consumed-update-peak-rate	Highest rate that the connected Directory Server has consumed updates sent by this replication server, measured over a 5 second period from the start of the replication server.
produced-update-recent-rate	Rate that the connected Directory Server has sent updates to this replication server, expressed as the number of updates per second and measured over the last 5 seconds.
produced-update-peak-rate	Highest rate that the connected Directory Server has sent updates to this replication server, measured over a 5 second period from the start of the replication server.
max-send-window	Maximum number of changes that can send to the LDAP server before requiring an ACK.

Monitor Attribute	Description
current-send-window	Current number of changes remaining to be sent to the LDAP server before requiring an ACK.
max-rcv-window	Maximum number of changes that can be received by the LDAP server before sending an ACK.
current-rcv-window	Number of changes remaining to be received by the LDAP server before sending an ACK.
degraded	Indicates that the generation ID of the replica does not match the generation ID of the server. When loading data into the topology, this is a temporary state. If this is not a temporary state, the replica has not been initialized.  Note: The degraded value should be false.

Summary of the Indirect LDAP Server Monitor information

Use this topic as a reference for Indirect LDAP Server Monitor attribute information.

These attributes provide information about a Directory Server that is connected to a different replication server in the topology.

The following is the distinguished name (DN) for the Indirect LDAP server monitor entry.

```
dn: cn=Indirect LDAP Server <baseDN> <serverID>,cn=monitor
```

The following table provides a description of the attributes in the `cn=Indirect LDAP Server` monitor entry.

Monitor Attribute	Description
replica-id: <serverID>	ID number identifying the replica
base-dn:<baseDN>	Base DN
connected-to: Remote Repl Server <baseDN> <host name:replPort> <replID>	Replication server to which the directory server is connected
replication-backlog	Number of changes that the replication server has not seen from the server
approximate-delay	Amount of time between the last change seen by this Directory Server and the most recent change seen by the remote replication server  Note: This value is the amount of time between the time stamps, not the amount of time required to synchronize the 2 servers.

Monitor Attribute	Description
generation-id	Generation ID for this suffix on this remote replication server
consumed-update-recent-rate	Rate that the connected Replication Server is consuming updates sent by this replication server This value is expressed as the number of updates per second and measured over the last 5 seconds.
consumed-update-peak-rate	Highest rate that the connected Replication Server has consumed updates sent by this replication server This value is measured over a 5 second period beginning at the start of the replication server.

Summary of the Remote Replication Server Monitor information

Use this topic as a reference for Remote Replication Server Monitor attribute information.

The following is the distinguished name (DN) for the Remote Replication Server monitor entry.

```
dn: cn=Remote Repl Server <baseDN> <host name:replPort>
   <serverID>,cn=monitor
```

The following table provides a description of the attributes in the `cn=Remote Repl Server` monitor entry.

Monitor Attribute	Description
replication-server: <host name>:<repl port>	Host name and replication port number of the Replication Server.
replication-server-id:<serverID>	Server ID for the Replication Server.
available	Indicates if the remote replication server is available or not. Values: true or false.
sending-paused	Indicates if sending is paused. Values: true or false.
receiving-paused	Indicates if receiving is paused. Values: true or false.
wan-gateway-priority	Specifies the WAN Gateway priority of the remote replication server.
is-wan-gateway	Indicates if the remote replication server is a WAN Gateway. Values: true or false.

Monitor Attribute	Description
wan-gateway-desired	<p>Indicates if the remote replication server is a desired gateway. Values: true or false. This entry together with the <code>is-wan-gateway</code> property indicates the desired state.</p> <p><code>is-wan-gateway=false, wan-gateway-desire=false</code></p> <p>Indicates another server with a higher gateway priority exists or the gateway priority is set to disabled.</p> <p><code>is-wan-gateway=false, wan-gateway-desire=true</code></p> <p>Indicates that the remote replication server wants to be a WAN gateway.</p> <p><code>is-wan-gateway=true, wan-gateway-desire=false</code></p> <p>Indicates that the remote replication server wants to give up its role as a WAN gateway.</p> <p><code>is-wan-gateway=false, wan-gateway-desire=true</code></p> <p>Indicates the remote replication server wants to remain as a gateway server.</p>
base-dn	base DN
ssl-encryption	Flag to indicate if SSL encryption is in use.
protocol-version	Replication protocol version.
generation-id	Generation ID for this suffix on this remote replication server.
restricted	Indicates that remote replication server is in an entry-balancing deployment.
add-sent	Number of protocol messages with an <code>ldapadd</code> sent to the remote replication server.
add-received	Number of protocol messages with an <code>ldapadd</code> received from the remote replication server.
delete-sent	Number of protocol messages with an <code>ldapdelete</code> sent to the remote replication server.
delete-received	Number of protocol messages with an <code>ldapdelete</code> received from the remote replication server.
done-sent	Number of done messages sent to the remote replication server. A done message indicates an end of online initialization session.
done-received	Number of done messages received from the remote replication server. A done message indicates an end of online initialization session.

Monitor Attribute	Description
entry-sent	Number of entry messages sent to the remote replication server. Entry messages carry replicated data to initialize replicas over the replication protocol.
entry-received	Number of entry messages received from the remote replication server. Entry messages carry replicated data to initialize replicas over the replication protocol.
error-sent	Number of error messages sent to the remote replication server.
error-received	Number of error messages received from the remote replication server.
heartbeat-sent	Number of heartbeat messages sent to the remote replication server.
heartbeat-received	Number of heartbeat messages received from the remote replication server.
initialize-request-sent	Number of initialize-request messages sent to the remote replication server. This message is used during online initialization from one replica to another.
initialize-request-received	Number of initialize-request messages received from the remote replication server. This message is used during online initialization from one replica to another.
initialize-target-sent	Number of initialize-target messages sent to the remote replication server. This message is used before online initialization from one replica to another.
initialize-target-received	Number of initialize-target messages received from the remote replication server. This message is used before online initialization from one replica to another.
modify-sent	Number of protocol messages with an <code>ldapmodify</code> sent to the remote replication server.
modify-received	Number of protocol messages with an <code>ldapmodify</code> received from the remote replication server.
modify-dn-sent	Number of protocol messages with an <code>ldapmodify DN</code> sent to the remote replication server.
modify-dn-received	Number of protocol messages with an <code>ldapmodify DN</code> received from the remote replication server.
monitor-sent	Number of monitor messages sent to the remote replication server. This message is used when communicating with directory servers running an earlier release.

Monitor Attribute	Description
monitor-received	Number of monitor messages received from the remote replication server. This message is primarily used when communicating with directory servers running an earlier release.
monitor-request-sent	Number of monitor requests sent to the remote replication server. The receiving server responds with a monitor message that includes server's information about the state of the topology.
monitor-request-received	Number of monitor requests received from the remote replication server. This server responds with a monitor message that includes server's information about the state of the topology.
monitor-v2-sent	<p>Number of monitor messages sent to the remote server.</p> <p> Note: This monitor message is only used with Directory Server 3.5 or later.</p>
monitor-v2-received	<p>Number of monitor messages received from the remote server.</p> <p> Note: This monitor message is only used with Directory Server 3.5 or later.</p>
pause-sending-updates-sent	Number of pause-sending-updates messages sent to the remote server. The remote server must stop sending update messages to this server when receiving this message.
pause-sending-updates-received	Number of pause-sending-updates messages received from the remote server. This server stops sending update messages to the remote server when it receives this message.
repl-server-start-sent	<p>Number of replication-server-start messages sent to the remote replication server. The Replication Server responds with this message to the replication-server-start message received from remote replication servers.</p> <p> Note: The number of messages should never be more than 1.</p>
repl-server-start-received	<p>Number of replication-server-start messages received from the remote replication server.</p> <p> Note: The number of messages should never be more than 1.</p>

Monitor Attribute	Description
reset-generation-id-sent	Number of reset generation ID messages received from the remote replication server. This message is sent before and after the data is initialized in the topology.
reset-generation-id-received	Number of reset generation ID messages sent to the remote replication server. This message is sent before and after the data is initialized in the topology.
server-info-sent	Number of replication server information messages sent to the remote replication server. This message tells other replication servers about the replicas directly connected to the sending server. This message is also used to distribute information about the location of replicas.
server-info-received	Number of replication server information messages received from the remote replication server. This message tells other replication servers about the replicas directly connected to the sending server. This message is also used to distribute information about the location of replicas.
set-source-location-sent	Number of <code>set-source-locations</code> messages sent to the remote replication server. This message is used by WAN gateway servers to request update messages from additional locations.
set-source-location-received	Number of <code>set-source-locations</code> messages sent to the remote replication server. This message is used by WAN gateway servers to request update messages from additional locations.
start-sending-updates-sent	Number of <code>start-sending-updates</code> messages sent to the remote replication server. The remote server can only start sending updates to this server after receiving this message.
start-sending-updates-received	Number of <code>start-sending-updates</code> messages received from the remote server. Sending update messages to the remote server may only start after receiving this message.
window-sent	Number of window messages sent to the remote replication server. Window messages are used for cumulative acknowledgment in the replication protocol.
window-received	Number of window messages received from the remote replication server. Window messages are used for cumulative acknowledgment in the replication protocol.
messages-sent	Total number of messages sent.
messages-received	Total number of messages received.
update-sent	Total number of updates sent.
update-received	Total number of updates received.

Monitor Attribute	Description
<code>server-state</code>	Displays the server state of the remote replication server. It displays the last change seen on the remote replication server.
<code>consumed-update-recent-rate</code>	Rate that the connected Directory Server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last 5 seconds.
<code>consumed-update-peak-rate</code>	Highest rate that the connected Directory Server has consumed updates sent by this replication server, measured over a 5 second period from the time the replication server was started.
<code>produced-update-recent-rate</code>	Rate that the connected Directory Server has sent updates to this replication server, expressed as the number of updates per second and measured over the last 5 seconds.
<code>produced-update-peak-rate</code>	Highest rate that the connected Directory Server has sent updates to this replication server, measured over a 5 second period since the replication server was started.
<code>max-send-window</code>	Maximum number of changes that can be sent to the remote replication server before requiring an ACK.
<code>current-send-window</code>	Number of changes remaining to be sent to the remote replication server before requiring an ACK.
<code>max-rcv-window</code>	Maximum number of changes that can be received from the remote replication server before sending an ACK.
<code>current-rcv-window</code>	Number of changes remaining to be received from the remote replication server before sending an ACK.
<code>degraded</code>	Indicates that the generation ID of the replica does not match the generation ID of the remote replication server. This is a temporary state when loading data into the topology or the replica has not been initialized.
	 Note: Normally, the <code>degraded</code> value should be <code>false</code> .

Summary of the Replica Monitor information

The following table provides a description of the attributes in the `cn=Replica` monitor entry for a specific base DN.

The following is the distinguished name (DN) for the Replica Monitor server monitor entry.

```
dn: cn=Replica <baseDN>,cn=monitor
```

Monitor Attribute	Description
base-DN: <baseDN>	Specified base DN The monitor entries track your company's base DN or base-DN: <baseDN>,dc=example,dc=com, cn=schema base-DN: and cn=topology, cn=config.
connected-to: Replication Server <replPort> <serverID>	Replication port number and server ID of the replication server to which this LDAP Server is connected The first number is the replication server port number and the second number is the server-id of the replication server.
lost-connections	Number of times the Directory Server has lost connection to a replication server
received-updates	Number of updates that the Directory Server Replica has received from the connected replication server
sent-updates	Number of updates sent to the replication server.
pending-updates	Number of updates pending to send to the replication server.
replayed-updates	Total number of updates from the replication server that have been replayed for this replica.
replayed-updates-ok	Number of updates for this replica that have been successfully replayed with no conflicts.
replayed-update-failed	Number of updates for this replica that were successfully replayed after automatically resolving a modify conflict.
resolved-modify-conflicts	Number of updates for this replica that were successfully resolved after a modify conflict.
resolved-naming-conflicts	Number of updates for this replica that were successfully resolved after a naming conflict.
unresolved-naming-conflicts	Number of updates for this replica that could not be replayed due to an unresolvable naming conflict.
replica-id	Server ID for this replica.
max-rcv-window	Maximum number of changes that the Directory Server Replica can receive at a time before sending an acknowledgment back to the replication server.
current-rcv-window	Current received window size for this replica.
max-send-window	Maximum number of changes that the Directory Server Replica can send at a time to the replication server before requiring an ACK.
current-rcv-window	Number of changes remaining to be received from the replication server before it must send an ACK.

Monitor Attribute	Description
max-send-window	Maximum number of changes that the Directory Server Replica can send at a time to the replication server before requiring an ACK.
current-send-window	Number of changes remaining to be sent to the replication server before requiring an ACK.
ssl-encryption	Flag to indicate if SSL encryption is in use.
generation-id	Generation ID for this suffix on the Directory Server.
replication-backlog	Number of changes that are from this replica.

Summary of the Replication Server Monitor information

Use this topic as a reference for the Replication Server Monitor attributes and information.

The following is the distinguish name (DN) for the replication server monitor entry.

```
dn: cn=Replication Server,cn=monitor
```

The following table provides a description of the attributes in the `cn=Replication Server` monitor entry.

Attribute	Description
replication-server-id	Server ID for the Replication server ID
replication-server-port	Port number on which the replication server listens for communication from other servers
base-dn: <baseDN>	Indicates the suffix to which this replication server database applies
Generation IDs by Base DN	List of generation IDs for each base DN on the server
num-outgoing-replication-server-connections	Number of outgoing connections from the replication server
num-incoming-replication-server-connections	Number of incoming connections into the replication server
num-incoming-replica-connections	Number of incoming connections to the replica

Summary of the Replication Server Database Monitor information

The following table provides a description of the attributes in the `cn=Replication Server database` monitor entry.

The following is the distinguished name (DN) for the Replica Server Database Monitor entry.

```
dn: cn=Replication Server database <baseDN> <replServerID>,cn=monitor
```

Replication Server Database Monitor Information

Monitor Attribute	Description
database-replica-id: <replicaID>	Specifies the replication server ID.
base-dn: <baseDN>	Indicates the suffix to which this replication server database applies.
first-change	<p>First change number that is in this replication database table for this suffix from this server-id.</p> <p>The following is an example entry.</p> <pre>0000012209EA622C390D00000002 Mon Jun 22 16:41:11 CDT 2011</pre>
last-change	<p>Last change number that is in this replication database table for this suffix from this server-id.</p> <p>The following is an example entry.</p> <pre>0000012209EA622C390D00000002 Mon Jun 22 16:41:11 CDT 2011</pre>
queue-size	Number of changes in the replication server queue waiting to be sent to this remote replication server database.
queue-size-bytes	Size in bytes of all the messages waiting in the queue.
records-added	Displays the number of records changed or added to the directory information tree (DIT).
records-removed	Displays the number of records removed from the DIT.

Summary of the Replication Server Database Environment Monitor information

The following table provides a description of the attributes in the `cn=Replication Server Database Environment` monitor entry, which includes the environment variables associated with the Oracle Berkeley Database Java Edition backend.

The following is the distinguished name (DN) for the Replica Server Database Monitor entry.

```
dn: cn=Replication Server Database Environment,cn=monitor
```

Monitor Attribute	Description
je-version	Current version of the Oracle Berkeley Java Edition.
current-db-cache-size	Current database (DB) cache size.
max-db-cache-size	Maximum DB cache size.
db-cache-percent-full	Percentage of the cache used by the Directory Server.
db-directory	Directory that holds the changelogDb file.

Monitor Attribute	Description
db-on-disk-size	Size of the DB on disk.
cleaner-backlog	Number of log files that must be cleaned for the cleaner to meet its target utilization.
random-read-count	Number of disk reads which required repositioning the disk head more than 1MB from the previous file position.
random-write-count	Number of disk writes which required repositioning the disk head by more than 1MB from the previous file position.
sequential-read-count	Number of disk reads which did not require repositioning the disk head more than 1MB from the previous file position.
sequential-write-count	Number of disk writes which did not require repositioning the disk head by more than 1MB from the previous file position.
nodes-evicted	Accumulated number of nodes evicted.
active-transaction-count	Number of currently active transactions.
num-checkpoints	Number of checkpoints. A checkpoint is a process that writes to your log files all the internal BTree nodes and structures modified as a part of write operations to your log files to facilitate a quick recovery.
checkpoint-in-progress: false	Indicates if a checkpoint is in progress.
total-checkpoint- duration-millis	Total time in milliseconds for all checkpoints.
average-checkpoint- duration-millis	Average time in milliseconds for all checkpoints.
last-checkpoint-duration- millis	Duration in milliseconds of the last checkpoint run.
last-checkpoint-start- time	Start time of the last checkpoint.
last-checkpoint-stop-time	Stop time of the last checkpoint.
millis-since-last- checkpoint	Time in milliseconds since the last checkpoint.
read-locks-held	Total read locks currently held.
write-locks-held	Total write locks currently held.
transactions-waiting-on- locks	Total transactions waiting for locks.

Monitor Attribute	Description
je-env-stat-AdminBytes	Number of bytes of JE cache used for log cleaning metadata and other administrative structure.
je-env-stat-BufferBytes	Total memory currently consumed by log buffers, in bytes.
je-env-stat-CacheDataBytes	Total memory of cache used for data.
je-env-stat-CacheTotalBytes	Total amount of JE cache in use, in bytes.
je-env-stat-CleanerBacklog	Number of files to be cleaned to reach the target utilization.
je-env-stat-CursorsBins	Number of bottom internal nodes (BINS) encountered by the INCompressor that had cursors referring to them when the compressor ran. The compressor thread cleans up the internal BTree as records are deleted to ensure unused nodes are not present.
je-env-stat-DataBytes	Amount of JE cache used for holding data, keys and internal Btree nodes, in bytes.
je-env-stat-DbClosedBins	Number of bins encountered by the INCompressor that had their database closed between the time they were put on the compressor queue and when the compressor ran.
je-env-stat-EndOfLog	Location of the next entry to be written to the log.
je-env-stat-InCompQueueSize	Number of entries in the INCompressor queue when the <code>getStats()</code> call was made.
je-env-stat-LastCheckpointEnd	Location in the log of the last checkpoint end.
je-env-stat-LastCheckpointId	ID of the last checkpoint.
je-env-stat-lastCheckpointStart	Location in the log of the last checkpoint start.
je-env-stat-lockBytes	Number of bytes of Java Edition (JE) cache used for holding locks and transactions.
je-env-stat-NBINSStripped	Number of BINS stripped by the evictor.
je-env-stat-NCacheMiss	Total number of requests for database objects that were not in memory.
je-env-stat-NCheckpoints	Total number of checkpoints run so far.
je-env-stat-NCleanerDeletions	Number of cleaner file deletions this session.

Monitor Attribute	Description
je-env-stat-NCleanerEntriesRead	Accumulated number of log entries read by the cleaner.
je-env-stat-NCleanerRuns	Number of cleaner runs this session.
je-env-stat-NClusterLNsProcessed	Accumulated number of leaf nodes (LNs) processed because they qualify for clustering.
je-env-stat-NDeltaINFlush	Accumulated number of delta internal nodes (INs) flushed to the log.
je-env-stat-NEvictPasses	Number of passes made to the evictor.
je-env-stat-NFSyncRequests	Number of fsyncs requested through the group commit manager. <code>fsync()</code> synchronizes the file system after a write or a transaction.
je-env-stat-NFSyncTimeouts	Number of fsync requests submitted to the group commit manager which timed out.
je-env-stat-NFSyncs	Number of fsyncs issued through the group commit manager.
je-env-stat-NFileOpens	Number of times a log file has been opened.
je-env-stat-NFullBINFlush	Accumulated number of full BINs flushed to the log.
je-env-stat-NFullINFlush	Accumulated number of full INs flushed to the log.
je-env-stat-NINsCleaned	Accumulated number of INs cleaned.
je-env-stat-NINsDead	Accumulated number of INs that were not found in the tree anymore (deleted).
je-env-stat-NINsMigrated	Accumulated number of INs migrated.
je-env-stat-NINsObsolete	Accumulated number of INs obsolete.
je-env-stat-NLNQueueHits	Accumulated number of LNs processed without a tree lookup.
je-env-stat-NLNsCleaned	Accumulated number of LNs cleaned.
je-env-stat-NLNsDead	Accumulated number of LNs that were not found in the tree anymore (deleted).
je-env-stat-NLNsLocked	Accumulated number of LNs encountered that were locked.
je-env-stat-NLNsMarked	Accumulated number of LNs that were marked for migration during cleaning.
je-env-stat-NLNsMigrated	Accumulated number of LNs migrated.
je-env-stat-NLNsObsolete	Accumulated number of LNs obsolete.
je-env-stat-NLogBuffers	Number of log buffers currently instantiated.

Monitor Attribute	Description
je-env-stat-NMarkedLNsProcessed	Accumulated number of LNs processed because they were previously marked for migration.
je-env-stat-NNodesExplicitlyEvicted	Accumulated number of nodes evicted.
je-env-stat-NNodesScanned	Accumulated number of nodes scanned to select the eviction set.
je-env-stat-NNodesSelected	Accumulated number of nodes selected to evict.
je-env-stat-NNotResident	Number of requests for database objects not contained within the in memory data structures.
je-env-stat-NOpenFiles	Number of files currently open in the file cache.
je-env-stat-NPendingLNsLocked	Accumulated number of pending LNs that could not be locked for migration because of a long duration application lock.
je-env-stat-NPendingLNsProcessed	Accumulated number of LNs processed because they were previously locked.
je-env-stat-NRandomReadBytes	Number of bytes read which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomReads	Number of disk reads which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomWriteBytes	Number of bytes written which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomWrites	Number of disk writes which required repositioning the disk head by more than 1MB from the previous file position.
je-env-stat-NRepeatFaultReads	Number of reads that had to be repeated when faulting in an object from disk because the read chunk size controlled by <code>je.log.faultReadSize</code> is too small.
je-env-stat-NRepeatIteratorReads	Number of times we try to read a log entry larger than the read buffer size and can't grow the log buffer to accommodate the large object.
je-env-stat-NRootNodesEvicted	Accumulated number of database root nodes evicted.
je-env-stat-NSequentialReadBytes	Number of bytes read which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialReads	Number of disk reads which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialWriteBytes	Number of bytes written which did not require repositioning the disk head more than 1MB from the previous file position.

Monitor Attribute	Description
je-env-stat-NSequentialWrites	Number of disk writes which did not require repositioning the disk head by more than 1MB from the previous file position.
je-env-stat-NSharedCacheEnvironments	Number of environments using the shared cache.
je-env-stat-NTempBufferWrites	Number of writes which had to be completed using the temporary marshalling buffer because the fixed size log buffers specified by <code>je.log.totalBufferBytes</code> and <code>je.log.numBuffers</code> were not large enough.
je-env-stat-NToBeCleanedLNsWithLNProcessed	Accumulated number of LNs processed because they are soon to be cleaned.
je-env-stat-NonEmptyBins	Number of non-empty bins.
je-env-stat-ProcessedBins	Number of bins that were successfully processed by the INCompressor.
je-env-stat-RequiredEvictBytes	Number of bytes that must be evicted to get within the memory budget.
je-env-stat-SharedCacheTotalBytes	Total amount of the shared JE cache in use in bytes.
je-env-stat-SplitBins	Number of bins encountered by the INCompressor that were split between the time they were put on the compressor queue and when the compressor ran.
je-env-stat-TotalLogSize	Approximation of the current total log size in bytes.
je-env-stat-NOwners	Total lock owners in the lock table.
je-env-stat-NReadLocks	Total read locks currently held.
je-env-stat-NRequests	Total number of lock requests to date.
je-env-stat-NTotalLocks	Total locks currently in the lock table.
je-env-stat-NWaiters	Total transactions waiting for locks.
je-env-stat-NWaits	Total number of lock waits to date.
je-env-stat-NWriteLocks	Total write locks currently held.
je-env-stat-LastCheckpointTime	Time of the last checkpoint.
je-env-stat-LastTxnId	Last transaction ID allocated.
je-env-stat-NAborts	Number of transactions that have aborted.

Monitor Attribute	Description
je-env-stat-NActive	Number of transactions that are currently active.
je-env-stat-NBegins	Number of transactions that have begun.
je-env-stat-NCommits	Number of transactions that have committed.
je-env-stat-NXAAborts	Number of XA transactions that have aborted.
je-env-stat-NXACommits	Number of XA transactions that have committed.
je-env-stat-NXAPrepares	Number of XA transactions that have been prepared.

Summary of the Replication Summary Monitor information

The following table provides a description of the attributes in the `cn=Replication Summary` monitor entry, `dn: cn=Replication Summary <baseDN>,cn=monitor`.

Monitor Attribute	Description
<code>base-dn:<baseDN></code>	Base DN summary.
<code>replica: replica-id, ldap-server connected-to, generation-id, replication-backlog, recent-update-rate, peak-update-rate, age-of-oldest- backlog-change</code>	Summary information for each replica in the topology. This entry appears for each replica in the topology with its own respective properties.
<code>replication-server: server-id, server, generation-id, status, last-connected, last-failed, failed-attempts, attributes.</code>	Summary information for each remote replication server only in the topology. This entry appears for each Replication Server in the topology with its own respective <code>serverID</code> and <code>server</code> properties.

Monitor Attribute	Description
<p>update-queue: id, max-count, current-count, max-size, current-size, polling-source, polling-source-changed</p>	<p>Summary information for each update queue on a server:</p> <p>id</p> <p>The ID of the receiving replica or replication server.</p> <p>max-count</p> <p>The maximum number of update messages that the sending replication server will keep in memory for the receiving replica or replication server. If the receiver cannot accept messages fast enough for any reason, such as high load and network latency, then this queue fills up.</p> <p>When that happens, the sending replication server reads update messages from the changelog backend and slows down the update processing considerably.</p> <p>current-count</p> <p>The number of update messages currently on the queue that have not been sent to the receiving replica or replication server. Every time the sending replication server sends an update to the receiving replica or replication server, this counter is decremented.</p> <p>max-size</p> <p>The maximum total size in bytes of update messages that can be in the queue.</p> <p>This queue is capped by both the <code>max-count</code> and the <code>max-size</code> setting, whichever is reached first.</p> <p>current-size</p> <p>The total size of update messages currently on the queue that have not been sent to the receiving replica or replication server. Every time the sending replication server sends an update to the receiving replica or replication server, this value is decremented by the size of the published update message.</p> <p>polling-source</p> <p>Set to either <code>memory</code> or <code>db</code>. If set to <code>memory</code>, the sending replication server relies only on the in-memory queue to push update messages to the receiving replica or replication server. If set to <code>db</code>, update messages are read and sorted from the changelog database, which is significantly slower than publishing updates from the in-memory queue.</p> <p>polling-source-changed</p> <p>The total number of times the <code>polling-source</code> attribute has changed value either from <code>db</code> to <code>memory</code> or from <code>memory</code> to <code>db</code>.</p> <div data-bbox="678 1717 1464 1892" style="border: 1px solid black; padding: 5px;"> <p> Tip:</p> <p>If this value changes frequently, the queue size setting is too low.</p> </div>

Summary of the replicationChanges Backend Monitor information

The following table provides a description of the attributes in the `cn=replicationChanges Backend Monitor` entry.

The following is the distinguished name (DN) for the replicationChanges Backend Monitor entry.

```
dn: cn=replicationChanges Backend,cn=monitor
```

Monitor Attribute	Description
<code>ds-backend-id</code>	ID descriptor for the backend.  Note: Typically, this is <code>replicationChanges</code> .
<code>ds-backend-base-dn</code>	Base DN for the backend.  Note: Typically, this is <code>replicationChanges</code> .
<code>ds-backend-is-private</code>	Flag to indicate if the backend is private.
<code>ds-backend-entry-count</code>	Entry count for the backend.
<code>ds-base-dn-entry-count</code>	Entry count for the base DN and the specified base DN.
<code>ds-backend-writability-mode</code>	Flag to indicate if the backend is writable or not.

Summary of the Replication Protocol Buffer Monitor information

The following table provides a description of the attributes in the `cn=Replication Protocol Buffer monitor` entry.

The following is the distinguished name (DN) for the Replication Protocol Buffer Monitor entry. The monitors provide information on the state of the buffer for protocol operations, which is kept in the local storage.

```
dn: cn=Replication Protocol Buffer,cn=monitor
```

Replication Protocol Buffer Monitor Information

Monitor Attribute	Description
<code>saved-buffers</code>	Number of protocol buffers.  Note: Initial buffer size is 4k.

Monitor Attribute	Description
reallocations	Number of times the buffers had to be reallocated due to insufficient size.
large-buffer-creates	Number of times a buffer larger than 512k was requested.
large-buffer-evictions	Number of times a buffer was removed from the thread local storage because it has grown above 512k.

Advanced topics reference

This section provides background reference information for advanced replication topics.

Topics in this section include:

- [Performing disaster recovery](#) on page 632

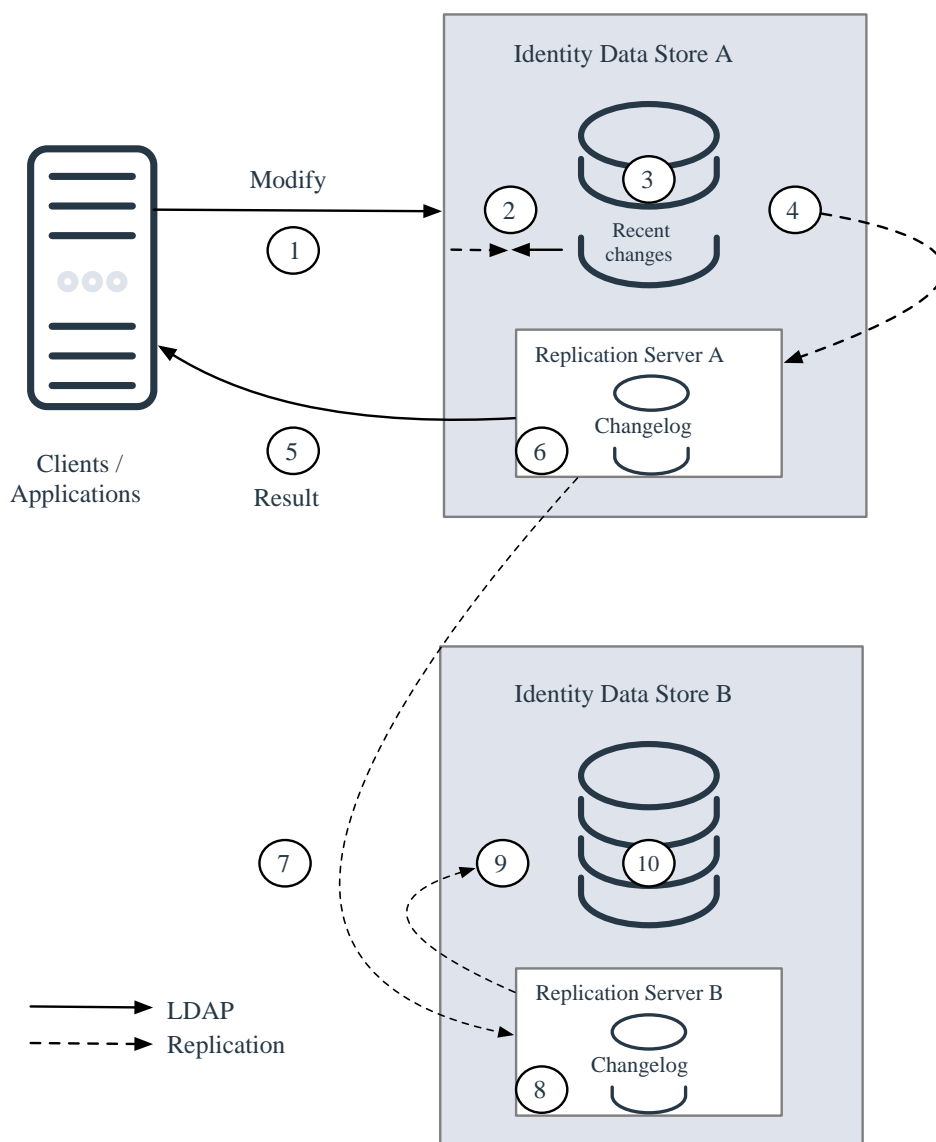

About the replication protocol

The topic covers the replication, topology, protocol process, and background information.

Replication communication uses a proprietary binary protocol that implements on top of the TCP/IP protocol using SSL encryption. Some protocol messages are used for administrative purposes, such as WAN Gateway server negotiation or flow control, some carry updates to replicated data, and others are directed to all servers for monitoring requests.

In a replicated topology, each participating Directory Server connects to every other server through the replication server port to monitor health. Servers that share the same location setting are connected to rapidly replicate changes, and the WAN Gateway servers are all interconnected to replicate changes across locations.

The Directory Servers keep connections open as long as possible to reduce the communication latency when exchanging messages. Heartbeat messages transmit on a regular basis to detect a network failure or an unresponsive directory server as early as possible. Heartbeat messages also prevent idle connections from being closed by firewalls.

1. The client sends a `MODIFY` request to Directory Server A.
2. Directory Server A assigns a unique change number to the operation. Conflict resolution is executed to see if the `MODIFY` request is in conflict with the existing attribute types or values in the existing entry. The change number is assigned before the Directory Server backend is updated to preserve the arrival order of client requests. Historical data in the target entry is updated to reflect the change.

Note:

Historical data is only updated for `ADD` and `MODIFY` operations.

3. Directory Server applies the modifications in the corresponding backend.
4. If the `MODIFY` operation successfully completes, then the Directory Server submits the update to its embedded `Replication Server`. The `Replication Server` is a component within the Directory Server process responsible for propagating updates to and from the replication topology. The Directory Server itself only communicates with a single replication server, whereas the replication server component is connected to all other replication servers. If the Directory Server process exits unexpectedly and some updates haven't been passed to the `Replication Server`, the backend has the ability to recover the last 50,000 recent changes that were processed at this server, guaranteeing that these changes can be

- replicated when the server starts up. The figure above also shows that replication protocol is used not just between replication servers but also between the Directory Server and the Replication Server.
5. The response is sent to the client. In this example, a successful response is assumed.
 6. The Replication Server records the update in its own Changelog backend, such as backend ID of `replicationChanges` and on disk with the path to `changelogDb` under the server root. The Replication Changelog backend keeps track of updates at each and every Directory Server in the replication topology. When a Directory Server joins the replication topology after being disconnected for some reason, updates from the Replication Changelog backend are re-sent to this Directory Server. Old records from the Replication Changelog backend are purged, which, by default, removes records older than 24 hours. If the backend doesn't contain all of the records that another Directory Server needed when rejoining the replication topology, then the replicated data set in the Directory Server must be re-initialized. In this case, the Directory Server enters lockdown mode and sends an administrative alert.
 7. The Replication Server submits the update to the replication server component in Directory Server B. If there were more Directory Servers in this example, the Replication Server would submit the update to all the other replication servers in the same location.
 8. Just like in Step 6, the Replication Server component receiving an update inserts the change into its Replication Changelog backend.
 9. The update forwards to the Replica in Directory Server B. Conflict resolution executes to see if the `MODIFY` request is in conflict with the existing attribute types or values in the existing entry.
 10. The Directory Server applies the modification in the corresponding backend. The Recent Changes database doesn't update because only updates that originate at this Directory Server record in the Recent Changes database.

Change number

This topic provides the change number purpose, functions, and components.

As detailed in [About the replication protocol](#) on page 625, the Directory Server assigns a unique change number to each update operation, specifically `ADD`, `DELETE`, `MODIFY`, or `MODIFY DN` operations, to track each request received from a client. The change number is attached to each update propagated through replication and allows each Directory Server to order updates exactly the same way.

The change number is composed of the following fields:

Timestamp

Identifies when the update was made. The timestamp is time-zone-independent and recorded with millisecond resolution.

Server ID

Uniquely identifies the Directory Server where the update was made.

Sequence number

Defines the order of the updates received from external clients at a particular directory server.

Tip:

The replication protocol sets a virtual clock that eliminates the need for synchronized time on servers. For troubleshooting purposes, you should keep the system clocks synchronized.

Conflict resolution

This topic covers background information, the conflict resolution process flow, and explanation of conflict resolution.

Replication employs an eventual-consistency model which can introduce a window where conflicting updates targeting the same entry might be applied at two different Directory Servers. In general, if the update that arrived later fails, two updates to the same Directory Server are in conflict. Conflict resolution,

when possible, corrects conflicts introduced by clients automatically. There are some exceptions, however, when manual administrative action is required. For example, adding an entry in one replica and simultaneously deleting the parent of this entry on another replica introduces a conflict that requires manual action. In a carefully implemented deployment, the risk of introducing conflicts that require manual action can be significantly reduced or even eliminated.

The conflict resolution algorithm in PingDirectory Server uses a mechanism that orders all updates in the replication topology. The Directory Server assigns a unique change number to each update. The change number is attached to each update propagated through replication and allows each Directory Server to order updates exactly the same way. See the following diagram for an example.

Conflict resolution process flow

The following diagram depicts adding a single-valued attribute with different values to an entry concurrently at two Directory Servers resulting in a conflict as well as the conflict resolution in the standalone environment versus the replicated environment.

Standalone

Replicated

Processing steps

1. The client sends a modify request to the Identity Data Store and succeeds.
2. The client sends another modify request that conflicts with the first.
3. In the standalone environment, the request is rejected. In the replicated environment, the request succeeds.
4. In the replicated environment only: Replication propagates the updates.

5. In the replicated environment only: Conflict resolution concludes with A ignores the update from B, B sets the attribute value to the value on A.

From the diagram example, you can make the following observations:

- The second operation fails if a client attempted to add the same attribute to the same entry at the same Directory Server.
- In a replicated environment, the conflict is not immediately seen if these updates are applied concurrently at two different Directory Servers.
- The conflict is handled only after replication propagates the updates.
- The Directory Servers resolve the conflict independently of the other server. On one Directory Server, the entry updates to reflect the correct value. On the other Directory Server, the value stays the same. As a result, each Directory Server independently resolves the conflict the same way based on the ordering of the updates.

WAN-friendly replication

Minimize latency with Directory Server if you are using a WAN for your client applications.

Many multinational corporations that have data centers in different countries must minimize latency over WAN to ensure acceptable performance for their client applications.

To minimize WAN latency, the Directory Server assigns one of following two roles to the replication servers:

- The role of standard replication transmitting updates to the other co-located replication servers.
- The role of a WAN-dedicated replication server designed to send updates to other WAN-designated replication servers in other locations.

This two-role system minimizes WAN traffic by pushing all replication updates onto the connected replication servers that are designated as WAN Gateway Servers. Only the designated WAN Gateway Servers can transmit the update messages to other connected WAN Gateway servers at other locations.

WAN Gateway Server

The Directory Server's replication mechanism relies on the server's location information to reduce protocol traffic on WAN links.

During protocol negotiation, the replication server with the highest WAN Gateway priority (priority 1 indicates the highest priority) automatically assumes the role as the WAN Gateway Server for that particular location. The Gateway Server's main function is to route update messages from other non-gateway servers at the same location to remote WAN Gateway servers at other locations. At the destination point, the replication server with the WAN Gateway role receives update messages from other WAN gateway servers at other locations and pushes them out to all replication servers at the current location.

This setup ensures that all WAN communication flows through the WAN Gateway Servers.

The following diagram shows a basic connection configuration for updates. All of the replication servers are fully connected to each other for monitoring or server negotiation purposes.

If the WAN Gateway Server is temporarily unavailable due to planned or unplanned downtime, the system dynamically re-routes updates to a newly-designated WAN Gateway Server in the same location. The replication server with the next highest WAN Gateway priority number automatically assumes the WAN Gateway role. For deployments with entry-balancing Directory Proxy Servers, there is one WAN Gateway Server per data set.

 **Note:**

By default, all servers are enabled to serve as WAN Gateways and all are set to priority 5, which makes them all equal. After replication has been enabled, you can change the WAN Gateway priority using `dsconfig`.

WAN message routing

Non-gateway replication servers forward update messages from replicas to co-located replication servers only. It is the responsibility of the WAN gateway server to forward these messages to WAN gateway servers at other locations.

The following figure illustrates how an update message is routed from a non-gateway server to a remote location.

Processing steps

1. Update received at Identity Data Store 1 at the north location is sent to the embedded Replication Server.
2. Replication Server 1 routes message to the WAN Gateway only.
3. The WAN Gateway at the North location (Identity Data Store 2) routes message to Replica 2 and to the WAN Gateway at the south location.
4. Replication Server 3, which is the WAN Gateway at the south location, routes the message to Replica 3.

WAN Gateway Server selection

The WAN Gateway role is dynamically assigned to the most suitable server in a particular location.

In most cases, the replication server with the higher WAN Gateway priority (priority 1 is the highest priority) assumes this role.

A replication server does not attempt to become a WAN Gateway if any of the following conditions exists:

- The WAN Gateway priority is set to 0.

- The replication server is backlogged at server startup.
- The current WAN Gateway has higher priority.
- The WAN Gateway has not been elected yet, but higher priority replication servers are present in the location.

The currently active WAN Gateway server gives up the gateway role in the following cases:

- The server has started the shutdown process.
- The server is preparing for a scheduled maintenance cycle.
- The server learns about a higher priority replication server in its location.

Replication servers send WAN Gateway information to other servers at regular intervals using the replication protocol. This allows the replication servers to take the appropriate action, such as to become a WAN Gateway, if necessary, without any manual administrative action.

WAN replication in mixed-version environments

This topic covers the WAN Gateway role, replication actions, and updates in PingDirectory Servers mixed version environments.

Consider the following when using the WAN Gateway role in mixed-version environments:

- WAN Gateway Role assignment is only available on PingDirectory Servers version 3.5 and later.
- Legacy servers earlier than 3.5, are never selected as WAN Gateways.
- Updates from legacy replication servers forward to all replication servers and do not funnel to a single WAN Gateway, which increases WAN during replication.
- Updates from remote WAN Gateways forward to the legacy replication servers, which increases WAN traffic during replication.

Recovering a replication changelog

If the replication changelog, `<server-root>/changelogDb`, is compromised because of a disk or NAS failure, you can recover a replication changelog.

About this task

To recover a replication changelog:

Steps

1. Stop the server.
2. Backup **replicationChanges** from a remote server using the following command.

```
$ bin/backup --backupDirectory /app/backups/replicationChanges \
--backendID replicationChanges
```

3. Copy the **replicationChanges** backup from the remote server and restore it on the local host using the following command.

```
$ bin/restore --backupDirectory /app/tmp/replicationChanges
```

4. Start the server.

Performing disaster recovery

If data is compromised across all systems and a restore is necessary, you can perform disaster recovery.

About this task

Note:

Consider the following for disaster recovery:

- With the default configuration, the server automatically exports all data nightly using the **Export All Non-Administrative Backends** recurring task. Up to 7 days of exports are maintained.

Note:

You should archive these exports on another system.

- The Data Recovery Log logs all changes in a reversible format to `logs/data-recovery/data-recovery`.
- The `bin/extract-data-recovery-log-changes` tool provides the ability to redo or undo any changes from the `logs/data-recovery/data-recovery` logs.

The combination of these allows you to either rebuild the data set to any point in time or to revert specific changes on a live data set, such as if an errant application mistakenly wipes out some data.

For more information about LDIF exports, see [LDIF export as a recurring task](#) on page 116.

Note:

These steps assume that no server performs read or write operations during this process.

To complete a restore of your systems and perform a disaster recovery:

Steps

1. Stop all servers.
2. Go to one of the servers and remove it from the topology:
Example: `bin/remove-defunct-server --performLocalCleanup --no-prompt`
3. Locate the backup or exported LDIF file that represents the last working copy of the database.
4. Restore the backup or import the LDIF file on a single server. If importing an LDIF file, use the `--excludeReplication` option with the `bin/import-ldif` command.
5. Start the restored server. The server can now receive client requests.
6. Clean up replication artifacts from the next server before starting it up:
Example: `bin/remove-defunct-server --performLocalCleanup --no-prompt`
7. Start the server in lockdown mode with the following command:
Example: `bin/start-server --skipPrime --lockdownMode`
8. Enable replication from the first server to the second server.
Example: `bin/dsreplication enable`
9. Initialize the second server from the first with the following command:
Example: `bin/dsreplication initialize`
10. Restart the second server or use the `bin/leave-lockdown-mode` command to exit lockdown mode.
The second server can now receive client requests.
11. Repeat steps 5 through 10 for any other servers.

Managing Logging

The PingDirectory Server supports a rich set of log publishers to monitor access, debug, and error messages that occur during normal server processing.

Administrators can view the standard set of default log files and configure custom log publishers with pre-defined filtering with its own log rotation and retention policies.

Default Directory Server logs

The Directory Server provides a standard set of default log files to monitor the server activity.

Directory Server Logs

View this set of logs in the `PingDirectory/logs` directory. The following default log files are available on the Directory Server and are defined in the following table.

Log File	Description
<code>access</code>	File-based Access Log that records operations processed by the Directory Server. Access log records can be used to provide information about problems during operation processing, such as unindexed searches, failed requests, and so forth, and provide information about the time required to process each operation.
<code>change-notifications.log</code>	Records changes to data anywhere in the server, which match one or more configured change subscriptions.
<code>config-audit.log</code>	Records information about changes made to the Directory Server configuration in a format that can be replayed using the <code>dsconfig</code> tool.
<code>errors</code>	File-based Error Log. Provides information about warnings, errors, and significant events that occur during server processing.
<code>expensive-ops</code>	Expensive Operations Log. Disabled by default. Provides only those operations that took longer than 1000 milliseconds to complete.
<code>failed-ops</code>	Failed Operations Log. Provides information on all operations that failed in single-line log format.
<code>replication</code>	Records any replication errors and publishes them to the file system.
<code>searches-returning-no-entries</code>	Searches Returning No Entries Log. Disabled by default. Provides information only on operations that did not return any entries.
<code>server.out</code>	Records anything written to standard output or standard error, which includes startup messages. If garbage collection debugging is enabled, then the information is written to <code>server.out</code> .
<code>server.pid</code>	Stores the server's process ID.
<code>server.status</code>	Stores the timestamp, a status code, and an optional message providing additional information on the server status.

Log File	Description
setup.log	Records messages that occur during the initial configuration of a Directory Server with the <code>setup</code> tool.
tools	Directory that holds logs for long running utilities <code>import-ldif</code> , <code>export-ldif</code> , <code>backup</code> , <code>restore</code> , and <code>verify-index</code> . Current and previous copies of the log are present in the Directory Server.
update.log	Records messages that occur during a Directory Server update.

Types of log publishers

The PingDirectory Server provides several classes of log publishers for parsing, aggregating, and filtering information events that occur during normal processing in the server.

There are three primary types of log publishers:

- Access log publishers
- Debug log publishers
- Error log publishers

Each type has multiple subtypes of log files based on the log server type.

Access log publishers

Access log publishers provide the requests received and the responses returned by the Directory Server. This information can be used to understand the operations performed by clients and to debug problems with the client applications. It can also be used for collecting usage information for performance and capacity planning purposes.

For information on tools that can analyze the access log to provide summaries of LDAP activity and performance, see [Monitoring PingDirectory metrics with Splunk](#) on page 690 and the `summarize-access-log` tool description in [Available command-line tools](#) on page 806.

Access log type	Description
File-based audit log	<p>Special type of access logger that provides detailed information about changes processed within the server.</p> <p>Disabled by default.</p> <p>Data Recovery Log</p> <p>Publishes information about each write operation processed in the server in a manner that allows those changes to be reverted or replayed (in conjunction with the <code>extract-data-recovery-log-changes</code> tool) if data recovery is needed.</p> <p>You can find this log publisher in the <code><pd_install>/logs/data-recovery/data-recovery</code> directory.</p>
JDBC-based access log	<p>Stores access log information using a Java Database Connectivity (JDBC) database connection.</p> <p>Disabled by default.</p>

Access log type	Description
File-based access logs	<p>Provides a character-based stream used by TextWriter publishers as a target for outputting log records. There are several types of file-based access loggers:</p> <p>Admin Alert Access Log</p> <p>Generates administrative alerts for any operations that match the criteria for this access logger. Disabled by default.</p> <p>File-based Access Log</p> <p>Publishes access log messages to the file system. Enabled by default.</p> <p>You can find this log publisher in the <code><pd_install>/logs/access</code> directory.</p> <p>Syslog-based Access Log</p> <p>Publishes access log messages to a syslogd port. Disabled by default.</p> <p>Expensive-Operations Access Log</p> <p>Publishes only those access log messages of operations that take longer than 1000 milliseconds. Disabled by default.</p> <p>You can find this log publisher in the <code><pd_install>/logs/expensive-ops</code> directory.</p> <p>Failed-Operations Access Log</p> <p>Publishes only those access log messages of operations that failed for any reason. Enabled by default.</p> <p>You can find this log publisher in the <code><pd_install>/logs/failed-ops</code> directory.</p> <p>Successful Searches with No Entries Returned Log</p> <p>Publishes only those access log messages of search operations that failed to return any entries. Disabled by default.</p> <p>JSON Access Logger</p> <p>Publishes JSON-formatted access log messages to the file system.</p> <p>You can find this log publisher in the <code><pd_install>/logs/access.json</code> directory.</p> <p>Console JSON Access Logger</p> <p>Publishes JSON-formatted access log messages to the Java virtual machine (JVM)'s standard output or standard error stream.</p> <div data-bbox="581 1608 1461 1812" style="border: 1px solid black; padding: 10px; margin: 10px 0;"> <p> Note:</p> <p>This log publisher is only recommended when the server is run in no-detach mode and is best suited for use in Docker or other containers that can capture log content written to standard output or standard error.</p> </div> <p>Third-Party Access Log Publisher</p> <p>Publishes access log messages using a custom log publisher created using the Server SDK.</p> <p>Third-Party File-Based Access Log Publisher</p> <p>Publishes access log messages to a file using a custom log publisher created using the Server SDK, including enhanced support for log file rotation and retention.</p>

Access log type	Description
HTTP operation log publishers	<p>Common Log File HTTP Operation Log Publisher</p> <p>Publishes information about HTTP requests in the W3C common log format.</p> <p>HTTP Detailed Access</p> <p>Publishes detailed information about HTTP requests processed by the server.</p> <p>You can find this log publisher in the <code><pd_install>/logs/http-detailed-access</code> directory.</p>

Debug log publishers

Debug log publishers provide information about warnings, errors, or significant events that occur within the server.

Debug log type	Description
Debug loggers	<p>Debug ACI Logger</p> <p>Stores debug information on access control instruction (ACI) evaluation for any request operations against the server.</p> <p>You can find this log publisher in the <code><pd_install>/logs/debug-aci</code> directory.</p> <p>Server SDK Extension Debug Logger</p> <p>Provides simplified access to debug messages generated by Server SDK extension.</p> <p>You can find this log publisher in the <code><pd_install>/logs/server-sdk-extension-debug</code> directory.</p>

Error log publishers

The Error log reports errors, warnings, and informational messages about events that occur during the course of the server's operation.

Error log type	
File-based error logs	<p>There are several types of File-based error logs:</p> <p>Error log</p> <p>Publishes error messages to the file system. Enabled by default.</p> <p>You can find this log publisher in the <code><pd_install>/logs/errors</code> directory.</p> <p>Replication log</p> <p>Publishes replication error messages to the file system. Enabled by default.</p> <p>You can find this log publisher in the <code><pd_install>/logs/replication</code> directory.</p> <p>JSON Error Logger</p> <p>Publishes JSON-formatted error log messages to the file system.</p> <p>You can find this log publisher in the <code><pd_install>/logs/errors.json</code> directory.</p> <p>Console JSON Access Logger</p> <p>Publishes JSON-formatted access log messages to the JVM's standard output or standard error stream.</p> <div data-bbox="581 978 1464 1184" style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;"> <p> Note:</p> <p>This log publisher is only recommended when the server is run in no-detach mode and is best suited for use in Docker or other containers that can capture log content written to standard output or standard error.</p> </div> <p>Third-Party Error Log Publisher</p> <p>Publishes error log messages using a custom log publisher created using the Server SDK.</p> <p>Third-Party File-Based Error Log Publisher</p> <p>Publishes error log messages to a file using a custom log publisher created using the Server SDK, including enhanced support for log file rotation and retention.</p>
JDBC-based error logs	Stores error log information using a Java Database Connectivity (JDBC) database connection. Disabled by default.
Syslog-based error logs	Publishes error messages to a syslog port.

Viewing the list of log publishers

View the list of log publishers on the Directory Server using the `dsconfig` tool.

About this task

 **Note:**

You must specifically configure the Java Database Connectivity (JDBC), syslog, and admin alert log publishers using `dsconfig` before they appear in the list of log publishers.

Steps

- To view the log publishers, run `dsconfig` with the `list-log-publishers` subcommand.

Example:

```
$ bin/dsconfig list-log-publishers
```

Result:

Log Publisher	Type	Enabled
enabled		
Debug ACI Logger	debug-access	false
Expensive Operations Access Logger	file-based-access	false
Failed Operations Access Logger	file-based-access	true
File-Based Access Logger	file-based-access	true
File-Based Audit Logger	file-based-audit	false
File-Based Debug Logger	file-based-debug	false
File-Based Error Logger	file-based-error	true
Replication Repair Logger	file-based-error	true
Successful Searches with No Entries Returned	file-based-access	false

Enabling or disabling a default log publisher

You can enable or disable any log publisher available on the Directory Server using the `dsconfig` tool.

About this task

By default, the following loggers are disabled and should only be enabled when troubleshooting an issue on the server:

- Expensive Operations Access Logger
- File-Based Audit Logger
- File-Based Debug Logger
- Successful Searches with No Entries Returned

Steps

- To enable an access log publisher, run `dsconfig` with the `set-log-publisher-prop` subcommand.

Example:

In this example, the Expensive Operations Access Logger is enabled, which records only those access log messages that take 1000 milliseconds or longer.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Expensive Operations Access Logger" --set
  enabled:true
```

Managing access and error log publishers

The access log records every request received and response returned by the Directory Server.

The access log stores the IDs for the client connection, operation, the LDAP message involved with each client request, and the server response. The information can be used to debug any problems with a client application by correlating the numeric operation identifier to the client request or response.

The Directory Server supports multiple classes of access log publishers depending on your logging requirements. The following types of access log publishers are available on the system:

File-Based Access Log Publishers

Provides a character-based TextWriter stream for outputting log records. There are three subclasses of TextWriter access logs:

File-Based Access Logs

Enabled by default. The File-based Access Log publishes access messages to the file system as `<server-root>/logs/access`. The Failed-Operations Log, Expensive-Operations Log, and the Searches with No Entries Returned Log are specialized types of the File-Based Access Log and shows only specific information necessary for troubleshooting purposes.

Admin-Alert Access Logs

Disabled by default. The Admin-Alert Access Log is a specialized type of logger that automatically generates administrative alerts for any operations that match a criteria for this access log publisher.

Syslog-Based Access Logs

Disabled by default. The Syslog Access Log publishes access messages to a syslogd port.

File-Based Audit Logs

Disabled by default. The Audit Log provides detailed information about modifications (writes) processed within the Directory Server. The File-based Audit Log publishes access messages to the file system as `<server-root>/logs/audit`.

JDBC-Based Access Logs

Disabled by default. The Java Database Connectivity (JDBC)-based Access Log provides information using a JDBC database connection.

JDBC-Based Error Logs

Disabled by default. The JDBC-based Error Log provides information using a JDBC database connection.

Managing file-based access log publishers

The PingDirectory Server supports a flexible and configurable access logging system that provides a full set of customized components to meet your system's logging requirements.

The default access log can be configured to write information to a log file with two records per operation, one for the request received and one for the response returned. It can also be configured to write one message per operation or configured to record information about a subset of operations processed by the server. In addition to modifying existing default log files, you can create custom log publishers to monitor specific properties or connection criteria. For more information, see [Creating New Log Publishers](#).

The Directory Server can be configured to use multiple access log publishers writing logs to different files using different configurations. This approach makes it possible to have fine-grained logging for various purposes, such as a log that contains only failed operations, a log that contains only operations requested by root users or a log that contains only operations that took longer than 20ms to complete.

The Directory Server provides an additional mechanism to filter access logs to record only a subset of messages of one or more types. The access log filtering mechanism uses the operation criteria (connection, request, result, search-entry, search-reference) to determine whether a given message should be logged based on information associated with the client connection as well as information in the operation request and response messages. For more information, see [Configuring Filtered Logging](#).

Access log format

The access log has a standard format that lists various elements identifying the connection and operation occurring within the Directory Server.

By default, each operation generates one access log message.

The access log displays the following common properties.

Property	Description
Timestamp	Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>
Connection Type	Displays the connection type requested by the client and the response by the server. Examples include the following: <ul style="list-style-type: none"> ▪ CONNECT ▪ BIND REQUEST/RESULT ▪ UNBIND REQUEST ▪ DISCONNECT ▪ SEARCH REQUEST/RESULT ▪ MODIFY REQUEST/RESPONSE ▪ ABANDON ▪ ADD ▪ COMPARE ▪ DELETE ▪ EXTENDED OPERATION ▪ MODIFY ▪ MODIFY DN
Connection ID	Numeric identifier, starting incrementally with 0, that identifies the client connection that is requesting the operation. The connection ID is unique for a span of time on a single server. Values of the connection ID are re-used when the server restarts or when it has had enough connections to cause the identifier to wrap back to zero.
Operation ID	Numeric identifier, starting incrementally with 0, that identifies the operation. The operation ID is unique for a span of time on a single server. Values of the operation ID are re-used when the server restarts or when it has serviced enough operations to cause the identifier to wrap back to zero.

Property	Description
Result Code	<p>LDAP result code that determines the success or failure of the operation result. Result messages include a result element that indicates whether the operation succeeded or failed, the general category for the failure, and an etime element that indicates the length of time in milliseconds that the server spent processing the operation.</p> <p>The Directory Server provides a useful tool <code><server-root>/bin/ldap-result-code</code> (UNIX, Linux) or <code><server-root>\bat\ldap-result-code</code> (Windows), that displays all of the result codes used in the system. You can use the utility if you are not sure what a result code means. For example, use the following:</p> <ul style="list-style-type: none"> ▪ <code>ldap-result-code --list</code> displays all of the defined result codes in the Directory Server. ▪ <code>ldap-result-code --int-value 16654</code> displays the name of the result code with a numeric value of 16654. ▪ <code>ldap-result-code --search operation</code> displays a list of all result codes whose name includes the substring "operation".
Elapsed Time	Displays the elapsed time (milliseconds) during which the operation completed its processing.
Message ID	Numeric identifier, starting incrementally with 1, that identifies the LDAP message used to request the operation.

Access log example

The following example shows output from the access log in `<server-root>/logs/access`.

```
[01/Jun/2011:14:48:17 -0500] CONNECT conn=0 from="10.8.1.243"
to="10.8.1.243" protocol="LDAP"
[01/Jun/2011:14:48:17 -0500] BIND REQUEST conn=0 op=0 msgID=1 version="3"
dn="cn=Directory Manager"
authType="SIMPLE"
[01/Jun/2011:14:48:17 -0500] BIND RESULT conn=0 op=0 msgID=1 resultCode=0
etime=26.357
authDN="cn=Directory Manager,cn=Root DNs,cn=config"
[01/Jun/2011:14:48:17 -0500] UNBIND REQUEST conn=0 op=1 msgID=2
[01/Jun/2011:14:48:17 -0500] DISCONNECT conn=0 reason="Client Unbind"
... (more output) ...
```

Modifying the access log using dsconfig interactive mode

The File-Based Access Log can be modified to include or exclude all log messages of a given type using the `dsconfig` tool in interactive or non-interactive mode.

About this task

Steps

1. Use `dsconfig` in interactive mode to modify the access log properties.

Example:

```
$ bin/dsconfig
```

2. Follow the prompts to specify the LDAP connection parameters for host name or IP address, connection type (LDAP, SSL, or StartTLS), port number, bind DN and password.
3. On the Directory Server main menu, type the number corresponding to the Log Publisher.
4. On the **Log Publisher Management** menu, enter the option to view and edit an existing log publisher.
5. On the **Log Publisher** menu, type the number corresponding to File-based Access Logger.
6. On the **File-Based Access Log Publisher** menu, enter the number corresponding to the property that you want to change, and then follow the prompts.
7. Type `f` to apply the changes.

Modifying the access log using dsconfig non-interactive mode

Use the `dsconfig` tool in non-interactive mode to modify a log publisher property on the command line or in a script.

About this task

For information on each property, see the Directory Server [Configuration Reference Guide](#), which is an HTML document listing the various properties for each Directory Server component.

Steps

- Use `dsconfig` with the `--no-prompt` option with the properties you want to modify or set for your access log.

Example:

In this example, enable the properties to include the instance name and startup ID.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Access
Logger" \
  --set include-instance-name:true --set include-startup-id:true
```

Modifying the maximum length of log message strings

Change the maximum length of log message strings by setting the `max-string-length` configuration property.

About this task

By default, the Directory Server sets the maximum length of log message strings to 2000 characters. This value is configurable for any access log publisher, except the syslog publisher, which is set to 500 characters. If any string has more than the configured number of characters, then that string is truncated and a placeholder is appended to indicate the number of remaining characters in the original string.

Steps

- To set the `max-string-length` property for an access log, run `dsconfig`.

Example:

The following command configures the File-based Access Logger to include the instance name and the maximum length of the log message strings to 5000 characters.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
```

```
--set include-instance-name:true \
--set max-string-length:5000
```

Disabling logging of inter-server periodic search requests

Disable logging of inter-server periodic search requests.

Steps

1. Create a request criteria that matches all search requests with the inter-server request control.

Example:

```
dsconfig create-request-criteria --criteria-name "Inter-server Searches" \
--type simple --set operation-type:search \
--set any-included-request-control:1.3.6.1.4.1.30221.2.5.42
```

2. Create a request criteria that matches all requests that are not searches with the inter-server request control.

Example:

```
dsconfig create-request-criteria --criteria-name "Exclude Inter-server Searches" \
--type aggregate --set "none-included-request-criteria:Inter-server Searches"
```

3. Configure the access logger to use the request criteria you created.

This disables the logging of internal search requests and their corresponding results to the access log.

Example:

```
dsconfig set-log-publisher-prop --publisher-name "File-Based Access Logger" \
--set "request-criteria:Exclude Inter-server Searches"
```

Generating access log summaries

The Directory Server provides a convenience tool, `summarize-access-log`, that generates a summary of one or more file-based access logs.

About this task

The summary provides analytical metric information that could be useful for administrators. The following metrics are provided in each summary:

- Total time span covered by the log files
- Number of connections established and the average rate of new connections per second
- IP addresses of up to the top 20 of the clients that most frequently connect to the server, the number of connections by each address, and the percentage of connections of each
- Total number of operations processed, the number of operations of each type, the percentage of each type out of the total number, and the average rate per second for each type of operation
- Average processing time for all operations and for each type of operation
- Histogram of the processing times for each type of operation
- Up to the 20 most common result codes for each type of operation, the number of operations of that type with that result code, and the percentage of operations of that type with that result code
- Number of unindexed searches processed by the server
- Breakdown of the scopes used for search operations with the number of percentage of searches with each scope

- Breakdown of the most common entry counts for search operations with the number and percentage of searches that returned that number of entries
- Breakdown of the most commonly used filter types for searches with a scope other than base (that is, those searches for which the server uses when processing the filter)

These filters are represented in a generic manner so that any distinct assertion values or substring assertion elements are replaced with question marks and attribute names in all lowercase characters such as `(givenName=John)` would be represented as `(givenName=?)`.

Steps

- Use the `bin/summarize-access-log` with the path to one or more access log files.

Example:

```
$ bin/summarize-access-log /path/to/logs/access
```

Result:

The system displays the following information.

```
Examining access log /path/to/logs/access Examined 500 lines in 1 file
  covering a total duration of 1 day, 22 hours, 57 minutes, 31 seconds

Total connections established: 69 (0.000/second)
Total disconnects: 69 (0.000/second)

Most common client addresses:
127.0.0.1: 61 (88.406)
10.8.1.209: 8 (11.594)

Total operations examined: 181 ...
(metric for each operation examined) ...

Average operation processing duration: 22.727ms
Average add operation processing duration: 226.600ms
Average bind operation processing duration: 5.721ms
Average delete operation processing duration: 77.692ms
Average modify operation processing duration: 35.530ms
Average search operation processing duration: 4.017ms

Count of add operations by processing time:
... (histogram for add operations) ...

Count of bind operations by processing time:
... (histogram for bind operations) ...

Count of delete operations by processing time:
... (histogram for delete operations) ...

Count of modify operations by processing time:
... (histogram for modify operations) ...

Count of search operations by processing time:
... (histogram for search operations) ...

Most common add operation result codes:
success: 11 (84.615%)
entry already exists: 2 (15.385%)

Most common bind operation result codes:
success: 4 (50.000%)
invalid credentials: 4 (50.000%)
```

```

Most common delete operation result codes:
success: 1 (100.000%)

Most common modify operation result codes:
success: 9 (69.231%)
no such object: 4 (30.769%)

Most common search operation result codes:
success: 133 (91.724%)
no such object: 12 (8.276%)

Number of unindexed searches: 0

Most common search scopes:
BASE: 114 (78.621%)
SUB: 16 (11.034%)
ONE: 15 (10.345%)

Most common search entry counts:
1: 119 (82.069%)
0: 17 (11.724%)
2: 5 (3.448%)
10: 4 (2.759%)

Most common generic filters for searches with a non-base scope:
(objectclass=?): 19 (61.290%)
(ds-backend-id=?): 12 (38.710%)

```

About log compression

The Directory Server supports the ability to compress log files as they are written.

This feature can significantly increase the amount of data that can be stored in a given amount of space so that log information can be kept for a longer period of time.

Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled at the time the logger is created. Compression cannot be turned on or off when the logger is configured. Because of problems in trying to append to an existing compressed file, if the server encounters an existing log file at startup, it rotates that file and begin a new one rather than attempting to append to the previous file.

Compression is performed using the standard gzip algorithm, so compressed log files can be accessed using readily available tools. The `summarize-access-log` tool can also work directly on compressed log files rather than requiring them to be uncompressed first.

However, because it can be useful to have a small amount of uncompressed log data available for troubleshooting purposes, administrators using compressed logging might want to have a second logger defined that does not use compression and has rotation and retention policies that minimizes the amount of space consumed by those logs while still making them useful for diagnostic purposes without the need to uncompress the files before examining them.

Configure compression by setting the `compression-mechanism` property to have the value of `gzip` when creating a new logger.

About log signing

The Directory Server supports the ability to cryptographically sign a log to ensure that it has not been modified in any way.

For example, financial institutions require audit logs for all transactions to check for correctness. Tamper-proof files are needed to ensure that these transactions can be properly validated and ensure that they have not been modified by any third-party entity or internally by unscrupulous employees.

Use the **dsconfig** tool to enable the `sign-log` property on a log publisher to turn on cryptographic signing.

When enabling signing for a logger that already exists and was enabled without signing, the first log file is not completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled are considered completely valid. For the same reason, if a log file is still open for writing, then signature validation does not indicate that the log is completely valid because the log doesn't include the necessary end signed content indicator at the end of the file.

To validate log file signatures, use the **validate-file-signature** tool provided in the `bin` directory of the server or the `bat` directory for Windows systems.

After you have enabled this property, you must disable and then re-enable the log publisher for the changes to take effect.

About encrypting log files

The Directory Server lets you encrypt log files as they are written.

The **encrypt-log** configuration property controls whether encryption is enabled for the logger. Enabling encryption causes the log file to have an `.encrypted` extension. If both encryption and compression are enabled, the extension is `.gz.encrypted`. Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption cannot be turned on or off after the logger is configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This reduces the overall size of the log file. The **encrypt-file** tool or custom code, using the LDAP SDK's `com.unboundid.util.PassphraseEncryptedInputStream`, is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the **encryption-settings create** command. By default, the encryption is performed with the server's preferred encryption settings definition.

To explicitly specify which definition should be used for the encryption, set the **encryption-settings-definition-id** property with the ID of that definition. You should set the encryption settings definition to be created from a passphrase so that the file can be decrypted by providing that passphrase even if the original encryption settings definition is no longer available. You can also create a randomly generated encryption settings definition, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data might remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it cannot write an incomplete block of data until the file is closed. This is not an issue for any log file that is not being actively written.

To examine the contents of a log file that is being actively written, use the **rotate-log** tool to force the file to be rotated before attempting to examine it.

Configuring log signing

Configure log signing.

Steps

1. To enable log signing for a log publisher, use **dsconfig**.

Example:

In this example, the `sign-log` property is set on the File-based Audit Log Publisher.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
  Logger" \
  --set sign-log:true
```

2. Disable and then re-enable the log publisher for the change to take effect.

Example:

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
  --set enabled:false
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
  --set enabled:true
```

Validating a signed file

The Directory Server provides a tool, **validate-file-signature**, that checks if a file has not been tampered with in any way.

Steps

- Run the **validate-file-signature** tool to check if a signed file has been tampered with.

Example:

For this example, assume that the `sign-log` property was enabled for the File-Based Audit Log Publisher.

```
$ bin/validate-file-signature --file logs/audit
```

Result:

```
All signature information in file 'logs/audit' is valid
```

Note:

If any validation errors occur, you will see a message similar to the one as follows.

```
One or more signature validation errors were encountered
while validating the contents of file 'logs/audit':
* The end of the input stream was encountered without
  encountering the end of an active signature block.
  The contents of this signed block cannot be trusted
  because the signature cannot be verified
```

Configuring log file encryption

Configure log file encryption.

Steps

1. To enable encryption for a log publisher, use **dsconfig**.

Example:

In this example, the File-based Access Log Publisher "Encrypted Access" is created, compression is set, and rotation and retention policies are set.

```
$ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted
Access" \
  --type file-based-access \
  --set enabled:true \
  --set compression-mechanism:gzip \
  --set encryption-settings-definition-
id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
```

```
--set encrypt-log:true \
--set log-file:logs/encrypted-access \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy" \
--set "retention-policy:Size Limit Retention Policy"
```

2. Decrypt and decompress the file.

Example:

```
$ bin/encrypt-file --decrypt \
--decompress-input \
--input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
--output-file decrypted-access
Initializing the server's encryption framework...Done
Writing decrypted data to file '/ds/Data-Sync/decrypted-access' using a
key generated from encryption settings definition
'332c846ef0dcd1d5187c1592e4c74cad33fc1e5fc20b726cd301cdd2b3ffbc2b'
Successfully wrote 123,456,789 bytes of decrypted data
```

Creating new log publishers

The server provides customization options to help you create your own log publishers with the `dsconfig` command.

When you create a new log publisher, you must also configure the log retention and rotation policies for each new publisher.

For more information, see [Configuring Log Rotation](#) and [Configuring Log Retention](#).

Creating a new log publisher

Steps

1. Use the `dsconfig` command in non-interactive mode to create and configure the new log publisher.

Example:

This example shows how to create a logger that only logs disconnect operations.

```
$ bin/dsconfig create-log-publisher \
--type file-based-access --publisher-name "Disconnect Logger" \
--set enabled:true \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set log-connects:false \
--set log-requests:false --set log-results:false \
--set log-file:logs/disconnect.log
```

Note:

To configure compression on the logger, add the `--set compression-mechanism: gzip` option to the previous command.

Because compression cannot be disabled or turned off after configured for the logger, plan carefully to determine your logging requirements, including log rotation and retention with regards to compressed logs.

- View log publishers with the following command.

```
$ bin/dsconfig list-log-publishers
```

Creating a log publisher using dsconfig interactive command-line mode

Steps

- In the command line, enter `bin/dsconfig`.
- Authenticate to the server by following the prompts.
- In the main menu, select the option to configure the log publisher.
- In the `Log Publisher` menu, select the option to create a new log publisher.
- Select the Log Publisher type.
For this example, select **File-Based Access Log Publisher**.
- Enter a name for the log publisher.
- Enable it.
- Enter the path to the log file, relative to the Directory Server root.
For this example, `logs/disconnect.log`.
- Select the rotation policy to use for this log publisher.
- Select the retention policy to use for this log publisher.
- In the `Log Publisher Properties` menu, select the option for `log-connects:false`, `log-disconnects:true`, `log-requests:false`, and `log-results:false`.
- Enter `f` to apply the changes.

Configuring log rotation

The Directory Server allows you to configure the log rotation policy for the server.

About this task

When any rotation limit is reached, the Directory Server rotates the current log and starts a new log.

If you create a new log publisher, you must configure at least one log rotation policy.

You can select the following properties:

Time Limit Rotation Policy

Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every 7 days.

Fixed Time Rotation Policy

Rotates the logs every day at a specified time (based on 24-hour time). The default time is 2359.

Size Limit Rotation Policy

Rotates the logs when the file reaches the maximum size for each log. The default size limit is 100 MB.

Never Rotate Policy

Used in a rare event that does not require log rotation.

Steps

- Use `dsconfig` to modify the log rotation policy for the access logger.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

Configuring log rotation listeners

The Directory Server provides two log file rotation listener, the copy log file rotation listener and the summarize log file rotation listener, which you can enable with a log publisher.

About this task

Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file is subject to deletion by a log file retention policy, but the copy is not automatically removed.

The summarize log file rotation listener invokes the `summarize-access-log` tool on a recently-rotated log file and writes its output to a file in a specified location. This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the `summarize-access-log` tool, including the `file-based-access` and `operation-timing-access` logger types.

Steps

- Use the following command to create a new copy log file rotation listener.

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Copy on Rotate" \
  --type copy \
  --set enabled:true \
  --set copy-to-directory:/path/to/archive/directory \
  --set compress-on-copy:true
```

Note:

The path specified by the `copy-to-directory` property must exist, and the file system containing that directory must have enough space to hold all of the log files that are written there. The server automatically monitors free disk space on the target file system and generates administrative alerts if the amount of free space gets too low.

- Use the following command to create a new summarize log file rotation listener.

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Summarize on Rotate" \
  --type summarize \
  --set enabled:true \
```

```
--set output-directory:/path/to/summary/directory
```

Note:

The summary output files have the same name as the rotated log file, with an extension of `.summary`. If the `output-directory` property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.

As with the copy log file rotation listener, summary files are not automatically deleted. Although files are generally small in comparison to the log files themselves, make sure that enough space is available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

Configuring log retention

The Directory Server allows you to configure the log retention policy for each log on the server.

About this task

When a retention limit is reached, the Directory Server removes the oldest archived log before creating a new log. Log retention is only effective if you have a log rotation policy in place.

If you create a new log publisher, you must configure at least one log retention policy.

File Count Retention Policy

Sets the number of log files you want the Directory Server to retain. The default file count is 10 logs. If the file count is set to 1, then the log continues to grow indefinitely without being rotated.

Free Disk Space Retention Policy

Sets the minimum amount of free disk space. The default free disk space is 500 MBytes.

Size Limit Retention Policy

Sets the maximum size of the combined archived logs. The default size limit is 500 MBytes.

Time Limit Retention Policy

Sets the maximum length of time that rotated log files should be retained.

Custom Retention Policy

Create a new retention policy that meets your Directory Server's requirements. This requires developing custom code to implement the desired log retention policy

Never Delete Retention Policy

Used in a rare event that does not require log deletion.

Steps

- Use `dsconfig` to modify the log retention policy for the access logger.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

Configuring filtered logging

The PingDirectory Server provides a mechanism to filter access log messages based on specific criteria.

About this task

You can use the filtered log with a custom log publisher to create and generate your own custom logs. Adding new filtered logs and associate publishers doesn't change the behavior of any existing logs. For example, adding a new log that only contains operations that were unsuccessful doesn't result in those operations being removed from the default access log.

The following example shows how to create a set of criteria that matches any operation that didn't complete successfully. It then explains how to create a custom access log publisher that logs only operations matching that criteria.

Note:

This log does not include messages for connects or disconnects, and only a single message is logged per operation. This message contains both the request and result details.

To run log filtering based on any operation result, such as result code, processing time, and response controls, turn off request logging and set the `include-request-details-in-result-messages` property to `TRUE`.

Because filtering based on the results of an operation can't be done until the operation completes, the server has no idea whether to log the request. Therefore, it might log request messages but not log any result messages. If you can only log result messages and include request details in the result messages, then only messages for operations that match the result criteria are logged. All pertinent information about the corresponding requests are included.

Steps

1. Use the `dsconfig` command in non-interactive mode to create a result criteria object set to `failure-result-codes`, a predefined set of result codes that indicate when an operation didn't complete successfully.

Example:

```
$ bin/dsconfig create-result-criteria --type simple \
  --criteria-name "Failed Operations" --set result-code-criteria:failure-
  result-codes
```

2. Use `dsconfig` to create the corresponding log publisher that uses the result criteria.

Note:

The log rotation and retention policies are also set with this command.

Example:

```
$ bin/dsconfig create-log-publisher \
  --type file-based-access \
  --publisher-name "Filtered Failed Operations" \
  --set enabled:true \
  --set log-connects:false \
  --set log-disconnects:false \
  --set log-requests:false \
  --set "result-criteria:Failed Operations" \
  --set log-file:logs/failed-ops.log \
  --set include-request-details-in-result-messages:true \
```

```
--set "rotation-policy:7 Days Time Limit Rotation Policy" \  
--set "retention-policy:Free Disk Space Retention Policy"
```

3. View the `failed-ops.log` in the `logs` directory and verify that only information about failed operations was written to it.

Managing Admin Alert Access Logs

Admin Alert Access Logs are a specialized form of filtered log that automatically generates an administrative alert when criteria configured for the log publisher matches those messages in the access log.

About access log criteria

Configuring an Admin Alert Access Log requires you to configure the criteria for the access log messages.

Each criteria can be either a Simple or an Aggregate type. The Simple type uses the set of properties for the client connection, operation request, and the contents of any operation-specific requests or results. The Aggregate type provides criteria that contains Boolean combination of other operation-specific criteria objects.

For more information, see the Ping Identity Directory Server [Configuration Reference](#).

The criteria can be one or more of the following:

Connection Criteria

Defines sets of criteria for grouping and describing client connections based on a number of properties, including:

- Protocol
- Client address
- Connection security
- Authentication state

Request Criteria

Defines sets of criteria for grouping and describing operation requests based on a number of properties, including:

- Properties for the associated client connection
- The type of operation
- Targeted entry
- Request controls
- Target attributes
- Other operation-specific terms

Result Criteria

Defines sets of criteria for grouping and describing operation results based on a number of properties, including:

- The associated client connection and operation request
- The result code
- Response controls
- Privileges missing or used
- Other operation-specific terms

Search Entry Criteria

Defines sets of criteria for grouping and describing search result entries based on a number of properties, including:

- The associated client connection and operation request
- The entry location and contents
- Included controls

Search Reference Criteria

Defines sets of criteria for grouping and describing search result references based on a number of properties, including:

- The associated client connection and operation request
- Reference contents
- Included controls

Configuring an Admin Alert Access Log publisher

Before configuring an Admin Alert Access Log, you must establish an administrative alert handler in your system.

About this task

For more information, see [Working with Administrative Alert Handlers](#).

Steps

1. To create a criteria object for the Admin Alert Access Log, use **dsconfig**.

If you are using the **dsconfig** tool in interactive mode, the menu items for the criteria operations are located in the `Standard objects` menu.

Example:

For this example, we want to log only write operations that target user entries. The following command matches any of the specified operations whose target entry matches the filter (`objectClass=person`).

```
$ bin/dsconfig create-request-criteria --type simple \
  --criteria-name "User Updates" \
  --set operation-type:add \
  --set operation-type:delete \
  --set operation-type:modify \
  --set operation-type:modify-dn \
  --set "any-included-target-entry-filter:(objectClass=person)"
```

2. To create a log publisher of type `admin-alert-access`, use **dsconfig**.

Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "User Updates Admin Alert Access Log" \
  --type admin-alert-access \
  --set "request-criteria:User Updates" \
  --set include-request-details-in-result-messages:true \
  --set enabled:true
```

Managing the Syslog-Based Access Log Publishers

The Directory Server supports access logging using the syslog protocol that is part of the Berkeley Software Distribution (BSD) operating systems.

Syslog provides a flexible, simple means to generate, store, and transfer log messages that's supported on most UNIX and Linux operating systems.

The quasi-standard syslog message format cannot exceed 1 KB and has three important parts:

PRI

Specifies the message priority based on its facility and severity. The message facility is a numeric identifier that specifies the type of log messages, such as kernel messages and mail system messages. The severity is a numeric identifier that specifies the severity level of the operation that is being reported. Together, the facility and the severity determine the priority of the log message indicated by angled brackets and 1-3 digit priority number. For example, <0>, <13>, and <103> are valid representations of the PRI.

Timestamp and host name

The timestamp displays the current date and time of the log. The host name or IP address displays the source of the log.

Message

Displays the actual log message.

You can configure syslog to handle log messages using log priorities that are based on the message's facility and severity. This feature allows users to configure the logging system so that messages with high severities are sent to a centralized repository while lower severity messages are stored locally on a server.

Note:

Because the numeric values of the severity and facility are operating system-dependent, the central repository must only include syslog messages from compatible OS types. Otherwise, the meaning of the PRI field is ambiguous.

Before you begin

You must identify the host name and port to which you want to connect.

Because the Syslog Protocol uses user datagram protocol (UDP) packets, you should use `localhost` and use some additional logging tools, such as `syslog-ng`. UDP is an unreliable and unsecure means to transfer data packets between hosts.

Logging with syslog

The PingDirectory Server can write log messages using the syslog protocol for both access and error logs.

This allows messages to be aggregated at the system level and potentially forwarded to a centralized system. The messages are written to syslog as they are generated, so attackers do not have a chance to alter these log messages.

If you want to use syslog-based logging, configure the server to log to a syslog server running on the local server over the loopback interface. The local syslog server can then forward the messages to a remote server over a secure connection.

Logging over TCP for improved reliability is supported.

UDP-based communication is in the clear, so a network observer can see all of the log messages. You should only use syslog to log to a local syslog server and have it forward messages to a remote server in a secure manner. TLS encryption for TCP-based communication is optionally supported, so you can safely configure the server to log directly to a remote syslog server.

UDP does not provide any feedback about whether messages are successfully delivered, but TCP does provide this feedback. When using TCP-based logging, you can optionally specify information about multiple syslog servers. If the primary syslog server becomes unavailable, the logger can fail over to an alternative syslog server.

Logging access and error log messages can be logged as JSON objects or in legacy space-delimited text format.

In addition to access and error logging over syslog, loggers that can write JSON-formatted audit and HTTP operation log messages are also provided.

Default access log severity level

All messages are logged at the syslog severity level of 6, which are `Informational: informational` messages.

Note:

This value is not standard across different types of UNIX or Linux systems. For more information, consult your operating system.

syslog-facility properties

Syslog Facility Properties

When using syslog, specify a facility for the access log messages. As an advanced property, you can select a number that corresponds to the facility you want to use. The default value for the `syslog-facility` property is 1 for user-level messages.

Note:

These values are not standard across different types of UNIX or Linux systems. Consult your particular operating system documentation for properties specific to that system.

Facility	Description
0	kernel messages
1	user-level messages (default)
2	mail system
3	system daemons
4	security/authorization messages
5	messages generated internally by syslogd
6	line printer subsystem
7	network news subsystem
8	UUCP subsystem
9	clock daemon
10	security/authorization messages
11	FTP daemon
12	NTP subsystem
13	log audit

Facility	Description
14	log alert
15	clock daemon
16	local use 0
17	local use 1
18	local use 2
19	local use 3
20	local use 4
21	local use 5
22	local use 6
23	local use 7

queue-size property

The `queue-size` property determines the maximum number of log records that can be stored in the asynchronous queue.

The default queue size set is 10000, which means that the server continuously flushes messages from the queue to the log. The server does not wait for the queue to fill up before flushing to the log. Lowering this value impacts performance.

Configuring a Syslog-Based Access Log Publisher

About this task

You can configure a Syslog-based Access Log Publisher using the `dsconfig` tool. We recommend that you use syslog locally on localhost and use `syslog-ng` to send the syslog messages to remote syslog servers.

Because syslog implementations differ by vendor, please review your particular vendor's syslog configuration.

Steps

- Use `dsconfig` to create a log publisher of type `syslog-based-access`.

If you are using the `dsconfig` tool in interactive mode, the menu item for Syslog Facility is an advanced property, which can be exposed by typing `a` (for "show advanced properties") on the Syslog-Based Access Log Publisher menu.

Example:

```
$ bin/dsconfig create-log-publisher \
--publisher-name "syslog-access" \
--type syslog-based-access \
--set syslog-facility:4 \
--set enabled:true
```

Managing the File-Based Audit Log Publishers

The Directory Server provides an audit log, a specialized version of the access log, for troubleshooting problems that might occur during processing.

The log records all changes to the data in LDIF format so that administrators can quickly diagnose the changes an application made to the data or replay the changes to another server for testing purposes.

The audit log does not record authentication attempts but can be used in conjunction with the access log to troubleshoot security-related issues. Because the audit log adversely impacts the server's write performance, it is disabled by default.

Audit log format

The audit log uses standard LDIF format so that administrators can analyze what changes occurred to the data. The audit log begins logging when enabled and should be used to debug any issues that might have occurred.

Common properties include:

Timestamp

Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>.

Connection ID

Numeric identifier, starting incrementally with 0, that identifies the client connection that is requesting the operation.

Operation ID

Numeric identifier, starting incrementally with 0, that identifies the operation.

Modifiers Name

Displays the distinguished name (DN) of the user who made the change.

Update Time

Records the `modifyTimestamp` operational attribute.

Audit log example

The following example shows output from the audit log in the `<server-root>/logs/audit`. The first entry shows when the audit log was enabled. The second entry show changes made to a user entry.

```
# 05/Jun/2011:10:29:04 -0500; conn=0; op=55
dn: cn=File-Based Audit Logger,cn=Loggers,cn=config
changetype: modify
replace: ds-cfg-enabled
ds-cfg-enabled: true
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z

# 05/Jun/2011:10:31:20 -0500; conn=2; op=1
dn: uid=user.996,ou=People,dc=example,dc=com
changetype: modify
replace: pager
pager: +1 115 426 4748
-
replace: homePhone
```

```
homePhone: +1 407 383 4949
-

modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z
```

Enabling the File-Based Audit Log Publisher

About this task

Enable the File-Based Audit Log Publisher using the `dsconfig` tool. The audit log impacts the Directory Server's write performance. Enable it only when troubleshooting.

Steps

- To enable the File-Based Audit Log Publisher, run `dsconfig`.

Example:

In this example, the instance name and startup ID are also enabled in the audit log.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
  --set include-instance-name:true \
  --set include-startup-id:true
```

Obscuring values in the audit log

About this task

Each value of an obscured attribute is replaced in the audit log with `***** OBSCURED VALUE *****`.

Steps

- To obscure the values of specific attributes in the audit log, use the `obscure-attribute` property.

By default, attributes are not obscured because the values of password attributes appear in hashed form rather than in cleartext.

Managing the JDBC Access Log Publishers

You can configure the Directory Server to implement a centralized logging system with different databases by connecting to a database.

The Directory Server supports the Java Database Connectivity (JDBC) API, which allows access to SQL datastores by means of its JDBC drivers. The JDBC 4.0 API, part of the Java SDK, provides a seamless method to interface with various database types in heterogeneous environments.

Centralized logging simplifies log correlation and analysis tasks and provides security by storing data in a single repository. However, data flow asymmetries might complicate synchronization or network provisioning and could unduly burden the central repository with heavy loads.

Before you begin

Before configuring the Java Database Connectivity (JDBC) Access Log Publisher, you must carry out two essential steps to set up the database.

To set up the database:

- Install the database drivers in the Directory Server `lib` directory.

- Define the log mapping tables needed to map access log elements to the database column data.

**Note:**

Only those elements in the log mapping table get logged by the JDBC log publisher.

Configuring the JDBC drivers

About this task

The Directory Server supports a number of JDBC drivers available in the market. You should use the JDBC 4 drivers supported in the Java platform. For example, for Oracle databases, you must use the `ojdbc.jar` driver for Java and any associated JAR files (National Language Support `.jars` and others) required to connect with the particular database. The following databases are supported:

- DB2
- MySQL
- Oracle Call Interface (OCI)
- Oracle Thin
- PostgreSQL
- SQL Server

Steps

- Obtain the `.jar` file or files for your particular database and copy them into the `<server-root>/lib` directory.

Configuring the log field mapping tables

About this task

The log field mapping table associates access log fields with the database column names. Configure the log field mapping table using the `dsconfig` tool, which generates a DDL file that you can import into your database. The DDL file is generated when you create the JDBC Log Publisher.

To uniquely identify a log record, you should map the following fields:

- `timestamp`
- `startupid`
- `message-type`
- `connection-id`
- `operation-type`
- `instance-name`

**Note:**

The table name is not part of this mapping.

The Directory Server also provides these options that you can select for creating a log field mapping table:

Complete JDBC Access Log Field Mappings

Maps all 52 object properties.

Complete JDBC Error Log Field Mappings

Maps all 8 object properties.

Simple JDBC Access Log Field Mappings

Maps a common set of object properties.

Custom JDBC Access Log Field Mappings

Create a custom set of JDBC log field mappings.

Custom JDBC Error Log Field Mappings

Create a custom set of JDBC error log field mappings.

Steps

1. Use `dsconfig` to create a log field mapping table.
2. In the main menu, enter `o` to change to the `Standard Object` menu, and enter the number corresponding to `Log Field Mapping`.
3. In the `Log Field Mapping management` menu, enter the option to create a new `Log Field Mapping`.
4. In the `Log Field Mapping template` menu, enter the option to select a complete `JDBC Access Log Field mapping` to use as a template for your new field mapping.
5. Enter a name for the new field mapping.
For this example, enter `my-jdbc-test`.
6. In the `Access Log Field Mapping Properties` menu, select a property for which you want to change the value.
Any property that is undefined is not logged by the `JDBC Access Log Publisher`.
7. Enter `f` to save and apply the changes.
8. In the `Log Field Mapping Management` menu, enter `q` to exit the menu.
9. View the existing `Log Mappings` on the system.

Example:

```
$ bin/dsconfig list-log-field-mappings
```

Result:

```
Log Field Mapping                : Type
-----:-----
Complete JDBC Access Log Field Mappings : access
Complete JDBC Error Log Field Mappings  : error
my-jdbc-test                       : access
Simple JDBC Access Log Field Mappings   : access
```

Configuring the JDBC Access Log Publisher using dsconfig interactive mode

About this task

After setting up the drivers and the log mapping table, use the `dsconfig` tool to configure the `JDBC Access Log Publisher` on the Directory Server. The following example uses `dsconfig` interactive mode to illustrate the steps required to configure the log publisher and the external database server.

Steps

1. Copy the database `.JAR` files to the `<server-root>/lib` directory, and then restart the Directory Server.

2. Launch the `dsconfig` tool in interactive command-line mode.

Example:

```
$ bin/dsconfig
```

3. Enter the connection parameters to bind to the Directory Server.

Enter the host name or IP address, type of LDAP connection (LDAP, SSL, or StartTLS) that you are using on the Directory Server, the LDAP listener port number, the user bind DN, and the bind DN password.

4. In the main menu, enter the number corresponding to `Log Publisher`.
5. In the `Log Publisher` management menu, enter the option to create a new log publisher.
6. In the `Log Publisher` template menu, enter `n` to create a new Log Publisher.
7. In the `Log Publisher Type` menu, enter the option to create a new JDBC-Based Access Log Publisher.
8. Enter a name for the JDBC Access Log Publisher.
9. In the `Enabled Property` menu, enter the option to enable the log publisher.
10. In the `Server Property` menu, enter the option to create a new JDBC External Server.
11. Enter the name for the JDBC External Server.
This is a symbolic name used to represent the database management system (DBMS).
12. In the `JDBC Driver Type Property` menu, enter the number corresponding to the type of JDBC database driver type.
13. Enter a name for the `database-name` property.
This is the DBMS database name. The database name must contain the table referred to in the generated DDL.
14. Enter the host name or IP address (`server-host-name`) of the external server.
15. Enter the server listener port.
For this example, enter `1541`.
16. Review the properties for the external server, and then enter `f` to apply the changes.
17. If you need to supply your own JDBC URL, enter `a` for advanced properties to open the `jdbc-driver-url` property and supply the appropriate URL.

Example:

The example below shows how to access an Oracle Thin Client connection using a SID instead of a Service.

```
>>>> Configure the properties of the JDBC External Server

Property Value(s)
-----
1) description -
2) jdbc-driver-type oraclethin
3) jdbc-driver-url jdbc:oracle:thin@myhost:1541:my_SID
4) database-name jdbc-test
5) server-host-name localhost
6) server-port 1541
7) user-name -
8) password -

?) help
f) finish - create the new JDBC External Server
a) hide advanced properties of the JDBC External Server
d) display the equivalent dsconfig arguments to create this object
b) back
```

```
q) quit
Enter choice [b]: f
```

Result:

When the JDBC Log Publisher is created, the Directory Server automatically generates a DDL file of the Log Field Mappings in the `<server-root>/logs/ddls/<name-of-logger>.sql` file, and you receive the following message.

```
JDBC External Server was created successfully
```

18. Import the DDL file to your database.

Configuring the JDBC Access Log Publisher using dsconfig non-interactive mode

About this task

The following example uses `dsconfig` non-interactive mode to illustrate the steps to configure the log publisher and the external database server presented in the previous section.

Steps

1. Use `dsconfig` with the `--no-prompt` option to create the JDBC external server.

Example:

```
$ bin/dsconfig --no-prompt create-external-server \
  --server-name jdbc-external \ --type jdbc \
  --set jdbc-driver-type:oraclethin \
  --set database-name:ubid_access_log \
  --set server-host-name:localhost --set server-port:1541
```

2. Use `dsconfig` to create the log publisher.

Example:

```
$ bin/dsconfig --no-prompt create-log-publisher \
  --publisher-name jdbc-test \
  --type jdbc-based-access \
  --set enabled:true \
  --set server:jdbc-external \
  --set "log-field-mapping:Simple JDBC Access Log Field Mappings"
```

Result:

When the JDBC Log Publisher is created, the Directory Server automatically generates a DDL file of the Log Field Mappings in the `<server-root>/logs/ddls/<name-of-logger>.sql` file.

3. Import the DDL file to your database.

The procedure to configure the JDBC-Based Error Log Publisher is similar to creating a JDBC-Based Access Log Publisher. You can run the previous `dsconfig` command with the `--type jdbc-based-error` as follows.

```
$ bin/dsconfig --no-prompt create-log-publisher \
  --publisher-name jdbc-error-test \
  --type jdbc-based-error \
  --set enabled:true \
  --set server:jdbc-external \
  --set "log-field-mapping:Simple JDBC Access Log Field Mappings"
```

Managing the File-Based Error Log Publisher

The Error Log reports errors, warnings, and informational messages about events that occur during the course of the Directory Server's operation.

Each entry in the error log records the following properties (some are disabled by default and must be enabled):

Timestamp

Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>

Category

Specifies the message category that is loosely based on the server components.

Severity

Specifies the message severity of the event, which defines the importance of the message in terms of major errors that need to be quickly addressed. The default severity levels are:

- fatal-error
- notice
- severe-error
- severe-warning

Message ID

Specifies the numeric identifier of the message.

Message

Stores the error, warning, or informational message.

Error log example

The following example displays the error log for the PingDataMetrics Server. The log is enabled by default and is accessible in the `<server-root>/logs/errors` file.

```

Modifying the File-Based Error Logs

Steps

- To modify the default File-Based Error Log, use `dsconfig`.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Error Logger" \
  --set include-product-name:true --set include-instance-name:true \
  --set include-startup-id:true
```

Managing the Syslog-Based Error Log Publisher

The Directory Server supports a Syslog-Based Error Log Publisher using the same mechanism as the Syslog-Based Access Log Publisher.

Configure the error logger using the `dsconfig` tool.

Syslog error mapping

The Directory Server automatically maps error log severities to the syslog severities. The following mappings are used.

Error Log Severities	Syslog Severity
FATAL_ERROR,0	Syslog Emergency
SEVERE_ERROR,1	Syslog Alert
SEVERE_WARNING,2	Syslog Critical
MILD_ERROR,3	Syslog Error
MILD_WARNING,4	Syslog Warn
NOTICE,5	Syslog Notice
INFORMATION,6	Syslog Info
DEBUG,7	Syslog Debug

Configuring a Syslog-Based Error Log Publisher

About this task

Configure a Syslog-based Error Log Publisher using the `dsconfig` tool. You should use syslog locally on `localhost` and use `syslog-ng` to send the data packets over the UDP protocol.

Because syslog implementations differ by vendor, review your particular vendor's syslog configuration.

Steps

- Use **dsconfig** to create a log publisher of type `syslog-based-error`.

Example:

In this example, set the syslog facility to 4 for security/authorization messages.

```
$ bin/dsconfig create-log-publisher --publisher-name "syslog-error" \
  --type syslog-based-error --set syslog-facility:4 --set enabled:true
```

Creating File-Based Debug Log Publishers

The Directory Server provides a File-Based Debug Log Publisher that can be configured when troubleshooting a problem that could occur during server processing.

Because the debug data might be too large to maintain during normal operations, the Debug Log Publisher must be specifically configured and enabled. The Debug Log reports the following types of information:

- Exception data thrown by the server.
- Data read or written to network clients.
- Data read or written to the database.
- Access control or password policy data made within the server.

Use the **dsconfig** tool to create a debug log publisher.

Note:

You should only create a debug logger when troubleshooting a problem because of the voluminous output the Directory Server generates.

Creating a File-Based Debug Log Publisher

Steps

- To create the debug log publisher, use **dsconfig**.

The `log-file` property (required) sets the debug log path. You must also specify the rotation and retention policy for the debug log.

Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "File-Based Debug Logger" \
  --type file-based-debug \
  --set enabled:true \
  --set log-file:/logs/debug \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy"
```

Deleting a File-Based Debug Log Publisher

Steps

- To create the debug log publisher, use **dsconfig**.

Example:

```
$ bin/dsconfig delete-log-publisher \
  --publisher-name "File-Based Debug Logger"
```

Managing Monitoring

PingDirectory Server provides a flexible monitoring framework so you can track server performance.

This framework exposes its monitoring information under the `cn=monitor` entry and provides interfaces through the PingDataMetrics Server, the Administrative Console, SNMP, Java Management Extensions (JMX), and over LDAP. The Directory Server also provides a tool, the Periodic Stats Logger, to profile server performance.

The monitor backend

Directory Server exposes its monitoring information under the `cn=monitor` entry.

Administrators can use various means to monitor the servers, including the PingDataMetrics Server, through SNMP, the Administrative Console, JConsole, LDAP command-line tools, and the Periodic Stats Logger.

Note:

To display server component activity and state, use the `bin/status` tool.

To see the list of all monitor entries, use `ldapsearch` as in the following example.

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
--bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
--baseDN "cn=monitor" "(objectclass=*)" cn
```

The following table describes a subset of the monitor entries.

Directory Server Monitoring Components

Component	Description
Active Operations	Provides information about the operations currently being processed by the Directory Server. Shows the number of operations, information on each operation, and the number of active persistent searches.
Backends	Provides general information about the state of a Directory Server backend, including the entry count. If the backend is a local database, there is a corresponding database environment monitor entry with information on cache usage and on-disk size.
Client Connections	Provides information about all client connections to the Directory Server. The client connection information contains a name followed by an equal sign and a quoted value, such as <code>connID="15"</code> , <code>connectTime="20100308223038Z"</code> and so forth.
Connection Handlers	Provides information about the available connection handlers on the Directory Server, which includes the LDAP and LDIF connection handlers. These handlers are used to accept client connections and to read requests and send responses to those clients.
Disk Space Usage	Provides information about the disk space available to various components of the Directory Server.

Component	Description
General	Provides general information about the state of the Directory Server, including product name, vendor name, server version, etc.
Index	The monitor captures the number of keys preloaded, and counters for read/write/remove/open-cursor/read-for-search. These counters provide insight into how useful an index is for a given workload.
HTTP/HTTPS Connection Handler Statistics	Provides statistics about the interaction that the associated HTTP connection handler has had with its clients, including the number of connections accepted, average requests per connection, average connection duration, total bytes returned, and average processing time by status code.
JVM Stack Trace	Provides a stack trace of all threads processing within the Java virtual machine (JVM).
LDAP Connection Handler Statistics	Provides statistics about the interaction that the associated LDAP connection handler has had with its clients, including the number of connections established and closed, bytes read and written, LDAP messages read and written, operations initiated, completed, and abandoned, etc.
Processing Time Histogram	Categorizes operation processing times into a number of user-defined buckets of information, including the total number of operations processed, overall average response time in milliseconds (ms), number of processing times between 0ms and 1ms, and so forth.
System Information	Provides general information about the system and the JVM on which the Directory Server is running, including system host name, operation system, JVM architecture, Java home, Java version, and so forth.
Version	Provides information about the Directory Server version, including build ID, version, revision number, etc.
Work Queue	<p>Provides information about the state of the Directory Server work queue, which holds requests until they can be processed by a worker thread, including the requests rejected, current work queue size, number of worker threads, and number of busy worker threads. The work queue configuration has a <code>monitor-queue-time</code> property set to <code>true</code> by default. This logs messages for new operations with a <code>qtime</code> attribute included in the log messages. Its value is expressed in milliseconds and represents the length of time that operations are held in the work queue.</p> <p>A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the <code>ldapsearch</code> command for example, use the <code>--useAdministrativeSession</code> option. The requester must have the <code>use-admin-session</code> privilege, which is included for root users. By default, eight threads are available for this purpose. This can be changed with the <code>num-administrative-session-worker-threads</code> property in the work queue configuration.</p>

Monitoring disk space usage

The disk space usage monitor provides information about the amount of usable disk space available for Directory Server components.

The disk space usage monitor evaluates the free space at locations registered through the `DiskSpaceConsumer` interface by various components of the server. Disk space monitoring excludes disk locations that do not have server components registered. However, other disk locations might still impact server performance, such as the operating system disk, if it becomes full. When relevant to the server, these locations include the server root, the location of the `/config` directory, the location of every log file, all Java Runtime Environment (JRE) backend directories, the location of the changelog, the location of the replication environment database, and the location of any server extension that registers itself with the `DiskSpaceConsumer` interface.

The disk space usage monitor provides the ability to generate administrative alerts and take additional action if the amount of usable space drops below the defined thresholds.

You can configure three thresholds for this monitor:

Low space warning threshold

This threshold is defined as either a percentage or absolute amount of usable space. If the amount of usable space drops below this threshold, then the Directory Server generates an administrative alert but remains fully functional. It generates alerts at regular intervals that you configure (such as once a day) unless action is taken to increase the amount of usable space. The Directory Server generates additional alerts as the amount of usable space is further reduced, such as each time the amount of usable space drops below a value 10% closer to the low space error threshold. If an administrator frees up disk space or adds additional capacity, then the server should automatically recognize this and stop generating alerts.

Low space error threshold

This threshold is also defined as either a percentage or absolute size. If the amount of usable space drops below this threshold, the server generates an alert notification and begins rejecting all operations requested by non-root users with `UNAVAILABLE` results. The server should continue to generate alerts during this time. When the server enters this mode, an administrator has to take some kind of action, such as, running a command to invoke a task or removing a signal file, before the server resumes normal operation. This threshold must be less than or equal to the low space warning threshold. If they are equal, the server begins rejecting requests from non-root users immediately upon detecting low usable disk space.

Out of space error threshold

This threshold can also be defined as a percentage or absolute size. If the amount of usable space drops below this threshold, the PingDirectory Server generates a final administrative alert and shuts itself down. This threshold must be less than or equal to the low space error threshold. If they are equal, the server shuts itself down rather than rejecting requests from non-root users.

The server monitors disk space consumption during processing for the `export-ldif`, `rebuild-index`, and `backup` tools. Space is monitored every 10 seconds if usable space for all monitored paths is greater than 15 percent of the capacity of those volumes. If usable space for any path drops below 15 percent, or below 10GB free, the space check frequency is increased to every second. Warning messages are generated if available space falls below 10 percent, or below 5GB free. If usable space for any path drops below two percent, or 1GB free, the tool processing is aborted and files can be removed to free up space.

The default configuration uses the same values for the low space error threshold and out of space error threshold. This is to prevent having the server online but rejecting requests, which causes problems with applications trying to interact with the server. The low space warning threshold generates an alert before the problem becomes serious, well in advance of available disk space dropping to a point that it is critical.

The default values might not be suitable for all disk sizes, and should be adjusted to fit the deployment. Determining the best values should factor in the size of the disk, how big the database might become, how much space log files might consume, and how many backups are stored.

The threshold values can be specified either as absolute sizes or as percentages of the total available disk space. You must specify all values as absolute values or as percentages. A mix of absolute values and percentages cannot be used. The low space warning threshold must be greater than or equal to the low space error threshold, the low space error threshold must be greater than or equal to the out of space error threshold, and the out of space error threshold must be greater than or equal to zero.

If the out of space error threshold is set to zero, then the server does not attempt to automatically shut itself down if it detects that usable disk space has become critically low. If the amount of usable space reaches zero, then the database preserves its integrity but might enter a state in which it rejects all operations with an error and requires the server, or at least the affected backends, to be restarted. If the low space error threshold is also set to zero, then the server generates periodic warnings about low available disk space but remains fully functional for as long as possible. If all three threshold values are set to zero, then the server does not attempt to warn about or otherwise react to a lack of usable disk space.

Monitoring with the PingDataMetrics Server

The PingDataMetrics Server is an invaluable tool for collecting, aggregating and exposing historical and instantaneous data from the various Ping Identity servers in a deployment.

The PingDataMetrics Server relies on a captive PostgreSQL datastore for the metrics that it collects from internal instrumentation across the instances, replicas, and data centers in your environment. The data is available through a Monitoring API that can be used to build custom dashboards and monitoring applications to monitor the overall health of your PingData Platform system. For more information, see the PingDataMetrics Server Administration Guide.

About the collection of system monitoring data

All PingDirectory Servers have the capability to monitor the health of the server and host system they run on for diagnostic review and troubleshooting.

Initially, the servers do not collect any performance data until they are prepared for monitoring by a Metrics Server using the `monitored-servers add-servers` tool or an administrator enables system health data collection for real-time inspection and querying. At a high level, all of the important server and machine metrics that can be monitored are available in the `cn=monitor` backend.

The Stats Collector plugin relies exclusively on entries in the `cn=monitor` backend to sample data using LDAP queries. The Stats Collector plugin is the primary driver of performance data collection for LDAP, server response, replication, local Java Runtime Environment (JRE) databases, and host system machine metrics. Stats Collector configuration determines the sample and collection intervals, granularity of data (basic, extended, verbose), types of host system collection (CPU, disk, network) and the type of data aggregation that occurs for LDAP application statistics. The Stats Collector plugin is configured with the `dsconfig` tool and collects data using LDAP queries.

For example, the `--server-info:extended` option includes collection for the following:

- CPU
- Java virtual machine (JVM) memory
- Memory
- Disk information
- Network information

Utilization metrics are gathered through externally invoked OS commands, such as `iostat` and `netstat`, using platform-specific arguments and version-specific output parsing.

Enabling the Host System monitor provider automatically gathers CPU and memory utilization but only optionally gathers disk and network information. Disk and network interfaces are enumerated in the

configuration by device names, such as `eth0` or `lo`, and by disk device names, such as `sd1`, `sdab`, `sda2`, `scsi0`.

Monitoring key performance indicators by application

PingDirectory Server can be configured to track many key performance metrics, such as throughput and response-time, by the client applications requesting them.

This feature is invaluable for measuring whether the Ping Identity identify infrastructure meets all of your service-level agreements (SLA) that have been defined for client applications.

When enabled, the per-application monitoring data:

- Can be accessed in the `cn=monitor` backend
- Can be accessed in the Periodic Stats Logger
- Can be made available for collection by the Metrics Server

For more information on using the Stats Logger, see [Profiling server performance using the Stats Logger](#) on page 683.

For details on configuring the server to expose metrics that interest you, see the Directory Server [Configuration section of the PingDataMetrics Server Administration Guide](#).

Tracked application information is exposed in the PingDataMetrics Server by metrics having the `application-name` dimension. For information on which metrics are available with the `application-name` dimension, see the documentation under `docs/metrics` of the PingDataMetrics Server.

Configuring the external Servers

Before you install the PingDataMetrics Server, you must configure the servers you want to monitor:

- PingDirectory Server
- PingDirectoryProxy Server
- PingDataSync Server

The PingDataMetrics Server requires all servers to be 3.5.0 or later. See the administration guides for each product for installation instructions.

After you have installed Directory Server, use the `dsconfig` tool to make configuration changes for the PingDataMetrics Server. When using the `dsconfig` tool interactively, set the complexity level to `Advanced` so that you can make all the necessary configuration changes.

Preparing the servers monitored by the PingDataMetrics Server

The Metrics Backend manages the storage of metrics and provides access to the stored blocks of metrics via LDAP. The Metrics Backend is configured to keep a maximum amount of metric history based on log retention policies.

The default retention policy uses the Default Size Limit Retention Policy, Free Disk Space Retention Policy, and the File Growth Limit Policy, limiting the total disk space used to 500 MB. This amount of disk typically contains more than 24 hours of metric history, which is ample. Directory Server keeps a metric history so that the PingDataMetrics Server can be down for a period and then catch up when it comes back online.

The following two commands create a Retention Policy that limits the number of files to 2000 and sets the Metrics Backend to flush data to a new file every 30 seconds.

```
$ bin/dsconfig create-log-retention-policy \
  --policy-name StatsCollectorRetentionPolicy \
  --type file-count --set number-of-files:2000

$ bin/dsconfig set-backend-prop \
  --backend-name metrics --set sample-flush-interval:30s \
  --set retention-policy:StatsCollectorRetentionPolicy
```

These commands configure the Metrics Backend to keep 16 hours of metric history, which consumes about 250 MB of disk, ensuring that captured metrics are available to the PingDataMetrics Server within 30 seconds of when the metric was captured. The value of the `sample-flush-interval` attribute determines the maximum delay between when a metric is captured and when it can be picked up by the PingDataMetrics Server.

You can set the flush interval between 15 seconds and 60 seconds, with longer values resulting in less processing load on the PingDataMetrics Server. However, this flush interval increases the latency between when the metric was captured and when it becomes visible in the Dashboard Application. If you change the `sample-flush-interval` attribute to 60 seconds in the example above, then the Directory Server keeps 2000 minutes of history. Because the number of metrics produced per unit of time can vary depending on the configuration, no exact formula can be used to compute how much storage is required for each hour of history. However, 20 MB per hour is a reasonable estimate.

Configuring the Processing Time Histogram plugin

The Processing Time Histogram plugin is configured on each Directory Server and Directory Proxy Server as a set of histogram bucket ranges.

When the bucket ranges for a histogram change, the PingDataMetrics Server notices the change and marks samples differently. This process allows for histograms with the same set of bucket definitions to be properly aggregated and understood when returned in a query. If different servers have different bucket definitions, then a single metric query cannot return histogram data from the servers.

You should try to keep the Processing Time Histogram bucket definitions the same on all servers. Having different definitions restricts the ability of the PingDataMetrics Server API to aggregate histogram data across servers and makes the results of a query asking "What percentage of the search requests took less than 12 milliseconds?" harder to understand.

For each server in your topology, you must set the `separate-monitor-entry-per-tracked-application` property of the Processing Time Histogram plugin to true. This property must be set to expose per-application monitoring information under `cn=monitor`. When the `separate-monitor-entry-per-tracked-application` property is set to true, then the `per-application-ldap-stats` property must be set to `per-application-only` on the Stats Collector plugin and vice versa.

The following `dsconfig` command line sets the required properties of the Processing Time Histogram plugin.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Processing Time Histogram" \
  --set separate-monitor-entry-per-tracked-application:true
```

The following `dsconfig` command-line sets the `per-application-ldap-stats` property of the Stats Collector plugin to `per-application-only`.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Stats Collector" \
  --set per-application-ldap-stats:per-application-only
```

Setting the connection criteria to collect SLA statistics by application

To collect data about your service level agreements (SLAs), configure connection criteria for each SLA that you want to track.

The connection criteria are used in many areas within the server. They are used by the client connection policies, and are used when the server needs to perform matching based on connection-level properties, such as filtered logging. For assistance using connection criteria, contact a Ping Identity support representative.

For example, if you are interested in collecting statistics on data that is accessed by clients authenticating as the Directory Manager, you should create connection criteria on the Directory Server that identifies any user authenticating as the Directory Manager. The connection criteria name corresponds to the `application-name` dimension value that clients specify when accessing the data through the API.

When you define the connection criteria, change the `included-user-base-dn` property to include the Directory Manager's full LDIF entry.

The following `dsconfig` command line creates connection criteria for the Directory Manager.

```
$ bin/dsconfig create-connection-criteria \  
  --criteria-name "Directory Manager" \  
  --type simple \  
  --set "included-user-base-dn:cn=Directory Manager,cn=Root DNs,cn=config"
```

Proxy considerations for tracked applications

In a proxy environment, the criteria should be defined in the Directory Proxy Server because Directory Proxy Server passes the application name through to the Directory Server in the intermediate client control.

If a client of Directory Proxy Server or Directory Server happens to use the intermediate client control, then the client name specified in the control is used as the application name regardless of the criteria listed in the `tracked-application` property.

Monitoring using SNMP

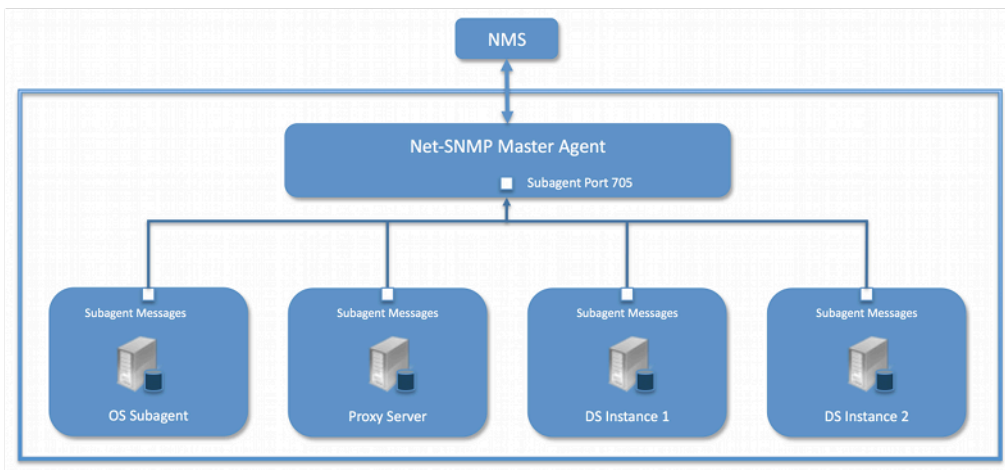

PingDirectory Server supports real-time monitoring using SNMP. Directory Server provides an embedded SNMPv3 subagent plugin that, when enabled, sets up the server as a managed device and exchanges monitoring information with a primary agent based on the AgentX protocol.

SNMP implementation

In a typical SNMP deployment, many production environments use a network management system (NMS) for a unified monitoring and administrative view of all SNMP-enabled devices.

The NMS communicates with a primary agent, whose main responsibility is to translate the SNMP protocol messages and multiplex any request messages to the subagent on each managed device, such as a Directory Server instance, Directory Proxy Server, Data Sync Server, or OS Subagent. The primary agent also processes responses or traps from the agents. Many vendors provide commercial NMS systems. Consult with your NMS system for specific information.

PingDirectory Server contains an SNMP subagent plugin that connects to a Net-SNMP primary agent over TCP. The main configuration properties of the plugin are the address and port of the primary agent, which default to localhost and port 705, respectively. When the plugin is initialized, it creates an AgentX subagent and a managed object server and then registers as a management information base (MIB) server with the Directory Server instance. After the plugin's startup method is called, it starts a session thread with the primary agent. Whenever the connection is lost, the subagent automatically attempts to reconnect with the primary agent. Directory Server's SNMP subagent plugin transmits only read-only values for polling or trap purposes. Set and inform operations are not supported. SNMP management applications cannot perform actions on the server on their own or through an NMS system.

Example SNMP Deployment

Note:

PingDirectory Server was designed to interface with a Net-SNMP (5.3.2.2 or later) primary agent implementation with AgentX over TCP. Many operating systems provide their own Net-SNMP module. However, Service Management Automation (SMA) disables some features present in the Net-SNMP package and only enables AgentX over UNIX Domain Sockets, which cannot be supported by Java. If your operating system has a native Net-SNMP primary agent that only enables UNIX Domain Sockets, you should download and install a separate Net-SNMP binary from its website.

Configuring SNMP

Because all server instances provide information for a common set of management information bases (MIBs), each server instance provides its information under a unique SNMPv3 context name equal to the server instance name.

About this task

The server instance name is defined in the Global Configuration and is constructed from the host name and the server LDAP port by default. Information must be requested using SNMPv3, specifying the context name that pertains to the desired server instance.

Note:

Directory Server supports SNMPv3, and only SNMPv3 can access the MIBs. For systems that implement SNMP v1 and v2c, Net-SNMP provides a proxy function to route requests in one version of SNMP to an agent using a different SNMP version.

Steps

1. To enable Directory Server's SNMP plugin, use the `dsconfig` tool.

Note:

The SNMPv3 context name is limited to 30 bytes maximum. Any context name longer than 30 characters returns an error message when you attempt to enable the plugin.

The default context server name is the server instance name and the LDAP port number, so take note of the length of the fully-qualified DNS host name.

- a. Specify the address and port of the SNMP primary agent.
- b. On each Directory Server instance, enable the SNMP subagent.
- c. Enable the SNMP Subagent Alert Handler so that the sub-agent sends traps for administrative alerts generated by the server.

Example:

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" --set enabled:true
```

2. View the error log.

Result:

A message displays that the primary agent is not connected because it is not yet online.

```
The SNMP sub-agent was unable to connect to the master
agent at localhost/705: Timeout
```

3. Edit the SNMP agent `snmpd.conf` configuration file and add the directive to run the agent as an AgentX primary agent.

The file is often located in `/etc/snmp/snmpd.conf`.

Example:

```
master agentx agentXSocket tcp:localhost:705
```

Note:

Using `localhost` means that only sub-agents running on the same host can connect to the primary agent. This is necessary because there are no security mechanisms in the AgentX protocol.

4. Add the trap directive to send SNMPv2 traps to `localhost` with the community name, `public` (or whatever SNMP community has been configured for your environment) and the port.

Example:

```
trap2sink localhost public 162
```

5. To create a SNMPv3 user, add the following lines to the `/etc/snmp/snmpd.conf` file.

Example:

```
rwuser initial
createUser initial MD5 setup_passphrase DES
```

6. To create the SNMPv3 user, run **snmpusm**.

Example:

```
snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
localhost create snmpuser initial
```

7. Start the **snmpd** daemon.

Result:

A message displays in the Directory Server error log.

```
The SNMP subagent connected successfully to the master agent
at localhost:705. The SNMP context name is host.example.com:389
```

8. To see the alerts that are generated by Directory Server, set up a trap client.

- Create a config file in `/tmp/snmptrapd.conf`.
- Add the `authcommunity log`, execute `public` directive to the file.

 **Note:**

The directive specifies that the trap client can process traps using the public community string and can log and trigger executable actions.

9. Install the MIB definitions for the Net-SNMP client tools in the `/usr/share/snmp/mibs` directory.

Example:

```
$ cp resource/mib/* /usr/share/snmp/mibs
```

10. To run the trap client, run the **snmptrapd** command.

Example:

This example specifies that the command should not create a new process using `fork()` from the calling shell (`-f`), should not read any configuration files (`-C`) except the one specified with the `-c` option, should print to standard output (`-Lo`), and then specifies that debugging output should be turned on for the User-based Security Module (`-Dusm`). The path after the `-M` option is a directory that contains the MIBs shipped with our product (`server-root/resource/mib`).

```
$ snmptrapd -f -C -c /tmp/snmptrapd.conf -Lf /root/trap.log -Dusm \
-m all -M +/usr/share/snmp/mibs
```

11. To test the feature, run the Net-SNMP client tools.

You must use the following options:

- `-v <SNMP version>`
- `-u <user name>`
- `-l <security level>`
- `-n <context name (instance name)>`
- `-A <user password>`

Example:

In this example, the `-m all` option loads all MIBs in the default MIB directory in `/usr/share/snmp/mibs` so that MIB names can be used in place of numeric OIDs.

```
$ snmpget -v 3 -u snmpuser -A password -l authNoPriv -n
host.example.com:389 \
-m all localhost localDBBackendCount.0
```

```
$ snmpwalk -v 3 -u snmpuser -A password -l authNoPriv -n
  host.example.com:389 \
-m all localhost systemStatus
```

MIBS

Directory Server provides SMIPv2-compliant management information base (MIB) definitions (RFC 2578, 2579, 2580) for distinct monitoring statistics. These MIB definition text files are in the server's `/resource/mib` directory.

Each MIB provides managed object tables for each specific SNMP management information as follows:

LDAP Remote Server MIB

Provides information related to the health and status of the LDAP servers that the Directory Proxy Server connects to and statistics about the operations invoked by the Directory Proxy Server on those LDAP servers.

LDAP Statistics MIB

Provides a collection of connection-oriented performance data that is based on a connection handler in the Directory Server.

A server typically contain only one connection handler and therefore supplies only one table entry.

Local DB Backend MIB

Provides key metrics related to the state of the local database backends contained in the server.

Processing Time MIB

Provides a collection of key performance data related to the processing time of operations broken down by several criteria but reported as a single aggregated data set.

Replication MIB

Provides key metrics related to the current state of replication that can help diagnose how much outstanding work replication might have to do.

System Status MIB

Provides a set of critical metrics for determining the status and health of the system in relation to its work load.

For information on the available monitoring statistics for each MIB available on Directory Server and the Directory Proxy Server, see the text files located in the server's `/resource/mib` directory.

Directory Server generates an extensive set of SNMP traps for event monitoring. The traps display the severity, description, name, OID, and summary. For information about the available alert types for event monitoring, see the `resource/mib/UNBOUNDDID-ALERT-MIB.txt` file.

Monitoring with the Administrative Console

Before you begin

Ensure that the Directory Server is running.

About this task

Ping Identity has an Administrative Console for administrators to configure directory server. The console also provides a status option that accesses the server's monitor content.

To view the **Monitor Dashboard**:

Steps

1. In your browser, enter `http://<server-name>:8443/console`.
2. Enter the root user distinguished name (DN) and password. Click **Login**.
3. In the top level navigation menu, select **Status**.
4. On the **Status** page, click the **Monitors** tab.

Result

The **Monitors** page opens, and you can monitor your server using the Administrative Console.

Accessing the Processing Time Histogram

PingDirectory Server provides a processing time histogram that classifies operation response time into user-defined buckets.

About this task

The histogram tracks the processing on a per-operation basis and as a percentage of the overall processing time for all operations. It also provides statistics for each operation type:

- add
- bind
- compare
- delete
- modify
- modifyDN
- search

Steps

1. From the Administrative Console, go to **Configuration # Status # Monitors**.
2. Select **Processing Time Histogram**.

Note:

You can access other monitor entries in similar ways.

Monitoring with JMX

PingDirectory Server supports monitoring the Java virtual machine (JVM) through a Java Management Extensions (JMX) management agent, which can be accessed using JConsole or any other kind of JMX client.

The JMX interface provides JVM performance and resource utilization information for applications running Java. In addition to the monitor information that Directory Server provides, you can monitor generic metrics exposed by the JVM, including:

- Memory pools
- Threads
- Loaded classes
- MBeans

You can also subscribe to receive JMX notifications for any administrative alerts that are generated within the server.

Running JConsole

Run `jconsole` to monitor the memory usage and thread activity of a Java virtual machine.

Before you begin

Before you can run `jconsole`, you must:

- Configure and enable the [MISSING glossAcronymn or glossSurfaceform for gJMX] Connection Handler for the server using the `dsconfig` tool.

Note:

For more information, see [Configuring the JMX connection handler and alert handler](#) on page 697.

- Invoke the `jconsole` executable by entering `jconsole` in your command-line interface or terminal.

Note:

If `<JDK_HOME>` is not set in your path, you can access `jconsole` in the `bin` directory of the `<JDK_HOME>` path.

Steps

1. To open the **Java Monitoring & Management Console**, run `jconsole`:

Choose from:

- To monitor a specific process ID for your application, run `jconsole <process ID>`.
- To run `jconsole` remotely, run `jconsole <hostname:port>`.

If SSL is configured on the JMX Connection Handler, you must specify the PingDirectory server `.jar` file in the class path when running `jconsole` over SSL, as in the following example:

```
$ jconsole \  
-J-Djavax.net.ssl.trustStore=/path/to/certStores/truststore \  
-J-Djavax.net.ssl.trustStorePassword=secret \  

```

```
-J-Djava.class.path=$SERVER_ROOT/lib/PingDirectory.jar:/Library/Java/JavaVirtualMachines/jdk-version.jdk/Contents/Home/lib/jconsole.jar
```

You need to set the following properties in the above command:

- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePath` property with the full trust store path.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStoreType` property if the default type, [MISSING glossAcronymn or glossSurfaceform for gJKS], is not used.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePin` property with the trust store file password, if there is one.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePinFile` property with the file path containing the trust store password in plain text.

Do not use this property if the

`com.unboundid.directory.server.protocol.jmx.trustStorePin` property is used.

Note:

When establishing a connection to `jconsole`, a window opens asking if you want to retry connecting insecurely. Click **Insecure connection**.

Although `jconsole` considers anything other than `SslRmiClientSocketFactory` to be insecure, choosing to retry insecurely will enable PingDirectory's secure client socket factory.

2. In the **Java Monitoring & Administrative Console** window, click **Local Process**, and then click the **PID** corresponding to the server.
3. Review the resource monitoring information.

Monitoring the Directory Server using JConsole

Set up JConsole to monitor the Directory Server using a remote process.

Steps

1. Start the Directory Server.

Example:

```
$ bin/start-server
```

2. Enable the Java Management Extensions (JMX) Connection handler using `dsconfig` with the `set-connection-handler-prop` option.

Note:

The handler is disabled by default.

Include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "JMX Connection Handler" --set enabled:true
```

3. Assign privileges to a regular user account with the `ldapmodify` tool.

Warning:

Do not use a root user account, as using a root user account would be a security risk.

Example:

This example grants `jmx-read`, `jmx-write`, and `jmx-notify` privileges to the user.

```
$ bin/ldapmodify --hostname server1.example.com --port 1389 \
  --bindDN "cn=Directory Manager" --bindPassword secret
dn: uid=admin,dc=example,dc=com
changetype: modify
replace: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: jmx-write
ds-privilege-name: jmx-notify
```

4. In the **Java Monitoring & Administrative Console**, click **Remote Process**, and enter the following JMX URL using the host and port of your Directory Server.

```
service:jmx:rmi:///jndi/rmi://<host>:<port>/
com.unboundid.directory.server.protocols.jmx.client-unknown
```

5. In the **Username** and **Password** fields, enter the bind distinguished name (DN) and password for a user that has at least the `jmx-read` privilege.
6. Click **Connect**.
7. Click **com.unboundid.directory.server**, and expand the `rootDSE` node and the `cn-monitor` sub-node.
8. Select a monitoring entry.

Monitoring using the LDAP SDK

To retrieve monitor entries from the Directory Proxy Server and retrieve specific types of monitor entries, you can use the monitoring API.

For example, you can retrieve all monitor entries published by the Directory Server and print the information contained in each using the generic API for accessing monitor entry data as follows.

```
for (MonitorEntry e : MonitorManager.getMonitorEntries(connection))
{
  System.out.println("Monitor Name: " + e.getMonitorName());
  System.out.println("Monitor Type: " + e.getMonitorDisplayName());
  System.out.println("Monitor Data:");
  for (MonitorAttribute a : e.getMonitorAttributes().values())
  {
    for (Object value : a.getValues())
    {
      System.out.println(" " + a.getDisplayName() + ": " +
String.valueOf(value));
    }
  }
  System.out.println();
}
```

For more information about the LDAP SDK and the methods in this example, see the [LDAP SDK repository on GitHub](#).

Monitoring over LDAP

PingDirectory Server exposes a majority of its information under the `cn=monitor` entry.

Steps

- To access these entries over LDAP, use the `ldapsearch` tool.

Example:

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --baseDN "cn=monitor" "(objectclass=*)"
```

Profiling server performance using the Stats Logger

Directory Server includes a built-in Stats Logger that is useful for profiling server performance for a given configuration.

At a specified interval, the Stats Logger can write server statistics to a JSON file or to a log file in a `.csv` file, which can be read by spreadsheet applications. The logger has a negligible impact on server performance unless the `log-interval` property is set to a value of less than 1 second. You can customize the statistics logged and their verbosity.

The Stats Logger can also be used to view historical information about server statistics, including:

- Replication
- LDAP operations
- Host information
- Gauges

To update the configuration of the existing Stats Logger Plugin, you can either:

- Set the advanced `gauge-info` property to `basic/extended` to include this information.
- Create a dedicated Periodic Stats Logger for information about statistics of interest.

For information about how to enable this logging and where to find the log file, see [Enabling the Stats Logger](#) on page 683.

Enabling the Stats Logger

About this task

By default, Directory Server's built-in Stats Logger is disabled. To enable the Stats Logger:

Steps

1. Run `dsconfig` in interactive mode.

When you are prompted, enter the LDAP or LDAPS connection parameters.

Example:

```
$ bin/dsconfig
```

2. To change to the `Advanced Objects` menu, enter `o`.
3. On the main menu, enter the selection for `Plugins`.
4. On the `Plugin` menu, enter the selection for `View and edit an existing plugin`.
5. From the `Plugin selection list`, enter the selection for `Stats Logger`.

6. On the `Stats Logger Plugin` menu, enter the selection to set the `enabled` property to `TRUE`. To save and apply the configuration, enter `f`.

Result: The default logger logs information about the server every second to `<server-root>/logs/dsstats.csv`. If the server is idle, nothing is logged.

Note:

To change the idle logging behavior, set the `suppress-if-idle` property to `FALSE`.

7. Run the Directory Server.

Example:

For example, if you are running in a test environment, you can run the `search-and-mod-rate` tool to apply some searches and modifications to the server.

Tip:

To see an example command, run `search-and-mod-rate --help`.

8. View the Stats Logger output at `<server-root>/logs/dsstats.csv`.

You can open the file in a spreadsheet.

Configuring multiple Periodic Stats Loggers

About this task

You can create multiple Periodic Stats Loggers to:

- Log different statistics
- View historical information about gauges
- To create a log at different intervals, such as logging cumulative operations statistics every hour

To create a new log, use the existing Stats Logger as a template to get reasonable settings, including rotation and retention policy.

Steps

1. Run `dsconfig` in interactive mode.

When prompted, enter the LDAP or LDAPS connection parameters.

Example:

```
$ bin/dsconfig
```

2. To change to the `Advanced Objects` menu, enter `o`.
3. In the main menu, enter the selection for `Plugins`.
4. In the `Plugin management` menu, enter the selection for `Create a new plugin`.
5. To use an existing plugin as a template, in the `Create a New Periodic Stats Logger Plugin` menu, enter `t`.
6. Enter the number corresponding to the existing stats logger as a template.
7. Enter a descriptive name for the new stats logger.

For this example, enter `Stats Logger-10s`.

8. Enter the log file path to the file.

For this example, enter `logs/dsstats2.csv`.

- In the menu, make any other changes to the logger. To save and apply the configuration, enter `f`.

Example:

For this example, change the `log-interval` to `10s`, and the `suppress-if-idle` to `FALSE`.

Result

You should see two loggers, `dsstats.csv` and `dsstats2.csv`, in the `logs` directory.

Enabling and configuring the StatsD monitoring endpoint

The Monitoring Endpoint configuration type provides the StatsD endpoint type that you can use to transfer metrics data in the StatsD format.

About this task

You can configure the Monitoring Endpoint using the `dsconfig` command or the Administrative Console.

Steps

- To create the StatsD monitoring Endpoint, use either of the following: Choose from:
 - To use the command-line, run `dsconfig` with the `create-monitoring-endpoint` option. This example configures a new StatsD Monitoring Endpoint to send UDP data to localhost port 8125 using `dsconfig`.

```
dsconfig create-monitoring-endpoint \
  --type statsd \
  --endpoint-name StatsDEndpoint \
  --set enabled:true \
  --set hostname:localhost \
  --set server-port:8125 \
  --set connection-type:unencrypted-udp
```
 - To use the Administrative Console:
 - From the Administrative Console, click **Show Advanced Configuration**.
 - In the **Logging, Monitoring, and Notifications** section, click **Monitoring Endpoints**.
 - Click **New Monitoring Endpoint**.

When you configure Monitoring Endpoint include:

- The endpoint's host name
- The endpoint's port
- A toggle to use TCP or UDP
- A toggle to use SSL if you use TCP

You can configure a StatsD Monitoring Endpoint with custom tags using the `additional-tags` property. This adds the defined tags to each metric message sent to the endpoint. Each tag should be created in a "key=value" format. Additional tags are appended to the end of the StatsD message. Here is a sample StatsD message with custom tags:

```
example.metric:123|g|#tag1:value1,tag2:value2
```

Note:

You can send data to any number of monitoring endpoints.

Enabling and configuring the Stats Collector Plugin

The Stats Collector Plugin controls the metrics used by the StatsD monitoring endpoint.

About this task

To send metrics with the StatsD monitoring endpoint, enable the Stats Collector Plugin and configure the plugin to indicate which metrics to send.

Examples of metrics you can send are:

- Busy worker thread count
- Garbage collection statistics
- Host system metrics such as CPU and memory

Tip:

For a list of available metrics, use the interactive `dsconfig` menu for the Stats Collector Plugin or in the Administrative Console, edit the Stats Collector plugin, as explained in the second example.

Steps

- To enable and configure the Stats Collector Plugin, use either of the following:
Choose from:

- To use the command-line, run `dsconfig` with the `set-plugin-prop` option.

This example enables the Stats Collector Plugin to send host CPU metric, memory metrics, and server status metrics using `dsconfig`.

```
dsconfig set-plugin-prop \
  --plugin-name "Stats Collector" \
  --set enabled:true \
  --set host-info:cpu \
  --set host-info:disk \
  --set status-summary-info:basic
```

Note:

If you are not using Data Metrics Server to monitor your server, you can disable the generation of some metrics files that are not necessary for the StatsD Monitoring Endpoint. To do this, set the `generate-collector-files` property on the Stats Collector Plugin to `false`.

- To use the Administrative Console:
 1. From the Administrative Console, click **Show Advanced Configuration**.
 2. In the **LDAP (Administration and Monitoring)** section, click **Plugin Root**.
 3. Edit the **Stats Collector** plugin and select the configuration options to indicate which metrics to send.

Next steps

After you enable the Stats Collector and create the StatsD monitoring endpoint, you can:

- Use the data with Splunk, as explained in [Sending Metrics to Splunk with StatsD](#) on page 1161.
- Configure other tools that support StatsD, such as CloudWatch or a Prometheus StatsD exporter, to use the data. For more information about this configuration, see your tool's StatsD documentation.

Adding custom logged statistics to a Periodic Stats Logger

Add custom statistics based on any attribute in any entry under `cn=monitor` with the Custom Logged Stats object.

This configuration object provides powerful controls for how monitor attributes are written to the log. For example, you can extract a value from a monitor attribute using a regular expression. New Custom Logged Stats are automatically included in the Periodic Stats Logger output.

In addition to allowing a straight pass-through of the values using the raw statistic-type, you can configure attributes to be treated as any of the following:

- A counter, where the interval includes the difference in the value since the last interval
- An average value held by the attribute during the specified interval
- A minimum value held by the attribute during the specified interval
- A maximum value held by the attribute during the specified interval

The value of an attribute can also be scaled by a fixed value or by the value of another monitor attribute.

Note:

Custom third-party server extensions written using the Server SDK can also expose interval statistics using a Periodic Stats Logger. The extension must first implement the SDK's `MonitorProvider` interface and register with the server. The monitor attributes produced by this custom `MonitorProvider` are then available to be referenced by a Custom Logged Stats object.

To illustrate how to configure a Custom Logged Statistics Logger, the following section reproduces the built-in `Consumer Total GB` column that displays in the output when the `included-resource-stat` property is set to `memory-utilization` on the Periodic Stats Logger.

The column is derived from the `total-bytes-used-by-memory-consumers` attribute of the `cn=JVM Memory Usage, cn=monitor` entry as follows.

```
dn: cn=JVM Memory Usage,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-memory-usage-monitor-entry
objectClass: extensibleObject
cn: JVM Memory Usage
...
total-bytes-used-by-memory-consumers: 3250017037
```

Configuring a custom logged statistic using dsconfig interactive

Steps

1. Run `dsconfig` and, when prompted, enter the LDAP or LDAPS connection parameters.

Example:

```
$ bin/dsconfig
```

2. In the Directory Server Advanced Objects menu, enter the selection for Custom Logged Stats.
3. In the Custom Logged Stats menu, enter the selection for Create a new Custom Logged Stats.
4. Select the Stats Logger Plugin from the list if more than one is present on the system. If you only have one stats logger, press Enter to confirm that you want to use the existing plugin.
5. Enter a descriptive name for the Custom Logged Stats.

For this example, enter `Memory Usage`.

6. From the `monitor-objectclass` property menu, enter the `objectclass` attribute to monitor.
For this example, enter `ds-memory-usage-monitor-entry`.

**Note:**

To view the entry, run `ldapsearch` using the base distinguished name (DN) `cn=JVM Memory Usage,cn=monitor` entry.

7. Enter the attributes of the monitor entry that you want to log in the stats logger, and then press Enter again to continue.
For this example, enter `total-bytes-used-by-memory-consumers`.
8. Specify the type of statistics for the monitored attribute to appear in the log file.
For this example, enter the option for `raw` statistics as recorded by the logger.
9. In the Custom Logged Stats menu, review the configuration.
10. To set up a column name that lists the memory usage, enter the option to change the `column-name` property.
11. To add a specific label for the column name, enter the option to add a value, and then enter `Memory Consumer Total (GB)`. To continue, press Enter.
12. Confirm that you want to use the `column-name` value that you entered in the previous step. To use the value, press Enter.
13. To scale the `Memory Consumer Totals (GB)` by 1 gigabyte (GB), in the Custom Logged Stats menu, enter the option to change the `divide-value-by` property.
14. In the `divide-value-by` property menu, enter the option to change the value, and then enter `1073741824`.
`1073741824` bytes is equivalent to 1 gigabyte.
15. In the Custom Logged Stats menu, review your configuration. To save and apply the settings, enter `f`.

Example:

```
>>>> Configure the properties of the Custom Logged Stats
>>>> via creating 'Memory Usage' Custom Logged Stats

Property                                Value(s)
-----
1) description                           -
2) enabled                                true
3) monitor-objectclass                    ds-memory-usage-monitor-entry
4) include-filter                          -
5) attribute-to-log                       total-bytes-used-by-memory-consumers
6) column-name                             Memory Consumer Total (GB)
7) statistic-type                          raw
8) header-prefix                           -
9) header-prefix-attribute                  -
10) regex-pattern                          -
11) regex-replacement                       -
12) divide-value-by                        1073741824
13) divide-value-by-attribute                -
14) decimal-format                          #.##
15) non-zero-implies-not-idle              false

?) help
f) finish - create the new Custom Logged Stats
a) hide advanced properties of the Custom Logged Stats
d) display the equivalent dsconfig arguments to create this object
b) back
```

```
q) quit
Enter choice [b]:
```

Result: A message of `The Custom Logged Stats was created successfully` is returned. After the Custom Logged Stats configuration change is completed, the new stats value should immediately show up in the Stats Logger output file.

Configuring a custom stats logger using `dsconfig` non-interactive

About this task

The following task replicates the previous procedure using `dsconfig` in non-interactive mode.

To create a custom stats logger:

Steps

- Run the `dsconfig` non-interactive command with the `create-custom-logged-stats` option.

Example:

In this example, the command produces a column named `Memory Consumer Total (GB)` that contains the value of the `total-bytes-used-by-memory-consumers` attribute pulled from the entry with the `ds-memory-usage-monitor-entry` objectclass. This value is scaled by 1073741824 to get to a value represented in GBs.

```
$ bin/dsconfig create-custom-logged-stats --plugin-name "Stats Logger" \
  --stats-name "Memory Usage" --type custom \
  --set monitor-objectclass:ds-memory-usage-monitor-entry \
  --set attribute-to-log:total-bytes-used-by-memory-consumers \
  --set "column-name:Memory Consumer Total (GB)" --set statistic-type:raw \
  --set divide-value-by:1073741824
```

Updating the Global Configuration

You must create Global Configuration tracked applications for each application (connection criteria) you intend to track.

About this task

The `tracked-application` property allows individual applications to be identified in the server by connection criteria.

Note:

The name of the tracked application is the same as the name you defined for the connection criteria.

Steps

- To add connection criteria to the list of tracked applications, run `dsconfig` with the `set-global-configuration-prop` option.

Example:

This example adds the connection criteria you created in the example in [Setting the connection criteria to collect SLA statistics by application](#) on page 673 to the list of tracked applications.

```
$ bin/dsconfig set-global-configuration-prop \
```

```
--set "tracked-application:Directory Manager"
```

Note:

The value of the `tracked-application` field corresponds to the value of the `application-name` dimension value that clients specify when accessing the data through the API.

Monitoring PingDirectory metrics with Splunk

Metrics from PingDirectory can be sent to Splunk through either StatsD or a Periodic Stats Logger

Ping provides a free Splunk (<https://splunkbase.splunk.com/app/5523/>) application for PingDirectory that customers can use to create dashboards.

Metrics from PingDirectory can be sent to Splunk either through StatsD pushed directly to Splunk, or through a Periodic Stats Logger that is monitored by a Splunk Universal Forwarder.

Sending PingDirectory metrics with StatsD

Monitoring Directory Server using StatsD and Splunk.

In order to send metrics from PingDirectory to Splunk with StatsD, you will need to create a StatsD Monitoring Endpoint. On the Splunk side you will need to open the corresponding port to receive the metrics.

Configuring a StatsD monitoring endpoint

The Stats Collector is used to create a StatsD monitoring endpoint.

Steps

1. To enable the Stats Collector plugin, run the following command.

```
dsconfig set-plugin-prop \
  --plugin-name "Stats Collector" \
  --set enabled:true
```

2. To create a StatsD monitoring endpoint, run the following command. After running the command, Directory Server will send StatsD messages to your Splunk server over UDP at port 8125.

```
dsconfig create-monitoring-endpoint \
  --endpoint-name StatsDEndpoint \
  --type statsd \
  --set enabled:true \
  --set hostname:your-splunk.example.com \
  --set server-port:8125 \
  --set connection-type:unencrypted-udp
```

Configuring Splunk to receive StatsD metrics

Splunk can be used to receive StatsD metrics.

About this task

Run the following commands to configure Splunk to receive StatsD metrics.

Steps

1. Log in to your Splunk dashboard at `http://your-splunk.example.com:8000`.
2. Go to **Settings > Data Inputs**.

3. Under Local inputs, click **UDP**.
4. Click **New Local UDP**.
5. Enter the following information:
 - Port:** 8125
6. Click **Next**.
7. Set **Source type** to **Metrics > statsd**.
8. Create a new **metrics** index for the input. Make a note of the index name you choose.
9. Set the **App Context** to `PingDirectory App for Splunk`.
10. Click **Review**.
11. Click **Submit**.

**Note:**

StatsD metrics are typically sent over UDP. Using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost. To more securely send metrics to Splunk, you can first send your StatsD metrics to a Splunk Universal Forwarder, and have the forwarder communicate with Splunk over SSL.

Sending Metrics with the Periodic Stats Logger and the Splunk Universal Forwarder

A Splunk Universal Forwarder can be used to forward Directory Server events to Splunk.

The Periodic Stats Logger plugin writes Directory Server metrics to a file in the server root. A Splunk Universal Forwarder can be configured to watch this file and forward the metrics to Splunk.

Configuring the Periodic Stats Logger

Directory Server can log various metrics, including LDAP operation counts and GC activity, to a JSON-formatted log.

About this task

To configure Directory Server to log to a JSON-formatted log file with various metrics, including LDAP operation counts and GC activity, run the following command. The metrics will be written to `logs/dsstats.json` in the server root.

```
dsconfig set-plugin-prop \
  --plugin-name "Stats Logger" \
  --set enabled:true \
  --set log-file:logs/dsstats.json \
  --set log-file-format:json \
  --set local-db-backend-info:extended \
  --set header-prefix-per-column:true \
  --set empty-instead-of-zero:false \
  --set per-application-ldap-stats:per-application-and-aggregate
```

Configuring the Splunk Universal Forwarder

You can use the Splunk Universal Forwarder to monitor the `logs/dsstats.json` file and forward the metrics to Splunk.

About this task

The Splunk Universal Forwarder can be configured to monitor the `logs/dsstats.json` file and forward the metrics to Splunk. Under the Splunk Forwarder application files, update the `etc/apps/search/local/inputs.conf` file with the following configuration for `dsstats.json`:

```
[monitor:///path/to/PingDirectory/logs/dsstats.json]
sourcetype=log2metrics_json
```

```
index=pdmetrics
disabled=false
host=pd1
```

The index name can be customized, and the host value can be configured to label where the metrics are being forwarded from.

Using the Directory Server app for Splunk

You can access several dashboards for monitoring Directory Server.

When you have installed the Directory Server application for Splunk, you will have access to several dashboards for monitoring metrics. To use these dashboards, you will need to select the index name and metrics source you configured. If you are sending metrics with StatsD, use the metrics index you defined when creating the UDP input in Splunk, and select the StatsD radio button at the top of each dashboard. If you are sending metrics with the Periodic Stats Logger, use the index you defined in the Splunk Universal Forwarder configuration and select the **dsstats.json** radio button at the top of each dashboard.

Managing Notifications and Alerts

PingDirectory Server provides delivery mechanisms for account status notifications and administrative alerts using SMTP, Java Management Extensions (JMX), or SNMP in addition to standard error logging.

Alerts and events reflect state changes within the server that might be of interest to a user or monitoring service.

Notifications are typically the delivery of an alert or event to a user or monitoring service.

Note:

Account status notifications are only delivered to the account owner, notifying a change in state in the account.

Account status notifications

PingDirectory Server supports notification handlers that can notify users, administrators, or both of significant changes related to password policy state for user entries.

The following notification handlers are available:

Error Log Account Status Notification Handler

Sends alerts to the error log when an account event occurs. Enabled by default.

SMTP Account Status Notification Handler

Sends notifications to designated email address. Disabled by default, but you can enable it using the **dsconfig** command.

Account status notification types

Notification handlers send alerts when one of the following account status events occurs during password policy processing.

Account Status Notification Types

Account Status Notification Types	Description
account-disabled	Generates a notification when a user account is disabled by an administrator.
account-enabled	Generates a notification when a user account is enabled by an administrator.
account-expired	Generates a notification when a user authentication attempt fails because the account has expired.
account-idle-locked	Generates a notification when a user authentication attempt fails because the account has been locked after idling for too long.
account-permanently-locked	Generates a notification when a user account is permanently locked, requiring administrative action to unlock the account after too many failed authentication attempts.
account-reset-locked	Generates a notification when an authentication attempt fails because the user account is locked after the user failed to change a password that was reset by an administrator within the required interval.
account-temporarily-locked	Generates a notification when a user account is temporarily locked after too many failed attempts.
account-unlocked	Generates a notification when a user account is unlocked by an administrator.
password-changed	Generates a notification when a user changes his or her own password.
password-expired	Generates a notification when a user authentication fails because the password has expired.
password-expiring	Generates a notification the first time a password expiration warning is encountered for a user password.
password-reset	Generates a notification when a user's password is reset by an administrator.

Working with the Error Log Account Status Notification Handler

The Error Log Account Status Notification Handler is enabled by default and sends alerts when one of the account status events occur.

You can view the log at `logs/error`.

Disabling the Error Log Account Status Notification Handler

Steps

- To disable the Error Log Handler, use the `dsconfig` tool.

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  ---handler-name "Error Log Handler" --set enabled:false
```

Removing a notification type from the Error Log Handler

Although you can remove an account status notification type from the Error Log Handler, it's not recommended.

About this task

For a list of notification types, see [Account status notification types](#) on page 693.

Steps

- To remove an account status notification type, use the `dsconfig` tool with the `--remove` option.

Example:

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  --handler-name "Error Log Handler" \
  --remove account-status-notification-type: password-reset
```

Working with the SMTP Account Status Notification Handler

You can enable account status notifications to be sent to designated email addresses of end users, administrators, or both through an outgoing SMTP server. The email message is automatically generated from template files that contain the text to use in the message body. For example, the message subject for the account-disabled event is:

```
account-disabled: Your directory account has been disabled.
```

The message templates are located in the `config/messages` directory. The typical message body template is as follows:

```
Your directory account has been disabled.
```

```
For further assistance, please contact a server administrator.
```

By default, the sender address is `notifications@example.com`, but you can configure your own address.

Before you enable the SMTP Account Status Notification Handler, you must configure the Directory Server to use at least one mail server as shown below. You can configure an SMTP server using `dsconfig` and the `set-global-configuration-prop` option.

Configuring the SMTP server

Steps

1. To configure a simple mail server, use the `dsconfig` command.

Example:

```
$ bin/dsconfig create-external-server --server-name smtp1 \
  --type smtp --set server-host-name:smtp.example.com
```

2. To configure an SMTP server, use the **dsconfig** command.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set smtp-server:smtp1
```

This command adds the server to the global list of mail servers that Directory Server can use.

Configuring a StartTLS connection to the SMTP server

Steps

1. To configure a StartTLS connection to the server, use the **dsconfig** command.

Example:

```
$ bin/dsconfig create-external-server \
  --server-name myTLSServer --type smtp \
  --set server-host-name:tls.smtp.example.com \
  --set server-port:587 \
  --set smtp-security:starttls \
  --set user-name:MyAccountName \
  --set password:AAD5yZ+DjvwiYkBSMer6GQ6B3szQ6gSSBjA=
```

2. To configure a newly-created SMTP server, use the **dsconfig** command.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  -set smtp-server:myTLSServer
```

This command adds the server to the global list of mail servers that Directory Server can use.

Configuring an SSL connection to the SMTP server

Steps

1. To create an external SMTP server using SSL, run the **dsconfig** command.

Example:

```
$ bin/dsconfig create-external-server \
  --server-name ssl.smtp.example.com \
  --type smtp --set server-host-name:smtp.gmail.com \
  --set server-port:465 \
  --set smtp-security:ssl \
  --set "user-name:my.name@example.com" \
  --set password:xxxxxx --set "smtp-timeout:10s"
```

2. To configure an SMTP server, run the **dsconfig** command.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set smtp-server:ssl.smtp.example.com
```

This command adds the server to the global list of mail servers that Directory Server can use.

Enabling the SMTP account status notification handler

Steps

- To enable the SMTP account status notification handler, use the `dsconfig` command.

Example:

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  --handler-name "SMTP Handler" --set enabled:true \
  --set "recipient-address:admin@example.com" \
  --set "sender-address:acct-status-notifications@example.com"
```

Viewing the account status notification handlers

After you enable the SMTP server, you can view the list of account status notification handlers.

Steps

- To view the list of account status notification handlers, run the `dsconfig` command.

Example:

```
$ bin/dsconfig list-account-status-notification-handlers
```

Result:

```
Account Status Notification Handler : Type      : enabled
-----:-----:-----
Error Log Handler                   : error-log : true
SMTP Handler                         : smtp      : true
```

Associating account status notification handlers with password policies

To generate notifications when password policy state changes occur in the server, you must configure the password policy that governs the entry being updated to use one or more account status notification handlers.

About this task

By default, password policies are not configured with such handlers, so no account status notifications are generated.

The `account-status-notification-handler` property controls the set of account status notification handlers for a password policy. You can be configure that property using `dsconfig` or the Administrative Console.

Steps

- To configure the `account-status-notification-handler` notification handler property, run `dsconfig`.

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "account-status-notification-handler:Error Log Handler"
```

This command updates the default password policy to trigger the error log account status notification handler for any appropriate password policy state changes.

Administrative alert handlers

The server provides mechanisms to send alert notifications to administrators when significant problems or events occur during processing, such as problems during server startup or shutdown. The Directory Server provides a number of alert handler implementations, including:

- **Error Log Alert Handler.** Sends administrative alerts to the configured server error logger(s).
- **Exec Alert Handler.** Executes a specified command on the local system if an administrative alert matching the criteria for this alert handler is generated by the Directory Server. Information about the administrative alert will be made available to the executed application as arguments provided by the command.
- **Groovy Scripted Alert Handler.** Provides alert handler implementations defined in a dynamically-loaded Groovy script that implements the `ScriptedAlertHandler` class defined in the Server SDK.
- **JMX Alert Handler.** Sends administrative alerts to clients using the Java Management Extensions (JMX) protocol. Ping Identity uses JMX for monitoring entries and requires that the JMX connection handler be enabled.
- **SMTP Alert Handler.** Sends administrative alerts to clients via email using the Simple Mail Transfer Protocol (SMTP). The server requires that one or more SMTP servers be defined in the global configuration.
- **SNMP Alert Handler.** Sends administrative alerts to clients using the Simple Network Monitoring Protocol (SNMP). The server must have an SNMP agent capable of communicating via SNMP 2c.
- **SNMP Subagent Alert Handler.** Sends SNMP traps to a primary agent in response to administrative alerts generated within the server.
- **Third Party Alert Handler.** Provides alert handler implementations created in third-party code using the Server SDK.

Administrative alert types

Directory Server can generate administrative alerts when the events occur.

A full listing of system alerts and their severity is available at `<server-root>/docs/admin-alerts-list.csv`.

Configuring the JMX connection handler and alert handler

You can configure the Java Management Extensions (JMX) connection handler and the alert handler using the `dsconfig` tool.

To allow users to receive JMX notifications, enable the `jmx-read` and `jmx-notify` privileges. By default, these privileges aren't granted to any users, including root users or global administrators.

For security reasons, you should create a separate user account that has only these privileges.

You can also configure the JMX connection handler and the alert handler using `dsconfig` in interactive command-line mode, which is visible in the `Standard object` menu.

Configuring the JMX connection handler

About this task

To enable the JMX connection handler:

Steps

1. Run `dsconfig`.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "JMX Connection Handler" \
  --set enabled:true \
```

```
--set listen-port:1689
```

2. Add a new non-root user account with the `jmx-read` and `jmx-notify` privileges using the `ldapmodify` tool using an LDIF representation.

Example:

```
dn: cn=JMX User,cn=Root DNs,cn=config
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-cfg-root-dn-user
givenName: JMX
sn: User
cn: JMX User
userPassword: password
ds-cfg-inherit-default-root-privileges: false
ds-cfg-alternate-bind-dn: cn=JMX User
ds-privilege-name: jmx-read
ds-privilege-name: jmx-notify
```

Configuring the JMX alert handler

About this task

To configure the Java Management Extensions (JMX) alert handler:

Steps

- Run `dsconfig`.

Example:

```
$ bin/dsconfig set-alert-handler-prop --handler-name "JMX Alert Handler" \
  --set enabled:true
```

Configuring the SMTP alert handler

To create a new instance of an SMTP alert handler, use the `dsconfig` tool.

About this task

By default, there is no configuration entry for an SMTP alert handler.

Steps

- Use the `dsconfig` tool to configure the SMTP Alert Handler.

Example:

```
$ bin/dsconfig create-alert-handler \
  --handler-name "SMTP Alert Handler" \
  --type smtp \
  --set enabled:true \
  --set "sender-address:alerts@example.com" \
  --set "recipient-address:administrators@example.com" \
  --set "message-subject:Directory Admin Alert \%%alert-type\%%" \
  --set "message-body:Administrative alert:\n\%%alert-message\%%"
```

Configuring the SNMP subagent alert handler

You can configure the SNMP subagent alert handler using the `dsconfig` tool, which is visible in the Standard object menu.

About this task

Before you begin, you need an SNMP subagent capable of communicating using SNMP2c. For more information about SNMP, see [Monitoring using SNMP](#) on page 674.

Directory Server also supports an SNMP alert handler, which is used in deployments that do not enable an SNMP subagent.

To configure the SNMP subagent alert handler:

Steps

- Run `dsconfig`.

Example:

In this example:

- The `server-host-name` is the address of the system running the SNMP subagent.
- The `server-port` is the port number on which the subagent is running.
- The `community-name` is the name of the SNMP community that is used for the traps.

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" \
  --set enabled:true \
  --set server-host-name:host2 \
  --set server-port:162 \
  --set community-name:public
```

Email account status notification handler

The e-mail account status notification handler enables the server to send messages that can contain either a plain-text body, an HTML-formatted body, or both.

If you configure the server to send both plain-text and HTML-formatted bodies, the recipient's email client determines which version to display. Messages can optionally include a set of attachments.

The `config/account-status-notification-email-templates` directory contains a set of template files that the server can use to generate multi-part email messages to send to end users and server administrators when certain events occur.

A separate template is used for each type of event so that the message contents, recipients, and other details can be customized for specific events.

Account status notification types

The following account status notification types are available.

- **account-temporarily-locked** -- A user's account has been temporarily locked due to too many failed authentication attempts. The account will remain locked until a configured length of time elapses, or until the password is reset by an administrator.
- **account-permanently-locked** -- A user's account has been permanently locked due to too many failed authentication attempts. The account will remain locked until the password is reset by an administrator.
- **account-idle-locked** -- An authentication attempt failed because it has been too long (longer than the `idle-lockout-interval` configured in the associated password policy) since the user last successfully authenticated to the server. The account will remain locked until the password is reset by an administrator.

- **account-reset-locked** -- An authentication attempt failed because the user's account was in a "must change password" state following an administrative password reset, but the user did not choose a new password in a timely manner (within the `max-password-reset-age` duration configured in the associated password policy). The account will remain locked until the password is reset again by an administrator.
- **account-unlocked** -- A locked user account has been unlocked (for example, by an administrative password reset).
- **account-disabled** -- A user's account has been administratively disabled (by setting the `ds-pwp-account-disabled` operational attribute to `true` in the user entry). The user will not be allowed to authenticate until this attribute is removed or its value is set to `false`.
- **account-enabled** -- A user's account has been administratively enabled (by setting the `ds-pwp-account-disabled` operational attribute to `false` in the user entry, or by removing this attribute from the entry).
- **account-not-yet-active** -- An authentication attempt failed because the user account is configured with an activation time (via the `ds-pwp-account-activation-time` operational attribute in the user's entry) that is in the future. The user will not be allowed to authenticate until this time arrives, until the activation time is removed, or until the activation time is set to a time in the past.
- **account-expired** -- An authentication attempt failed because the user account is configured with an expiration time (via the `ds-pwp-account-expiration-time` operational attribute in the user's entry) that is in the past. The user will not be allowed to authenticate until the expiration time is removed or set to a time in the future.
- **password-expired** -- An authentication attempt failed because the user's password has expired. The user will not be allowed to authenticate until their password is reset by an administrator (or until they change their own password if `allow-expired-password-changes` is set to `true` in the associated password policy).
- **password-expiring** -- The user successfully authenticated, but their password will expire in the near future (as determined by the `password-expiration-warning-interval` setting in the associated password policy). This notification type will only be generated the first time that a user authenticated within a given warning interval.
- **password-reset** -- A user's password has been reset by an administrator.
- **password-changed** -- A user changed their own password.
- **account-created** -- A new account was created in an add request that matches the criteria specified in the `account-creation-notification-request-criteria` property of the account status notification handler configuration.
- **account-updated** -- An existing account was updated in a modify or modify DN request that matches the criteria specified in the `account-update-notification-request-criteria` property of the account status notification handler configuration.

Message template file format

An email message for the email account status notification handler contains the following structure:

- A required header section describing the sender, recipients, subject, and other header elements
This section must appear exactly once, and it must be the first section of the template file.
- An optional section providing a plain-text version of the message body
This section may appear at most once, and at least one of the plain-text and HTML-formatted body sections must be present.
- An optional section providing an HTML-formatted version of the message body
This section may appear at most once, and at least one of the plain-text and HTML-formatted body sections must be present.
- An optional section providing information about an attachment to include in the message
This section can be included zero, one, or multiple times, and all attachment sections must appear after all other sections.

Header section

A message template file must start with a header section that specifies the recipient and sender addresses, the message subject, and the values of any custom headers that should appear in the message. It also indicates whether the template should be enabled and used to send email messages.

The header section must begin with the line `----- BEGIN HEADERS -----` and can contain a number of name-value pairs that provide information about the message. Each name-value pair should appear on a separate line, and the name and value must be separated by a colon and optional spaces. The header section can include the following:

ENABLED

Specifies whether this template is enabled and should be used to generate an email message.

This element must be present and must have a value of either `true` or `false`. This is primarily intended for cases in which a message should only be generated under certain circumstances.

Tip:

If you don't want a message sent for a particular notification type, don't specify a template file for that notification type in the configuration for the multi-part email account status notification handler.

TO

Specifies a primary recipient for the email message. This recipient is visible to all recipients.

The value can be either an email address, such as `jd@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jd@example.com>`.

To specify multiple **TO** recipients, specify this element multiple times.

It can be omitted if the message should have only **CC** or **BCC** recipients, but the message must have at least one **TO**, **CC**, or **BCC** recipient.

CC

Specifies a carbon-copied recipient for the email message. This recipient is visible to all recipients.

The value can be either an email address, such as `jd@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jd@example.com>`.

To specify multiple **CC** recipients, specify this element multiple times.

It can be omitted if the message should have only **TO** or **BCC** recipients, but the message must have at least one **TO**, **CC**, or **BCC** recipient.

BCC

Specifies a blind carbon-copied recipient for the email message. This recipient is not visible to other recipients.

The value can be either an email address, such as `jd@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jd@example.com>`.

To specify multiple **BCC** recipients, specify this element multiple times.

It can be omitted if the message should have only **TO** or **CC** recipients, but the message must have at least one **TO**, **CC**, or **BCC** recipient.

FROM

Specifies the address from which the email message should appear to be sent.

This value can be either an email address, such as `jsdoe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdoe@example.com>`.

This element must be specified exactly once.

REPLY-TO

Specifies the default address to which users should send replies.

The value can be either an email address, such as `jdoe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdoe@example.com>`.

This element is optional and can only be specified once.

SUBJECT

Specifies the subject for the email message.

This element must be specified exactly once.

HEADER

Defines a custom header for the email message.

The header value itself should be a name-value pair with the name and value separated by a colon and optional spaces, such as `X-Custom-Header-Name: Custom Header Value`.

This is an optional element and can be specified multiple times to specify multiple headers with the same or different names.

Body sections

The header section must be followed by plain-text body sections, HTML-formatted body sections, or both. Each of these sections consists of free-form text that can span multiple lines and continues until the beginning of the next section or the end of the template file is reached.

If a plain-text body is included, it must begin with the line `----- BEGIN PLAIN-TEXT BODY -----`. If an HTML-formatted body is included, it must begin with the line `----- BEGIN HTML BODY -----`. At least one of these sections must be included. If an HTML-formatted body section is included, you should add a plain-text body for the benefit of clients that prefer plain text or cannot handle HTML content. Any blank lines at the beginning or end of the body text are removed, but blank lines in the middle of the body are preserved.

Attachment sections

The template can contain any number of optional attachment sections that describe any attachments that should be included in the message. Specify each attachment in its own section at the end of the template, after the header, plain-text, and HTML-formatted body sections. Each attachment section must begin with the line `----- BEGIN ATTACHMENT -----` and can include the following elements, using the same colon-delimited syntax used in the header section:

FILENAME

The name (without any path information) of the file to be attached. This must be specified, and the file must exist in the same directory as the template file.

CONTENT-TYPE

The `MIME` type for the attachment. This is an optional element. If it is not specified, a default content-type of `application/octet-stream` is used.

INLINE

If present, this value must be either `true` or `false`. If it is omitted, a default value of `false` is assumed.

If `true`, indicates that the attachment should be an inline attachment. For example, if you include an image that should be referenced within the HTML body, the image source path should be `cid:` followed by the filename, such as `cid:company-logo.png`.

Customizing the message content

Before the server parses the template file to generate a message, it pre-processes the file with the Apache Velocity templating engine. This enables you to customize the message content with information from the account status notification, details from the associated user entry, and other information. For more information about Apache Velocity, see <https://velocity.apache.org/>.

The following variables are defined for use with custom directives.

Variable	Description
<code>\$account_entry</code>	The entry for the user associated with the account status notification.
<code>\$notification_type</code>	The name of the notification type for the account status notification.
<code>\$notification_message</code>	A human-readable message that provides a basic description of the account status notification.
<code>\$before_entry</code>	<p>A version of the associated entry as it appeared before the operation was processed.</p> <p> Note: This is only available for notifications generated as a result of modify or modify distinguished name (DN) operations.</p>
<code>\$after_entry</code>	<p>A version of the associated entry as it appeared after the operation was processed.</p> <p> Note: This is only available for notifications generated as a result of modify or modify DN operations.</p>

In addition to the built-in directives provided by Velocity, the following custom directives are also available.

Directive	Syntax	Description
<code>#getEntryDN</code>	<code>entry, variableName</code>	Retrieves a string representation of the provided entry's DN and stores it in the specified Velocity context variable.

Directive	Syntax	Description
#getHasAttribute	<i>entry, attributeName, variableName</i>	Determines if the provided entry includes the specified attribute. If it contains the specified attribute, a value of <code>true</code> is stored in the specified Velocity context variable. If not, a value of <code>false</code> is stored.
#getUserAttributeNames	<i>entry, variableName</i>	Retrieves a list of the names of the user attributes contained in the provided entry and stores this list in the specified Velocity context variable.
#getOperationalAttributeNames	<i>entry, variableName</i>	Retrieves a list of the names of the operational attributes contained in the provided entry and stores this list in the specified Velocity context variable.
#getAttributeValue	<i>entry, attributeName, variableName</i>	Retrieves the first value for the indicated attribute from the provided entry and stores it in the specified Velocity context variable. If the attribute is not present in the entry, the variable is removed from the context.
#getAttributeValues	<i>entry, attributeName, variableName</i>	Retrieves the list of values for the indicated attribute from the provided entry and stores this list in the specified Velocity context variable. If the attribute is not present in the entry, an empty list is stored.
#getEntryMatchesLDAPFilter	<i>entry, filterString, variableName</i>	Determines if the provided entry matches the LDAP filter with the given string representation. If the entry matches, a value of <code>true</code> is stored in the Velocity context variable. Otherwise, a value of <code>false</code> is stored.

Directive	Syntax	Description
#getJSONObjectValue	<i>entry, attributeName, variableName</i>	<p>Retrieves the first value that can be parsed as a JSON object for the indicated attribute and stores this object in the specified variable in the Velocity context.</p> <p>If the attribute does not exist in the provided entry, or if none of its values can be parsed as a JSON object, the variable is removed from the context.</p>
#getJSONObjectValues	<i>entry, attributeName, variableName</i>	<p>Retrieves a list of all values that can be parsed as JSON objects for the indicated attribute and stores this list in the specified variable in the Velocity context.</p> <p>If the attribute does not exist in the provided entry, or if none of its values can be parsed as JSON objects, an empty list is stored.</p>
#getJSONFieldValue	<i>jsonObject, fieldName, variableName</i>	<p>Retrieves the first value for the indicated field from the provided JSON object and stores its string representation in the specified Velocity context variable.</p> <p>Nested fields can be targeted by using the period as a delimiter between field names.</p> <p>For example, <code>name.first</code> targets the <code>first</code> field inside a JSON object that is a value for the outer <code>name</code> field.</p> <p>If the field does not exist in the provided object, the variable is removed from the context.</p>

Directive	Syntax	Description
#getJSONFieldValues	<i>jsonObject, fieldName, variableName</i>	<p>Retrieves all values for the indicated field from the provided JSON object and stores a list of their string representations in the specified Velocity context variable.</p> <p>Nested fields can be targeted by using the period as a delimiter between field names.</p> <p>For example, <code>name.first</code> targets the <code>first</code> field inside a JSON object that is a value for the outer <code>name</code> field.</p> <p>If the field does not exist in the provided object, or if its value is an empty array, an empty list is stored.</p>
#getJSONObjectMatchesFilter	<i>jsonObject, jsonObjectFilterString, variableName</i>	<p>Determines if the provided JSON object matches the JSON object filter with the given string representation.</p> <p>If the JSON object matches, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.</p>
#getEntry	<i>entryDN, variableName</i>	<p>Retrieves the entry with the provided DN from the server and stores it in the specified Velocity context variable.</p> <p>If the entry does not exist, the variable is removed from the context.</p>
#searchForEntries	<i>baseDN, scopeString, filterString, variableName</i>	<p>Performs an internal search with the provided base DN; scope, which must be one of <code>base</code>, <code>one</code>, <code>sub</code>, or <code>subordinates</code>; and filter; and stores the list of matching entries in the specified variable in the context.</p> <p>If the search does not match any entries, if it matches more than 20 entries, or if the search criteria is not indexed, then an empty list is stored.</p>

Directive	Syntax	Description
#getParentDN	<i>entryDN, variableName</i>	<p>Determines the parent DN for the provided entry DN and stores it in the specified Velocity context variable.</p> <p>If the provided DN contains only a single component, an empty string is stored.</p> <p>If the provided DN is the null DN, and therefore does not have a parent, the variable is removed from the context.</p>
#getIsAttributeModified	<i>beforeEntry, afterEntry, attributeName, variableName</i>	<p>Determines if the indicated attribute has been modified between the provided before and after representations of the entry.</p> <p>If the attribute has been modified, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.</p>
#getIsAnyAttributeModified	<i>beforeEntry, afterEntry, attributeName1, attributeName2, ..., variableName</i>	<p>Determines if at least one of the listed attributes has been modified between the provided before and after representations of the entry.</p> <p>If at least one of the listed attributes has been modified, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.</p> <p>The first two arguments to this directive must be the before and after representations of the target entry, and the last argument must be the name of the variable in which to store the result. All arguments in between these are treated as the names or OIDs of the attributes for which to make the determination. At least one attribute name or OID must be provided.</p>

Directive	Syntax	Description
<code>#getModifiedAttributeNames</code>	<code>beforeEntry, afterEntry, variableName</code>	Determines which attributes have been modified between the provided before and after representations of the entry, and stores a list of their names in the specified Velocity context variable. If the provided entries are identical, an empty list is stored.
<code>#getModifiedAttributeAddedValues</code>	<code>beforeEntry, afterEntry, attributeName, variableName</code>	Retrieves a list of the values that have been added between the provided before and after representations of an entry for the indicated attribute, and stores this list in the specified Velocity context variable. If the attribute was not altered, or if values were only removed from the attribute, an empty list is stored.
<code>#getModifiedAttributeRemovedValues</code>	<code>beforeEntry, afterEntry, attributeName, variableName</code>	Retrieves a list of the values that have been removed between the provided before and after representations of an entry for the indicated attribute, and stores this list in the specified Velocity context variable. If the attribute was not altered, or if values were only added to the attribute, an empty list is stored.
<code>#getOperationMatchesConnectionCriteria</code>	<code>criteriaDN, variableName</code>	Determines if the operation that triggered the notification matches the connection criteria defined in the entry with the specified DN. If it matches, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.
<code>#getOperationMatchesRequestCriteria</code>	<code>criteriaDN, variableName</code>	Determines if the operation that triggered the notification matches the request criteria defined in the entry with the specified DN. If it matches, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.

Directive	Syntax	Description
<code>#getNotificationPropertyNames</code>	<code>variableName</code>	Retrieves a list of the names of the account status notification properties that are defined for the notification and stores this list in the specified Velocity context variable.
<code>#getNotificationPropertyValue</code>	<code>propertyName, variableName</code>	Retrieves the first value for the given account status notification property and stores it in the specified Velocity context variable. If the property is not defined, the variable is removed from the context. Refer to the following table for <i>propertyName</i> values.
<code>#getNotificationPropertyValues</code>	<code>propertyName, variableName</code>	Retrieves the list of values for the given account status notification property and stores this list in the specified Velocity context variable. If the property is not defined, an empty list is stored. Refer to the following table for <i>propertyName</i> values.
<code>#getFormattedTimestamp</code>	<code>timestamp, formatString, variableName</code>	Retrieves a representation of the provided timestamp, which must be in generalized time form, formatted with the provided format string, which must be compatible with the <code>java.text.SimpleDateFormat</code> class, and stores it in the specified Velocity context variable. The default time zone of the JVM is used.

Directive	Syntax	Description
<code>#getFormattedTimestamp</code>	<i>timestamp, formatString, timeZone, variableName</i>	Retrieves a representation of the provided timestamp, which must be in generalized time form, formatted with the given format string, which must be compatible with the <code>java.text.SimpleDateFormat</code> class, in the indicated time zone, which must be compatible with the <code>java.time.ZoneId</code> class, and stores it in the specified Velocity context variable.
<code>#getFileExistsInTemplateDirectory</code>	<i>fileName, variableName</i>	Determines if a file with the provided name, which must not contain path information, exists in the same directory as the template. If the file exists, a value of <code>true</code> is stored in the specified Velocity context variable. Otherwise, a value of <code>false</code> is stored.

The following account status notification properties are available for use in conjunction with the `#getNotificationPropertyValue` and `#getNotificationPropertyValues` directives.

Property	Description
<code>notification-type</code>	The name of the account status notification type.
<code>notification-time</code>	A generalized time representation of the time that the notification was generated.
<code>account-dn</code>	The DN of the entry for the associated user account.
<code>password-policy-dn</code>	The DN of the password policy that governs the associated user account.
<code>password-changed-time</code>	A generalized time representation of the time the user's password was last changed.
<code>seconds-since-password-change</code>	The number of seconds since the account's password was last changed.
<code>time-since-password-change</code>	A human-readable duration indicating the length of time since the user's password was last changed.

Property	Description
<code>account-is-usable</code>	The value is <code>true</code> if the account is considered usable, or <code>false</code> if it is not usable. The account is considered unusable if, for example, the account is locked, expired, or not yet active; if the password is expired; if the user must choose a new password; and so on.
<code>account-usability-errors</code>	A list of human-readable strings providing information about any errors that currently affect the account's usability.
<code>account-usability-warnings</code>	A list of human-readable strings providing information about any warning conditions that have the potential to affect the account's usability in the near future.
<code>account-usability-notice</code>	A list of human-readable strings providing information about any notable account state conditions that are not expected to affect the account's usability in the near future.
<code>account-is-disabled</code>	The value is <code>true</code> if the account has been administratively disabled, or <code>false</code> if it has not been administratively disabled.
<code>account-is-not-yet-active</code>	The value is <code>true</code> if the account has an activation time in the future, or <code>false</code> if not.
<code>account-activation-time</code>	A generalized time representation of the account activation time, if defined.
<code>seconds-until-account-activation</code>	The number of seconds until the account becomes active if it has an activation time in the future.
<code>time-until-account-activation</code>	A human-readable duration indicating the length of time until the account becomes active if it has an activation time in the future.
<code>seconds-since-account-activation</code>	The number of seconds since the account became active if it has an activation time in the past.
<code>time-since-account-activation</code>	A human-readable duration indicating the length of time since the account became active if it has an activation time in the past.
<code>account-is-expired</code>	The value is <code>true</code> if the account has an expiration time in the past, or <code>false</code> if not.
<code>account-expiration-time</code>	A generalized time representation of the account expiration time, if defined.

Property	Description
<code>seconds-until-account-expiration</code>	The number of seconds until the account expires if it has an expiration time in the future.
<code>time-until-account-expiration</code>	A human-readable duration indicating the length of time until the account expires if it has an expiration time in the future.
<code>seconds-since-account-expiration</code>	The number of seconds since the account expired if it has an expiration time in the past.
<code>time-since-account-expiration</code>	A human-readable duration indicating the length of time since the account expired if it has an expiration time in the past.
<code>account-is-failure-locked</code>	The value is <code>true</code> if the account has been temporarily or permanently locked due to too many failed authentication attempts, or <code>false</code> if not.
<code>failure-locked-time</code>	A generalized time representation of the time that the account became failure-locked, if applicable.
<code>account-unlock-time</code>	A generalized time representation of the time that the account will be automatically unlocked, if it is temporarily locked due to too many failed authentication attempts.
<code>seconds-until-unlock</code>	The number of seconds until the account unlock time, if applicable.
<code>time-until-unlock</code>	A human-readable duration indicating the length of time until the account unlock time, if applicable.
<code>failure-lockout-count</code>	The number of failed authentication attempts required to lock an account, if configured.
<code>failure-lockout-duration-seconds</code>	The number of seconds that a failure-locked account will be prevented from authenticating, if defined.
<code>failure-lockout-duration</code>	A human-readable duration that indicates how long a failure-locked account will be prevented from authenticating, if defined.
<code>account-is-idle-locked</code>	The value is <code>true</code> if the account is locked because it has been too long since the user last authenticated, or <code>false</code> if not.
<code>idle-lockout-interval-seconds</code>	The maximum number of seconds that can pass between successful authentications before an account becomes idle-locked, if configured.

Property	Description
<code>idle-lockout-interval</code>	A human-readable duration that indicates how much time can pass between successful authentications before an account becomes idle-locked, if configured.
<code>last-login-time</code>	A generalized time representation of the time that the user last successfully authenticated, if available.
<code>seconds-since-last-login</code>	The number of seconds that have passed since the user last successfully authenticated, if available.
<code>time-since-last-login</code>	A human-readable duration indicating the length of time that has passed since the user last successfully authenticated, if available.
<code>last-login-ip-address</code>	The IP address of the client from which the user last authenticated, if available.
<code>account-is-reset-locked</code>	The value is <code>true</code> if the account is locked because the user failed to choose a new password in a timely manner after an administrative password reset, or <code>false</code> if not.
<code>maximum-password-reset-age-seconds</code>	The maximum number of seconds that a user has to choose a new password after an administrative password reset before the account becomes reset-locked, if defined.
<code>maximum-password-reset-age</code>	A human-readable duration indicating the maximum length of time that a user has to choose a new password after an administrative password reset before the account becomes reset-locked, if defined.
<code>must-change-password</code>	The value is <code>true</code> if the user will be required to choose a new password before they are allowed to perform any other operations on the server, or <code>false</code> if not.
<code>account-was-unlocked</code>	The value is <code>true</code> if the account had been locked but was just unlocked by the associated operation, or <code>false</code> if not.
<code>password-is-expired</code>	The value is <code>true</code> if the account has an expired password, or <code>false</code> if not.
<code>password-is-expiring</code>	The value is <code>true</code> if the account has a password that will expire in the near future, as determined by the <code>password-expiration-warning-interval</code> property in the associated password policy, or <code>false</code> if not.

Property	Description
<code>maximum-password-age-seconds</code>	The maximum number of seconds that an account is permitted to keep the same password before it expires, if defined.
<code>maximum-password-age</code>	A human-readable duration indicating the maximum length of time that an account is permitted to keep the same password before it expires, if defined.
<code>maximum-password-age</code>	A human-readable duration indicating the maximum length of time that an account is permitted to keep the same password before it expires, if defined.
<code>password-expiration-time</code>	A generalized time representation of the time that the account's password did or will expire, if applicable.
<code>seconds-until-password-expiration</code>	The number of seconds until the account's password will expire, if it has an expiration time in the future.
<code>time-until-password-expiration</code>	A human-readable duration indicating the length of time until the account's password will expire, if it has an expiration time in the future.
<code>seconds-since-password-expiration</code>	The number of seconds since the account's password expired, if it has an expiration time that is in the past.
<code>time-since-password-expiration</code>	A human-readable duration indicating the length of time since the account's password expired, if it has an expiration time in the past.
<code>old-password</code>	The clear-text password that the account had before the associated operation was processed, if available.
<code>new-password</code>	The clear-text password that the account has after the associated operation was processed, if available.
<code>new-generated-password</code>	The clear-text password that was generated for the account by the associated operation, if applicable.
<code>requester-ip-address</code>	The IP address of the client that requested the associated operation, if available.
<code>requester-dn</code>	The DN of the account that requested the associated operation.
<code>operation-type</code>	The name of the operation type for the associated operation.

Property	Description
<code>operation-id</code>	A string representation of the operation ID for the associated operation.
<code>connection-id</code>	A string representation of the connection ID for the associated operation.
<code>server-uuid</code>	A string representation of the unique identifier generated for the server instance that processed the associated operation.
<code>instance-name</code>	The instance name for the server instance that processed the associated operation.

Working with the Alerts Backend

Directory Server stores recently-generated admin alerts in an Alerts Backend under the `cn=alerts` branch.

The backend makes it possible to obtain admin alert information over LDAP. The backend's primary job is to process search operations for alerts. It does not support `add`, `modify`, or `modify DN` operations of entries in the `cn=alerts` backend.

The alerts persist on the server in the `config/alerts.ldif` file so they can survive server restarts. By default, the alerts remain in the system for seven days before being removed. Administrators can configure the number of days alerts are retained by using the `dsconfig` tool.

The administrative alerts of `Warning` level or worse that have occurred in the last 48 hours are viewable from the output of the status command-line tool and in the Administrative Console.

Viewing information in the Alerts Backend

About this task

To view admin alerts:

Steps

- Run `ldapsearch`.

Example:

```
$ bin/ldapsearch --port 1389 --bindDN "cn=Directory Manager" \
  --bindPassword secret --baseDN cn=alerts "(objectclass=ds-admin-alert) "
```

Result:

```
dn: ds-alert-id=3d1857a2-e8cf-4e80-ac0e-ba933be59eca,cn=alerts
objectClass: top
objectClass: ds-admin-alert
ds-alert-id: 3d1857a2-e8cf-4e80-ac0e-ba933be59eca
ds-alert-type: server-started
ds-alert-severity: info
ds-alert-type-oid: 1.3.6.1.4.1.32473.2.11.33
ds-alert-time: 20110126041442.622Z
ds-alert-generator: com.unboundid.directory.server.core.directory.server
ds-alert-message: The Directory Server has started successfully
```

Modifying the alert retention time

Steps

- To change the retention time of admin alerts, run **dsconfig**.

Example:

```
$ bin/dsconfig set-backend-prop --backend-name "alerts" \
  --set "alert-retention-time: 2 weeks"
```

After this time, the information is purged from the Directory Server. The minimum retention time is 0 milliseconds, which immediately purges the alert information.

- To view the `alert-retention-time` property, use **dsconfig**.

Example:

```
$ bin/dsconfig get-backend-prop --backend-name "alerts" \
  --property alert-retention-time
```

Result:

```
Property : Value(s)
-----:-----
alert-retention-time : 2 w
```

Configuring duplicate alert suppression

About this task

The `duplicate-alert-time-limit` property specifies the length of time that must pass before duplicate messages are sent over the administrative alert framework.

The `duplicate-alert-limit` property specifies the maximum number of duplicate alert messages that can be sent over the administrative alert framework in the time limit specified in the `duplicate-alert-time-limit` property.

To configure the maximum number of times an alert is generated within a particular timeframe for the same condition:

Steps

- Run **dsconfig**.

Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set duplicate-alert-limit:2 \
  --set "duplicate-alert-time-limit:3 minutes"
```

Working with alarms, alerts, and gauges

Alarms, alerts, and gauges alert administrators to changes in server conditions that might require attention.

Alarms

An alarm represents a stateful condition of the server or a resource that might indicate a problem, such as low disk space or external server unavailability.

Alarms have severity, name, and message. Alarms will always have a Condition property, and can have a Specific Problem or Resource property. If surfaced through SNMP, a Probable Cause property and

Alarm Type property are also listed. You can configure alarms to generate alerts when the alarm's severity changes.

You can configure the Alarm Manager, which governs the actions performed when an alarm state is entered, through the `dsconfig` tool and Administrative Console. A complete list of system alerts, alarms, and their severity is available in `<server-root>/docs/admin-alerts-list.csv`.

Directory Server complies with the International Telecommunication Union CCITT Recommendation X.733 (1992) standard for generating and clearing alarms. If configured, entering or exiting an alarm state might result in one or more alerts.

An alarm state is exited when the condition no longer applies. An `alarm_cleared` alert type is generated by the system when an alarm's severity changes from a non-normal severity to any other severity. An `alarm_cleared` alert will correlate to a previous alarm when the Condition and Resource properties are the same. The Condition corresponds to the Summary column in the `admin-alerts-list.csv` file.

Like the Alerts Backend, which stores information in `cn=alerts`, the Alarm Backend stores information within the `cn=alarms` backend. Unlike alerts, alarm thresholds have a state over time that can change in severity and be cleared when a monitored value returns to normal. You can view alarms with the `status` tool. As with other alert types, you can configure alert handlers can to manage the alerts generated by alarms.

Alerts

There are two alert types supported by the server: standard and alarm-specific.

The server constantly monitors for conditions that might need administrator attention, such as low disk space. For this condition, the standard alert is `low-disk-space-warning`, and the alarm-specific alert is `alarm-warning`.

You can configure the server to generate alarm-specific alerts as well as standard alerts. By default, standard alerts are generated for conditions internally monitored by the server. However, gauges can only generate alarm-alerts.

Gauges

A gauge defines a set of threshold values with a specified severity that, when crossed, cause the server to enter or exit an alarm state.

Numeric gauges monitor continuous values like CPU load or free disk space. Indicator gauges monitor enumerated set of values such as 'server unavailable' or 'server unavailable'. Gauges generate alarms when the gauge's severity changes due to changes in the monitored value.

Directory Server installs a set of gauges that are specific to the product and that can be cloned or configured through the `dsconfig` tool. You can tailor existing gauges to fit each environment by adjusting the update interval and threshold values. Configuration of system gauges determines the criteria by which alarms are triggered.

Use the Stats Logger to view historical information about the value and severity of all system gauges. For more information, see [Profiling server performance using the Stats Logger](#) on page 683.

Viewing information in the Alarms Backend

About this task

Use `ldapsearch` to view alarms.

Steps

- To display the listing for the CPU usage alarm, run the following command.

```
$ bin/ldapsearch --port 1389 --bindDN "cn=Directory Manager" \
```

```
--bindPassword secret --baseDN cn=alarms "(objectclass=ds-admin-alarm) "
```

Result:

```
dn: ds-alarm-id=CPU Usage (Percent)-Host System,cn=alarms
dn: ds-alarm-id=CPU Usage (Percent)-Host System,cn=alarms
objectClass: top
objectClass: ds-admin-alarm
ds-alarm-id: CPU Usage (Percent)-Host System
ds-alarm-condition: CPU Usage (Percent)
ds-alarm-specific-resource: Host System
ds-alarm-severity: CRITICAL
ds-alarm-previous-severity: CRITICAL
ds-alarm-details: Gauge CPU Usage (Percent) for Host System
                    has value 99, having had a value of 83.13 in the
                    previous interval. The severity is critical, having
                    assumed this severity Thu Sep 25 10:24:20 CDT 2014
                    when the value crossed threshold 80
ds-alarm-additional-text: If CPU use is high, check the server's current
                        workload
                        and other processes on this system and make any needed
                        adjustments. Reducing
                        the load on the system will lead to better response times
ds-alarm-start-time: 20140925152420.004Z
ds-alarm-critical-last-time: 20140925152420.004Z
ds-alarm-critical-total-duration-millis: 0
```

Testing alerts and alarms

After alarms and alert handlers are configured, you can manually increase the severity of a gauge to verify that the server takes the appropriate action when an alarm state change.

You can then use the **status** tool to verify alarms and alerts.

Testing alarms and alerts**Steps**

1. Use **dsconfig** to configure a gauge and set the **override-severity** property to critical.

The following example configures the CPU Usage (Percent) gauge.

Example:

```
$ dsconfig set-gauge-prop \
  --gauge-name "CPU Usage (Percent)" \
  --set override-severity:critical
```

2. Run the **status** tool to verify that an alarm was generated with corresponding alerts.

The **status** tool provides a summary of the server's current state with key metrics and a list of recent alerts and alarms.

Example:

The sample output has been shortened to show just the alarms and alerts information.

```
$ bin/status

--- Administrative Alerts ---

```

Indeterminate alarms

Directory Server raises indeterminate alarms for a server condition for which a severity cannot be determined.

In most cases these alarms are benign and do not issue alerts, nor do they appear in the output of the **status** tool or Administrative Console by default.

These alarms are usually caused by an enabled gauge that is intended to measure an aspect of the server that is not currently enabled. For example, gauges intended to monitor metrics related to replication might produce indeterminate alarms if a directory server is not currently replicating data. The gauge can be disabled if needed.

For more information about indeterminate alarms, view the gauge's associated monitor entry. There might be messages that can help determine the issue.

The following is sample output from the **status** tool run with the `--alarmSeverity=indeterminate` option.

```

          --- Alarms ---
Severity   : Severity Start : Condition      : Resource      : Details
           : Time                  :               :              :
-----:-----:-----:-----:-----
Normal    : 26/Aug/2014         : Startup Begun : cn=config    : The Directory
Server

```

```

      : 14:16:29 -0500 :           :           : is starting.

Managing SCIM Servlet Extensions

The PingDirectory Server provides two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure, fast, and simple way. The SCIM 1.1 implementation is provided by the servlet extension named SCIM. The SCIM 2 implementation is provided by the servlet extension named SIMC2.

SCIM 1.1 and 2.0 servlet extensions management

The Server provides two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure, fast, and simple way. SCIM is an alternative to LDAP, allowing identity data provisioning between cloud-based applications over HTTPS. One servlet implements SCIM 1.1 and the other servlet implements SCIM 2.

This section describes fundamental SCIM concepts and provides information on configuring SCIM on your server.

Overview of SCIM 1.1 fundamentals

Understanding the basic concepts of SCIM can help you use the SCIM extension to meet your deployment needs. SCIM allows you to:

- **Provision identities.** Through the API, you have access to the basic create, read, update, and delete functions, as well as other special functions.
- **Provision groups.** SCIM also allows you to manage groups.
- **Interoperate using a common schema.** SCIM provides a well-defined, platform-neutral user and group schema, as well as a simple mechanism to extend it.

The SCIM extension implements the 1.1 version of the SCIM specification. Familiarize yourself with this specification to help you understand and make efficient use of the SCIM extension and the SCIM SDK. The SCIM specifications are located on the Simplecloud website.

Note:

SCIM 1.1 will be deprecated in a future release.

Summary of SCIM 1.1 protocol support

the Server supports all required features of the SCIM 1.1 protocol and most optional features. The following table describes SCIM features and whether they are supported.

SCIM Protocol Support

SCIM Feature	Supported
Etags	Yes
JSON	Yes
XML*	Yes
Authentication/Authorization	Yes, via HTTP basic authentication or OAuth 2.0 bearer tokens
Service Provider Configuration	Yes
Schema	Yes
User resources	Yes
Group resources	Yes
User-defined resources	Yes
Resource retrieval via GET	Yes
List/query resources	Yes
Query filtering*	Yes
Query result sorting*	Yes
Query result pagination*	Yes (Directory Server, not Directory Proxy Server)
Resource updates via PUT	Yes
Partial resource updates via PATCH*	Yes
Resource deletes via DELETE	Yes

SCIM Feature	Supported
Resource versioning*	Yes (requires configuration for updated servers)
Bulk*	Yes
HTTP method overloading	Yes
Raw LDAP Endpoints**	Yes

* denotes an optional feature of the SCIM protocol.

** denotes a the Server extension to the basic SCIM functionality.

About the Identity Access API

The PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server support an extension to the SCIM 1.1 standard called the Identity Access API. The Identity Access API provides an alternative to LDAP by supporting CRUD (create, read, update, and delete) operations to access directory server data over an HTTP connection.

SCIM 1.1 and the Identity Access API are provided as a unified service through the SCIM HTTP Servlet Extension. The SCIM HTTP Servlet Extension can be configured to only enable core SCIM resources (e.g., 'Users' and 'Groups'), only LDAP object classes (e.g., `top`, `domain`, `inetOrgPerson`, or `groupOfUniqueNames`), or both. Because SCIM and the Identity Access API have different schemas, if both are enabled, there may be two representations with different schemas for any resources defined in the `scim-resources.xml` file: the SCIM representation and the raw LDAP representation. Likewise, because resources are exposed by an LDAP object class, and because these are hierarchical (e.g., `top` --> `person` --> `organizationalPerson` --> `inetOrgPerson`, etc.), a client application can access an entry in multiple ways due to the different paths/URIs to a given resource.

This chapter provides information on configuring the SCIM and the Identity Access API services on the Server.

Configuring SCIM 1.1

This section discusses details about the PingDirectory Server implementation of the SCIM protocol. Before reading this chapter, familiarize yourself with the SCIM Protocol specification, available on the Simplecloud website.

Creating your own SCIM 1.1 application

To create your own System for Cross-domain Identity Management (SCIM) 1.1 application, you must download the SCIM 1.1 SDK.

SCIM is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 1.1 SDK is available for download at <https://github.com/pingidentity/scim>.

Note:

The value of a read-only SCIM attribute can be set by a POST operation if the SCIM attribute is a custom attribute in the `scim-resource.xml` config file, but not if the SCIM attribute is a core SCIM attribute.

Configuring the SCIM 1.1 servlet extension

The Directory Server provides a default SCIM HTTP Servlet Extension that can be enabled and configured using a `dsconfig` batch script located in the `config` directory. The script runs a series of commands that enables an HTTPS Connection Handler, increases the level of detail logged by the HTTP Detailed Access log publisher, and adds access controls to allow access to LDAP controls used by the SCIM Servlet

Extension. There are additional optional configurations (e.g., changing the log format, enable `entryDN` virtual attribute and using VLV indexes) that you can make by altering the `dsconfig` batch script.

The SCIM resource mappings are defined by the `scim-resources.xml` file located in the `config` directory. This file defines the SCIM schema and maps it to the LDAP schema. This file can be customized to define and expose deployment specific resources. See [Managing the SCIM Schema](#) for more information.

The following procedures show how to configure SCIM on the server. The first example procedure shows the steps to manually configure SCIM without using the script. The second example procedure uses the `dsconfig` batch script to configure SCIM.

Configuring SCIM manually

About this task

The following example procedure assumes that you have configured the Directory Server using the default settings, which means that SSL and the HTTPS Connection Handler have not been configured. The example also shows the `dsconfig` non-interactive commands. You can easily use the `dsconfig` interactive commands, which uses a menu-driven interface. If you use the `dsconfig` interactive, you must change to the Standard or Advanced object menu to access many of these configuration settings.

Steps

1. Set up your certificates. Follow the examples shown in the section *Managing Certificates*. You should have a keystore and truststore set up in the `config` directory. Make sure that the `keystore.pin` and `truststore.pin` are set.
2. Enable the key manager provider. The key manager provider accesses the certificate during the SSL handshaking process. If running `dsconfig` interactive, open the main menu, select "Key Manager Provider" -> "View and edit an existing Key Manager Provider" -> "JKS" (or the type of certificate you are working with) -> "enabled" and then set the value to "true". Click "finish" to save the setting.

Example:

```
$ bin/dsconfig create-key-manager-provider \
  --provider-name JKS \
  --type file-based --set enabled:true \
  --set key-store-file:config/keystore \
  --set key-store-type:JKS \
  --set key-store-pin-file:config/keystore.pin
```

3. Enable the trust manager provider. The trust manager provider determines if a presented certificate can be trusted. If running `dsconfig` interactive, open the main menu, select "Trust Manager Provider" -> "View and edit an existing Trust Manager Provider" -> "JKS" (or the type of certificate you are working with) -> "enabled" and then set the value to "true". Click "finish" to save the setting.

Example:

```
$ bin/dsconfig create-trust-manager-provider \
  --provider-name JKS \
  --type file-based --set enabled:true \
  --set trust-store-file:config/truststore \
  --set trust-store-type:JKS \
  --set trust-store-pin-file:config/truststore.pin
```

4. Configure the HTTPS Connection Handler. If not already created, this command creates and enables the connection handler, specifies the SCIM HTTP servlet extension and sets the listen port to a port of your choice, in this example, use 8443. The command also specifies the type of key manager and trust manager providers and sets the log publisher to "HTTP Detailed Access." If running `dsconfig` interactive, open the main menu, select "Connection Handler" -> "View and edit an existing

Connection Handler" -> "HTTPS Connection Handler". Change the parameters to match your setup, and then, click "finish" to save the setting.

Example:

```
$ bin/dsconfig create-connection-handler \
  --handler-name "HTTPS Connection Handler" \
  --type http --set enabled:true \
  --set listen-port:8443 \
  --set use-ssl:true \
  --set http-servlet-extension:SCIM \
  --set "http-operation-log-publisher:HTTP Detailed Access" \
  --set key-manager-provider:JKS --set trust-manager-provider:JKS
```

If the HTTPS Connection Handler already exists, use the following:

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:SCIM
```

5. Turn on the connection handler.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:SCIM
```

6. Add access controls to allow access to LDAP controls used by the SCIM Servlet Extension. These controls are the Post-Read Request Control (1.3.6.1.1.13.2), Server-Side Sort Request Control (1.2.840.113556.1.4.473), Simple Paged Results Control (1.2.840.113556.1.4.319), and Virtual List View Request Control (2.16.840.1.113730.3.4.9). We recommend using the following command to add access control instructions, rather than its **dsconfig** interactive equivalent.

Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetcontrol="1.3.6.1.1.13.2 ||
  1.2.840.113556.1.4.473 || 1.2.840.113556.1.4.319 ||
  2.16.840.1.113730.3.4.9")
  (version 3.0;acl "Authenticated access to controls used by the SCIM
  servlet
  extension"; allow (all) userdn="ldap:///all";)'
```

7. Add access controls to allow read access to operational attributes used by the SCIM Servlet Extension. We recommend using the following non-interactive command to add access control instructions, rather than its **dsconfig** interactive equivalent.

Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id
  ||
  createTimestamp || modifyTimestamp")
  (version 3.0;acl "Authenticated read access to operational attributes \
  used by the SCIM servlet extension"; allow (read,search,compare)
  userdn="ldap:///all";)'
```

8. Optional. The SCIM HTTP Connection Handler automatically uses a detailed HTTP log publisher, which is implemented in a proprietary format. If you need a standard W3C common log format publisher, enter the following command. If running **dsconfig** interactive, open the main menu, select "Log Publisher" -> "Create a new Log Publisher" -> "new Log Publisher created from scratch" -> "File Based Access Log Publisher", enter the parameters to match your setup, and then, click "finish" to save the setting. Go back to the main menu, select "Connection Handler" -> "HTTPS Connection

Handler", and then add "HTTP Common Access" to the `http-operation-log-publisher` property. Click "finish" to save the setting.

Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access" \
  --type common-log-file-http-operation --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add "http-operation-log-publisher:HTTP Common Access"
```

9. Optional. To support searching or filtering by DN using the Identity Access API, you can enable the `entryDN` virtual attribute. If running `dsconfig` interactive, open the main menu, select "Virtual Attribute" -> "View and edit an existing Virtual Attribute" -> "Entry DN", and then change the enabled property to "true". Click "finish" to save the setting.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name entryDN --set enabled:true
```

10. Optional. To support pagination, create some Virtual List View indexes. If running `dsconfig` interactive, open the main menu, select "Local DB VLV Index" -> "Create a new Local DB VLV Index" and then enter the properties needed for your setup. Click "finish" to save the setting. Repeat again for the "ascending-sn" index. Then, run the `rebuild-index` command to let the VLV Indexes take effect.

Example:

```
$ bin/dsconfig create-local-db-ylv-index --backend-name userRoot \
  --index-name ascending-uid --set base-dn:dc=example,dc=com \
  --set scope:whole-subtree \
  --set "filter:(objectclass=inetorgperson)" \
  --set "sort-order:+uid"

$ bin/dsconfig create-local-db-ylv-index --backend-name userRoot \
  --index-name ascending-sn \
  --set base-dn:dc=example,dc=com \
  --set scope:whole-subtree \
  --set "filter:(objectclass=inetorgperson)" \
  --set "sort-order:+sn"

$ bin/rebuild-index --baseDN dc=example,dc=com \
  --index vlv.ascending-uid \
  --index vlv.ascending-sn
```

Enabling resource versioning

About this task

Resource versioning is enabled by default in new installations. Upgraded servers that had SCIM enabled need additional configuration to enable resource versioning.

Steps

1. Enable the **ds-entry-checksum** virtual attribute.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop \
  --name ds-entry-checksum \
  --set enabled:true
```

2. Remove any existing access controls required by SCIM for read access to operational attributes:

Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --remove 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-
  unique-id || createTimeStamp || ds-create-time || modifyTimeStamp
  || ds-update-time")(version 3.0;acl "Authenticated read access to
  operational attributes used by the SCIM servlet extension"; allow
  (read,search,compare) userdn="ldap:///all"'
```

3. Add new access controls required by SCIM for read access to operational attributes with the addition of the **ds-entry-checksum**:

Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-
  unique-id || createTimeStamp || ds-create-time || modifyTimeStamp || ds-
  update-time || ds-entry-checksum")(version 3.0;acl "Authenticated read
  access to operational attributes used by the SCIM servlet extension";
  allow (read,search,compare) userdn="ldap:///all"'
```

4. Enable SCIM resource versioning using the entry checksum virtual attribute:

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM \
  --set entity-tag-ldap-attribute:ds-entry-checksum
```

Result: If enabled, the value of the **ds-entry-checksum** attribute is returned as the **ETag** header value when accessing the resource through SCIM, and is checked against the **If-Match** header when updating the resource. When accessing the resource through LDAP, use the **ds-entry-checksum** attribute instead.

Configuring the SCIM servlet extension using the batch script

About this task

The following example procedure assumes that you have set up your certificates, keystore, and truststore

Steps

1. Open the `<server-root>/config/scim-config-ds.dsconfig` script in a text editor.
2. For the optional elements (W3C common log, filtering by DN, and VLV Indexes, remove the comment (#) symbol on the **dsconfig** commands. Save the file when finished editing.
3. To enable the SCIM servlet extension, run the **dsconfig** batch file. Remember to include the bind parameters.

Example:

```
$ bin/dsconfig --batch-file config/scim-config-ds.dsconfig
```

Result:

SCIM 1.1 servlet extension authentication

The SCIM 1.1 servlet supports authentication using either the HTTP Basic authentication scheme, or OAuth 2.0 bearer tokens. When authenticating using HTTP Basic authentication, the SCIM 1.1 servlet attempts to correlate the user name component of the Authorization header to a DN in the Directory Server. If the user name value cannot be parsed directly as a DN, it is correlated to a DN using an Identity Mapper. The DN is then used in a simple bind request to verify the password.

In deployments that use an OAuth authorization server, the SCIM 1.1 extension can be configured to authenticate requests using OAuth bearer tokens. The SCIM 1.1 extension supports authentication with OAuth 2.0 bearer tokens (per RFC 6750) using an OAuth Token Handler Server SDK Extension. Because the OAuth 2.0 specification does not specify how contents of a bearer token are formatted, the Server provides the token handler API to decode incoming bearer tokens and extract or correlate associated authorization DNs.

Neither HTTP Basic authentication nor OAuth 2.0 bearer token authentication are secure unless SSL is used to encrypt the HTTP traffic.

Configuring basic authentication using an identity mapper

About this task

By default, the SCIM servlet is configured to use the Exact Match Identity Mapper, which matches against the `uid` attribute. In this example, an alternate Identity Mapper is created so that clients can authenticate using `cn` values.

Steps

1. Create a new Identity Mapper that uses a match attribute of `cn`.

Example:

```
$ bin/dsconfig create-identity-mapper \
  --mapper-name "CN Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:cn
```

2. Configure the SCIM servlet to use the new Identity Mapper.

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM \
  --set "identity-mapper:CN Identity Mapper"
```

Enabling OAuth authentication

About this task

To enable OAuth authentication, you need to create an implementation of the `OAuthTokenHandler` using the API provided in the Server SDK. For details on creating an `OAuthTokenHandler` extension, see the Server SDK documentation.

Steps

1. Install your OAuth token handler on the server using `dsconfig`.

Example:

```
$ bin/dsconfig create-oauth-token-handler \
  --handler-name ExampleOAuthTokenHandler \
  --type third-party \
```

```
--set extension-  
class:com.unboundid.directory.sdk.examples.ExampleOAuthTokenHandler
```

2. Configure the SCIM servlet extension to use it as follows:

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \  
--extension-name SCIM \  
--set oauth-token-handler:ExampleOAuthTokenHandler
```

Verifying the SCIM 1.1 servlet extension configuration

About this task

You can verify the configuration of the SCIM 1.1 extension by navigating to a SCIM resource URL via the command line or through a browser window.

To verify the SCIM servlet extension configuration:

Steps

- Run `curl` to verify that the SCIM extension is running. The `-k` (or `--insecure`) option is used to turn off curl's verification of the server certificate, since the example Directory Server is using a self-signed certificate.

Example:

```
$ curl -u "cn=Directory Manager:password" \  
-k "https://localhost:8443/scim/ServiceProviderConfigs"  
  
{ "schemas": ["urn:scim:schemas:core:1.0"], "id": "urn:scim:schemas:core:1.0",  
  "patch": {"supported": true}, "bulk": {"supported": true, "maxOperations": 10000,  
  "maxPayloadSize": 10485760}, "filter": {"supported": true, "maxResults": 100},  
  "changePassword": {"supported": true}, "sort": {"supported": true},  
  "etag": {"supported": false}, "authenticationSchemes": [{"name": "HttpBasic",  
  "description": "The HTTP Basic Access Authentication scheme. This scheme is  
  not considered to be a secure method of user authentication (unless used  
  in  
  conjunction with some external secure system such as SSL), as the user  
  name and password are passed over the network as cleartext.", "specUrl":  
  "http://www.ietf.org/rfc/rfc2617", "documentationUrl":  
  "http://en.wikipedia.org/wiki/Basic_access_authentication"}]}
```

- If the user ID is a valid DN (such as `cn=Directory Manager`), the SCIM extension authenticates by binding to the Directory Server as that user. If the user ID is not a valid DN, the SCIM extension searches for an entry with that `uid` value, and binds to the server as that user. To verify authentication to the server as the user with the `uid` of `user.0`, run the following command:

Example:

```
$ curl -u "user.0:password" \  
-k "https://localhost:8443/scim/ServiceProviderConfigs"
```

Configuring the Identity Access API

Once you have run the `<server-root>/config/scim-config-ds.dsconfig` script, the resources defined in the `scim-resources.xml` will be available as well as the Identity Access API. However, to allow SCIM access to the raw LDAP data, you must set a combination of configuration properties on the SCIM Servlet Extension using the `dsconfig` tool.

- include-ldap-objectclass.** Specifies a multi-valued property that lists the object classes for entries that will be exposed. The object class used here will be the one that clients need to use when referencing Identity Access API resources. This property allows the special value `"*` to allow all object

classes. If "*" is used, then the SCIM servlet uses the same case used in the Directory Server LDAP Schema.

- **exclude-ldap-objectclass.** Specifies a multi-valued property that lists the object classes for entries that will not be exposed. When this property is specified, all object classes will be exposed except those in this list.
- **include-ldap-base-dn.** Specifies a multi-valued property that lists the base DN's that will be exposed. If specified, only entries under these base DN's will be accessible. No parent-child relationships in the DN's are allowed here.
- **exclude-ldap-base-dn.** Specifies a multi-valued property that lists the base DN's that will not be exposed. If specified, entries under these base DN's will not be accessible. No parent-child relationships in the DN's are allowed here.

Using a combination of these properties, SCIM endpoints will be available for all included object classes, just as if they were SCIM Resources defined in the `scim-resources.xml` file.

Configuring the Identity Access API

Steps

1. Ensure that you have run the `scim-config-ds.dsconfig` script to configure the SCIM interface. Be sure to enable the entryDN virtual attribute. See the Configure SCIM section for more information.
2. Set a combination of properties to allow the SCIM clients access to the raw LDAP data: `include-ldap-objectclass`, `exclude-ldap-objectclass`, `include-ldap-base-dn`, or `exclude-ldap-base-dn`.

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM --set 'include-ldap-objectclass:*' \
  --set include-ldap-base-dn:ou=People,dc=example,dc=com
```

Result: The SCIM clients now have access to the raw LDAP data via LDAP object class-based resources as well as core SCIM resources as defined in the `scim.resource.xml` file.

Disabling core SCIM resources

Steps

1. Open the `config/scim-resources.xml` file, and comment out or remove the `<resource>` elements that you would like to disable.
2. Disable and re-enable the HTTP Connection Handler, or restart the server to make the changes take effect. In general, changing the `scim-resources.xml` file requires a HTTP Connection Handler restart or server restart.

Note:

When making other changes to the SCIM configuration by modifying the SCIM HTTP Servlet Extension using `dsconfig`, the changes take effect immediately without any restart required.

Verifying the Identity Access API configuration

Steps

- Perform a curl request to verify the Identity Access API configuration.

Result:

```
$ curl -k -u "cn=directory manager:password" \
  -H "Accept: application/json" \
  "https://example.com/top/56c9fd6b-f870-35ef-9959-691c783b7318?
  attributes=entryDN,uid,givenName,sn,entryUUID"
```

```

    {"schemas":
["urn:scim:schemas:core:1.0", "urn:unboundid:schemas:scim:ldap:1.0"],
  "id": "56c9fd6b-f870-35ef-9959-691c783b7318",
  "meta": {"lastModified": "2013-01-11T23:38:26.489Z",
"location": "https://example.com:443/v1/top/56c9fd6b-
f870-35ef-9959-691c783b7318"},
  "urn:unboundid:schemas:scim:ldap:1.0": {"givenName": ["Rufus"], "uid":
["user.1"],
  "sn": ["Firefly"], "entryUUID": ["56c9fd6b-
f870-35ef-9959-691c783b7318"],
  "entrydn": "uid=user.1,ou=people,dc=example,dc=com"} }

```

Monitoring the SCIM servlet extension

The SCIM SDK provides a command-line tool, `scim-query-rate`, that measures the SCIM query performance for your extension. The SCIM extension also exposes monitoring information for each SCIM resource, such as the number of successful operations per request, the number of failed operations per request, the number of operations with XML or JSON to and from the client. Finally, the Directory Server automatically logs SCIM-initiated LDAP operations to the default File-based Access Logger. These operations will have an `origin='scim'` attribute to distinguish them from operations initiated by LDAP clients. You can also create custom logger or request criteria objects that can track incoming HTTP requests, which the SCIM extension rewrites as internal LDAP operations.

Testing SCIM query performance

You can use the `scim-query-rate` tool, provided in the SCIM SDK, to test query performance, by performing repeated resource queries against the SCIM server.

The `scim-query-rate` tool performs searches using a query filter or can request resources by ID. For example, you can test performance by using a filter to query randomly across a set of one million users with eight concurrent threads. The user resources returned to the client in this example is in XML format and includes the `userName` and `name` attributes.

```

scim-query-rate --hostname server.example.com --port 80 \
--authID admin --authPassword password --xml \
--filter 'userName eq "user.[1-1000000]"' --attribute userName \
--attribute name --numThreads 8

```

You can request resources by specifying a resource ID pattern using the `--resourceID` argument as follows:

```

scim-query-rate --hostname server.example.com --port 443 \
--authID admin --authPassword password --useSSL --trustAll \
--resourceName User \
--resourceID 'uid=user.[1-150000],ou=people,dc=example,dc=com'

```

The `scim-query-rate` tool reports the error `"java.net.SocketException: Too many open files"` if the open file limit is too low. You can increase the open file limit to increase the number of file descriptors.

Monitoring resources using the SCIM extension

The monitor provider exposes the following information for each resource:

- Number of successful operations per request type (such as GET, PUT, and POST).
- Number of failed operations and their error codes per request type.
- Number of operations with XML or JSON from client.
- Number of operations that sent XML or JSON to client.

In addition to the information about the user-defined resources, monitoring information is also generated for the schema, service provider configuration, and monitor resources. The attributes of the monitor entry are formatted as follows:

```
{resource name}-resource-{request type}-{successful or error status code}
```

You can search for one of these monitor providers using an `ldapsearch` such as the following:

```
$ bin/ldapsearch --port 1389 bindDN uid=admin,dc=example,dc=com \
  --bindPassword password --baseDN cn=monitor \
  --searchScope sub "(objectclass=scim-servlet-monitor-entry)"
```

For example, the following monitor output was produced by a test environment with three distinct SCIM servlet instances, Aleph, Beth, and Gimel. Note that the first instance has a custom resource type called `host`.

```
$ bin/ldapsearch --baseDN cn=monitor \
  '(objectClass=scim-servlet-monitor-entry)'
dn: cn=SCIM Servlet (SCIM HTTP Connection Handler),cn=monitor
objectClass: top

About the HTTP log publishers

HTTP operations may be logged using either a Common Log File HTTP Operation Log Publisher or a Detailed HTTP Operation Log Publisher. The Common Log File HTTP Operation Log Publisher is a built-in log publisher that records HTTP operation information to a file using the W3C common log format. Because the W3C common log format is used, logs produced by this log publisher can be parsed by many existing web analysis tools.

Log messages are formatted as follows:

- IP address of the client.
- RFC 1413 identification protocol. The Ident Protocol is used to format information about the client.

- The user ID provided by the client in an Authorization header, which is typically available server-side in the REMOTE_USER environment variable. A dash appears in this field if this information is not available.
- A timestamp, formatted as "[dd/MM/yyyy:HH:mm:ss Z]"
- Request information, with the HTTP method followed by the request path and HTTP protocol version.
- The HTTP status code value.
- The content size of the response body in bytes. This number does not include the size of the response headers.

The HTTP Detailed Access Log Publisher provides more information than the common log format in a format that is familiar to administrators who use the File-Based Access Log Publisher.

The HTTP Detailed Access Log Publisher generates log messages such as the following. The lines have been wrapped for readability.

```
[15/Feb/2012:21:17:04 -0600] RESULT requestID=10834128
from="10.2.1.114:57555" method="PUT"
url="https://10.2.1.129:443/Aleph/Users/6272c691-
38c6-012f-d227-0dfae261c79e" authorizationType="Basic"
requestContentType="application/json" statusCode=200
etime=3.544 responseContentLength=1063
redirectURI="https://server1.example.com:443/Aleph/Users/6272c691-38c6-012f-
d227-0dfae261c79e"
responseContentType="application/json"
```

In this example, only default log publisher properties are used. Though this message is for a RESULT, it contains information about the request, such as the client address, the request method, the request URL, the authentication method used, and the Content-Type requested. For the response, it includes the response length, the redirect URI, the Content-Type, and the HTTP status code.

You can modify the information logged, including adding request parameters, cookies, and specific request and response headers. For more information, refer to the `dsconfig` command-line tool help.

Configuring advanced SCIM 1.1 extension features

The following sections show how to configure advanced SCIM 1.1 servlet extension features, such as bulk operation implementation, mapping SCIM resource IDs, and transformations.

Managing the SCIM 1.1 schema

This section describes the SCIM schema and provides information on how to map LDAP schema to the SCIM resource schema.

About the SCIM schema

SCIM provides a common user schema and extension model, making it easier to interoperate with multiple Service Providers. The core SCIM schema defines a concrete schema for user and group resources that encompasses common attributes found in many existing schemas.

Each attribute is defined as either a single attribute, allowing only one instance per resource, or a multi-valued attribute, in which case several instances may be present for each resource. Attributes may be defined as simple, name-value pairs or as complex structures that define sub-attributes.

While the SCIM schema follows an object extension model similar to object classes in LDAP, it does not have an inheritance model. Instead, all extensions are additive, similar to LDAP Auxiliary Object Classes.

Mapping the LDAP schema to the SCIM resource schema

The resources configuration file is an XML file that is used to define the SCIM resource schema and its mapping to LDAP schema. The default configuration of the `scim-resources.xml` file provides definitions for the standard SCIM Users and Groups resources, and mappings to the standard LDAP `inetOrgPerson` and `groupOfUniqueNames` object classes.

The default configuration may be customized by adding extension attributes to the Users and Groups resources, or by adding new extension resources. The resources file is composed of a single `<resources>` element, containing one or more `<resource>` elements.

For any given SCIM resource endpoint, only one `<LDAPAdd>` template can be defined, and only one `<LDAPSearch>` element can be referenced. If entries of the same object class can be located under different subtrees or base DN's of the Directory Server, then a distinct SCIM resource must be defined for each unique entry location in the Directory Information Tree. This can be implemented in many ways. For example:

- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, and each running under a unique HTTP connection handler.
- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, each running under a single, shared HTTP connection handler, but each with a unique context path.

Note that LDAP attributes are allowed to contain characters that are invalid in XML (because not all valid UTF-8 characters are valid XML characters). The easiest and most-correct way to handle this is to make sure that any attributes that may contain binary data are declared using `"dataType=binary"` in the `scim-resources.xml` file. Likewise, when using the Identity Access API make sure that the underlying LDAP schema uses the Binary or Octet String attribute syntax for attributes which may contain binary data. This will cause the server to automatically base64-encode the data before returning it to clients and will also make it predictable for clients because they can assume the data will always be base64-encoded.

However, it is still possible that attributes that are not declared as binary in the schema may contain binary data (or just data that is invalid in XML), and the server will always check for this before returning them to the client. If the client has set the content-type to XML, then the server may choose to base64-encode any values which are found to include invalid XML characters. When this is done, a special attribute is added to the XML element to alert the client that the value is base64-encoded. For example:

```
<scim:value base64Encoded="true">AAABPB0EBZc</scim:value>
```

The remainder of this section describes the mapping elements available in the `scim-resources.xml` file.

About the `resource` element

A `resource` element has the following XML attributes:

- `schema`: a required attribute specifying the SCIM schema URN for the resource. Standard SCIM resources already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom resources using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the resource used to access it through the SCIM REST API.
- `mapping`: a custom Java class that provides the logic for the resource mapper. This class must extend the `com.unboundid.scim.ldap.ResourceMapper` class.

A `resource` element contains the following XML elements in sequence:

- `description`: a required element describing the resource.
- `endpoint`: a required element specifying the endpoint to access the resource using the SCIM REST API.
- `LDAPSearchRef`: a mandatory element that points to an `LDAPSearch` element. The `LDAPSearch` element allows a SCIM query for the resource to be handled by an LDAP service and also specifies how the SCIM resource ID is mapped to the LDAP server.
- `LDAPAdd`: an optional element specifying information to allow a new SCIM resource to be added through an LDAP service. If the element is not provided then new resources cannot be created through the SCIM service.
- `attribute`: one or more elements specifying the SCIM attributes for the resource.

About the `attribute` element

An `attribute` element has the following XML attributes:

- `schema`: a required attribute specifying the schema URN for the SCIM attribute. If omitted, the schema URN is assumed to be the same as that of the enclosing resource, so this only needs to be provided for SCIM extension attributes. Standard SCIM attributes already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom SCIM attributes using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the SCIM attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- `required`: an optional attribute indicating whether the SCIM attribute is required to be present in the resource. The default value is `false`.

An `attribute` element contains the following XML elements in sequence:

- `description`: a required element describing the attribute. Then just one of the following elements:
 - `simple`: specifies a simple, singular SCIM attribute.
 - `complex`: specifies a complex, singular SCIM attribute.
 - `simpleMultiValued`: specifies a simple, multi-valued SCIM attribute.
 - `complexMultiValued`: specifies a complex, multi-valued SCIM attribute.

About the `simple` element

A `simple` element has the following XML attributes:

- `dataType`: a required attribute specifying the simple data type for the SCIM attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `decimal`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `simple` element contains the following XML element:

- `mapping`: an optional element specifying a mapping between the SCIM attribute and an LDAP attribute. If this element is omitted, then the SCIM attribute has no mapping and the SCIM service ignores any values provided for the SCIM attribute.

About the `complex` element

The `complex` element does not have any XML attributes. It contains the following XML element:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute, and an optional mapping to LDAP. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

About the `simpleMultiValued` element

A `simpleMultiValued` element has the following XML attributes:

- `childName`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard emails SCIM attribute is `email`.
- `dataType`: a required attribute specifying the simple data type for the plural SCIM attribute (i.e. the data type for the value sub-attribute). The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `simpleMultiValued` element contains the following XML elements in sequence:

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.
- `mapping`: an optional element specifying a default mapping between the SCIM attribute and an LDAP attribute.

About the `complexMultiValued` element

A `complexMultiValued` element has the following XML attribute:

- `tag`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard addresses SCIM attribute is `address`.

A `complexMultiValued` element contains the following XML elements in sequence:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute. The standard type, primary, and display sub-attributes do not need to be specified.
- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.

About the `subAttribute` element

A `subAttribute` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- `required`: an optional attribute indicating whether the SCIM sub-attribute is required to be present in the SCIM attribute. The default value is `false`.
- `dataType`: a required attribute specifying the simple data type for the SCIM sub-attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `subAttribute` element contains the following XML elements in sequence:

- `description`: a required element describing the sub-attribute.
- `mapping`: an optional element specifying a mapping between the SCIM sub-attribute and an LDAP attribute. This element is not applicable within the `complexMultiValued` element.

About the `canonicalValue` element

A `canonicalValue` element has the following XML attribute:

- `name`: specifies the value of the type sub-attribute. For example, `work` is the value for emails, phone numbers and addresses intended for business purposes.

A `canonicalValue` element contains the following XML element:

- `subMapping`: an optional element specifying mappings for one or more of the sub-attributes. Any sub-attributes that have no mappings will be ignored by the mapping service.

About the `mapping` element

A `mapping` element has the following XML attributes:

- `ldapAttribute`: A required element specifying the name of the LDAP attribute to which the SCIM attribute or sub-attribute map.
- `transform`: An optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described in the [Mapping LDAP Entries to SCIM Using the SCIM-LDAP API](#) section.

About the `subMapping` element

A `subMapping` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute that is mapped.
- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM sub-attribute maps.
- `transform`: an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described later. The available transformations are described in [Mapping LDAP Entries to SCIM Using the SCIM-LDAP API](#).

About the `LDAPSearch` element

An `LDAPSearch` element contains the following XML elements in sequence:

- `baseDN`: a required element specifying one or more LDAP search base DN's to be used when querying for the SCIM resource.
- `filter`: a required element specifying an LDAP filter that matches entries representing the SCIM resource. This filter is typically an equality filter on the LDAP object class.
- `resourceIDMapping`: an optional element specifying a mapping from the SCIM resource ID to an LDAP attribute. When the element is omitted, the resource ID maps to the LDAP entry DN. Note The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them via an ID attribute.

Note:

The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them via an ID attribute.

About the `resourceIDMapping` element

The `resourceIDMapping` element has the following XML attributes:

- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM resource ID maps.
- `createdBy`: a required element specifying the source of the resource ID value when a new resource is created by the SCIM consumer using a POST operation. Allowable values for this element include `scim-consumer`, meaning that a value must be present in the initial resource content provided by the SCIM consumer, or `Directory Server`, meaning that a value is automatically provided by the Directory Server (as would be the case if the mapped LDAP attribute is `entryUUID`).

The following example illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

```
<LDAPSearch id="userSearchParams">
  <baseDN>ou=people,dc=example,dc=com</baseDN>
  <filter>(objectClass=inetOrgPerson)</filter>
  <resourceIDMapping ldapAttribute="entryUUID" createdBy="directory"/>
</LDAPSearch>
```

About the `LDAPAdd` element

An `LDAPAdd` element contains the following XML elements in sequence:

- `DNTemplate`: a required element specifying a template that is used to construct the DN of an entry representing a SCIM resource when it is created. The template may reference values of the entry after it has been mapped using `{ldapAttr}`, where `ldapAttr` is the name of an LDAP attribute.
- `fixedAttribute`: zero or more elements specifying fixed LDAP values to be inserted into the entry after it has been mapped from the SCIM resource.

About the `fixedAttribute` element

A `fixedAttribute` element has the following XML attributes:

- `ldapAttribute`: a required attribute specifying the name of the LDAP attribute for the fixed values.

- `onConflict`: an optional attribute specifying the behavior when the LDAP entry already contains the specified LDAP attribute. The value `merge` indicates that the fixed values should be merged with the existing values. The value `overwrite` indicates that the existing values are to be overwritten by the fixed values. The value `preserve` indicates that no changes should be made. The default value is `merge`.

A `fixedAttribute` element contains one or more `fixedValue` XML element, which specify the fixed LDAP values.

Validating the updated SCIM schema

The Server SCIM extension is bundled with an XML Schema document, `resources.xsd`, which describes the structure of a `scim-resources.xml` resource configuration file. After updating the resource configuration file, you should confirm that its contents are well-formed and valid using a tool such as `xmllint`.

For example, you could validate your updated file as follows:

```
$ xmllint --noout --schema resources.xsd scim-resources.xml
scim-resources.xml validates
```

Mapping SCIM resource IDs

The default `scim-resources.xml` configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. The `entryUUID` attribute, whose read-only value is assigned by the Directory Server, meets the requirements of the SCIM specification regarding resource ID immutability. However, configuring a mapping to the attribute may result in inefficient group processing, since LDAP groups use the entry DN as the basis of group membership. The resource configuration allows the SCIM resource ID to be mapped to the LDAP entry DN. However, the entry DN does not meet the requirements of the SCIM specification regarding resource ID immutability. LDAP permits entries to be renamed or moved, thus modifying the DN. Likewise, you can use the Identity Access API to change the value of an entry's RDN attribute, thereby triggering a MODDN operation.

A resource may also be configured such that its SCIM resource ID is provided by an arbitrary attribute in the request body during POST operations. This SCIM attribute must be mapped to an LDAP attribute so that the SCIM resource ID may be stored in the Directory Server. By default, it is the responsibility of the SCIM client to guarantee ID uniqueness. However, the UID Unique Attribute Plugin may be used by the Directory Server to enforce attribute value uniqueness. For information about the UID Unique Attribute Plugin, see "Working with the UID Unique Attribute plugin" in the *PingDirectory Server Administration Guide*.

Note:

Resource IDs may not be mapped to virtual attributes. For more information about configuring SCIM Resource IDs, see "About the `<resourceIDMapping>` Element".

Using pre-defined transformations

Transformations are required to change SCIM data types to LDAP syntax values. The following pre-defined transformations may be referenced by the `transform` XML attribute:

- `com.unboundid.scim.ldap.BooleanTransformation`. Transforms SCIM boolean data type values to LDAP Boolean syntax values and vice-versa.
- `com.unboundid.scim.ldap.GeneralizedTimeTransformation`. Transforms SCIM `dateTime` data type values to LDAP Generalized Time syntax values and vice-versa.
- `com.unboundid.scim.ldap.PostalAddressTransformation`. Transforms SCIM formatted address values to LDAP Postal Address syntax values and vice-versa. SCIM formatted physical mailing addresses are represented as strings with embedded new lines, whereas LDAP uses the `$` character to separate address lines. This transformation interprets new lines in SCIM values as address line separators.
- `com.unboundid.scim.ldap.TelephoneNumberTransformation`. Transforms LDAP Telephone Number syntax (E.123) to RFC3966 format and vice-versa.

You can also write your own transformations using the SCIM API described in the following section.

Mapping LDAP entries to SCIM using the SCIM-LDAP API

In addition to the SCIM SDK, the Server provides a library called SCIM-LDAP, which provides facilities for writing custom transformations and more advanced mapping.

You can add the SCIM-LDAP library to your project using the following dependency:

```
<dependency>
  <groupId>com.unboundid.product.scim</groupId>
  <artifactId>scim-ldap</artifactId>
  <version>1.5.0</version>
</dependency>
```

Create your custom transformation by extending the `com.unboundid.scim.ldap.Transformation` class. Place your custom transformation class in a jar file in the server's `lib` directory.

Note:

The Identity Access API automatically maps LDAP attribute syntaxes to the appropriate SCIM attribute types. For example, an LDAP `DirectoryString` is automatically mapped to a SCIM string.

SCIM authentication

SCIM requests to the LDAP endpoints will support HTTP Basic Authentication and OAuth2 Authentication using a bearer token. There is existing support for this feature in the Directory Server and the Directory Proxy Server using the `OAuthTokenHandler` API (i.e., via a Server SDK extension, which requires some technical work to implement).

Note that our implementation only supports the HTTP Authorization header for this purpose; we do not support the form-encoded body parameter or URI query parameter mechanisms for specifying the credentials or bearer token.

SCIM logging

The Directory Server already provides a detailed HTTP log publisher to capture the SCIM and HTTP request details. To be able to correlate this data to the internal LDAP operations that are invoked behind the scenes, the Access Log Publisher will use `origin=scim` in access log messages that are generated by the SCIM servlet.

For example, you will see a message for operations invoked by replication:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="replication" dn="uid=user.3,ou=people,dc=example,dc=com"
```

Likewise for SCIM messages, you will see a message like this:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="scim" dn="uid=user.3,ou=people,dc=example,dc=com"
```

SCIM monitoring

There are two facilities that can be used to monitor the SCIM activity in the server.

- **HTTPConnectionHandlerStatisticsMonitorProvider** -- Provides statistics straight about total and average active connections, requests per connection, connection duration, processing time, invocation count, etc.
- **SCMServletMonitorProvider** -- Provides high level statistics about request methods (POST, PUT, GET, etc.), content types (JSON, XML), and response codes, for example, `"user-patch-404:26"`.

The LDAP object class endpoints are treated as their own resource types, so that for requests using the Identity Access API, there will be statistics, such as `person-get-200` and `inetorgperson-post-401`.

Managing the SCIM 2.0 servlet extension

The PingDirectory Server provides a servlet extension that implements version 2.0 of the System for Cross-domain Identity Management (SCIM) specification. The SCIM 2.0 extension does not replace the existing SCIM 1.1 extension, and there are significant differences in how they are configured..

Supported SCIM 2.0 endpoints

PingDirectory Server supports the following SCIM 2.0 endpoints:

Endpoint	Description	Supported HTTP methods
/ServiceProviderConfig	<p>Provides metadata that indicates the PingDirectory Server's authentication scheme (which is always OAuth 2.0) and its support for features that are optional in the SCIM standard.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/Schemas	<p>Lists the SCIM schemas that are configured for use on PingDirectory Server, and defines the various attributes available to resource types.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/Schemas/<schema>	<p>Retrieves a specific SCIM schema, as specified by the schema ID.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/ResourceTypes	<p>Lists all of the SCIM resource types that are configured for use on PingDirectory Server. Clients can use this information to determine the endpoint, core schema, and extension schemas of any resource types that the server supports.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET

Endpoint	Description	Supported HTTP methods
/ResourceTypes/<resourceType>	Retrieves a specific SCIM resource type, as specified by its ID. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
/<resourceType>	Creates a new resource (POST), or lists and filters resources (GET).	GET, POST
/<resourceType>/search	Lists and filters resources. This is used if passing query parameters in the URL is undesirable.	POST
/<resourceType>/<resourceId>	Retrieves a single resource (GET), modifies a single resource (PUT, PATCH), or deletes a single resource (DELETE).	GET, PUT, PATCH, DELETE

Creating Your Own SCIM 2 application

The System for Cross-domain Identity Management (SCIM) is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 2 SDK is available for download at <https://github.com/pingidentity/scim2>.

Authentication requirements for SCIM 2.0 requests

All SCIM requests on a PingDirectory Server must use OAuth 2.0 bearer token authentication. Bearer tokens are evaluated using the SCIM 2 servlet extension's configured Access Token Validators. Basic authentication is not supported.

In addition to requiring bearer tokens, the server will not process any SCIM requests unless it has at least one encryption-settings definition in its encryption-settings database. You can create the necessary definition(s) with the encryption-settings command-line tool. See [Encrypting Sensitive Data](#) on page 404 for more information.

Note:

Encryption settings need to be defined on the Proxy and all backend PD servers, and the encryption settings should match.

Defining permissions for SCIM 2.0 requests

Whether or not a SCIM request is executed on a server depends primarily on both the configured Access Control Instructions (ACIs) in the server and the scopes which are present in the provided OAuth bearer token used to authenticate the request.

SCIM 2.0 requests can be authorized in one of the two following ways:

- By default, requests are processed using the `cn=SCIM2 Servlet,cn=Root DNs,cn=config` service account. Whether a requested operation is allowed depends on the ACIs that apply to the operation, which can include both the rights granted to that service account and any rights granted to scopes contained in the OAuth bearer token using the `oauthscope` ACI bind rule.
- If user mapping is enabled, the subject of the OAuth bearer token is mapped to an account in the server. In this case, whether a requested operation is allowed depends on the ACIs that apply to the mapped user for the requested operation. You can also use the `oauthscope` bind rule to grant rights based on scopes in the presented token.

Because of implementation details, access to the `objectclass` operational LDAP attribute is necessary for SCIM requests to properly execute. However, you shouldn't give the service account access to `objectclass` on a global level. Instead, add the ACI granting `objectclass` access to the LDAP subtree you want to expose to clients. See [Configuring permissions for SCIM 2.0 operations](#) on page 751 for an example of this.

Note:

ACIs that don't use the `oauthscope` bind rule can still apply to requested operations. For example, an ACI that grants unconditional read access to any authenticated LDAP user will also grant unconditional read access to SCIM requests regardless of the provided OAuth scopes because the requests are processed through the service account.

Enabling user mapping for SCIM 2.0 operations

About this task

Access token validator identity mapping ties a local user account to an operation performed in the SCIM 2.0 servlet in PingDirectory Server.

The default configuration for the Directory Server for the SCIM 2.0 servlet doesn't require an access token to map to a local user, and operations are recorded in the logs as the `SCIM2 Servlet` user. For more detailed logging and auditing, enable the `map-access-tokens-to-local-users` property to require access tokens to map to a local user.

Note:

The users that are being mapped to the access tokens must have the necessary access control rights required to perform the operations that the SCIM 2.0 servlet will invoke on their behalf.

You should update the authorization server to issue tokens that include the `scim2` scope alongside any other scopes you need for access control purposes.

The `map-access-tokens-to-local-users` property is an optional configuration with the three settings shown in the following table.

Setting	Definition
Disabled (default)	The server doesn't attempt to map SCIM 2.0 access tokens to local users and operations are processed under the authority of the <code>SCIM2 Servlet user</code> .
Optional	The server attempts to map SCIM 2.0 access tokens to local users and, if successful, the operations are processed under the authority of that user. The distinguished name (DN) of the mapped user appears in the access logs. If unsuccessful, the server falls back to the default behavior.
Required	The server must map the SCIM 2.0 access token to one local user or the operation is rejected.

To set the `map-access-tokens-to-local-users` property:

Steps

- Run `dsconfig` with the `set-http-servlet-extension-prop` option. Choose from:

- To set the property to `required`, run the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set map-access-tokens-to-local-users:required
```

- To set property to `optional`, run the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set map-access-tokens-to-local-users:optional
```

- To reset the property to the default setting, `disabled`, run the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set map-access-tokens-to-local-users:disabled
```

SCIM 2.0 components

Unlike the SCIM 1.1 servlet extension, the SCIM 2.0 system is configured through the Administrative Console or with the `dsconfig` command-line tool. The SCIM 2.0 system consists of the following components:

- SCIM resource types
- SCIM schemas
 - SCIM attributes
 - SCIM sub-attributes
- SCIM attribute mappings (mapping resource types only)
- Correlated LDAP Data Views

A SCIM resource type defines a class of resources, such as users or devices. Every SCIM resource type features at least one SCIM schema, which defines the attributes that are available to each resource. If enabled for use, a SCIM resource type must also have a designated LDAP structural objectclass as well as an associated base DN.

The two types of SCIM resource types, mapping and pass-through, differ based on the definitions of the SCIM schema the resource types use.

- An LDAP mapping SCIM resource type requires an explicitly defined SCIM schema with explicitly defined mappings of SCIM attributes to LDAP attributes. Use a mapping SCIM resource type to exercise detailed control over the SCIM schema and its attributes and mappings.
- An LDAP pass-through SCIM resource type, by contrast, does not use an explicitly defined SCIM schema. Instead, an implicit schema is generated dynamically, based on the underlying LDAP schema. Use a pass-through SCIM resource type when you need to get started quickly.

A SCIM schema defines a collection of SCIM attributes, grouped under an identifier called a schema URN. Each SCIM resource type possesses a single core schema and can feature schema extensions, which act as secondary attribute groupings that the schema URN namespaces. SCIM Schemas are defined independently of SCIM resource types, and multiple SCIM resource types can use a single SCIM schema as a core schema or schema extension.

A SCIM attribute defines an attribute that is available under a SCIM schema. The configuration for a SCIM attribute defines its data type, regardless of whether it is required, single-valued, or multi-valued. When a SCIM attribute consists of SCIM sub-attributes, it is defined as a complex attribute.

A SCIM attribute mapping defines the manner in which a SCIM resource type maps the attributes in its SCIM schemas to native LDAP attributes of the PingDirectory Server.

A Correlated LDAP Data View allows a single SCIM resource that consists of attributes that are retrieved from multiple LDAP entries (see [Correlated LDAP data views](#) on page 745).

Correlated LDAP data views

Correlated LDAP data views can be attached to a SCIM resource type to allow that resource type to use attributes from other LDAP entries. A SCIM resource type can have multiple data views configured.

Correlated LDAP data views share many configuration settings with SCIM resource types. The following exceptions are below:

- **primary-correlation-attribute**: The LDAP attribute from the SCIM Resource Type whose value will be used to match entries in the data view. This property must be defined.
- **secondary-correlation-attribute**: The LDAP attribute from the data view whose value will be matched with the primary-correlation-attribute. This property must be defined.
- **ldap-correlation-attribute-pair**: Optional correlation attribute pairs. If these are configured, entries between the SCIM resource type and the correlated LDAP data view must also have matching values for the specified attributes for them to be returned together.

Note:

A correlated LDAP Data View cannot provide attributes from more than one LDAP entry at a time. If there are multiple LDAP entries with secondary-correlation-attribute values that match the primary-correlation-attribute from the SCIM resource type's entry, an error will be thrown.

If the correlated LDAP data view is attached to a pass-through SCIM resource type, its attributes will appear as schema extensions, similar to the following:

```
{
  ...
  "uid": [
    "user.8"
  ],
  "entryDN": "uid=user.8,ou=people,dc=example,dc=com",
```

```

"urn:pingidentity:schemas:correlated:Document": {
  "documentIdentifier": [
    "user.8"
  ],
  "description": [
    "This is the description for the document user.8 under
ou=Documents,dc=example,dc=com."
  ],
  ...
},
...
"schemas": [
  "urn:pingidentity:schemas:correlated:Document",
  "urn:pingidentity:schemas:passthrough:PassthroughUsers"
]
}

```

If the correlated LDAP data view is attached to a Mapping SCIM resource type, its attributes must be mapped to a schema used by the SCIM resource type. This is done through the `correlated-ldap-data-view` property in a SCIM attribute mapping.

Configuring an LDAP Mapping SCIM 2.0 resource type

About this task

This example shows how to add a simple mapping SCIM 2.0 resource type to a PingDirectory Server, backed by the `inetOrgPerson` LDAP objectclass. This example assumes that the PingDirectory Server has been configured using the default settings, meaning that sample data has been imported into the server and that data encryption has been set up.

Steps

1. Create the SCIM schema that the resource type will use:

```

dsconfig create-scim-schema \
--schema-name urn:pingidentity:schemas:User:1.0 \
--set display-name:User

```

2. Under this schema, add the following SCIM attributes.

```

dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name displayName
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--set type:complex
dsconfig create-scim-subattribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--subattribute-name familyName
dsconfig create-scim-subattribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--subattribute-name formatted
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name userName

```

3. Create the LDAP mapping SCIM resource type on the PingDirectory Server.

```

dsconfig create-scim-resource-type \

```

```
--type-name Users \
--type ldap-mapping \
--set enabled:true \
--set endpoint:Users \
--set structural-ldap-objectclass:inetOrgPerson \
--set include-base-dn:ou=People,dc=example,dc=com \
--set lookthrough-limit:500 \
--set core-schema:urn:pingidentity:schemas:User:1.0
```

4. Run the following commands to create the SCIM attribute mappings.

```
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name displayName \
--set scim-resource-type-attribute:displayName \
--set ldap-attribute:displayName
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.formatted \
--set scim-resource-type-attribute:name.formatted \
--set ldap-attribute:cn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.familyName \
--set scim-resource-type-attribute:name.familyName \
--set ldap-attribute:sn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name userName \
--set scim-resource-type-attribute:userName \
--set ldap-attribute:uid \
--set searchable:true
```

5. Configure the SCIM2 HTTP Servlet Extension to use a Mock Access Token Validator. Note that Mock Access Token Validators should never be used in production environments or with sensitive data.

```
dsconfig create-access-token-validator \
--validator-name "SCIM2 Mock Validator" \
--type mock \
--set enabled:true
dsconfig set-http-servlet-extension-prop \
--extension-name SCIM2 \
--set "access-token-validator:SCIM2 Mock Validator"
```

6. Send the following request to the SCIM /ResourceTypes endpoint to confirm that the new resource type has been added.

```
curl -k -X GET \
https://localhost:8443/scim/v2/ResourceTypes \
-H 'Authorization: Bearer {"active":true}'
```

7. The following JSON object should appear in the response in the “Resources” array:

```
{
...
"Resources": [{
"schemas":["urn:ietf:params:scim:schemas:core:2.0:ResourceType"],
"id":"Users",
"name":"Users",
"endpoint":"Users",
"schema":"urn:pingidentity:schemas:Users:1.0",
```

```
"meta":{
  "resourceType":"ResourceType",
  "location":"https://localhost:8443/scim/v2/ResourceTypes/Users"
}
}]
...
}
```

Configuring a correlated LDAP data view

About this task

The following example shows how to add a correlated LDAP data view to a LDAP mapping SCIM resource type on a PingDirectory server. The SCIM resource type will be a user, and the correlated LDAP data view will allow access to a document that matches their user ID.

In this example, a new PingDirectory server is set up using custom sample data. When configuring the correlation, administrators should use attributes that are inherently either immutable or non-volatile, such as `uid` or `entryUUID`. This prevents errors produced by a conflict between the values of primary and secondary correlation attributes.

Note:

Administrators can make the correlation SCIM attributes immutable by setting the `--set mutability:read-only` property when defining an attribute in the SCIM schema configuration. That way, SCIM requests cannot modify the values of those attributes.

Steps

1. Copy the following text into the server root directory and save it as `entries.ldif.template`:

```
define suffix=dc=example,dc=com
define maildomain=example.com
define numusers=101

branch: [suffix]
subordinateTemplate: admin:1
aci: (targetattr="*")(version 3.0; acl "Grant full access for the
  scim2allaccess OAuth 2 scope"; allow (all) oauthscope="scim2allaccess");

branch: ou=People,[suffix]
subordinateTemplate: person:[numusers]

branch: ou=Documents,[suffix]
subordinateTemplate: document:[numusers]

template: admin
rdnAttr: uid
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
uid: admin
givenName: Admin
sn: User
cn: Admin User
userPassword: password

template: person
rdnAttr: uid
```

```

objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
employeeNumber: <sequential:0>
uid: user.{employeeNumber}
sn: {uid}
cn: {uid}
userPassword: password

template: document
rdnAttr: documentIdentifier
objectClass: top
objectClass: document
documentIdentifier: user.<sequential:0>
description: This is the description for the document
{documentIdentifier} under ou=Documents,dc=example,dc=com.

```

2. Run the following command:

```
$ bin/make-ldif --templateFile entries.ldif.template --ldifFile
entries.ldif
```

3. Run setup for the PingDirectory server.

Make sure to import the created `entries.ldif` file and set up encryption settings. After this is done, set up the SCIM resource type and the Correlated LDAP Data View.

4. Run the following command to define the SCIM schema:

```
"dsconfig create-scim-schema --schema-name urn:example:Users \
--set "description:Users schema" --set display-name:Users
dsconfig create-scim-attribute --schema-name urn:example:Users \
--attribute-name email --set required:true --set multi-valued:true
dsconfig create-scim-attribute --schema-name urn:example:Users \
--attribute-name uid --set required:true --set mutability:read-only
dsconfig create-scim-attribute --schema-name urn:example:Users \
--attribute-name documentId
dsconfig create-scim-attribute --schema-name urn:example:Users \
--attribute-name documentDescription"
```

5. Run the following command to create the SCIM resource type:

```
dsconfig create-scim-resource-type \
--type-name Users \
--type ldap-mapping \
--set core-schema:urn:example:Users \
--set enabled:true \
--set endpoint:Users \
--set structural-ldap-objectclass:inetOrgPerson \
--set include-base-dn:ou=people,dc=example,dc=com \
--set create-dn-pattern:entryUUID=generated,ou=people,dc=example,dc=com
```

6. Run the following command to create the Correlated LDAP Data View:

```
dsconfig create-correlated-ldap-data-view \
--type-name Users \
--view-name Document \
--set structural-ldap-objectclass:document \
--set include-base-dn:ou=documents,dc=example,dc=com \
--set create-dn-
pattern:entryUUID=generated,ou=documents,dc=example,dc=com \
--set primary-correlation-attribute:uid \
```

```
--set secondary-correlation-attribute:documentIdentifier
```

7. Run the following command to create the attribute mappings for the SCIM resource type attributes.

Note that the **correlated-ldap-data-view** property is not set.

```
# The uid attribute, provided by the base SCIM Resource Type
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name uid \
  --set scim-resource-type-attribute:uid --set ldap-attribute:uid \
  --set writable:false --set searchable:true

# The email attribute, provided by the base SCIM Resource Type
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name email \
  --set scim-resource-type-attribute:email --set ldap-attribute:mail \
  --set searchable:true
```

8. Run the following command to create the **DocumentId** attribute mapping for the correlated LDAP data view attributes.

Note:

The only meaningful difference between mappings for SCIM resource type attributes and correlated LDAP data view attributes is the value of the **correlated-ldap-data-view** property.

```
# The documentId attribute
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name document.id \
  --set correlated-ldap-data-view:Document \
  --set scim-resource-type-attribute:documentId --set ldap-
attribute:documentIdentifier

# The documentDescription attribute
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name description \
  --set correlated-ldap-data-view:Document \
  --set scim-resource-type-attribute:documentDescription \
  --set ldap-attribute:description
```

9. Run the following command to send a SCIM request:

```
curl -k -X GET \
  https://localhost:8443/scim/v2/Users \
  -H 'Authorization: Bearer {"active":true, "scope":"scim2allaccess}"'
```

The response should look similar to the following. Notice that 'uid' and 'documentId' have the same value, as they are in a correlation attribute pair.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 101,
  "Resources": [
    {
      "uid": "user.8",
      "id": "3715c022-1f34-36d9-bebc-7e74912106ec",
      "documentDescription": "This is the description \
for the document user.8 under
ou=Documents,dc=example,dc=com.",
```

```

        "documentId": "user.8",
        "meta": {
            "resourceType": "Users",
            "location": "https://localhost:8443/scim/v2/
Users/3715c022-1f34-36d9-bebc-7e74912106ec"
        },
        "schemas": [
            "urn:example:Users"
        ]
    },
    ...
}

```

Configuring permissions for SCIM 2.0 operations

About this task

This example shows how to correctly configure permissions so POST requests with the "userAdd" scope will succeed. This example assumes that you have set up an LDAP mapping SCIM 2.0 Resource Type for the `inetOrgPerson` objectclass (see [Configuring an LDAP Mapping SCIM 2.0 resource type](#) on page 746).

Steps

1. If the SCIM Resource Type being targeted already has a value for the `create-dn-pattern` property, skip to step 2. Otherwise, the following `dsconfig` command can be used:

```

dsconfig set-scim-resource-type-prop \
  --type-name Users \
  --set create-dn-pattern:entryUUID=generated,ou=People,dc=example,dc=com

```

2. Send the following request to the SCIM /Users endpoint:

```

curl -k -X POST \
  https://localhost:8443/scim/v2/Users/ \
  -H 'Authorization: Bearer {"active":true}' \
  -H 'Content-type: application/json' \
  --data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'

```

The response from the server should have a status of 403 and contain a correlation ID, similar to the following:

```

{
  "schemas":["urn:ietf:params:scim:api:messages:2.0:Error"],
  "status":"403",
  "detail":"Request failed:
correlationID='faa707b3-5d48-42e6-9e78-2c8dbb1e2cac' "
}

```

This is the expected response since this SCIM request does not have the permission needed to write to an entry. See [Troubleshoot the SCIM 2.0 servlet extension](#) on page 756 for instructions on viewing the full server error message.

3. An ACI should now be added to the `ou=People,dc=example,dc=com` subtree. This will grant permission to add entries to the said subtree as long as the SCIM request includes the 'userAdd' scope. This can be done by running the following `ldapmodify` command. Note that this ACI does not grant write access to attributes, which means modify operations will fail. See [Overview of access control](#) for more information on configuring ACIs.

```

$ ldapmodify

```

```
dn:ou=People,dc=example,dc=com
changetype:modify
add:aci
aci:(version 3.0; acl "ACI for userAdd scope"; allow (add)
oauthscope="userAdd");)
```

4. Send the POST request to the SCIM / Users endpoint again, this time including the `userAdd` scope in the bearer token:

```
curl -k -X POST \
https://localhost:8443/scim/v2/Users \
-H 'Authorization: Bearer {"active":true, "scope":"userAdd"}' \
-H 'Content-type: application/json' \
--data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'
```

The response from the server should now contain the created SCIM resource, which should also contain values for the name and username attributes, similar to the following:

```
{
  "name":{
    "familyName":"User",
    "formatted":"Test"
  },
  "username":"user.test",
  "id":"6f9a89b8-e766-478c-9667-def049daf6bc",
  "meta":{
    "resourceType":"Users",
    "location":"https://localhost:8443/scim/v2/Users/6f9a89b8-e766-478c-9667-def049daf6bc"
  },
  "schemas":["urn:pingidentity:schemas:User:1.0"]
}
```

SCIM 2.0 searches

To prevent exhausting server resources, we recommend capping the total number of resources that are matched by a search. The configuration for each SCIM 2.0 resource type contains a `lookthrough-limit` property that defines this limit (the default `lookthrough-limit` value is 500).

If a search request exceeds the lookthrough limit, the client receives a 400 response with an error message similar to the following:

```
{
  "detail": "The search request matched too many results",
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:Error"],
  "scimType": "tooMany",
  "status": "400"
}
```

To prevent this error, you have these options:

- The client must refine its search filter to return fewer matches.
- Configure paged searches as explained in [Using paged SCIM searches](#) on page 752.

Using paged SCIM searches

When searching large data sets, the results can be numerous and produce errors about a request matching too many results relative to the lookthrough limit. Paged searches avoid these errors and also reduce memory utilization.

About this task

PingDirectory does SCIM searches using LDAP requests. After you complete the steps below, PingDirectory creates LDAP requests that include request controls to sort and page the search results before returning the results.

If your SCIM searches result in an error because the request matched too many results, as discussed in [SCIM 2.0 searches](#) on page 752, you can avoid the error by using paged searches.

Complete the following steps for each search.

Steps

1. Decide your SCIM search.

Note:

To get paged results, your search must include at least one of these parameters: `startIndex`, `count`, or `sortBy`.

For example, your search might look like the following search.

```
https://<directory-hostname>:<directory-port>/scim/v2/Users/?filter=st eq
"TX"&sortBy=sn&sortOrder=ascending
```

Here is the corresponding encoded version.

```
https://<directory-hostname>:<directory-port>/scim/v2/Users/?filter=st
%20eq%20%22TX%22&sortBy=sn&sortOrder=ascending
```

On your PingDirectory Server, collect some information to use later. Find the SCIM resource type, `structural-ldap-objectclass`, `include-base-dn`, and `include-filter` values by running this command.

```
$ dsconfig get-scim-resource-type-prop --type-name <SCIM-resource-type-
name> \
--property structural-ldap-objectclass \
--property include-base-dn \
--property include-filter
```

2. On the PingDirectory server, complete the following steps.
 - a. Create a Virtual List View (VLV) index for your search.

Each SCIM search that you want to produce paged results must have its own VLV index.

Create this index using `dsconfig create-local-db-ylv-index` with the following options.

Option	Description
<code>--index-name</code>	Names the index.
<code>--backend-name</code>	Specifies the name of the local database backend in which to place the index. The default database backend for PingDirectory is <code>userRoot</code> .

Option	Description
<code>--set base-dn</code>	Specifies the desired base dn. This value must match the value of the <code>include-base-dn</code> property that you found in the previous step.
<code>--set scope</code>	Is always <code>whole-subtree</code> .
<code>--set filter</code>	<p>Specifies the filter.</p> <p>Specify</p> <pre>"(objectclass=<name-of-SCIM-resource-type-objectclass>)"</pre> <p>where <code><name-of-SCIM-resource-type-objectclass></code> is the name of the objectclass used by the SCIM resource type, which you found in the previous step.</p> <p>If the SCIM resource type has the <code>include-filter</code> property set, also specify that property value in the filter. For example, if the filter for the objectclass is <code>(objectclass=inetorgperson)</code> and the <code>include-filter</code> value is <code>(st=CA)</code>, specify the <code>--set filter</code> argument as <code>"(&(objectclass=inetorgperson)(st=CA))"</code>.</p> <p>Specify the LDAP attributes for all the components of your SCIM search filter.</p> <p>For example, if a mapping SCIM resource type maps the LDAP attribute <code>st</code> to the SCIM attribute <code>address.region</code> and the SCIM search filter requires that <code>address.region eq TX</code>, then this filter must include <code>(st = TX)</code> instead of <code>(address.region = TX)</code>.</p>
<code>--set sort-order</code>	<p>Specifies whether to sort ascending (+) or descending (-) and the LDAP attribute to sort by.</p> <p>If the SCIM search does not specify the <code>sortBy</code> parameter, specify the sort order as <code>+entryUUID</code>.</p>

Recall the original, decoded SCIM search, shown here.

```
https://<directory-hostname>:<directory-port>/scim/v2/Users/?filter=st
eq "TX"&sortBy=sn&sortOrder=ascending
```

For example, to create a VLV index for that search, run the following command.

```
$ dsconfig create-local-db-ylv-index --index-name sn \
--backend-name userRoot --set base-dn:ou=people,dc=example,dc=com \
--set scope:whole-subtree \
```

```
--set filter:"(&(objectclass=inetorgperson)(st=TX))" --set sort-order:
+sn
```

- b. Stop the server. Rebuild the index. Start the server. Run the `rebuild-index` command specifying the baseDN and the name of the index.

```
$ rebuild-index --baseDN <baseDN-value> --index <name-of-index>
```

For example, run these commands.

```
$ stop-server
$ rebuild-index --baseDN dc=example,dc=com --index vlv.sn
$ start-server
```

3. Run your SCIM search filter.

Note:

The search can include only the filter you specified with `--set filter` in the earlier step without the `"(objectclass=<name-of-SCIM-resource-type-objectclass>)"` portion.

In addition to the Virtual List View request control, PingDirectory adds a Server Side request control to the LDAP request. These request controls require certain parameters be set. To satisfy this requirement, PingDirectory uses the following parameters. If the client does not provide values for one of the parameters, the search uses the corresponding default value shown in the following table.

Parameter	Default
startIndex	1
count	The value of the <code>lookthrough-limit</code> property of the SCIM resource type being searched. That default is 500.
sortBy	entryUUID With this default, the results appear unsorted.
sortOrder	ascending

SCIM 2.0 PATCH operations

When using a `PATCH` request to modify a SCIM 2.0 resource that has one or more required SCIM 2.0 attributes, the requester must have permissions to read the values of these required attributes in addition to write permissions for the attributes being modified, even if the `PATCH` request does not alter said requirements.

For example, assume we want to modify an LDAP Mapping SCIM 2.0 resource type using the following schema definition, where `uid` and `cn` are mapped to their LDAP equivalents:

```
{
  "schemas": ["urn:ietf:params:scim:schemas:core:2.0:Schema"],
  "id": "urn:test:schema:person",
  "attributes": [
    {
      "name": "uid",
      "type": "string",
      "multiValued": false,
      "required": true,
      "caseExact": false,
      "mutability": "readWrite",

```

```

    "returned": "default",
    "uniqueness": "none"
  },
  {
    "name": "cn",
    "type": "string",
    "multiValued": false,
    "required": false,
    "caseExact": false,
    "mutability": "readWrite",
    "returned": "default",
    "uniqueness": "none"
  }
],
...
}

```

The following PATCH operation will fail if the SCIM 2 service account does not have access to both `uid` and `cn`:

```

{
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:PatchOp"],
  "Operations": [{
    "op": "add",
    "path": "cn",
    "value": "new cn value"
  }]
}

```

Troubleshoot the SCIM 2.0 servlet extension

For security reasons, error messages specifically regarding LDAP systems are suppressed and do not appear in the HTTP responses from the server. Instead, you will see something similar to the following:

```

{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": "400",
  "detail": "Request failed:
correlationID='073eb1a8-8c51-48b3-83a0-380e1d4b4ab9'"
}

```

To view these messages, the Debug Trace Logger needs to be enabled. You can do this through the Administrative Console or with the following `dsconfig` command:

```

dsconfig set-log-publisher-prop --publisher-name "Debug Trace Logger" \
  --set enabled:true --add scim-message-type:error

```

After the Debug Trace Logger is enabled, the server will begin logging information related to SCIM operations to the file `/logs/debug-trace`, which will look somewhat like the following:

```

[09/Jun/2020:05:23:10.992 -0500] HTTP REQUEST requestID=3
correlationID="073eb1a8-8c51-48b3-83a0-380e1d4b4ab9" product="Ping Identity
Directory Server" instanceName="example" startupID="Xt9fJg==" threadID=173
from=[0:0:0:0:0:0:0:1]:53978 method=POST
url="https://0:0:0:0:0:0:0:1:9443/scim/v2/Users"

```

Note the presence of `correlationID` in these messages. By matching the id in the HTTP responses to the messages in the debug-trace log, the appropriate LDAP error message can be determined.

Disabling the SCIM 2.0 servlet extension

If you do not need to expose data through the SCIM 2 servlet, you can disable the SCIM 2.0 servlet extension by removing the SCIM2 HTTP servlet extension from the HTTPS connection handler, or from any other HTTP connection handler, and restart the handler:

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --remove http-servlet-extension:SCIM2 \
  --set enabled:false

dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true
```

Managing Server SDK Extensions

The Server provides support for any custom extensions that you create using the Server SDK. This chapter summarizes the various features and extensions that can be developed using the Server SDK.

About the Server SDK

You can create extensions that use the Server SDK to extend the functionality of your Directory Server. Extension bundles are installed from a .zip archive or a file system directory. You can use the **manage-extension** tool to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

**Note:**

The **manage-extension** tool may only be used with Java extensions packaged using the extension bundle format. Groovy extensions do not use the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation, which describes the extension bundle format and how to build an extension.

Available types of extensions

The Server SDK provides support for creating a number of different types of extensions for Ping Identity Server Products, including the PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server. Some of those extensions include:

Cross-Product Extensions

- Access Loggers
- Alert Handlers
- Error Loggers
- Key Manager Providers
- Monitor Providers
- Trust Manager Providers
- OAuth Token Handlers
- Manage Extension Plugins

PingDirectory Server Extensions

- Certificate Mappers
- Change Subscription Handlers
- Extended Operation Handlers

- Identity Mappers
- Password Generators
- Password Storage Schemes
- Password Validators
- Plugins
- Tasks
- Virtual Attribute Providers

PingDirectoryProxy Server Extensions

- LDAP Health Checks
- Placement Algorithms
- Proxy Transformations

PingDataSync Server Extensions

- JDBC Sync Sources
- JDBC Sync Destinations
- LDAP Sync Source Plugins
- LDAP Sync Destination Plugins
- Sync SourcesSync Destinations
- Sync Pipe Plugins

For more information on the Server SDK, see the documentation available in the SDK build.

DevOps and infrastructure-as-code

Limitations when automating PingDirectory Server deployments

PingDirectory Server is a stateful application. User data is associated with it, and servers in a topology must be able to communicate bidirectionally with each other. The deployment of stateful applications is generally more challenging to automate than the deployment of stateless applications. However, by following certain industry-wide best practices, the deployment of stateful applications becomes easier to manage.

For stateful applications, we recommend maintaining a well-known network identifier for a server that does not change over its lifetime. Without this guarantee, the deployment automation workflows for the PingDirectory Server software does not work as expected. On infrastructure platforms like AWS, servers are generally assigned cattle-like internal host names. This strategy is acceptable if a well-defined external name is registered in a service discovery or lookup service, such as DNS.

Another important recommendation for stateful applications is the use of external, redundant persistent storage that is always available, and that functions independently of the server itself. Servers might come and go, but they are always guaranteed to be attached to the same persistent storage when they are resurrected. Although the PingDirectory Server software does not require this guarantee, we recommend it for simpler, less error-prone deployment automation and for easier disaster recovery. For more information, see [Deployment automation](#) on page 765.

Server profiles

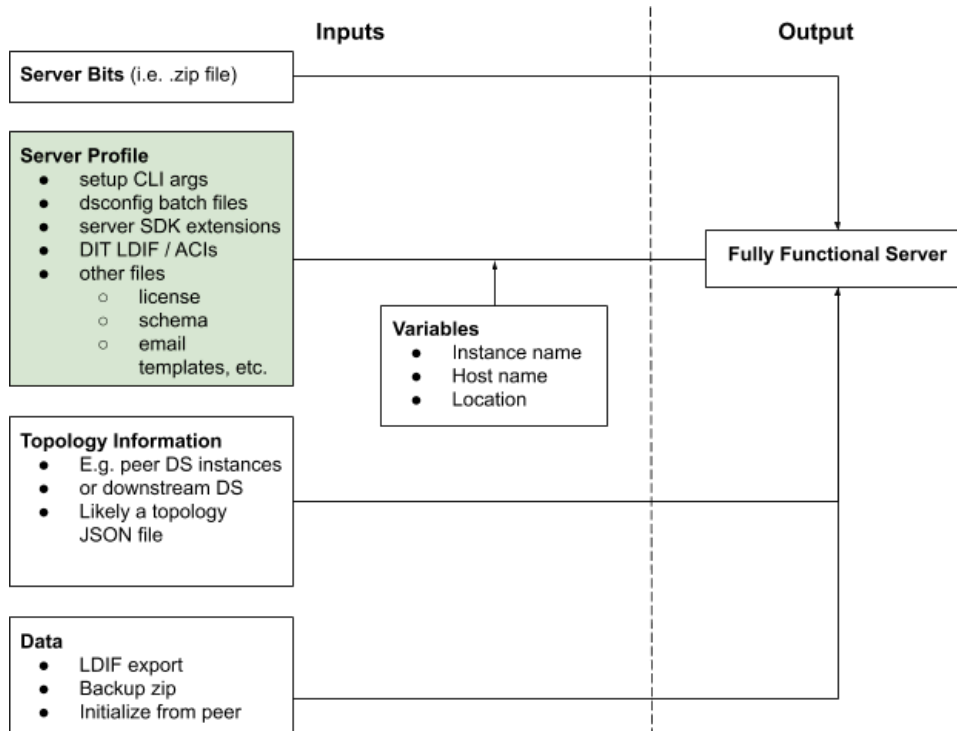

Regardless of the service model that your company follows, *server profiles* help you achieve your goals. At a basic level, a server profile defines a format for the configuration of a server by combining the following files into a single concrete structure:

- `dsconfig`
- Initial DIT
- Setup arguments

- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDirectory Server and related products by using deployment automation frameworks. When products support this capability, the amount of scripting that is required across automation frameworks – like Docker, Kubernetes, and Ansible – is reduced considerably.

The following image shows the role that a server profile plays in building a fully functional running server.

As a declarative form of a full server configuration, a server profile provides the following advantages:

- Provides a more complete and easily comparable way to define an individual server's configuration. Changes between different servers are easier to understand, and incremental changes to a server's configuration are easier to track.
- Ensures that each server instance is configured identically to its peers.
- Can be applied directly to new as well as previously installed instances.
- Shares a common configuration across a deployment pipeline of development, test, and production environments without unnecessary duplication. For information about substituting variables that differ by environment, see [Variable substitution](#) on page 760.
- Facilitates deployment automation by representing configuration as code.
- Reduces the number of additional configuration steps that are required to place a server into production.
- Makes the execution of various configuration changes more consistent and repeatable. The strategy of using a server profile to represent the final state of a server is less error-prone than recording a step-by-step process to attain that state.
- Can be managed easily in a version-control system.
- Simplifies the management of servers outside deployment automation frameworks.

A continuous deployment workflow can work with server profiles to make certain that changes to a server profile are moved automatically into production. In a stateful environment, the **manage-profile replace-profile** subcommand can be used to update existing servers. In a stateless environment, in which servers are considered immutable, **manage-profile setup** can be used to deploy new servers

whenever a profile changes. With multiple environments, this deployment can be performed in a test environment before moving to production.

When working with zipped server SDK extensions and other files that might not be stored in a version-control system, the server profile can be modified to include these files prior to its use. For example, if the code for an extension is stored in a separate repository, it can be built and dropped into the server profile immediately before the `manage-profile` tool is run. This process is part of the deployment automation logic that uses the server profile, and it can be followed for any files that are needed by the server profile but whose versions are not controlled.

For more information about the `manage-profile` tool, see [About the manage-profile tool](#) on page 763.

Variable substitution

You can use the `manage-profile` tool to substitute different variables in server profiles.

The `manage-profile` tool uses the format `${VARIABLE}` to support the substitution of variables in profiles. This format can be escaped by using another `$`. For example, after substitution, `$$ {VARIABLE}` becomes `${VARIABLE}`.

Variable values can be read from a profile variables file or from environment variable values. If both options are used, the values that are specified in the file overwrite any environment variables.

The following code provides an example of how you can set user-defined variables by using a variables file in the server profile.

```
HOSTNAME=testserver.example.com
PORT=389
```

The following table describes built-in variables that can also be referenced in the server profile. Use these variables in the format previously described.

Built-in variable	Description
PING_SERVER_ROOT	Evaluates to the absolute path of the server's root directory
PING_PROFILE_ROOT	Evaluates to the individual profile's root directory <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> Note:</p> <p>Use <code>PING_PROFILE_ROOT</code> only with files that are not needed after initial setup, such as password files in <code>setup-arguments.txt</code>. Do not use the <code>PING_PROFILE_ROOT</code> variable for files needed while the server is running. The <code>manage-profile</code> tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under <code>PING_PROFILE_ROOT</code> when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's <code>server-root/pre-setup</code> directory, and then refer to the files using with the <code>PING_SERVER_ROOT</code> variable.</p> </div>

For more information about the tool's usage, run the command `bin/manage-profile --help`.

Profile structure

Use either of the following methods to create a server profile:

- Use the template named `server-profile-template.zip`, which is located in the `resource/` directory.
- Run the `manage-profile generate-profile` subcommand. The `manage-profile` tool references a file system directory structure rather than a ZIP file.

Files can be added to each directory as needed.

The following hierarchy represents the file structure of a basic server profile:

```
-server-profile/
|-- dsconfig/
|-- ldif/
|   |-- userRoot/
|-- misc-files/
|-- server-root/
|   |-- post-setup/
|   |-- pre-setup/
|-- server-sdk-extensions/
|-- setup-arguments.txt
|-- variables-ignore.txt
```

setup-arguments.txt

When creating a [profile](#), the first step is to add arguments to the `setup-arguments.txt` file, located in the `resources/server-profile-template.zip` archive.

When you run the `manage-profile setup` command, these arguments are passed to the server's setup tool. To view the arguments available in this file, run the server's `setup --help` command.

To provide the equivalent, non-interactive command-line interface (CLI) arguments after any prompts have been completed, run `setup` interactively. The `setup-arguments.txt` file in the server profile template contains an example set of arguments that can be changed.

`setup-arguments.txt` is the only required file in the profile.

dsconfig/

`dsconfig` batch files can be added to the `dsconfig` directory. These files, each of which must include a `.dsconfig` extension, contain `dsconfig` commands to apply to the server.

Note:

`dsconfig` batch files in the server profile can't make changes to any topology configuration, including topology admin users and server instances. You should make topology configuration changes outside of the server profile.

Because the `dsconfig` batch files are ordered lexicographically, `00-base.dsconfig` runs before `01-second.dsconfig`, and so on.

Tip:

To produce a `dsconfig` batch file that reproduces the current configuration, run `bin/config-diff`.

server-root/

Any server root files can be added to the `server-root` directory, including schema files, email template files, custom password dictionaries, and other files that must be present on the final server root. Add these

files to the `server-root/pre-setup` or `server-root/post-setup` directory, depending on when they need to be copied to the server root. Most server root files are added to the `server-root/pre-setup` directory.

ldif/

Use LDIF files in the server profile to supply a base DIT, but not to import user data. Add LDIF files under the `ldif` directory. Place each LDIF file in a subdirectory that indicates the backend to which it is imported, such as `ldif/userRoot/` for the `userRoot` backend.

LDIF files require an `.ldif` extension and are ordered lexicographically.

server-sdk-extensions/

Add server SDK extension `.zip` files to the `server-sdk-extensions` directory. Include any configuration that is necessary for the extensions in the profile's `dsconfig` batch files.

variables-ignore.txt

The `variables-ignore.txt` file is an optional component of the server profile. It is useful when adding bash scripts to the server root because such files often contain expressions that the `manage-profile` tool normally interprets as variables.

Add `variables-ignore.txt` to a profile's root directory to indicate the relative paths of any files that are not to have their variables substituted.

The following example shows the contents of a typical `variables-ignore.txt` file:

```
server-root/pre-setup/script-to-ignore.sh
server-root/post-setup/another-file-to-ignore.txt
```

server-root/permissions.properties

The `permissions.properties` file, located in the `server-root` directory, is an optional file that specifies the permissions to apply to files that are copied to the server root. These permissions are represented in octal notation. By default, server root files maintain their permissions when copied.

The following example shows the contents of a typical `permissions.properties` file:

```
default=700
file-with-special-permissions.txt=600
new-subdirectory/file-with-special-permissions.txt=644
bin/example-script.sh=760
```

misc-files/

Additional documentation and other files can be added to the `misc-files` directory, which the `manage-profile` tool does not use. Use the variable `PING_PROFILE_ROOT` to refer to files in this directory from other locations, such as `setup-arguments.txt`.

Note:

Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using with the `PING_SERVER_ROOT` variable.

For example, a password file named `password.txt` in the `misc-files` directory could be referenced with `${PING_PROFILE_ROOT}/misc-files/password.txt` in `setup-arguments.txt`. Use a reference like this example to supply the file for the `--rootUserPasswordFile` argument in `setup-arguments.txt`.

About the `manage-profile` tool

The `manage-profile` tool is provided with the server to work with server profiles. It includes subcommands for creating, applying, and replacing server profiles, all of which significantly reduce the effort required by an administrator to configure a server appropriately.

The following sections describe these subcommands in more detail. For more information about the `manage-profile` tool, run `manage-profile --help`. For more information about each individual subcommand and its options, run `manage-profile <subcommand> --help`.

`manage-profile generate-profile`

To create a server profile from a configured server, use the `generate-profile` subcommand. The generated profile contains the following information, which provides a base for completing a profile:

- Command-line arguments that were used to set up the server
- `dsconfig` commands necessary to configure the server
- Installed server SDK extensions
- Files that are added to the server root

To produce a complete profile, some parts of the generated profile might require modifications, such as adding password files that `setup-arguments.txt` uses. The `--instanceName` and `--localHostName` arguments in `setup-arguments.txt` are made variables by `generate-profile`, and must be provided values when other `manage-profile` subcommands use the generated profile.

LDIF files must also be added manually to the generated profile.

`manage-profile setup`

To apply a server profile to a fresh, unconfigured server, use the `setup` subcommand, which replaces the normal setup tool when using a server profile. Run `manage-profile setup` to complete the following tasks:

- Copies the pre-setup files to the server root
- Runs the setup tool
- Copies the post-setup files to the server root
- Installs any server SDK extensions
- Runs any `dsconfig` batch files
- Imports any LDIF files
- Starts the server

While `manage-profile setup` is running, a copy of the profile is created in a temporary directory that can be specified by using the `--tempProfileDirectory` argument. The command leaves the server in a complete and running state when finished, unless the `--doNotStart` argument is specified.

`manage-profile replace-profile`

Run the `replace-profile` subcommand on a server that was originally set up with a server profile to replace its configuration with a new profile. The tool applies a specified server profile to an existing server while preserving its data, topology configuration, and replication configuration. New LDIF files from the replacement server profile are not imported.

While `manage-profile replace-profile` is running, the existing server is stopped and moved to a temporary directory that the `--tempServerDirectory` argument can specify. A fresh, new server is subsequently installed and set up with the new profile. The final server is left running if it was running before the command was started, and remains stopped if it was stopped.

Run `manage-profile replace-profile` from a second unzipped server install package on the same host as the existing server, similar to the `update` tool. Use the `--serverRoot` argument to specify the root of the existing server that will have its profile replaced.

If files have been added or modified in the server root since the most recent `manage-profile setup` or `manage-profile replace-profile` was run, they are included in the final server with the replaced profile. Otherwise, files specifically added from the `server-root` directory of the previous server profile are absent from the final server with the replaced profile. If errors occur during the subcommand, such as the new profile having an invalid `setup-arguments.txt` file, the existing server returns to its original state from before `manage-profile replace-profile` was run.

Note:

The `manage-profile replace-profile` tool can update the server version when needed.

Note:

The `manage-profile replace-profile` tool can directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to `dsconfig`.

Server Profiles in a Pets Service Model

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server. Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new pet server has been set up with a server profile, `manage-profile replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see [About the manage-profile tool](#) on page 763.

Topology-management tools

Because PingDirectory Server topology-management tools like `dsreplication` and `remove-defunct-server` feature internal retries, external deployment automation scripts are not required to incorporate retries. This approach mitigates transient failures and makes servers more robust in automated environments.

To support this approach, `dsreplication` and `remove-defunct-server` include a `--retryTimeoutSeconds` option, which specifies a timeout value for the entire command. If the command fails, it is retried until the timeout value is reached. The command is not aborted if the timeout expires mid-execution, so it is guaranteed to be executed at least once. The default value of zero indicates the command does not have a timeout and is not retried upon initial failure.

The `remove-defunct-server` tool can also be used to complete the following tasks:

- Remove an online server.

Because a server runs as a container's main process, and because shutting down a server re-spins the container, this task was impossible to complete in deployment automation environments that use containers. Automation scripts often resorted to hacks like impersonating an offline server by taking down the LDAP connection handler. In environments where security concerns prevented the use of LDAP, removing an online server was never an option.

- Remove servers without forcing a topology primary when you do not have a quorum majority of online servers.

The topology registry uses a primary-secondary architecture in which all write requests are chained through a single write-primary. When a primary could not be nominated, the topology becomes read-only. To work around this issue, a single server had to be forced as a primary to apply changes.

- Remove servers concurrently.

The `--ignoreOnline` option can be used to remove an online server, and the `--retryTimeoutSeconds` option can be used to increase robustness in concurrent environments.

Finally, `dsreplication enable` provides internal support for a seed server before the replication topology exists. To prevent the creation of separate islands of replicating servers when simultaneously enabling replication on multiple hosts with a topology JSON file, the server that appears first in lexicographical order in the topology JSON file is designated as the seed server. When enabling replication on the seed server itself with the topology JSON file, it stops and returns a `ERROR_SEED_AND_TARGET_SERVER_ARE_THE_SAME` code. This precaution avoids deadlocking a `dsreplication` process when replication is invoked concurrently. On the seed server itself, deployment automation scripts can treat this code as being successful.

Deployment automation

Automated workflows help shift the deployment process from a pets service model to a cattle service model. The primary tools that are required to manage the replication topology are `dsreplication` and `remove-defunct-server`.

Another key to every topology-management workflow is the `topology.json` file, which represents the intended state of the topology at any time. An administrator should create this file manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.

The following code shows an example `topology.json` file:

```
{
  "serverInstances" : [
    {
      "instanceName" : "ds-0",
      "hostname" : "ds-0.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-1",
      "hostname" : "ds-1.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
```

```

    "product" : "DIRECTORY"
  },
  {
    "instanceName" : "ds-2",
    "hostname" : "ds-2.ds-topology.production.svc.cluster.local",
    "location" : "Austin",
    "ldapPort" : 389,
    "ldapsPort" : 636,
    "replicationPort" : 989,
    "startTLSEnabled" : true,
    "preferredSecurity" : "SSL",
    "product" : "DIRECTORY"
  },
  {
    "instanceName" : "ds-3",
    "hostname" : "ds-3.ds-topology.production.svc.cluster.local",
    "location" : "Austin",
    "ldapPort" : 389,
    "ldapsPort" : 636,
    "replicationPort" : 989,
    "startTLSEnabled" : true,
    "preferredSecurity" : "SSL",
    "product" : "DIRECTORY"
  },
  ...
]
}

```

The remaining sections in this chapter describe the deployment automation that is necessary to satisfy the following workflows:

- Setting up the initial topology
- Initializing data on all servers
- Replacing crashed instances and scaling up
- Scaling down
- Rolling updates

Consistent network identifiers are required for each server instance. Additionally, we strongly recommend persistent storage for all server bits. The required level of automation changes slightly when this recommendation is not followed, as noted in each section.

Setting up the initial topology

About this task

The `server.uuid` file in the server's `config` directory indicates whether the server is being set up initially or being updated.

Note:

If you're not using persistent storage, set up a new server and skip step 3. If you are using persistent storage, start on step 3.

For more information about server profiles, see [Server profiles](#) on page 758.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation.

When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using `manage-topology export`.

2. To install and configure a server instance, run the `manage-profile` command with the `setup` option.

Example:

```
manage-profile setup \
  --profile /path/to/server-profile \
  --profileVariablesFile /path/to/instance-specific-variables.properties
```

3. If you're using persistent storage, replace the current server profile. Otherwise, proceed to step 4. To replace the current profile, run the `manage-profile replace-profile` command from a second, extracted server install package on the same host as the existing server.

Example:

```
manage-profile replace-profile \
  --profile /path/to/server-profile \
  --profileVariablesFile /path/to/instance-specific-variables.properties
--serverRoot /path/to/existing/server
```

4. To enable replication within the topology, run `dsreplication` with the `enable` option.

Example:

```
dsreplication enable \
  --topologyFilePath /path/to/topology.json \
  --retryTimeoutSeconds 120
```

5. To initialize the replication data, run `dsreplication` with the `initialize` option.

Example:

```
dsreplication initialize \
  --topologyFilePath /path/to/topology.json
```

Prefer topology administrator accounts over root users

In PingDirectory Server, administrative accounts can be placed in any of three places.

- They can be created as root users. These accounts exist in the configuration (after `cn=Root DNs,cn=config`) and are not synchronized across server instances. If you want to use root accounts across multiple servers, then you must create the account in each server and keep it up to date across all of them. Root user accounts can optionally automatically inherit a default set of privileges, and you can also explicitly grant and revoke privileges as needed.
- They can be created as topology administrators. These accounts also exist in the configuration (after `cn=Topology Admin Users,cn=topology,cn=config`), and these accounts are automatically synchronized between server instances within the same topology. Topology administrators can also automatically inherit a default set of privileges, and you can also explicitly grant or revoke privileges.
- They can be created in the user data. These accounts will be replicated across all Directory Servers and they can be used to authenticate to PingDirectory and PingDirectoryProxy Servers, but they cannot be used to authenticate to PingDataSync or PingDataMetrics Servers. They cannot automatically inherit a default set of privileges, but you can explicitly grant privileges to them as needed. Accounts created in the user data can also be unavailable if the backend containing that data is offline, such as when performing an online restore, replica initialization, or LDIF import.

We recommend using topology administrator accounts over root users or accounts created in the user data. Topology administrators have all of the same capabilities as root users, and their accounts are also

automatically synchronized across all servers in the topology so there is no need to apply the same change across multiple servers.

See the `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file for more information about creating topology administrator accounts. The contents of the `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file are shown below:

```
# Although setup automatically creates an initial root user account that can
# be used to manage the server, we strongly recommend creating a separate
# account for each administrator rather than using a single shared account.
# This offers several benefits, including:
#
# * It is easier to determine which administrator performed a given action.
# * There is no need to share credentials or coordinate password changes.
# * It is easier to use strong authentication options like certificates or
#   two-factor mechanisms.
# * You can customize the level of access that each administrator has.
#
# We also recommend creating topology admin user accounts rather than root
# user accounts. If you create a root user account, then it is only created
# in that one instance. If you create a topology admin user, then that
# account will be available in all instances in the topology.
#
# Because administrative accounts are very powerful, they are high-priority
# targets for attackers to try to compromise. They should be required to
# have
# strong credentials, and you may wish to require that they use strong
# authentication mechanisms (see other dsconfig batch files for configuring
# password validators and other password policy features). You may also
# want
# to give them usernames that are not likely to be guessed by an attacker,
# even if they know information about the individuals administering the
# service. For example, you may not want to use their name in the DN or
# username, choosing instead something that is less predictable or even
# completely random like a UUID.
#
# Once each administrator has their own account, we recommend that you
# disable
# or remove the initial root user created during setup. See the
# disable-or-remove-the-initial-root-user.dsconfig batch file for more
# information about that.

#
# NOTE: Do not edit this file directly. Changing this file could prevent
# it
# from being updated during a server upgrade. If you want to alter the
# dsconfig commands below before applying the configuration changes, copy
# this
# file to another directory and edit that copy.
#

# Create a new topology administrator account. In this example, the user
# will
# be able to read the configuration but will not be allowed to update it,
# and
# will be given the bypass-read-acl privilege rather than bypass-acl, which
# only ensures they will be able to read entries but they will not be
# permitted to update them unless permitted by the server's access control
# configuration. They will also only be permitted to communicate with the
# server over a secure connection, and they will only be permitted to
```

```
# authenticate with the EXTERNAL or UNBOUNDID-TOTP mechanisms.
dsconfig create-topology-admin-user \
  --user-name "[USER_NAME]" \
  --set "password:[PASSWORD]" \
  --set "first-name:[FIRST_NAME]" \
  --set "last-name:[LAST_NAME]" \
  --set "user-id:[USER_NAME]" \
  --set inherit-default-root-privileges:true \
  --set privilege:bypass-read-acl \
  --set privilege:-bypass-acl \
  --set privilege:-config-write \
  --set search-result-entry-limit:0 \
  --set time-limit-seconds:0 \
  --set look-through-entry-limit:0 \
  --set idle-time-limit-seconds:0 \
  --set require-secure-authentication:true \
  --set require-secure-connections:true \
  --set "allowed-authentication-type:SASL EXTERNAL" \
  --set "allowed-authentication-type:SASL UNBOUNDID-TOTP"
```

Initializing data on all servers

About this task

Skip this step if you are using one of the following methods to load data during the initial setup:

- Each server instance imports the same user data from one or more LDIF backup files
- Data is synchronized from another source, such as an Active Directory server, to all servers
- No data is imported initially

Data must be imported and available on a single server only. Servers that do not feature user data must be initialized reliably and quickly.

Note:

The absence of user data during the initial setup does not prevent the the environment from being set up correctly.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. Import data into one of the server instances, as follows:

```
import-ldif --backendID userRoot \
  --ldifFile userData0.ldif \
  --ldifFile userData1.ldif
```

3. Initialize data on each server by using this server as the initial source:

```
dsreplication initialize \
  --topologyFilePath /path/to/topology.json \
  --retryTimeoutSeconds 120
```

For the sake of simplicity, other `dsreplication` options are not shown.

Replacing crashed instances and scaling up

About this task

The automation for this scenario is identical to the automation for [Setting up the initial topology](#) on page 766.

Scaling down

About this task

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. If the server is not present in the topology JSON file, remove it from the topology, as follows:

```
remove-defunct-server --topologyFilePath /path/to/topology.json \
  --ignore-online \
  --serverInstanceName instance-name
--retryTimeoutSeconds 120
```

For the sake of simplicity, LDAP bind options are omitted.

Rolling updates

About this task

The presence of the file `server.uuid` in the server's `config` directory indicates whether the server is being set up initially or being updated.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. Extract the new server bits to a directory.
3. From the same directory's `bin` directory, replace the new server profile, as follows:

```
manage-profile replace-profile \
  --profile /path/to/server-profile \
  --profileVariablesFile /path/to/instance-specific-variables.properties \
  --serverRoot /path/to/existing/server
```

Troubleshooting the PingDirectory Server

The PingDirectory Server provides a highly-reliable service that satisfies your company's objectives. However, if problems do arise (whether from issues in the Directory Server itself or a supporting component, like the JVM, operating system, or hardware), then it is essential to be able to diagnose the problem quickly to determine the underlying cause and the best course of action to take towards resolving it.

This chapter provides information about how to perform this analysis to help ensure that the problem is resolved as quickly as possible. This chapter presents the following information:

Directory Server gauges

The Directory Server provides a number of built-in gauges to monitor Directory Server performance. These gauges are listed in the following table:

Directory Server Gauges

Gauge Name	Enabled by default?	Description
Active Cleaner Threads (Percent)	true	Monitors the percentage of database cleaner threads that are active in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the <code>list-backends</code> command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends may be included or excluded from monitoring by specifying its backend ID in the <code>include resource</code> and <code>exclude resource</code> properties respectively. To keep the database from growing on disk, database cleaner threads copy database information from older, mostly obsolete database files to new database files. At a single point in time, 100% of the cleaner threads might be active, but when averaged over time, the percentage of active cleaner threads should remain relatively low. Even environments that sustain a very high write load do not typically see an average cleaner percent busy over 50%. If the percentage exceeds 90% for over an hour, it is a sign that the database cleaner is not progressing and the act of cleaning is producing as much garbage as it cleans. This typically occurs in environments that are not fully cached, and have not given sufficient memory to the database cache. Either increase the memory available to the database cache (by increasing the JVM size or increasing the <code>db-cache-percent</code> setting on the backend) or reduce the <code>db-cleaner-min-utilization</code> setting, which reduces the burden on the cleaner thread(s).
Authentication Failure Rate	false	Rate of LDAP bind failures per second. A high rate of failures may indicate a misconfigured client application or a malicious attack.
Available File Descriptors	true	Monitors the number of file descriptors available to the server process. The server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. The number of file descriptors that the server will use can be configured by either using a <code>NUM_FILE_DESCRIPTOR</code> environment variable, or by creating a <code>config/num-file-descriptors</code> file with a single line such as <code>NUM_FILE_DESCRIPTOR=12345</code> . If these are not set, the default of 65535 is used. Running out of available file descriptors can lead to unpredictable behavior and severe system instability.

Gauge Name	Enabled by default?	Description
Certificate Expiration (Days)	true	Monitors the expiration dates of key server certificates. A server certificate expiring may cause server unavailability, degradation, or loss of key server functionality. Certificates nearing the end of their validity should be replaced as soon as possible. See the status tool, or Status in the Administrative Console, for more information about server certificates and how they are managed.
Changelog Database Target Size (Percent)	true	Monitors the size of a changelog database on disk relative to the configured target-database-size value for the Replication Server changelog and the LDAP Changelog Backend (cn=changelog). The resource identifier indicates the changelog environment that is being monitored. The server aims to keep the disk usage of the changelog to between 95% and 100% of the target-database-size value. The most common reason that the server exceeds this limit is that there are no more changes that are old enough to purge. This is controlled with the replication-purge-delay setting on the Replication Server configuration object and the changelog-maximum-age setting on the 'changelog' Backend configuration object. If this is the case, the effective-purge-delay monitor attribute will match the configured purge delay. To eliminate the alarm in this case reduce the purge delay or increase the target-database-size value. Another reason that the disk usage could exceed this limit is that an export-ldif or online backup of the corresponding backend is running since database files on disk cannot be deleted while this operation is in progress. In practice, this will not occur unless the purge delay and target-database-size setting are configured to very small values and/or the backup is throttled with the --maxMegabytesPerSecond option so that it takes an especially long time to complete. The final reason that the limit could be exceeded is that the target-database-size setting is unreasonably small like less than one gigabyte.

Gauge Name	Enabled by default?	Description
Cleaner Backlog (Number Of Files)	true	Monitors the cleaner backlog in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the list-backends command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends may be included or excluded from monitoring by specifying its backend ID in the include resource and exclude resource properties respectively. The backlog is the number of database files that need to be cleaned to reach the target level of utilization. The value over time should stay close to zero. If it remains high or continues to grow, then consider updating the backend configuration to increase the <code>db-num-cleaner-threads</code> setting or reduce the <code>db-cleaner-min-utilization</code> setting. Temporary spikes in cleaner backlog are common during rebuild-index, export-ldif, and backup operations. The backlog should decrease automatically once these commands complete.
CPU Usage (Percent)	true	Monitors server CPU use and provides an averaged percentage for the interval defined. The monitored resource is the host system's CPU, which does not include a resource identifier. If CPU use is high, check the server's current workload and other processes on this system and make any needed adjustments. Reducing the load on the system will lead to better response times.
Database Cache Full (Percent)	true	Monitors the percentage capacity of the database cache currently populated with entries, per backend. The resource identifier for this gauge is a backend ID. Use the list-backends command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends may be included or excluded from monitoring by specifying its backend ID in the include-resource and exclude-resource properties respectively. Server performance can drop off dramatically when the database cache can no longer hold the entire data set. Most deployments are designed to keep the database cache usage comfortably within the configured limits. If this server is intentionally disk-bound, this gauge should be disabled.
Disk Busy (Percent)	true	Monitors disk busy percentage over the update interval. This gauge requires that the Host System Monitor Provider be enabled and that any monitored disks be registered using the disk-devices property of that Monitor Provider. The resource identifier for this gauge is the disk device name. Use the iostat command or a similar system utility to see a list of disk device names. A separate gauge monitor entry will be created for each monitored disk. High disk usage may be indicative of a Directory Server whose database cache and/or JVM heap size are not large enough to contain the entire data set.

Gauge Name	Enabled by default?	Description
HTTP Processing (Percent)	true	Monitors the percentage of time that request handler threads spend processing HTTP requests. This percentage represents the inverse of the server's ability to handle new requests without queueing.
JVM Memory Usage (Percent)	true	Monitors the percentage of Java Virtual Machine memory that is in use. This value naturally fluctuates due to garbage collection, so the minimum value within an interval is reported since it is a better indication of overall memory growth. When the memory usage exceeds 90%, this should be reported to customer support since the server is either misconfigured or has a memory leak. As memory usage approaches 100%, the server is more and more likely to experience garbage collection pauses, which leave the server unresponsive for a long time. Restarting the server is likely the only remedy for this situation. Prior to restarting the server, please run <code>collect-support-data</code> and capture the output of <code>jmap -histo</code> to provide to customer support. The pid of the server can be found from <code>/logs/server.pid</code> .
LDAP Operation Average Response Time (Milliseconds)	false	Monitors the average response time across all LDAP operations processed by this server since it was started. There is no resource identifier associated with this gauge. The monitored resource is overall response time of all LDAP operations processed by this server since it was started. High response times may be indicative of a number of factors including a disk-bound server, network latency, or misconfiguration. Enabling the Stats Logger plugin may help isolate problems. See the administration guide for more information on common problems and solutions.
LDAP Operations Failed (Percent)	false	Monitors the percentage of all LDAP operations processed by this server that have failed since it was started. There is no resource identifier associated with this gauge. The monitored resource is overall number of failed LDAP operations processed by this server since it was started. A high percentage of failed operations may indicate misconfiguration of a client or server in a topology.
License Expiration (Days)	true	Monitors the expiration date of the product license. An expired license will cause warnings to appear in the server's logs and in the status tool output. Request a license key through the Ping Identity licensing website https://www.pingidentity.com/en/account/request-license-key.html or contact sales@pingidentity.com . Use the <code>dsconfig</code> tool to update the License configuration's license key property.

Gauge Name	Enabled by default?	Description
Memory Usage (Percent)	false	Monitors the percentage of memory use averaged over the update interval defined. The monitored resource is the host system's memory use, which does not have a resource identifier. Some operating systems, including Linux, use the majority of memory for file system cache, which is freed as applications need it. If memory use is high, check the applications that are running on the server.
Purge Expired Data Backlog (Number of Entries)	true	Monitors the backlog of entries that need to be purged by a Purge Expired Data Plugin. The resource identifier for this gauge is the name of the configured plugin. Increasing the max-updates-per-second configuration property on the plugin can increase the rate that the plugin purges expired data. It might also be necessary to refine the search that the plugin performs to be more efficient.
Recent Changes Database-to-JVM Heap Size Ratio (Percent)	true	The recent changes database keeps a number of recent changes made by update operations in changelog change entry form. This database is used by replication and the changelog backends, and unexpected growth affects server start time, memory consumption and space on disk. The ratio of the recent changes database to the overall heap size is used to track the impact on memory consumption. If you expect large changes and the server isn't experiencing issues, increase the alarm threshold. After processing large changes the alarm should clear itself, if not, it may necessary to perform an export and re-import of the data to resolve the issue.
Replication Conflict Growth Rate	false	Growth rate of the number of unresolved conflicts per second over the update interval. The resource identifier for this gauge is the base DN of the replica. Use the dsreplication status command to see a list of replicated base DNs. A separate gauge monitor entry will be created for each monitored replica. Replicas may be included or excluded from monitoring by specifying a replication base DN in the include resource and exclude resource properties respectively. Updates to Directory Server entries in a replication topology may happen independently, since replication guarantees only eventual consistency, not strong consistency. The eventual consistency model means that conflicting changes can be applied at different Directory Server instances. In most cases, the Directory Server is able to resolve these conflicts automatically and in a consistent manner. However, in some scenarios, manual administrative action is required. Attention should be paid to the origin of client write requests to prevent conflicts.

Gauge Name	Enabled by default?	Description
Replication Connection Status	false	Indicates the connection status of remote replication servers this servers replication topology. The 'cn=schema' backend as well as the local replication server, are excluded using the include-filter property. For all other remote servers in the topology, separate monitor entries will be created per server and replication base DN. The resource identifier for this gauge is a concatenated string containing the data set name, the host and port of the replication server and the replication server ID. A replicated data set depends upon the availability of servers replicating the data. So long as there are other replicas available in a replication topology, a single replica being unavailable should not affect the overall performance of the replication topology. However, unavailable replicas may increase the likelihood of data loss or performance degradation.
Replication Latency (Milliseconds)	false	Average amount of time it takes a modification on one replica to propagate and commit on another replica, in milliseconds. The resource identifier for this gauge is the base DN of the replica. Use the dsreplication status command to see a list of replicated base DNs. A separate gauge monitor entry will be created for each monitored replica. Replicas may be included or excluded from monitoring by specifying its base DN in the include-resource and exclude-resource properties respectively. Replication latency can be reported as high after the server starts, if the global configuration property startup-min-replication-backlog-count is not set. That property limits the number of outstanding changes any replica can have before the server will complete the startup process and begin accepting connections. This limits how out of the sync the server is at start up.
Replication Purge Delay (Hours)	true	For the replication server indicates the effective purge delay. In order to protect against missing changes the effective purge delay should be large enough to accommodate servers that have been offline as well as the need to restore from backups.
Replication Servers Available	false	Strong Encryption Not Available
Strong Encryption Not Available	true	The JVM does not appear to support strong encryption algorithms, like 256-bit AES. The server will fall back to using weaker algorithms, like 128-bit AES. To enable support for strong encryption, update your JVM to a newer version that supports it by default, or install or enable the unlimited encryption strength jurisdiction policy files in your Java installation.

Gauge Name	Enabled by default?	Description
Undeletable Database Files (Percent)	true	Monitors the percentage of undeletable database files in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the <code>list-backends</code> command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends may be included or excluded from monitoring by specifying its backend ID in the <code>include resource</code> and <code>exclude resource</code> properties respectively. The percentage of undeletable database files tracks the percentage of database files that have been cleaned but cannot be deleted because they are being used by a database maintenance operation. This could be a separate, offline process such as <code>export-ldif</code> or <code>verify-index</code> , or it could be a task running within the server such as a backup or replication initialization. A small percentage of undeletable files is expected when these commands are running, but a high percentage could indicate that one of these operations is having problems and should be canceled and restarted to avoid the database growing too large on disk.
Work Queue Size (Number Of Requests)	true	Number of requests in the server's work queue waiting to be processed, averaged over the update interval. There is no resource identifier associated with this gauge. The monitored resource is the server's work queue. If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available.

Working with the `collect-support-data` tool

The Directory Server provides a significant amount of information about its current state including any problems that it has encountered during processing. If a problem occurs, the first step is to run the `collect-support-data` tool in the `bin` directory. The tool aggregates all relevant support files into a zip file that administrators can send to your authorized support provider for analysis. The tool also runs data collector utilities, such as `jps`, `jstack`, and `jstat` plus other diagnostic tools, and bundles the results in the zip file.

The tool may only archive portions of certain log files to conserve space, so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

The data collected by the `collect-support-data` tool varies between systems. However, the tool always tries to get the same information across all systems for the target Directory Server. The data collected includes the configuration directory, summaries and snippets from the `logs` directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

Server commands used in the `collect-support-data` tool

The following presents a summary of the data collectors that the `collect-support-data` tool archives in zip format. If an error occurs during processing, you can re-run the specific data collector command and send the results to your authorized support provider.

Directory Server Commands Used in the Collect-Support-Data Tool

Data Collector	Description
status	Runs <code>status -F</code> to show the full version information of the Directory Server (Unix, Windows).
server-state	Runs <code>server-state</code> to show the current state of the Directory Server process (Unix, Windows).

JDK commands used in the collect-support-data tool**JDK Commands Used in the Collect-Support-Data Tool**

Data Collector	Description
jps	Java Virtual Machine Process status tool. Reports information on the JVM (Linux, Windows, Mac OS).
jstack	Java Virtual Machine Stack Trace. Prints the stack traces of threads for the Java process (Linux, Windows, Mac OS).
jstat	Java Virtual Machine Statistics Monitoring Tool. Displays performance statistics for the JVM (Linux, Windows, Mac OS).
jjinfo	Displays the Java configuration information for the Java process (Linux, Windows, Mac OS).

Linux commands used in the collect-support-data tool**Linux Commands Used in the Collect-Support-Data Tool**

Data Collector	Description
tail	Displays the last few lines of a file. Tails the <code>/var/logs/messages</code> directory.
uname	Prints system, machine, and operating system information.
ps	Prints a snapshot of the current active processes.
df	Prints the amount of available disk space for file systems in 1024-byte units.
cat	Concatenates the following files and prints to standard output: <ul style="list-style-type: none"> ▪ <code>/proc/cpuinfo</code> ▪ <code>/proc/meminfo</code> ▪ <code>/etc/hosts</code> ▪ <code>/etc/nsswitch.conf</code> ▪ <code>/etc/resolv.conf</code>
netstat	Prints the state of network interfaces, protocols, and the kernel routing table.
ifconfig	Prints information on all interfaces.
uptime	Prints the time the server has been up and active.
dmesg	Prints the message buffer of the kernel.
vmstat	Prints information about virtual memory statistics.
iostat	Prints disk I/O and CPU utilization information.
mpstat	Prints performance statistics for all logical processors.

Data Collector	Description
pstack	Prints an execution stack trace on an active process specified by the pid.
top	Prints a list of active processes and how much CPU and memory each process is using.

MacOS commands used in the collect-support-data tool

MacOS Commands Used in the Collect-Support-Data Tool

Data Collector	Description
uname	Prints system, machine, and operating system information.
uptime	Prints the time the server has been up and active.
ps	Prints a snapshot of the current active processes.
system_profiler	Prints system hardware and software configuration.
vm_stat	Prints machine virtual memory statistics.
tail	Displays the last few lines of a file. Tails the <code>/var/log/system.log</code> directory.
netstat	Prints the state of network interfaces, protocols, and the kernel routing table.
ifconfig	Prints information on all interfaces.
df	Prints the amount of available disk space for file systems in 1024-byte units.
sample	Profiles a process during an interval.

Invoking the collect-support-data tool as an administrative task

You can invoke `collect-support-data` as an administrative task, including as a recurring task that can be automatically invoked on a regular basis.

For more information, see [About recurring tasks and task chains](#) on page 114.

Available tool options

The `collect-support-data` tool has some important options that you should be aware of:

- **--noLdap**. Specifies that no effort should be made to collect any information over LDAP. This option should only be used if the server is completely unresponsive or will not start and only as a last resort.
- **--pid {pid}**. Specifies the ID of an additional process from which information is to be collected. This option is useful for troubleshooting external server tools and can be specified multiple times for each external server, respectively.
- **--sequential**. Use this option to diagnose “Out of Memory” errors. The tool collects data in parallel to minimize the collection time necessary for some analysis utilities. This option specifies that data collection should be run sequentially as opposed to in parallel. This action has the effect of reducing the initial memory footprint of this tool at a cost of taking longer to complete.
- **--reportCount {count}**. Specifies the number of reports generated for commands that supports sampling (for example, `vmstat`, `iostat`, or `mpstat`). A value of 0 (zero) indicates that no reports will be generated for these commands. If this option is not specified, it defaults to 10.
- **--reportInterval {interval}**. Specifies the number of seconds between reports for commands that support sampling (for example, `mpstat`). This option must have a value greater than 0 (zero). If this option is not specified, it default to 1.
- **--maxJstacks {number}**. Specifies the number of jstack samples to collect. If not specified, the default number of samples collected is 10.

- **--collectExpensiveData**. Specifies that data on expensive or long running processes be collected. These processes are not collected by default, because they will impact the performance of a running server.
- **--comment {comment}**. Provides the ability to submit any additional information about the collected data set. The comment will be added to the generated archive as a README file.
- **--includeBinaryFiles**. Specifies that binary files be included in the archive collection. By default, all binary files are automatically excluded in data collection.
- **--adminPassword {adminPassword}**. Specifies the global administrator password used to obtain `dsreplication status` information.
- **--adminPasswordFile {adminPasswordFile}**. Specifies the file containing the password of the global administrator used to obtain `dsreplication status` information.
- **--outputPath**. Specifies the path (and optionally, the name) for the support data archive file. If the path specifies a filename, the archive is written to that file. If the path specifies a directory, the file is written into that directory with a server-generated name.
- **--useRemoteServer**. Invokes the tool against a remote server instance and streams the output and resulting support data archive back to the client. This option can be especially useful when the server instance is running in a container because it might otherwise be difficult to invoke commands or access files in that container. See also: **--proxyToServerAddress** and **--proxyToServerPort**.
- **--proxyToServerAddress** and **--proxyToServerPort**. Use these options with **--useRemoteServer** to indicate that the support data archive should be retrieved from a server that is not directly accessible but can be accessed through a Directory Proxy Server.

Running the collect-support-data tool

Steps

1. Go to the server root directory.
2. Use the `collect-support-data` tool. Make sure to include the host, port number, bind DN, and bind password.

Example:

```
$ bin/collect-support-data --hostname 127.0.0.1 --port 389 \
  --bindDN "cn=Directory Manager" --bindPassword secret \
  --serverRoot /opt/the --pid 1234
```

3. Email the zip file to your Authorized Support Provider.

Directory Server Troubleshooting information

The Directory Server has a comprehensive default set of log files and monitor entries that are useful when troubleshooting a particular server problem.

Error log

By default, this log file is available at `logs/errors` below the server install root and it provides information about warnings, errors, and other significant events that occur within the server. A number of messages are written to this file on startup and shutdown, but while the server is running there is normally little information written to it. In the event that a problem does occur, however, the server writes information about that problem to this file.

The following is an example of a message that might be written to the error log:

```
[11/Apr/2011:10:31:53.783 -0500] category=CORE severity=NOTICE msgID=458887
msg="The Directory Server has started successfully"
```

The category field provides information about the area of the server from which the message was generated. Available categories include:

ACCESS_CONTROL, ADMIN, ADMIN_TOOL, BACKEND, CONFIG, CORE, DSCONFIG, EXTENSIONS, PROTOCOL, SCHEMA, JEB, SYNC, LOG, PLUGIN, PROXY, QUICKSETUP, REPLICATION, RUNTIME_INFORMATION, TASK, THIRD_PARTY, TOOLS, USER_DEFINED, UTIL, VERSION.

The severity field provides information about how severe the server considers the problem to be. Available severities include:

- **DEBUG** – Used for messages that provide verbose debugging information and do not indicate any kind of problem. Note that this severity level is rarely used for error logging, as the Directory Server provides a separate debug logging facility as described below.
- **INFORMATION** – Used for informational messages that can be useful from time to time but are not normally something that administrators need to see.
- **MILD_WARNING** – Used for problems that the server detects, which can indicate something unusual occurred, but the warning does not prevent the server from completing the task it was working on. These warnings are not normally something that should be of concern to administrators.
- **MILD_ERROR** – Used for problems detected by the server that prevented it from completing some processing normally but that are not considered to be a significant problem requiring administrative action. Administrator
- **NOTICE** – Used for information messages about significant events that occur within the server and are considered important enough to warrant making available to administrators under normal conditions.
- **SEVERE_WARNING** – Used for problems that the server detects that might lead to bigger problems in the future and should be addressed by administrators.
- **SEVERE_ERROR** – Used for significant problems that have prevented the server from successfully completing processing and are considered important.
- **FATAL_ERROR** – Used for critical problems that arise which might leave the server unable to continue processing operations normally.

The messages written to the error log may be filtered based on their severities in two ways. First, the error log publisher has a `default-severity` property, which may be used to specify the severity of messages logged regardless of their category. By default, this includes the NOTICE, SEVERE_WARNING, SEVERE_ERROR, and FATAL_ERROR severities.

You can override these severities on a per-category basis using the `override-severity` property. If this property is used, then each value should consist of a category name followed by an equal sign and a comma-delimited set of severities that should be logged for messages in that category. For example, the following override severity would enable logging at all severity levels in the PROTOCOL category:

```
protocol=debug,information,mild-warning,mild-error,notice,severe-
warning,severe-error,fatal-error
```

AdmNote that for the purposes of this configuration property, any underscores in category or severity names should be replaced with dashes. Also, severities are not inherently hierarchical, so enabling the DEBUG severity for a category will not automatically enable logging at the INFORMATION, MILD_WARNING, or MILD_ERROR severities.

The error log configuration may be altered on the fly using tools like `dsconfig`, the Administrative Console, or the LDIF connection handler, and changes will take effect immediately. You can configure multiple error logs that are active in the server at the same time, writing to different log files with different configurations. For example, a new error logger may be activated with a different set of default severities to debug a short-term problem, and then that logger may be removed once the problem is resolved, so that the normal error log does not contain any of the more verbose information.

server.out log

The `server.out` file holds any information written to standard output or standard error while the server is running. Normally, it includes a number of messages written at startup and shutdown, as well as information about any administrative alerts generated while the server is running. In most cases, this information is also written to the error log. The `server.out` file can also contain output generated by the

JVM. For example, if garbage collection debugging is enabled, or if a stack trace is requested via "kill -QUIT" as described in a later section, then output is written to this file.

Debug log

The debug log provides a means of obtaining information that can be used for troubleshooting problems but is not necessary or desirable to have available while the server is functioning normally. As a result, the debug log is disabled by default, but it can be enabled and configured at any time.

Some of the most notable configuration properties for the debug log publisher include:

- **enabled** – Indicates whether debug logging is enabled. By default, it is disabled.
- **log-file** – Specifies the path to the file to be written. By default, debug messages are written to the `logs/debug` file.
- **default-debug-level** – Specifies the minimum log level for debug messages that should be written. The default value is "error," which only provides information about errors that occur during processing (for example, exception stack traces). Other supported debug levels include warning, info, and verbose. Note that unlike error log severities, the debug log levels are hierarchical. Configuring a specified debug level enables any debugging at any higher levels. For example, configuring the info debug level automatically enables the warning and error levels.
- **default-debug-category** – Specifies the categories for debug messages that should be written. Some of the most useful categories include caught (provides information and stack traces for any exceptions caught during processing), database-access (provides information about operations performed in the underlying database), protocol (provides information about ASN.1 and LDAP communication performed by the server), and data (provides information about raw data read from or written to clients).

As with the error and access logs, multiple debug loggers can be active in the server at any time with different configurations and log files to help isolate information that might be relevant to a particular problem.

Note:

Enabling one or more debug loggers can have a significant impact on server performance. We recommend that debug loggers be enabled only when necessary, and then be scoped so that only pertinent debug information is recorded.

Debug targets can be used to further pare down the set of messages generated. For example, you can specify that the debug logs be generated only within a specific class or package. If you need to enable the debug logger, you should work with your authorized support provider to best configure the debug target and interpret the output.

Replication repair log

The replication repair log is written to `logs/replication` by default and records information about processing performed by the replication repair service. This log is used to resolve replication conflicts that can arise. For example, if the same entry is modified at the same time on two different systems, or if an attempt is made to create entries with the same DN at the same time on two different systems, the Directory Server records these events.

Config audit log and the configuration archive

The configuration audit log provides a record of any changes made to the server configuration while the server is online. This information is written to the `logs/config-audit.log` file and provides information about the configuration change in the form that may be used to perform the operation in a non-interactive manner with the `dsconfig` command. Other information written for each change includes:

- Time that the configuration change was made.
- Connection ID and operation ID for the corresponding change, which can be used to correlate it with information in the access log.

- DN of the user requesting the configuration change and the method by which that user authenticated to the server.
- Source and destination addresses of the client connection.
- Command that can be used to undo the change and revert to the previous configuration for the associated configuration object.

In addition to information about the individual changes that are made to the configuration, the Directory Server maintains complete copies of all previous configurations. These configurations are provided in the `config/archived-configs` directory and are gzip-compressed copies of the `config/config.ldif` file in use before the configuration change was made. The file names contain timestamps that indicate when that configuration was first used.

Access and audit log

The access log provides information about operations processed within the server. The default access log file is written to `logs/access`, but multiple access loggers can be active at the same time, each writing to different log files and using different configurations.

By default, a single access log message is generated, which combines the elements of request, forward, and result messages. If an error is encountered while attempting to process the request, then one or more forward-failed messages may also be generated.

```
[01/Jun/2011:11:10:19.692 -0500] CONNECT conn=49 from="127.0.0.1"
to="127.0.0.1"
  protocol="LDAP+TLS" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.764 -0500] BIND RESULT conn=49 op=0 msgID=1 version="3"
  dn="cn=Directory Manager" authType="SIMPLE" resultCode=0 etime=0.401
  authDN="cn=Directory Manager,cn=Root DNs,cn=config"
  clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.769 -0500] SEARCH RESULT conn=49 op=1 msgID=2
  base="ou=People,dc=example,dc=com" scope=2 filter="(uid=1)" attrs="ALL"
  resultCode=0 etime=0.549 entriesReturned=1
[01/Jun/2011:11:10:19.788 -0500] DISCONNECT conn=49 reason="Client Unbind"
```

Each log message includes a timestamp indicating when it was written, followed by the operation type, the connection ID (which is used for all operations processed on the same client connection), the operation ID (which can be used to correlate the request and response log messages for the operation), and the message ID used in LDAP messages for this operation.

The remaining content for access log messages varies based on the type of operation being processed, and whether it is a request or a result message. Request messages generally include the most pertinent information from the request, but generally omit information that is sensitive or not useful.

Result messages include a `resultCode` element that indicates whether the operation was successful or if failed and an `etime` element that indicates the length of time in milliseconds that the server spent processing the operation. Other elements that might be present include the following:

- **origin=replication** – Operation that was processed as a result of data synchronization (for example, replication) rather than a request received directly from a client.
- **message** – Text that was included in the `diagnosticMessage` field of the response sent to the client.
- **additionalInfo** – Additional information about the operation that was not included in the response sent back to the client.
- **authDN** – DN of the user that authenticated to the server (typically only included in bind result messages).
- **authzDN** – DN of an alternate authorization identify used when processing the operation (for example, if the proxied authorization control was included in the request).
- **authFailureID** – Unique identifier associated with the authentication failure reason (only included in non-successful bind result messages).

- **authFailureReason** – Information about the reason that a bind operation failed that might be useful to administrators but was not included in the response to the client for security reasons.
- **responseOID** – OID included in an extended response returned to the client.
- **entriesReturned** – Number of matching entries returned to the client for a search operation.
- **unindexed=true** – Indicates that the associated search operation could not be sufficiently processed using server indexes and a significant traversal through the database was required.

Note that this is not an exhaustive list, and elements that are not listed here may also be present in access log messages. The LDAP SDK for Java provides an API for parsing access log messages and provides access to all elements that they may contain.

The Directory Server provides a second access log implementation called the *audit log*, which is used to provide detailed information about write operations (add, delete, modify, and modify DN) processed within the server. If the audit log is enabled, the entire content of the change is written to the audit log file (which defaults to `logs/audit`) in LDIF form.

The server also provides a very rich classification system that can be used to filter the content for access log files. This can be helpful when debugging problems with client applications, because it can restrict log information to operations processed only by a particular application (for example, based on IP address and/or authentication DN), only failed operations, or only operations taking a long time to complete, etc.

Setup log

The **setup** tool writes a log file providing information about the processing that it performs. By default, this log file is written to `logs/setup.log` although a different name may be used if a file with that name already exists, because the **setup** tool has already been run. The full path to the setup log file is provided when the **setup** tool has completed.

Tool log

Many of the administrative tools provided with the Directory Server (for example, **import-ldif**, **export-ldif**, **backup**, **restore**, etc.) can take a significant length of time to complete write information to standard output or standard error or both while the tool is running. They also write additional output to files in the `logs/tools` directory (for example, **logs/tools/import-ldif.log**). The information written to these log files can be useful for diagnosing problems encountered while they were running. When running via the server tasks interface, log messages generated while the task is running may alternately be written to the server error log file.

je.info and je.config files

The primary datastore used by the Directory Server is the Oracle Berkeley DB Java Edition (JE). The Directory Server provides two primary sources of information about processing within the database.

The first is logging performed by the JE code itself, and is written into the `je.info.0` file in the server containing the database files (for example, `db/userRoot/je.info.0`). In the event of a problem within JE itself, useful information about the nature of the problem may be written to this log. The level of information written to this log file is controlled by the `db-logging-level` property in the backend configuration object. It uses the standard Java logging framework for logging messages, so the standard SEVERE, WARNING, INFO, CONFIG, FINE, FINER, and FINEST levels are available.

The second is configuration information used when opening the database environment. When the backend database environment is opened, then the Directory Server will also write a file named `je.config` in the server containing the database files (for example, `db/userRoot/je.config`) with information about the configuration used.

LDAP SDK debug log

This log can be used to help examine the communication between the Directory Server and the Directory Proxy Server. It contains information about exceptions that occur during processing, problems establishing and terminating network connections, and problems that occur during the reading and writing of LDAP messages and LDIF entries. You can configure the types of debugging that should be enabled, the debug

level that should be used, and whether debug messages should include stack traces. As for other file-based loggers, you can also specify the rotation and retention policies.

About the monitor entries

While the Directory Server is running, it generates a significant amount of information available through monitor entries. Monitor entries are available over LDAP in the `cn=monitor` subtree. The types of monitor entries that are available include:

- **General Monitor Entry (cn=monitor)** – Provides a basic set of general information about the server.
- **Active Operations Monitor Entry (cn=Active Operations,cn=monitor)** – Provides information about all operations currently in progress in the server.
- **Backend Monitor Entries (cn={id} Backend,cn=monitor)** – Provides information about the backend, including the number of entries, the base DN(s), and whether it is private.
- **Client Connections Monitor Entry (cn=Client Connections,cn=monitor)** – Provides information about all connections currently established to the server.
- **Connection Handler Monitor Entry (cn={name},cn=monitor)** – Provides information about the configuration of each connection handler and the client connections established to it.
- **Database Environment Monitor Entries (cn={id} Database Environment,cn=monitor)** – Provides statistics and other data from the Oracle Berkeley DB Java Edition database environment used by the associated backend.
- **Disk Space Usage Monitor Entry (cn=Disk Space Usage,cn=monitor)** – Provides information about the amount of usable disk space available to server components.
- **JVM Memory Usage Monitor Entry (cn=JVM Memory Usage,cn=monitor)** – Provides information about garbage collection activity, the amount of memory available to the server, and the amount of memory consumed by various server components.
- **JVM Stack Trace Monitor Entry (cn=JVM Stack Trace,cn=monitor)** – Provides a stack trace of all threads in the JVM.
- **LDAP Statistics Monitor Entries (cn={name} Statistics,cn=monitor)** – Provides information about the number of each type of operation requested and bytes transferred over the connection handler.
- **Processing Time Histogram Monitor Entry (cn=Processing Time Histogram,cn=monitor)** – Provides information about the number of percent of operations that completed in various response time categories.
- **SSL Context Monitor Entry (cn=SSL Context,cn=monitor)** – Provides information about the available and supported SSL Cipher Suites and Protocols on the server.
- **System Information Monitor Entry (cn=System Information,cn=monitor)** – Provides information about the underlying JVM and system.
- **Version Monitor Entry (cn=Version,cn=monitor)** – Provides information about the Directory Server version.
- **Work Queue Monitor Entry (cn=Work Queue,cn=monitor)** – Provides information about the state of the Directory Server work queue, including the number of operations waiting on worker threads and the number of operations that have been rejected because the queue became full.

Directory Server troubleshooting tools

The Server provides a set of tools that can also be used to obtain information for diagnosing and solving problems.

Server version information

If it becomes necessary to contact your authorized support provider, then it will be important to provide precise information about the version of the Directory Server software that is in use. If the server is running, then this information can be obtained from the `"cn=Version,cn=monitor"` entry. It can also be obtained using the command:

```
$ bin/status --fullVersion
```

This command outputs a number of important pieces of information, including:

- Major, minor, point and patch version numbers for the server.
- Source revision number from which the server was built.
- Build information including build ID with timestamp, OS, user, Java and JVM version for the build.
- Auxiliary software versions: Jetty, JZlib, SNMP4j (SNMP4J, Agent, Agentx), Groovy, LDAP SDK for Java, and the Server SDK.

LDIF connection handler

The Directory Server provides an LDIF connection handler that provides a way to request operations that do not require any network communication with the server. This can be particularly helpful if a configuration problem or bug in the server has left a connection handler unusable, or if all worker threads are busy processing operations.

The LDIF connection handler is enabled by default and looks for LDIF files to be placed in the `config/auto-process-ldif` directory. This Directory Server does not exist by default, but if it is created and an LDIF file is placed in it that contains one or more changes to be processed, then those changes will be applied.

Any changes that can be made over LDAP can be applied through the LDIF connection handler. It is primarily intended for administrative operations like updating the server configuration or scheduling tasks, although other types of changes (including changes to data contained in the server) can be processed. As the LDIF file is processed, a new file is written with comments for each change providing information about the result of processing that change.

dbtest tool

The `dbtest` tool provides a utility that can be used to obtain general information about the data in a backend database. The tool dumps information about entries or keys, and raw data from the database. It can also find keys that have exceeded the entry limit.

For example, the following command can be used to dump a list of all keys in the `objectClass.equality` that have exceeded the entry threshold:

```
$ bin/dbtest dump-database-container \
  --backendID userRoot \
  --baseDN "dc=example,dc=com" \
  --databaseName objectClass.equality \
  --onlyExceedingLimit
```

On a large database, many `dbtest` operations may take a long time to complete, since every record in the associated database is examined. Use the database name option to list a specific database. The following command displays information about the `uid.equality` database in the `dc=example,dc=com` entry container in the `userRoot` backend.

```
$ bin/dbtest list-database-containers -n userRoot -b "dc=example,dc=com" -d
uid.equality
```

Index key entry limit

Indexes have keys that maintain a list of matching entries, up to the index entry limit. When that limit is reached, the key will not contain or maintain that list, and will just maintain a count of matching entries. To determine if index keys are approaching their limit, use either the `dbtest` tool or the `verify-index` tool.

While the `dbtest` tool can be used to gather general information, the `verify-index` tool provides statistical data about the percent of entries covered by the keys.

For example, the following command can be used to retrieve a list of keys that have exceeded the entry threshold:

```
$ bin/verify-index \
```

```
--baseDN dc=example,dc=com \  
--listKeysExceedingIndexEntryLimit
```

The following is a sample of the data returned:

```
[12:06:05] Checked 6003 entries and found 0 error(s) in 2 seconds (average  
rate 2453.2/sec)  
[12:06:05] Statistics for records that have exceeded the entry limit:  
[12:06:05] The st.equality index has 48 such record(s) limit=100 min=103  
max=152 median=118  
[12:06:05] 1. or (152 entries / 2.53% of all entries)  
[12:06:05] 2. ma (132 entries / 2.20% of all entries)  
.....  
[12:06:05] The id2subtree index has 2 such record(s) limit=4000 min=6000  
max=6002 median=6001  
[12:06:05] 1. 1 => dc=example,dc=com (6002 entries / 99.98% of all entries)  
.....  
[12:06:05] The id2children index has 1 such record(s) limit=4000 min=6000  
max=6000 median=6000  
[12:06:05] 1. 2 => ou=People,dc=example,dc=com (6000 entries / 99.95% of all  
entries)  
[12:06:05] The objectClass.equality index has 4 such record(s) limit=4000  
min=6001 max=6003 median=6001  
[12:06:05] 1. top (6003 entries / 100.00% of all entries)  
.....
```

Embedded profiler

If the Directory Server appears to be running slowly, then it is helpful to know what operations are being processed in the server. The JVM Stack Trace monitor entry can be used to obtain a point-in-time snapshot of what the server is doing, but in many cases, it might be useful to have information collected over a period of time.

The embedded profiler is configured so that it is always available but is not active by default so that it has no impact on the performance of the running server. Even when it is running, it has a relatively small impact on performance, but it is recommended that it remain inactive when it is not needed. It can be controlled using the `dsconfig` tool or the Administrative Console by managing the "Profiler" configuration object in the "Plugin" object type, available at the standard object level. The `profile-action` property for this configuration object can have one of the following values:

- **start** – Indicates that the embedded profiler should start capturing data in the background.
- **stop** – Indicates that the embedded profiler should stop capturing data and write the information that it has collected to a `logs/profile{timestamp}` file.
- **cancel** – Indicates that the embedded profiler should stop capturing data and discard any information that it has collected.

Any profiling data that has been captured can be examined using the `profiler-viewer` tool. This tool can operate in either a text-based mode, in which case it dumps a formatted text representation of the profile data to standard output, or it can be used in a graphical mode that allows the information to be more easily understood.

Invoking the profile viewer in text-based mode

Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option.
Example:

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z
```

Invoking the profile viewer in GUI mode

Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option. To invoke GUI mode, add the option `--useGUI`.

Example:

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z --useGUI
```

Oracle Berkeley DB Java Edition utilities

The Oracle Berkeley DB Java Edition (JE) itself provides a number of utilities that can be used for performing various types of low-level debugging in the database environment. These utilities should generally not be used unless you are advised to do so by your authorized support provider, but they provide access to information about the underlying database environment that is not available through any other means.

Troubleshooting resources for Java applications

Because the Server is written entirely in Java, it is possible to use standard Java debugging and instrumentation tools when troubleshooting problems with the Directory Server. In many cases, obtaining the full benefit of these tools requires access to the Directory Server source code. These Java tools should be used under the advisement of your authorized support provider.

Java troubleshooting tools

The Java Development Kit provides a number of very useful tools to obtain information about Java applications and diagnosing problems. These tools are not included with the Java Runtime Environment (JRE), so the full Java Development Environment (JDK) should always be installed and used to run the Server.

jps

The `jps` tool is a Java-specific version of the UNIX `ps` tool. It can be used to obtain a list of all Java processes currently running and their respective process identifiers. When invoked by a non-root user, it will list only Java processes running as that user. When invoked by a root user, then it lists all Java processes on the system.

This tool can be used to see if the Directory Server is running and if a process ID has been assigned to it. This process ID can be used in conjunction with other tools to perform further analysis.

This tool can be run without any arguments, but some of the more useful arguments that include:

- `-v` – Includes the arguments passed to the JVM for the processes that are listed.
- `-m` – Includes the arguments passed to the main method for the processes that are listed.
- `-l` – (lowercase L). Include the fully qualified name for the main class rather than only the base class name.

jstack

The `jstack` tool is used to obtain a stack trace of a running Java process, or optionally from a core file generated if the JVM happens to crash. A stack trace can be extremely valuable when trying to debug a problem, because it provides information about all threads running and exactly what each is doing at the point in time that the stack trace was obtained.

Stack traces are helpful when diagnosing problems in which the server appears to be hung or behaving slowly. Java stack traces are generally more helpful than native stack traces, because Java threads can have user-friendly names (as do the threads used by the Server), and the frame of the stack trace may include the line number of the source file to which it corresponds. This is useful when diagnosing problems and often allows them to be identified and resolved quickly.

To obtain a stack trace from a running JVM, use the command:

```
jstack {processID}
```

where {processID} is the process ID of the target JVM as returned by the `jps` command. To obtain a stack trace from a core file from a Java process, use the command:

```
jstack {pathToJava} {pathToCore}
```

where {pathToJava} is the path to the java command from which the core file was created, and {pathToCore} is the path to the core file to examine. In either case, the stack trace is written to standard output and includes the names and call stacks for each of the threads that were active in the JVM.

In many cases, no additional options are necessary. The `-l` option can be added to obtain a long listing, which includes additional information about locks owned by the threads. The `-m` option can be used to include native frames in the stack trace.

jmap

The `jmap` tool is used to obtain information about the memory consumed by the JVM. It is very similar to the native `pmmap` tool provided by many operating systems. As with the `jstack` tool, `jmap` can be invoked against a running Java process by providing the process ID, or against a core file, like:

```
jmap {processID}
jmap {pathToJava} {pathToCore}
```

Some of the additional arguments include:

- **-dump:live,format=b,file=filename** – Dump the live heap data to a file that can be examined by the `jhat` tool
- **-heap** – Provides a summary of the memory used in the Java heap, along with information about the garbage collection algorithm in use.
- **-histo:live** – Provides a count of the number of objects of each type contained in the heap. If the `:live` portion is included, then only live objects are included; otherwise, the count include objects that are no longer in use and are garbage collected.

jhat

The `jhat` (Java Heap Analysis Tool) utility provides the ability to analyze the contents of the Java heap. It can be used to analyze a heap dump file, which is generated if the Directory Server encounters an out of memory error (as a result of the `-XX:+HeapDumpOnOutOfMemoryError` JVM option) or from the use of the `jmap` command with the `-dump` option.

The `jhat` tool acts as a web server that can be accessed by a browser in order to query the contents of the heap. Several predefined queries are available to help determine the types of objects consuming significant amounts of heap space, and it also provides a custom query language (OQL, the Object Query Language) for performing more advanced types of analysis.

The `jhat` tool can be launched with the path to the heap dump file, like:

```
jhat /path/to/heap.dump
```

This command causes the `jhat` web server to begin listening on port 7000. It can be accessed in a browser at `http://localhost:7000` (or `http://address:7000` from a remote system). An alternate port number can be specified using the `-port` option, like:

```
jhat -port 1234 /path/to/heap.dump
```

To issue custom OQL searches, access the web interface using the URL `http://localhost:7000/oql/` (the trailing slash must be provided). Additional information about the OQL syntax may be obtained in the web interface at `http://localhost:7000/oqlhelp/`.

jstat

The `jstat` tool is used to obtain a variety of statistical information from the JVM, much like the `vmstat` utility that can be used to obtain CPU utilization information from the operating system. The general manner to invoke it is as follows:

```
jstat {type} {processID} {interval}
```

The `{interval}` option specifies the length of time in milliseconds between lines of output. The `{processID}` option specifies the process ID of the JVM used to run the Directory Server, which can be obtained by running `jps` as mentioned previously. The `{type}` option specifies the type of output that should be provided. Some of the most useful types include:

- **-class** – Provides information about class loading and unloading.
- **-compile** – Provides information about the activity of the JIT complex.
- **-printcompilation** – Provides information about JIT method compilation.
- **-gc** – Provides information about the activity of the garbage collector.
- **-gccapacity** – Provides information about memory region capacities.

Java diagnostic information

In addition to the tools listed in the previous section, the JVM can provide additional diagnostic information in response to certain events.

JVM crash diagnostic information

If the JVM itself should happen to crash for some reason, then it generates a fatal error log with information about the state of the JVM at the time of the crash. By default, this file is named `hs_err_pid{processID}.log` and is written into the base directory of the Directory Server installation. This file includes information on the underlying cause of the JVM crash, information about the threads running and Java heap at the time of the crash, the options provided to the JVM, environment variables that were set, and information about the underlying system.

Troubleshooting resources in the operating system

The underlying operating system also provides a significant amount of information that can help diagnose issues that impact the performance and the stability of the Directory Server. In some cases, problems with the underlying system can be directly responsible for the issues seen with the Directory Server, and in others system, tools can help narrow down the cause of the problem.

Identifying problems with the underlying system

If the underlying system itself is experiencing problems, it can adversely impact the function of applications running on it. To look for problems in the underlying system view the system log file (`/var/log/messages` on Linux). Information about faulted or degraded devices or other unusual system conditions are written there.

Examining CPU utilization

Observing CPU utilization for the Directory Server process and the system as a whole provides clues as to the nature of the problem.

System-Wide CPU utilization

To investigate CPU consumption of the system as a whole, use the `vmstat` command with a time interval in seconds, like:

```
vmstat 5
```

The specific output of this command varies between different operating systems, but it includes the percentage of the time the CPU was spent executing user-space code (user time), the percentage of time spent executing kernel-space code (system time), and the percentage of time not executing any code (idle time).

If the CPUs are spending most of their time executing user-space code, the available processors are being well-utilized. If performance is poor or the server is unresponsive, it can indicate that the Directory Server is not optimally tuned. If there is a high system time, it can indicate that the system is performing excessive disk and/or network I/O, or in some cases, there can be some other system-wide problem like an interrupt storm. If the system is mostly idle but the Directory Server is performing poorly or is unresponsive, there can be a resource constraint elsewhere (for example, waiting on disk or memory access, or excessive lock contention), or the JVM can be performing other tasks like stop-the-world garbage collection that cannot be run heavily in parallel.

Per-CPU utilization

To investigate CPU consumption on a per-CPU basis, use the `mpstat` command with a time interval in seconds, like:

```
mpstat 5
```

On Linux systems, it might be necessary to add `-P ALL` to the command, like:

```
mpstat -P ALL 5
```

Among other things, this shows the percentage of time each CPU has spent in user time, system time, and idle time. If the overall CPU utilization is relatively low but `mpstat` reports that one CPU has a much higher utilization than the others, there might be a significant bottleneck within the server or the JVM might be performing certain types of garbage collection which cannot be run in parallel. On the other hand, if CPU utilization is relatively even across all CPUs, there is likely no such bottleneck and the issue might be elsewhere.

Per-process utilization

To investigate CPU consumption on a per-process basis, use a command such as the `top`. If the Directory Server is consuming a significant amount of available CPU, it might be interfering with the ability of the Directory Server to run effectively.

Examining disk utilization

If the underlying system has a very high disk utilization, it can adversely impact Directory Server performance. It could delay the ability to read or write database files or write log files. It could also raise concerns for server stability if excessive disk I/O inhibits the ability of the cleaner threads to keep the database size under control.

The `iostat` tool may be used to obtain information about the disk activity on the system.

On Linux systems, `iostat` should be invoked with the `-x` argument, like:

```
iostat -x 5
```

A number of different types of information will be displayed, but to obtain an initial feel for how busy the underlying disks are, look at the `%util` column on Linux. This field shows the percentage of the time that the underlying disks are actively servicing I/O requests. A system with a high disk utilization likely exhibits poor Directory Server performance.

If the high disk utilization is on one or more disks that are used to provide swap space for the system, the system might not have enough free memory to process requests. As a result, it might have started swapping blocks of memory that have not been used recently to disk. This can cause very poor server performance. It is important to ensure that the server is configured appropriately to avoid this condition. If this problem occurs on a regular basis, then the server is likely configured to use too much memory. If swapping is not normally a problem but it does arise, then check to see if there are any other processes running, which are consuming a significant amount of memory, and check for other potential causes of significant memory consumption (for example, large files in a `tmpfs` file system).

Examining process details

There are a number of tools provided by the operating system that can help examine a process in detail.

ps

The standard `ps` tool can be used to provide a range of information about a particular process. For example, the command can be used to display the state of the process, the name of the user running the process, its process ID and parent process ID, the priority and nice value, resident and virtual memory sizes, the start time, the execution time, and the process name with arguments:

```
ps -fly -p {processID}
```

Note that for a process with a large number of arguments, the standard `ps` command displays only a limited set of the arguments based on available space in the terminal window.

pstack

The `pstack` command can be used to obtain a native stack trace of all threads in a process. While a native stack trace might not be as user-friendly as a Java stack trace obtained using `jstack`, it includes threads that are not available in a Java stack trace. For example, the command displays those threads used to perform garbage collection and other housekeeping tasks. The general usage for the `pstack` command is:

```
pstack {processID}
```

dbx / gdb

A process debugger provides the ability to examine a process in detail. Like `pstack`, a debugger can obtain a stack trace for all threads in the process, but it also provides the ability to examine a process (or core file) in much greater detail, including observing the contents of memory at a specified address and the values of CPU registers in different frames of execution. The GNU debugger `gdb` is widely-used on Linux systems.

Note that using a debugger against a live process interrupts that process and suspends its execution until it detaches from the process. In addition, when running against a live process, a debugger has the ability to actually alter the contents of the memory associated with that process, which can have adverse effects. As a result, it is recommended that the use of a process debugger be restricted to core files and only used to examine live processes under the direction of your authorized support provider.

pfiles / lsof

To examine the set of files that a process is using (including special types of files, like sockets), you can use a tool such as `lsof` on Linux systems, (

```
lsof -p {processID}
```

)

Tracing process execution

If a process is unresponsive but is consuming a nontrivial amount of CPU time, or if a process is consuming significantly more CPU time than is expected, it might be useful to examine the activity of that process in more detail than can be obtained using a point-in-time snapshot. For example, if a process is performing a significant amount of disk reads and/or writes, it can be useful to see which files are being accessed. Similarly, if a process is consistently exiting abnormally, then beginning tracing for that process just before it exits can help provide additional information that cannot be captured in a core file (and if the process is exiting rather than being terminated for an illegal operation, then no core file may be available).

This can be accomplished using the `strace` tool on Linux (

```
strace -f -p {processID}
```

).

Consult the `strace` manual page for additional information.

Problems with SSL communication

Enable TLS debugging in the server to troubleshoot SSL communication issues:

```
$ dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name
com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
  --set debug-level:verbose \
  --set include-throwable-cause:true
```

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true \
  --set default-debug-level:disabled
```

In the `java.properties` file, add `-Djavax.net.debug=ssl` to the `start-server` line, and run `bin/dsjavaproperties` to make the option take effect on a scheduled server restart.

Examining network communication

Because the Server is a network-based application, it can be valuable to observe the network communication that it has with clients. The Directory Server itself can provide details about its interaction with clients by enabling debugging for the protocol or data debug categories, but there may be a number of cases in which it is useful to view information at a much lower level. A network sniffer, like the `tcpdump` tool on Linux, can be used to accomplish this.

There are many options that can be used with these tools, and their corresponding manual pages will provide a more thorough explanation of their use. However, to perform basic tracing to show the full details of the packets received for communication on port 389 with remote host 1.2.3.4, the following command can be used on Linux:

```
tcpdump -i {interface} -n -XX -s 0 host 1.2.3.4 and port 389
```

It does not appear that the `tcpdump` tool provides support for LDAP parsing. However, it is possible to write capture data to a file rather than displaying information on the terminal (using `-w {path}` with `tcpdump`), so that information can be later analyzed with a graphical tool like Wireshark, which provides the ability to interpret LDAP communication on any port.

Note that enabling network tracing generally requires privileges that are not available to normal users and therefore may require root access.

Common problems and potential solutions

This section describes a number of different types of problems that can occur and common potential causes for them.

General troubleshooting methodology

When a problem is detected, Ping Identity recommends using the following general methodology to isolate the problem:

1. Run the `bin/status` tool or look at the server status in the Administrative Console. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts.
2. Look in the server logs. In particular, view the following logs:
 - `logs/errors`
 - `logs/failed-ops`
 - `logs/expensive-ops`
3. Use system commands, such as `vmstat` and `iostat` to determine if the server is bottle-necked on a system resource like CPU or disk throughput.

4. For performance problem (especially intermittent ones like spikes in response time), enabling the `periodic-stats-logger` can help to isolate problems, because it stores important server performance information on a per-second basis. The `periodic-stats-logger` can save the information in a csv-formatted file that can be loaded into a spreadsheet. The information this logger makes available is very configurable. You can create multiple loggers for different types of information or a different frequency of logging (for example, hourly data in addition to per-second data). For more information, see "Profiling Server Performance Using the Periodic Stats Logger".
5. For replication problem, run `dsreplication status` and look at the `logs/replication` file.
6. For more advanced users, run the `collect-support-data` tool on the system, unzip the archive somewhere, and look through the collected information. This is often useful when administrators most familiar with the PingData Platform do not have direct access to the systems where the production servers are running. They can examine the `collect-support-data` archive on a different server. For more information, see Using the Collect Support Data Tool.

Important:

Run the `collect-support-data` tool whenever there is a problem whose cause is not easily identified, so that this information can be passed back to your authorized support provider before corrective action can be taken.

The Server will not run setup

If the `setup` tool does not run properly, some of the most common reasons include the following:

A suitable Java environment is not available

The Server requires that Java be installed on the system and made available to the server, and it must be installed prior to running `setup`. If the `setup` tool does not detect that a suitable Java environment is available, it will refuse to run.

To ensure that this does not happen, the `setup` tool should be invoked with an explicitly-defined value for the `JAVA_HOME` environment variable that specifies the path to the Java installation that should be used. For example:

```
env JAVA_HOME=/ds/java ./setup
```

If this still does not work for some reason, then it can be that the value specified in the provided `JAVA_HOME` environment variable can be overridden by another environment variable. If that occurs, try the following command, which should override any other environment variables that can be set:

```
env UNBOUNDID_JAVA_HOME="/ds/java" UNBOUNDID_JAVA_BIN="" ./setup
```

Oracle Berkeley DB Java Edition is not available

If the version of the Directory Server that you are using was not provided with the Oracle Berkeley DB Java Edition library, then it must be manually downloaded and the appropriate JAR file placed in the `lib` directory before running `setup`. See the `lib/downloading-je.txt` file for instructions on obtaining the appropriate library.

Unexpected arguments provided to the JVM

If the `setup` script attempts to launch the `java` command with an invalid set of Java arguments, it might prevent the JVM from starting. By default, no special options are provided to the JVM when running `setup`, but this might not be the case if either the `JAVA_ARGS` or `UNBOUNDID_JAVA_ARGS` environment variable is set. If the `setup` tool displays an error message that indicates that the Java environment could not be started with the provided set of arguments, then invoke the following command before trying to re-run `setup`:

```
unset JAVA_ARGS UNBOUNDID_JAVA_ARGS
```

The Server has already been configured or used

The **setup** tool is only intended to provide the initial configuration for the Directory Server. It refuses to run if it detects that the **setup** tool has already been run, or if an attempt has been made to start the Directory Server prior to running the **setup** tool. This protects an existing Directory Server installation from being inadvertently updated in a manner that could harm an existing configuration or data set.

If the Directory Server has been previously used and if you want to perform a fresh installation, it is recommended that you first remove the existing installation, create a new one and run **setup** in that new installation. However, if you are confident that there is nothing of value in the existing installation (for example, if a previous attempt to run **setup** failed to complete successfully for some reason but it will refuse to run again), the following steps can be used to allow the **setup** program to run:

- Remove the `config/config.ldif` file and replace it with the `config/update/config.ldif.{revision}` file containing the initial configuration.
- If there are any files or subdirectories below the `db` directory, then remove them.
- If a `config/java.properties` file exists, then remove it.
- If a `lib/setup-java-home` script (or file on Microsoft Windows) exists, then remove it.

The Server will not start

If the Directory Server does not start, then there are a number of potential causes.

The Server or other administrative tool is already running

Only a single instance of the Directory Server can run at any time from the same installation root. If an instance is already running, then subsequent attempts to start the server will fail. Similarly, some other administrative operations can also prevent the server from being started. In such cases, the attempt to start the server should fail with a message like:

```
The PingDataSync Server could not acquire an exclusive lock on file
/ds/the/locks/server.lock: The exclusive lock requested for file
/ds/the/locks/ server.lock was not granted, which indicates
that another process already holds a shared or exclusive lock on that
file. This generally means that another instance of this server is already
running
```

If the Directory Server is not running (and is not in the process of starting up or shutting down) and there are no other tools running that could prevent the server from being started, and the server still believes that it is running, then it is possible that a previously-held lock was not properly released. In that case, you can try removing all of the files in the `locks` directory before attempting to start the server.

If you wish to have multiple instances running at the same time on the same system, then you should create a completely separate installation in another location on the file system.

There is not enough memory available

When the Directory Server is started, the JVM attempts to allocate all memory that it has been configured to use. If there is not enough free memory available on the system, then the Directory Server generates an error message that indicates that the server could not be started with the specified set of arguments. Note that it is possible that an invalid option was provided to the JVM (as described below), but if that same set of JVM arguments has already been used successfully to run the server, then it is more likely that the system does not have enough memory available.

There are a number of potential causes for this:

- If the amount of memory in the underlying system has changed (for example, system memory has been removed, or if the Directory Server is running in a zone or other type of virtualized container and a change has been made to the amount of memory that container will be allowed to use), then the Directory Server might need to be re-configured to use a smaller amount of memory than had been previously configured.
- Another process running on the system is consuming a significant amount of memory so that there is not enough free memory available to start the server. If this is the case, then either terminate the other

process to make more memory available for the Directory Server, or reconfigure the Directory Server to reduce the amount of memory that it attempts to use.

- The Directory Server was just shut down and an attempt was made to immediately restart it. In some cases, if the server is configured to use a significant amount of memory, then it can take a few seconds for all of the memory that had been in use by the server, when it was previously running, to be released back to the operating system. In that case, run the `vmstat` command and wait until the amount of free memory stops growing before attempting to restart the server.
- If the system is configured with one or more memory-backed file systems, verify whether any large files might be consuming a significant amount of memory in any of those locations. If so, remove them or relocate them to a disk-based file system.
- For Linux systems only, if a mismatch exists between the huge pages setting for the JVM and the huge pages reserved in the operating system.

If nothing else works and there is still not enough free memory to allow the JVM to start, then as a last resort, try rebooting the system.

An invalid Java Environment or JVM option was used

If an attempt to start the Directory Server fails with an error message indicating that no valid Java environment could be found, or indicates that the Java environment could not be started with the configured set of options, then you should first ensure that enough memory is available on the system as described above. If there is a sufficient amount of memory available, then other causes for this error can include the following:

- The Java installation that was previously used to run the server no longer exists (for example, an updated Java environment was installed and the old installation was removed). In that case, update the `config/java.properties` file to reference to path to the new Java installation and run the `bin/dsjavaproperties` command to apply that change.
- The Java installation used to run the server has been updated and the server is trying to use the correct Java installation but one or more of the options that had worked with the previous Java version no longer work with the new version. In that case, it is recommended that the server be re-configured to use the previous Java version, so that it can be run while investigating which options should be used with the new installation.
- If an `UNBOUNDID_JAVA_HOME` or `UNBOUNDID_JAVA_BIN` environment variable is set, then its value may override the path to the Java installation used to run the server as defined in the `config/java.properties` file. Similarly, if an `UNBOUNDID_JAVA_ARGS` environment variable is set, then its value might override the arguments provided to the JVM. If this is the case, then explicitly unset the `UNBOUNDID_JAVA_HOME`, `UNBOUNDID_JAVA_BIN`, and `UNBOUNDID_JAVA_ARGS` environment variables before trying to start the server.

Note that any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration. If a problem with the previous Java configuration prevents the `bin/dsjavaproperties` tool from running properly, then it can be necessary to remove the `lib/set-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) and invoke the `bin/dsjavaproperties` tool with an explicitly-defined path to the Java environment, like:

```
env UNBOUNDID_JAVA_HOME=/ds/java bin/dsjavaproperties
```

An invalid command-line option was provided

There are a small number of arguments that are provided when running the `bin/start-server` command, but in most cases, none are required. If one or more command-line arguments were provided for the `bin/start-server` command and any of them is not recognized, then the server provides an error message indicating that an argument was not recognized and displays version information. In that case, correct or remove the invalid argument and try to start the server again.

The Server has an invalid configuration

If a change is made to the Directory Server configuration using an officially-supported tool like `dsconfig` or the Administrative Console, the server should validate that configuration change before applying it.

However, it is possible that a configuration change can appear to be valid at the time that it is applied, but does not work as expected when the server is restarted. Alternately, a change in the underlying system can cause a previously-valid configuration to become invalid.

In most cases involving an invalid configuration, the Directory Server displays (and writes to the error log) a message that explains the problem, and this can be sufficient to identify the problem and understand what action needs to be taken to correct it. If for some reason the startup failure does not provide enough information to identify the problem with the configuration, then look in the `logs/config-audit.log` file to see what recent configuration changes have been made with the server online, or in the `config/archived-configs` directory to see if there might have been a recent configuration change resulting from a direct change to the configuration file itself that was not made through a supported configuration interface.

If the server does not start as a result of a recent invalid configuration change, then it can be possible to start the server using the configuration that was in place the last time that the server started successfully (for example, the "last known good" configuration). This can be achieved using the `--useLastKnownGoodConfig` option:

```
$ bin/start-server --useLastKnownGoodConfig
```

Note that if it has been a long time since the last time the server was started and a number of configuration changes have been made since that time, then the last known good configuration can be significantly out of date. In such cases, it can be preferable to manually repair the configuration.

If there is no last known good configuration, if the server no longer starts with the last known good configuration, or if the last known good configuration is significantly out of date, then manually update the configuration by editing the `config/config.ldif` file. In that case, you should make sure that the server is offline and that you have made a copy of the existing configuration before beginning. You might wish to discuss the change with your authorized support representative before applying it to ensure that you understand the correct change that needs to be made.

Note:

In addition to manually-editing the config file, you can look at previous archived configurations to see if the most recent one works. You can also use the `ldif-diff` tool to compare the configurations in the archive to the current configuration to see what is different.

You do not have sufficient permissions

The Directory Server should only be started by the user or role used to initially install the server. In most cases, if an attempt is made to start the server as a user or role other than the one used to create the initial configuration, then the server will fail to start, because the user will not have sufficient permissions to access files owned by the other user, such as database and log files. However, if the server was initially installed as a non-root user and then the server is started by the root account, then it can no longer be possible to start the server as a non-root user because new files that are created would be owned by root and could not be written by other users.

If the server was inadvertently started by root when it is intended to be run by a non-root user, or if you wish to change the user account that should be used to run the server, then it should be sufficient to simply change ownership on all files in the Directory Server installation, so that they are owned by the user or role under which the server should run. For example, if the Directory Server should be run as the "ds" user in the "other" group, then the following command can be used to accomplish this (invoked by the root user):

```
chown -R ds:other /ds/the
```

The Server has crashed or shut itself down

You can first check the current server state by using the `bin/server-state` command. If the Directory Server was previously running but is no longer active, then the potential reasons include the following:

- The Directory Server was shut down by an administrator. Unless the server was forcefully terminated (for example, using “kill -9”), then messages are written to the `error` and `server.out` logs explaining the reason for the shutdown.
- The Directory Server was shut down when the underlying system crashed or was rebooted. If this is the case, then running the `uptime` command on the underlying system shows that it was recently booted.
- The Directory Server process was terminated by the underlying operating system for some reason (for example, the out of memory killer on Linux). If this happens, then a message will be written to the system error log.
- The Directory Server decided to shut itself down in response to a serious problem that had arisen. At present, this should only occur if the server has detected that the amount of usable disk space has become critically low, or if significant errors have been encountered during processing that left the server without any remaining worker threads to process operations. If this happens, then messages are written to the `error` and `server.out` logs (if disk space is available) to provide the reason for the shutdown.
- The JVM in which the Directory Server was running crashed. If this happens, then the JVM should dump a fatal error log (a `hs_err_pid{processID}.log` file) and potentially a core file.

In the event that the operating system itself crashed or terminated the process, then you should work with your operating system vendor to diagnose the underlying problem. If the JVM crashed or the server shut itself down for a reason that is not clear, then contact your authorized support provider for further assistance.

Conditions for automatic server shutdown

All PingDirectory Server servers will shutdown in an out of memory condition, a low disk space error state, or for running out of file descriptors. The Directory Server will enter lockdown mode on unrecoverable database environment errors, but can be configured to shutdown instead with this setting:

```
$ dsconfig set-global-configuration-prop \
    --set unrecoverable-database-error-mode:initiate-server-shutdown
```

The Server will not accept client connections

You can first check the current server state by using the `bin/server-state` command. If the Directory Server does not appear to be accepting connections from clients, then potential reasons include the following:

- The Directory Server is not running.
- The underlying system on which the Directory Server is installed is not running.
- The Directory Server is running but is not reachable as a result of a network or firewall configuration problem. If that is the case, then connection attempts should time out rather than be rejected.
- If the Directory Server is configured to allow secure communication via SSL or StartTLS, then a problem with the key manager and/or trust manager configuration can cause connections to be rejected. If that is the case, then messages should be written to the server access log for each failed connection attempt.
- If the Directory Server has been configured with a maximum allowed number of connections, then it can be that the maximum number of allowed client connections are already established. If that is the case, then messages should be written to the server access log for each rejected connection attempt.
- If the Directory Server is configured to restrict access based on the address of the client, then messages should be written to the server access log for each rejected connection attempt.
- If a connection handler encounters a significant error, then it can stop listening for new requests. If this occurs, then a message should be written to the server error log with information about the problem. Another solution is to restart the server. A third option is to restart the connection handler using the LDIF connection handler to make it available again. To do this, create an LDIF file that disables and then re-enables the connection handler, create the `config/auto-process-ldif` directory if it does not already exist, and then copy the LDIF file into it.

The Server is unresponsive

You can first check the current server state by using the `bin/server-state` command. If the Directory Server process is running and appears to be accepting connections but does not respond to requests received on those connections, then potential reasons for this behavior include:

- If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available. If this is the case, then a stack trace obtained using the `jstack` command shows that all of the worker threads are busy and none of them are waiting for new requests to process.

A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the `ldapsearch` command for example, use the `--useAdministrativeSession` option. The requester must have the `use-admin-session` privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

Note:

If all of the worker threads are tied up processing the same operation for a long time, the server will also issue an alert that it might be deadlocked, which may not actually be the case. All threads might be tied up processing unindexed searches.

- If a request handler is stuck performing some expensive processing for a client connection, then other requests sent to the server on connections associated with that request handler is forced to wait until the request handler is able to read data on those connections. If this is the case, then only some of the connections can experience this behavior (unless there is only a single request handler, in which it will impact all connections), and stack traces obtained using the `jstack` command shows that a request handler thread is continuously blocked rather than waiting for new requests to arrive. Note that this scenario is a theoretical problem and one that has not appeared in production.
- If the JVM in which the Directory Server is running is not properly configured, then it can be forced to spend a significant length of time performing garbage collection, and in severe cases, could cause significant interruptions in the execution of Java code. In such cases, a stack trace obtained from a `pstack` of the native process should show that most threads are idle but at least one thread performing garbage collection is active. It is also likely that one or a small number of CPUs is 100% busy while all other CPUs are mostly idle. The server will also issue an alert after detecting a long JVM pause (due to garbage collection). The alert will include details of the pause.
- If the JVM in which the Directory Server is running has hung for some reason, then the `pstack` utility should show that one or more threads are blocked and unable to make progress. In such cases, the system CPUs should be mostly idle.
- If a network or firewall configuration problem arises, then attempts to communicate with the server cannot be received by the server. In that case, a network sniffer like `snoop` or `tcpdump` should show that packets sent to the system on which the Directory Server is running are not receiving TCP acknowledgement.
- If the system on which the Directory Server is running has become hung or lost power with a graceful shutdown, then the behavior is often similar to that of a network or firewall configuration problem.

If it appears that the problem is with the Directory Server software or the JVM in which it is running, then you need to work with your authorized support provider to fully diagnose the problem and determine the best course of action to correct it.

The Server is slow to respond to client requests

If the Directory Server is running and does respond to clients, but clients take a long time to receive responses, then the problem can be attributable to a number of potential problems. In these cases, use the Periodic Stats Logger, which is a valuable tool to get per-second monitoring information on the Directory Server. The Periodic Stats Logger can save the information in csv format for easy viewing in a

spreadsheet. For more information, see "Profiling Server Performance Using the Periodic Stats Logger". The potential problems that cause slow responses to client requests are as follows:

- The server is not optimally configured for the type of requests being processed, or clients are requesting inefficient operations. If this is the case, then the access log should show that operations are taking a long time to complete and they will likely be unindexed. In that case, updating the server configuration to better suit the requests, or altering the requests to make them more efficient, could help alleviate the problem. In this case, view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second. You can also run the `bin/status` command or view the status in the Administrative Console to see the Directory Server's Work Queue information (also see the next bullet point).
- The server is overwhelmed with client requests and has amassed a large backlog of requests in the work queue. This can be the result of a configuration problem (for example, too few worker thread configured), or it can be necessary to provision more systems on which to run the Directory Server software. Symptoms of this problem appear similar to those experienced when the server is asked to process inefficient requests, but looking at the details of the requests in the access log show that they are not necessarily inefficient requests. Run the `bin/status` command to view the Work Queue information. If everything is performing well, you should not see a large queue size or a server that is near 100% busy. The %Busy statistic is calculated as the percentage of worker threads that are busy processing operations.

```

--- Work Queue ---
: Recent : Average : Maximum
-----:-----:-----:-----
Queue Size : 10   : 1     : 10
% Busy      : 17   : 14    : 100

```

You can also view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second.

- The server is not configured to fully cache all of the data in the server, or the cache is not yet primed. In this case, `iostat` reports a very high disk utilization. This can be resolved by configuring the server to fully cache all data, and to load database contents into memory on startup. If the underlying system does not have enough memory to fully cache the entire data set, then it might not be possible to achieve optimal performance for operations that need data which is not contained in the cache. For more information, see Disk-Bound Deployments.
- If the JVM is not properly configured, then it will need to perform frequent garbage collection and periodically pause execution of the Java code that it is running. In that case, the server error log should report that the server has detected a number of pauses and can include tuning recommendations to help alleviate the problem.
- If the Directory Server is configured to use a large percentage of the memory in the system, then it is possible that the system has gotten low on available memory and has begun swapping. In this case, `iostat` should report very high utilization for disks used to hold swap space, and commands like `cat /proc/meminfo` on Linux can report a large amount of swap memory in use. Another cause of swapping is if `swappiness` is not set to 0 on Linux. For more information, see Disable File System Swapping.
- If another process on the system is consuming a significant amount of CPU time, then it can adversely impact the ability of the Directory Server to process requests efficiently. Isolating the processes (for example, using processor sets) or separating them onto different systems can help eliminate this problem.

The Server returns error responses to client requests

If a large number of client requests are receiving error responses, then view the `logs/failed-ops` log, which is an access log for only failed operations. The potential reasons for the error responses include the following:

- If clients are requesting operations that legitimately should fail (for example, they are targeting entries that do not exist, are attempting to update entries in a way that would violate the server schema, or are

performing some other type of inappropriate operation), then the problem is likely with the client and not the server.

- If a portion of the Directory Server data is unavailable (for example, because an online LDIF import or restore is in progress), then operations targeting that data will fail. Those problems will be resolved when the backend containing that data is brought back online. During the outage, it might be desirable to update proxies or load balancers or both to route requests away from the affected server. As of Directory Server version 3.1 or later, the Directory Server will indicate that it is in a degraded status and the Directory Proxy Server will route around it.
- If the Directory Server work queue is configured with a maximum capacity and that capacity has been reached, then the server begins rejecting all new requests until space is available in the work queue. In this case, it might be necessary to alter the server configuration or the client requests or both, so that they can be processed more efficiently, or it might be necessary to add additional server instances to handle some of the workload.
- If an internal error occurs within the server while processing a client request, then the server terminates the connection to the client and logs a message about the problem that occurred. This should not happen under normal circumstances, so you will need to work with your authorized support provider to diagnose and correct the problem.
- If a problem is encountered while interacting with the underlying database (for example, an attempt to read from or write to disk failed because of a disk problem or lack of available disk space), then it can begin returning errors for all attempts to interact with the database until the backend is closed and re-opened and the database has been given a change to recover itself. In these cases, the `je.info.*` file in the database directory should provide information about the nature of the problem.

The Server must disconnect a client connection

If a client connection must be disconnected due to the expense of the client's request, such as an unindexed search across a very large database, perform the following:

- Find the client's connection ID by looking in the `cn=Active Operations,cn=monitor monitor` entry.

```
$ bin/ldapsearch -baseDN cn=monitor "cn=active operations" \
  --bindDN "cn=directory manager" \
  --bindPassword password
```

- The monitor entry will contain attribute values for `operation-in-progress`, which look like an access log message. Look for the value of `conn` in the client request that should be disconnected. In the following example, the client to be disconnected is requesting a search for (`description=expensive`), which is on connection 6.

```
dn: cn=Active Operations,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-active-operations-monitor-entry
objectClass: extensibleObject
cn: Active Operations
num-operations-in-progress: 2
operation-in-progress: [15/Dec/2014:10:55:35 -0600] SEARCH conn=6 op=3
msgID=4
  clientIP="10.8.4.21"
  authDN="cn=apl,ou=applications,dc=example,dc=com" base="dc
    =example,dc=com" scope=wholeSubtree filter="(description=expensive)"
  attrs="A
    LL" unindexed=true
operation-in-progress: [15/Dec/2014:10:56:11 -0600] SEARCH conn=7 op=1
msgID=2
  clientIP="127.0.0.1" authDN="cn=Directory Manager,cn=Root
  DNs,cn=config" base="c
    n=monitor" scope=wholeSubtree filter="(cn=active operations)"
  attrs="ALL"
  num-persistent-searches-in-progress: 0
```

- With the connection ID value, create a file with the following contents, named **disconnect6.ldif**.

```
dn: ds-task-id=disconnect6,cn=scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-disconnect
ds-task-disconnect-connection-id: 6
ds-task-id: disconnect6
ds-task-class-name:
  com.unboundid.directory.server.tasks.DisconnectClientTask
```

- This LDIF file represents a task entry. The connection ID value 6 is assigned to **ds-task-disconnect-connection-id**. The value for **ds-task-id** value does not follow a specific convention. It must be unique among other task entries currently cached by the server.
- Disconnect the client and cancel the associated operation by adding the task entry to the server:

```
$ bin/ldapmodify --filename disconnect6.ldif \
  --defaultAdd --bindDN "cn=directory manager" \
  --bindPassword password
```

The Server is experiencing problems with replication

If replication does not appear to be functioning properly, then first check the **dsreplication status** command, which shows all of the servers that are replicating and whether they are back-logged or not. Next, you can check the server error log, replication repair log, and replication monitor entries may provide information about the nature of the underlying problem. Potential reasons that replication may not be functioning as expected include the following:

- Replication has not yet been configured between systems or has been disabled.
- If a server has been offline for a period of time or has fallen far enough behind such that it is missing changes, which are no longer present in any of the replication databases, then that server must be re-initialized with an up-to-date copy of the data from another server.
- If the environment is comprised of a heterogeneous set of systems, then it is possible that some of the systems might not be able to keep up with the maximum throughput achieved by other servers in the topology. In such cases, the slower servers might not be fast enough to remain in sync with the other servers in the environment.
- If the environment contains systems in multiple data centers and the network links between the data centers are insufficient for the volume of changes that must be processed, then servers might not be able to remain in sync under a high volume of changes.
- A network or firewall configuration problem has arisen, which prevents or interferes with communication between servers.
- An internal problem within the server has caused replication to stop functioning properly. The Directory Server logs the event in the error log in this case. Run the **collect-support-data** tool, so that the details of the problems can be passed to your authorized support provider. Then, try restarting the Directory Server.

How to regenerate the Server ads-certificate

At setup time, the server generates a private key and certificate for use when secure communication between servers is required. This certificate, **ads-certificate**, is stored in `config/ads-truststore` and should typically remain unchanged for the life of the server deployment. If the need arises for a new **ads-certificate** to be created, say because the server-root has been copied to a new host, then the private key and certificate will be recreated by the startup process if the `config/ads-truststore` and `config/ads-truststore.pin` files are first manually removed while the server is offline. Note that if replication is enabled, the server must have replication disabled before regeneration of the **ads-certificate**.

For example, the Directory Server allows easy copying of its installation, which can then be used to install another server instance. If a server (`ldap1.example.com:389`) is enabled with its own copy (`ldap2.example.com:389`), **dsreplication** will exit with the following error message:

Replication cannot be enabled between servers `ldap1.example.com:389` and `ldap2.example.com:389` because they are using the same instance key.

The solution is to stop the server, remove `config/adtruststore` and `config/adtruststore.pin` and re-start the server. Upon startup, a new `adtruststore`, containing the server's instance key, will be generated. Then, you can re-run `dsreplication enable` to set up replication between the two servers.

The Server behaves differently from Sun/Oracle

After migrating from a Sun/Oracle configuration to a PingDirectory Server, follow the tuning procedures in [Sun/Oracle Compatibility](#) if the Directory Server behaves differently from the Sun/Oracle server.

Troubleshooting ACI evaluation

The Directory Server provides the ability to collect debug information related to ACI evaluation for any operation by enabling the Debug ACI Logger. The Debug ACI Logger is highly configurable and can be scoped to trace very specific request operations in order to narrow on any ACI issue that may arise in the field. Parameters for non-request operations, such as `log-connects`, `log-disconnects`, `log-security-negotiation`, `log-results`, `log-assurance-completed`, `log-search-entries`, `log-search-references`, `log-intermediate-responses` are set to `false` by default and should remain so.

Here is an example to enable the Debug ACI Logger:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Debug ACI Logger" \
  --set enabled:true
```

Using this debug tracer is often more efficient by limiting the output using request and result criteria to match specific types of operations. An example result criteria for operations that fail due to insufficient access rights can be added to the logger as follows:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Debug ACI Logger" \
  --set "result-criteria:Insufficient Access Rights"
```

Once the logger is enabled, all matching operations begin writing ACI evaluation traces to the log file. The amount of information is quite large for each evaluation that is done. However, this information is useful if there is an ACI issue that is difficult to resolve. Most operations result in multiple "ACI DEBUG" traces in the log, since it usually requires multiple ACI rights to perform an operation, each of which requires a separate evaluation. In particular, you can expect a lot of debug tracing when dealing with ACIs for controls, extended operations, and proxied authorization.

The ACI DEBUG traces contain the following pieces of information:

- **Operation.** Specifies a dump of the operation object that you can use to correlate to the original request operation.
- **ACI Container.** Specifies the context of the ACI evaluation being performed.
 - **Client Entry.** Specifies an LDIF dump of the client request access.
 - **Resource Entry.** Specifies an LDIF dump of the target resource.
 - **isProxiedAuth.** Specifies if the client is attempting to proxy as another user.
 - **Original Auth.** Specifies the original client DN if authorization is currently via the proxy.
 - **Rights.** Specifies a list of the ACI rights being requested on the resource entry.
 - **Control.** Specifies the OIDs when evaluating ACIs for a control.
 - **ExtOp.** Specifies the OIDs when evaluating ACIs for an extended operation.
- **ACI Candidates.** Specifies a list of all the ACIs known to this operation, sorted by origin.
- **Applicable ACIs.** Specifies a list of ACIs relevant to the current evaluation. These ACIs are separated by type into "Denies" and "Allows".

- **Deny ACI Evaluations.** Specifies the results of evaluating each "deny" ACI. If any of these evaluate to TRUE, then the operation will be denied.
- **Allow ACI Evaluations.** Specifies the results of evaluating each "allow" ACI. At least one of these must evaluate to "TRUE" or the operation will be denied.

For users with the `bypass-acl` privilege, the Debug ACI Logger will not provide any ACI debug tracing since evaluations are not done for those operations. However, you will see the following trace if you have ACI debugging enabled (`debug-aci-enabled` is set to TRUE) for those operations:

Bypassing ACL Evaluation for Operation

To avoid unnecessary tracing of these operations, the "Debug ACI Logger" uses a "Client Connection Criteria" called "Clients subject to Access Control" that excludes requests from users with the `bypass-acl` privilege. It is recommended that you create and use your own criteria which specifically targets the clients that you are trying to debug in order to make analyzing the tracing output easier.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Restricted Clients" \
  --type simple \
  --set none-included-user-privilege:bypass-acl
```

Note:

Do not use Result Criteria with the Debug ACI Logger. Result criteria is evaluated after ACIs, so it will not be taken into consideration for this type of debugging.

Problems with the Administrative Console

If a problem arises when trying to use the Administrative Console, then potential reasons for the problem may include the following:

- The web application container used to host the console is not running. If an error occurs while trying to start it, then consult the logs for the web application container.
- If a problem occurs while trying to authenticate to the web application container, then make sure that the target Directory Server is online. If it is online, then the access log may provide information about the reasons for the authentication failure.
- If a problem occurs while attempting to interact with the Directory Proxy Server instance using the Administrative Console, then the access and error logs for that Directory Server instance might provide additional information about the underlying problem.

Problems with the Administrative Console: JVM memory issues

Console runs out of memory (PermGen). An inadequate PermSize setting in the server, while hosting web applications like the Administrative Console may result in errors like this in the error log:

```
[02/Mar/2016:07:50:27.017 -0600] threadID=2 category=UTIL
severity=SEVERE_ERROR msgID=-1 msg="The server experienced an unexpected
error. Please report this problem and include this log file.
OutOfMemoryError: PermGen space
() \ncom.unboundid.directory.server.core.DirectoryServer.uncaughtException
(DirectoryServer.java:15783) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1057) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1052) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1052) \njava.lang.Thread.dispatchUncaughtException
(Thread.java:1986) \nBuild revision: 22496\n"
```

This is only relevant for servers running Java 7.

Problems with the HTTP Connection Handler

When problems with the HTTP Connection Handler occur, first look at the HTTP connection handler log to diagnose the issue. The following section shows HTTP log examples when various errors occur.

- **Failed Request Due to a Non-Existent Resource.** The server receives a status code 404, which indicates the server could not match the URI.

```
[15/Mar/2012:17:39:39 -0500] RESULT requestID=0 from="10.2.1.113:52958"
method="GET" url="https://10.2.1.113:443/Aleph/Users/uid=user.1,ou=people,
dc=example,dc=com" requestHeader="Host: x2270-11.example.lab"
requestHeader="Accept: */*" requestHeader="User-Agent: curl/7.21.6
(i386-pc-centos2.10) libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22
libssh2/1.2.7" authorizationType="Basic" statusCode=404 etime=81.484
responseContentLength=103 responseHeader="Access-Control-Allow-
Credentials:true"
responseContentType="application/json"
```

- **Failed Request due to a Malformed Request Body.** The server receives a status code 400, which indicates that the request had a malformed syntax in its request body.

```
[15/Mar/2012:17:47:23-0500] RESULT requestID=10 from="10.2.1.113:55284"
method="POST" url="https://10.2.1.113:443/Aleph/Users" requestHeader="Host:
x2270-11.example.lab" requestHeader="Expect: 100-continue"
requestHeader="Accept: */*" requestHeader="Content-Type: application/json"
requestHeader="User-Agent: curl/ 7.21.6 (i386-pc-centos2.10) libcurl/7.21.6
OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22 libssh2/1.2.7"
authorizationType="Basic"
requestContentType="application/json" requestContentLength=5564
statusCode=400
etime=15.272 responseContentLength=133 responseContentType="application/
json"
```

- **Failed Request due to an unsupported HTTP method.** The server receives a status code 405, which indicates that the specified method (e.g., "PATCH") in the request line is not allowed for the resource identified in the URI.

```
[15/Mar/2012:17:48:59-0500] RESULT requestID=11 from="10.2.1.113:55763"
method="PATCH" url="https://10.2.1.113:443/Aleph/Users"
requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: */*" requestHeader="Content-
Type:
application/json" requestHeader="User-Agent: curl/7.21.6 (i386-pc-
centos2.10)
libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22 libssh2/1.2.7"
authorizationType="Basic" requestContentType="application/json"
statusCode=405
etime=6.807 responseContentLength=0 responseHeader="Allow: POST, GET,
OPTIONS, HEAD"
```

- **Failed Request due to an Unsupported Media Type.** The server receives a status code 415, which indicates that the request entity is in a format that is not supported by the requested resource.

```
[15/Mar/2012:17:44:45-0500] RESULT requestID=4 from="10.2.1.113:54493"
method="POST" url="https://10.2.1.113:443/Aleph/Users"
requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: */*" requestHeader="Content-
Type:
application/atom+xml" requestHeader="User-Agent: curl/7.21.6 (i386-pc-
centos2.10)
libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22 libssh2/1.2.7"
authorizationType="Basic" requestContentType="application/atom+xml"
requestContentLength=3 statusCode=415 etime=6.222
responseContentLength=1402
responseHeader="Cache-Control: must-revalidate,no-cache,no-store"
responseContentType="text/html; charset=ISO-8859-1"
```

- **Failed Request due to an Authentication Error.** The server receives a status code 401, which indicates that the request requires user authentication.

```
[15/Mar/2012:17:46:06-0500] RESULT requestID=8 from="10.2.1.113:54899"
method="GET" url="https://10.2.1.113:443/Aleph/Schemas"
requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: */*" requestHeader="User-
Agent:
curl/7.21.6 (i386-pc-centos2.10) libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5
libidn/1.22 libssh2/ 1.2.7" authorizationType="Basic" statusCode=401
etime=2.751 responseContentLength=63 responseHeader="WWW-Authenticate:
Basic
realm=SCIM" responseHeader="Access-Control-Allow-Credentials: true"
responseContentType="application/json"
```

Virtual process size on RHEL6 Linux is much larger than the heap

Red Hat Linux introduced a change in glib 2.11 that creates larger per-thread address spaces aligned at 64MB. This change results in a virtual process size much larger than those seen in previous versions of `glibc`. This is not considered a bug by RedHat, as noted in https://bugzilla.redhat.com/show_bug.cgi?id=640286, and does not affect the physical memory needed by the server process. To see the version of `glibc` on your system, use the command `yum info glibc`.

Providing information for support cases

If a problem arises that you are unable to fully diagnose and correct on your own, then contact your authorized support provider for assistance. To ensure that the problem can be addressed as quickly as possible, be sure to provide all of the information that the support personnel may need to fully understand the underlying cause by running the `collect-support-data` tool, and then sending the generated zip file to your authorized support provider. It is good practice to run this tool and send the ZIP file to your authorized support provider before any corrective action has taken place.

Command-Line Tools

The Server provides a full suite of command-line tools necessary to administer the server. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

Available command-line tools

PingDirectory provides the following command-line tools, which you can run in interactive, non-interactive, or script mode.

Tools Help

For	Use this option	Example
Information about arguments and subcommands Usage examples	<code>--help</code>	<code>dsconfig --help</code>
A list of subcommands	<code>--help-subcommands</code>	<code>dsconfig --help-subcommands</code>
More information about a subcommand	<code>--help</code> with the subcommand	<code>dsconfig list-log-publishers --help</code>

**Note:**

For detailed information and examples of the command-line tools, see the *Ping Identity Directory Server Command-Line Tool Reference*.

Command-Line Tools

audit-data-security	<p>Invoke data security audit processing in order to identify potential risks or other notable security characteristics contained in directory data.</p> <p>This tool schedules an internal task with the server that examines all or a subset of entries in the server, writing a series of reports on potential risks with the data. Reports are written to the output directory organized by backend name and audit items. The list of available auditors can be obtained using <code>dsconfig list-data-security-auditors --advanced --property name</code>. Either the <code>--includeAuditor</code> or the <code>--excludeAuditor</code> arguments may be used to limit the scope of the audit.</p> <p>Additionally, the entries scanned can be limited by specifying the backends to scan, or by specifying an LDAP filter that is used to selected entries to be processed.</p> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
authrate	<p>Perform repeated authentications against Directory Server, where each authentication consists of a search to find a user followed by a bind to verify the credentials for that user.</p>
backup	<p>Back up one or more directory server backends.</p> <p>Each backend backup is stored in a separate backend backup directory. A backend backup directory may contain multiple backups of the backend. Each backend backup directory contains a <code>backup.info</code> file providing information about each backup in the directory and an archive file for each backup. The name of the archive file includes both the backend ID and the backup ID. The backup ID may be provided to the backup command, or an ID is generated from a current timestamp.</p> <p>Backups may be full or incremental. The archive file for incremental backups contains the incremental changes since a previous backup. Each backup can be optionally compressed, encrypted, hashed or signed. A backup taken on one system can be restored on another system.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the directory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
base64	<p>Encode raw data using the base64 algorithm or decode base64-encoded data back to its raw representation.</p>

collect-support-data	<p>Collect and package system information useful in troubleshooting problems. The information is packaged as a zip archive that can be sent to a technical support representative.</p> <p>Information collected may include configuration files, server monitor entries, portions of log files, JVM thread stack dumps, system metrics, and other data that may be helpful in diagnosing problems, understanding server performance, or otherwise assisting with support requests. Although the tool will do its best to obscure or omit sensitive data, and the entire archive may be encrypted if you desire, you may wish to review the resulting support data archive to ensure verify its contents. Further, the archive will include a summary of any potential problems or concerns that are identified in the course of collecting the support data.</p>
config-diff	<p>Compares Directory Server configurations and produces a <code>dsconfig</code> batch file needed to bring the source inline with the target.</p> <p>Its uses include comparing multiple servers for configuration differences, producing a batch file to reconfigure a server from scratch from the out-of-the-box configuration, and comparing a local server against an expected configuration.</p> <p>Both the source and the target configurations can be retrieved over LDAP, accessed from the local server's file system, extracted from a specific file, or retrieved from every server in a configuration server group. Also, with the exception of accessing a configuration from a specific file, the source and/or target configurations can be compared as they existed at any point in the past, including the baseline, pre-installation configuration.</p> <p>Some configuration differences (those that will always differ between instances, like instance-name) are excluded by default to reduce the amount of spurious output, but these can be included by specifying the <code>--includeExpectedDifferences</code> command. Further differences can be excluded with the <code>--exclude</code> option.</p> <p>This tool attempts to generate a batch file that can be applied to the source server without any errors. However, there are some edge case configurations that the tool is not sophisticated enough to handle. For example, it cannot handle two peer configuration objects that would require swapping values for a property (for example, evaluation-order-index) that must be unique within the server. It will still generate a <code>dsconfig</code> batch file that includes these changes, but they might be rejected by the server. In these rare cases, the batch file can be hand edited so that it can be applied to a running server or it can be applied with the server shut down using <code>dsconfig --offline</code>.</p>
create-rc-script	<p>Create a Run Control (RC) script that you can use to start, stop, and restart the Directory Server on UNIX-based systems.</p>

create-systemd-script	<p>Create a systemd script to start and stop the Directory Server on Linux-based systems.</p> <p>Each local DB backend has a root container, identified by backend ID. Each root container has an entry container for each base DN in the backend, identified by base DN. Each entry container has a number of database containers that store entries, attribute indexes and system indexes. The <code>dbtest</code> command allows the contents of root containers, entry containers and database containers to be inspected.</p>
dbtest	<p>Inspect the contents of Directory Server local DB backends that store their information in Berkeley DB Java Edition databases. Only backends of type local DB can be inspected by this tool.</p> <p>Each local DB backend has a root container, identified by backend ID. Each root container has an entry container for each base DN in the backend, identified by base DN. Each entry container has a number of database containers that store entries, attribute indexes and system indexes. The <code>dbtest</code> command allows the contents of root containers, entry containers and database containers to be inspected.</p>
deliver-one-time-password	<p>Generate and deliver a one-time password to a user through some out-of-band mechanism. That password can then be used to authenticate via the UNBOUNDID-DELIVERED-OTP SASL mechanism.</p>
deliver-password-reset-token	<p>Generate and deliver a single-use token to a user through some out-of-band mechanism. The user can provide that token to the password modify extended request in lieu of the user's current password in order to select a new password.</p>
dsconfig	<p>View and edit the Directory Server configuration.</p> <p>This utility offers three primary modes of operation, the interactive mode, the non-interactive mode and batch mode. The interactive mode supports viewing and editing the configuration via an intuitive, menu driven environment. Running <code>dsconfig</code> in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the server. To start <code>dsconfig</code> in interactive command-line mode, simply invoke the <code>dsconfig</code> shell script or batch file without any arguments.</p> <p>The <code>dsconfig</code> non-interactive command-line mode provides a simple way to make arbitrary changes to the PingDirectory Server by invoking it on the command-line. If you want to use administrative scripts to automate the configuration process, then run the <code>dsconfig</code> command in non-interactive mode.</p> <p>The <code>dsconfig</code> tool provides a batching mechanism that reads multiple <code>dsconfig</code> invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting in that it minimizes LDAP connections and JVM invocations that normally occur with each <code>dsconfig</code> call. You can view the <code>logs/config-audit.log</code> file to review the configuration changes made to the PingDirectory Server and use them in the batch file.</p>

dsjavaproperties	<p>Configure the JVM arguments used to run the Directory Server and associated tools.</p> <p>The options managed by this tool are stored in <code>config/java.properties</code>. Typically you should not edit that file directly but rather run this tool specifying <code>--jvmTuningParameter</code> arguments to customize JVM options appropriate for this system. It is necessary however that this tool be run in the event that <code>config/java.properties</code> must be edited by hand. Note that the changes will only apply to this Directory Server installation. No modifications will be made to your environment variables.</p> <p>Memory and other settings for the tool JVMs including the start-server tool can be tuned during initialization by specifying one or more instances of the <code>--jvmTuningParameter</code> option when invoking this tool. Supported values are as follows:</p> <ul style="list-style-type: none"> ▪ <code>NONE</code> Explicitly specify no parameters ▪ <code>AGGRESSIVE</code> This system is dedicated to running only this server. The amount of memory allocated to this server will be computed accordingly ▪ <code>SEMI_AGGRESSIVE</code> This system is shared by multiple server processes. The amount of memory allocated to this server will be computed accordingly <p>If no parameters are specified the parameters specified by the previous invocation of this tool or setup will be used. Use the <code>NONE</code> option to explicitly specify no parameters.</p>
dsreplication	<p>Manage data replication between two or more Directory Server instances.</p> <p>For replication to work, you must first enable replication using the <code>enable</code> option. Then, you initialize the contents of one of the servers with the contents of the other using the 'initialize' subcommand.</p>
dump-dns	<p>Obtain a listing of all of the DNSs for all entries below a specified base DN in the Directory Server.</p>
encode-password	<p>Encode user passwords with a specified storage scheme or determine whether a given clear-text value matches a provided encoded password.</p>
encrypt-file	<p>Encrypt or decrypt data using a key generated from a user-supplied passphrase, a key generated from an encryption settings definition, or a key shared among servers in the topology. The data to be processed can be read from a file or standard input, and the resulting data can be written to a file or standard output. You can use this command to encrypt and subsequently decrypt arbitrary data, or to decrypt encrypted backups, LDIF exports, and log files generated by the server.</p>
encryption-settings	<p>Manage the server encryption settings database.</p> <p>More information about the cipher algorithms and transformations available for use may be found in the Java Cryptography Architecture Reference Guide, as well as the Standard Algorithm Name Documentation for your chosen JDK implementation used by this server.</p>

enter-lockdown-mode	<p>Request that the Directory Server enter lockdown mode, during which it only processes operations requested by users holding the <code>lockdown-mode</code> privilege.</p> <p>While in lockdown mode, the Directory Server rejects all requests from users that do not hold the lockdown-mode privilege.</p>
export-ldif	<p>Export data from the Directory Server backend in LDIF form.</p> <p>To export data from a remote Directory Server, the Directory Server must be running and connection parameters must be supplied. You can specify options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The data may be appended to an existing file instead of overwriting it, and the output may be optionally compressed.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
export-reversible-passwords	<p>Requests that the server export entries from a specified backend in LDIF form, including clear-text representations of any passwords encoded with a reversible storage scheme. This tool may only be used over a secure connection and when authenticated as a user with the <code>permit-export-reversible-passwords</code> privilege. The output will be encrypted using a key generated from either a user-supplied passphrase or an encryption settings definition.</p>

<p>extract-data-recovery-log-changes</p>	<p>Extract changes matching a given set of criteria from a Directory Server audit log so that they can be replayed (for example, as part of a disaster recovery process) or reverted (for example, to back out changes made in error).</p> <p>This tool is designed to be used in conjunction with the server's data recovery log files (in the logs/data-recovery directory). It may be used in conjunction with other audit log files, but for best results, the logger should be configured to operate in reversible form, to include the requester DN and IP address, and to include information about any intermediate client control that may have been provided in the request.</p> <p>This tool must not be used with a log file that the server may update while the tool is running, or that may have some content stored in an unwritten buffer (which is especially likely if the log is compressed or encrypted). To use this tool with the server online, you should only specify a log file that has already been rotated to ensure that no more writes will be made to that file. If necessary, you may use the rotate-log tool to force the current active file to be rotated.</p> <p>To use this tool to revert an inappropriate set of changes, run it with '--direction revert' and an additional set of arguments that identify which changes should be reverted (for example, based on the address of the client, the authorization DN of the requester, the time frame in which the changes were applied, etc.).</p> <p>To use this tool to replay changes that were previously applied (for example, after restoring an old backup or importing an old LDIF file), run it with <code>--direction replay</code> and an appropriate set of arguments to select the desired set of changes. Also, make sure to use <code>dsreplication pre-external-initialization</code> before performing the restore or import and applying the changes, and then use <code>dsreplication post-external-initialization</code> after the changes have been applied. See the Directory Server Administration Guide for additional information.</p> <p>This tool will extract changes from the selected log file (and any previously rotated files, unless the <code>--doNotFollowRotationChain</code> argument is provided) and output them in LDIF change format. If the <code>--outputFile</code> argument is provided, then the changes will be written to that file; otherwise, they will be written to standard output. If changes are to be written to a file, then the output will be compressed if the input files were compressed (unless the <code>--doNotCompressOutput</code> argument was provided), and the output will be encrypted if the input files were encrypted (unless <code>--doNotEncryptOutput</code> was provided). You may wish to first run the tool without specifying an output file so that you can verify that the selected changes are correct. Once you are certain that the appropriate changes have been selected, then you can use a tool like <code>ldapmodify</code> or <code>parallel-update</code> to apply those changes to the server.</p>
<p>generate-totp-shared-secret</p>	<p>Generate a shared secret that you can use to generate time-based one-time password (TOTP) authentication codes for use in authenticating with the UNBOUNDID-TOTP SASL mechanism or with the validate TOTP password extended operation.</p>

identify-references-to-missing-entries	This tool may be used to identify entries containing one or more attributes which reference entries that do not exist. This may require the ability to perform unindexed searches and/or the ability to use the simple paged results control.
identify-unique-attribute-conflicts	This tool may be used to identify unique attribute conflicts. That is, it may identify values of one or more attributes which are supposed to exist only in a single entry but are found in multiple entries.
import-ldif	<p>Import LDIF data into a Directory Server backend.</p> <p>Connection parameters are not required when importing to a local Directory Server that is not running. However, connection parameters are required if the Directory Server is remote, or if the Directory Server is running locally and it is inconvenient to have to stop it for the import. You can use the options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The input file may be compressed.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.</p>
indent-ldap-filter	Parse a provided LDAP filter string and display it a multiline form that makes it easier to understand its hierarchy and embedded components. If possible, it might also simplify the provided filter in certain ways (for example, by removing unnecessary levels of hierarchy, like an AND embedded in an AND).
ldap-debugger	Intercept and decode LDAP communication.

`ldap-diff`

Compare the contents of two LDAP servers.

The `ldap-diff` tool outputs the difference between data stored in two LDAP servers into an LDIF file. This file could be used with the `ldapmodify` command to bring the source directory server in sync with the target directory server. The specific entries to compare can be controlled with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. Specific attributes can also be excluded by prepending a `^` character to the attribute. On Windows operating systems, excluded attributes must be quoted, for example, `"^attrToExclude"`. When retrieving entries from a PingDirectory Server, the `@objectClassName` notation can be used to compare only attributes that are defined for a given objectclass.

This command can be used on servers actively being modified, without reporting false positives due to replication delays, by checking differing entries multiple times. By default, it will re-check each differing entry twice, pausing two seconds between checks. These settings can be configured with the `--numPasses` and `--secondsBetweenPass` options. The output is formatted so that delete operations come first, modify operations come next, and add operations come last. This gives the best chance that the resulting output file can be used to bring the source server into sync with the target server without causing any conflicts. This takes into account attribute uniqueness constraints as well as that child entries must be deleted before parents and parents must be added before children.

The directory user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the PingDirectory Server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry:

- `ds-cfg-default-root-privilege-name: unindexed-search`
- `ds-cfg-default-root-privilege-name: bypass-acl`
- `ds-rlim-size-limit: 0`
- `ds-rlim-time-limit: 0`
- `ds-rlim-idle-time-limit: 0`
- `ds-rlim-lookthrough-limit: 0`

For servers from other vendors, consult their documentation for configuring the proper privileges.

The `ldap-diff` tool tries to make efficient use of memory, but it must store the DN's of all entries in memory. For directories that contain tens of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by `ldap-diff` can be customized by editing the `ldap-diff.java-args` setting in the `config/java.properties` file and running the `dsjavaproperties` command.

<p><code>ldap-result-code</code></p>	<p>Display and query LDAP result codes.</p> <p>This tool may be used to list all known defined LDAP result codes, retrieve the name of the result code with a given integer value, or search for all result codes with names containing a given substring.</p> <p>At most one of the <code>--list</code>, <code>--int-value</code>, and <code>--search</code> arguments may be provided. If none of them is provided, then the <code>--list</code> option will be chosen by default.</p>
<p><code>ldapcompare</code></p>	<p>Perform compare operations in an LDAP Directory Server. Compare operations can be used to efficiently determine whether a specified entry has a given value.</p> <p>The exit code for this tool will indicate whether processing was successful or unsuccessful, and to provide a basic indication of the reason for unsuccessful attempts. By default, it will use an exit code of zero (which corresponds to the LDAP 'success' result) if all compare operations completed with a result code of either 'compare false' or 'compare true' (integer values 5 and 6, respectively), but if the <code>--useCompareResultCodeAsExitCode</code> argument is provided, only one compare assertion is performed, and it yields an exit code of 'compare false' or 'compare true', then the numeric value for that result code will be used as the exit code. If any error occurs during processing, then the exit code will be a nonzero value that reflects the first error result that was encountered.</p> <p>The attribute type and assertion value to use for the compare operations will typically be provided as the first unnamed trailing argument provided on the command line. It should be formatted with the name or OID of the target attribute type followed by a single colon and the string representation of the assertion value. Alternatively, the attribute name or OID may be followed by two colons and the base64-encoded representation of the assertion value, or it may be followed by a colon and a less-than symbol to indicate that the assertion value should be read from a file (in which case the exact bytes of the file, including line breaks, will be used as the assertion value).</p> <p>The DNs of the entries to compare may either be provided on the command line as additional unnamed trailing arguments after the provided attribute-value assertion, or they may be read from a file whose path is provided using the <code>--dnFile</code> argument.</p> <p>If the attribute-value assertion is provided on the command line as an unnamed trailing argument, then the same assertion will be performed for all operations. If multiple types of assertions should be performed, then you may use the <code>--assertionFile</code> argument to specify the path to a file containing both attribute-value assertions and entry DNs.</p>
<p><code>ldapdelete</code></p>	<p>Apply a set of add, delete, modify, and/or modify DN operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the <code>ldifFile</code> argument. Change records must be separated by at least one blank line.</p>
<p><code>ldapmodify</code></p>	<p>Apply a set of add, delete, modify, and/or modify DN operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the <code>ldifFile</code> argument. Change records must be separated by at least one blank line.</p>

ldappasswordmodify	<p>Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in RFC 3062), a standard LDAP modify operation, or an Active Directory-specific modification.</p> <p>Unless the password change method is explicitly specified (using the <code>--passwordChangeMethod</code> argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password change method will be selected, using a regular LDAP modify to update the <code>unicodePwd</code> attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute.</p> <p>Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in RFC 3062), a standard LDAP modify operation, or an Active Directory-specific modification.</p> <p>Unless the password change method is explicitly specified (using the <code>--passwordChangeMethod</code> argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password change method will be selected, using a regular LDAP modify to update the <code>unicodePwd</code> attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute.</p> <p>The new password to set for the user may be specified in one of several ways. It may be directly provided on the command line, read from a specified file, interactively prompted from the user, or automatically generated by this tool. If the new password is not specified using any of those methods, and if the password is to be updated using the password modify extended operation, then the new password field of the request will be left blank to indicate that the server should generate a new password for the user and include it in the response to the client. If no new password is specified and some other password change method is selected, then the tool will exit with an error.</p> <p>The current password for the user may also be specified. This is optional, although some servers may require a user to provide their current password when setting a new one. If a current password is provided (whether given as a command-line argument, read from a specified file, or interactively requested from the user), and if a regular LDAP modify operation is used to change the password, then the resulting modify request will include a delete of the current value and an add of the new value. If no current password is provided, then the modify request will replace any existing password(s) with the new value.</p>
--------------------	--

ldapsearch	<p>Process one or more searches in an LDAP directory server.</p> <p>The criteria for the search request can be specified in a number of different ways, including providing all of the details directly via command-line arguments, providing all of the arguments except the filter via command-line arguments and specifying a file that holds the filters to use, or specifying a file that includes a set of LDAP URLs with the base DN, scope, filter, and attributes to return.</p>
ldif-diff	<p>Compare the contents of two files containing LDIF entries. The output will be an LDIF file containing the add, delete, and modify change records needed to convert the data in the source LDIF file into the data in the target LDIF file.</p> <p>This tool works best with small LDIF files because it reads the entire contents of the source and target LDIF files into memory so they can be quickly compared. If you encounter an out of memory error while running the tool, you may need to increase the amount of memory available to the JVM used to invoke it.</p> <p>The amount of memory available to the JVM may be customized by invoking the JVM with the <code>-Xms</code> and <code>-Xmx</code> arguments (which specify the initial and maximum amounts of memory that it may use, respectively). These arguments should be immediately followed (without any intervening space) by an integer and a unit to specify the amount of memory that may be used. The unit may be either <code>m</code> to indicate that the size is in megabytes, or <code>g</code> to indicate that it is in gigabytes. For example, <code>-Xms512m</code> indicates that the JVM should be given an initial heap size of 512 megabytes, while <code>-Xmx2g</code> indicates that it should be given a maximum heap size of two gigabytes.</p> <p>When invoking the <code>ldif-diff</code> tool included in the installation of a Ping Identity server product, you may edit the <code>config/java.properties</code> file to specify the arguments to use when invoking the JVM. After modifying the file, run the <code>dsjavaproperties</code> tool to ensure that those changes will be used for subsequent tool invocations.</p>

ldifmodify	<p>Apply a set of changes (including add, delete, modify, and modify DN operations) to a set of entries contained in an LDIF file. The changes will be read from a second file (containing change records rather than entries), and the updated entries will be written to a third LDIF file. Unlike <code>ldapmodify</code>, the <code>ldifmodify</code> command cannot read the changes to apply from standard input.</p> <p>All of the change records will be read into memory before processing begins, so it is important to ensure that the tool is given enough memory to hold those change records. However, it will only operate on a single source entry at a time, so the size of the source LDIF file does not significantly impact the amount of memory that the tool requires.</p> <p>Note that the tool will attempt to correctly handle multiple changes affecting the same entry. However, because it only operates on one entry at a time, it cannot always behave in exactly the same way as if it were applying the changes over LDAP to a server populated with the source LDIF file. For example, it is not possible to reject an attempt to delete an entry that has subordinates, so any delete will be treated as a subtree delete.</p> <p>Further, not all types of modify DN change records are supported. In particular, modify DN change records are not permitted if they target any entry that has been targeted by a previous change record (for example, renaming an entry that was created by a previous add change record).</p> <p>Finally, it cannot perform other types of validation, like ensuring that all of the necessary superior entries exist when adding a new entry, or ensuring that a modify DN will not introduce a conflict with an existing entry.</p>
ldifsearch	Search one or more LDIF files to identify entries matching a given set of criteria.
leave-lockdown-mode	<p>Request that the Directory Server leave lockdown mode and resume normal operation.</p> <p>While in lockdown mode, the Directory Server rejects all requests from users that do not hold the lockdown-mode privilege.</p> <p>Note that the Directory Server may place itself in lockdown mode under certain conditions (for example, if it detects a security problem like a malformed access control rule that may have otherwise resulted in exposure of sensitive data).</p>
list-backends	List the backends and base DNs configured in Directory Server.
load-ldap-schema-file	Loads the schema definitions contained in a specified LDIF file into the schema for a running server. This tool may only be used in conjunction with a server instance running on the local system.
make-ldif	Generate LDIF data based on a definition in a template file. See the server's <code>config/MakeLDIF</code> directory for example template files. In particular, the <code>examples-of-all-tags.template</code> file shows how to use all of the tags for generating values.

manage-account	Retrieve or update information about the current state of a user account. Processing will be performed using the password policy state extended operation, and you must have the password-reset privilege to use this extended operation.
manage-certificates	Manage certificates and private keys in a JKS, PKCS #12, PKCS #11, or BCFKS key store.
manage-extension	Install or update PingDirectory Server extension bundles. An extension bundle is a package of extension(s) that utilize the Server SDK to extend the functionality of PingDirectory Server. Extension bundles are installed from a zip archive or file system directory. PingDirectory Server will be restarted if running to activate the extension(s).
manage-profile	Generate, compare, install, and replace server profiles. Server profiles define a format for the configuration of a server, including dsconfig , initial DIT, setup arguments, server SDK extensions, and other files. These are combined into one concrete structure. This tool provides subcommands that can be used to generate a new profile from an existing server, to set up a new server, and to replace an existing server's profile with a different profile. A template server profile file structure can be found in the resource/ directory.
manage-tasks	Access information about pending, running, and completed tasks scheduled in the Directory Server.
manage-topology	Tool to manage the topology registry. The topology registry is a branch of the configuration DIT (cn=Topology,cn=config). It stores all metadata about server instances, including their instance and listener certificates, secret keys, server groups and administrative user accounts. In addition, it also stores information about the replication topology (replication server ID and replication domain ID) when replication is enabled among servers in a Directory topology. Last but not least, it stores the license key required to install the server. Changes to the topology registry on one server are automatically mirrored to other servers in the topology. The dsconfig tool, configuration API or the management console may be used to make changes to the topology registry. This tool allows some additional capability such as exporting the contents of the registry as a JSON file.
migrate-ldap-schema	Migrate schema information from an existing LDAP server into a PingDirectory Server instance. This tool may be used to migrate schema information from an existing LDAP server into this PingDirectory Server instance. The source server may be any standards-compliant LDAPv3 server. All attribute type and objectclass definitions which are contained in the source LDAP server but not in the target PingDirectory Server instance will be either added to the target instance or written to a schema file.

migrate-sun-ds-config	<p>Update an instance of the PingDirectory Server to match the configuration of an existing Sun Java System Directory Server 5.x, 6.x, or 7.x.</p> <p>This tool may be used to compare the configuration of Sun Java System Directory Server 5.x, 6.x, or 7.x and PingDirectory Server instances in order to identify any differences and update the PingDirectory Server configuration to more closely match that of the Sun server instance.</p>
modrate	Perform repeated modifications against an LDAP directory server.
move-subtree	Move all entries in a specified subtree from one server to another.
oid-lookup	<p>Search the OID registry to retrieve information about items that match a given OID or name.</p> <p>The string to use to search the OID registry should be provided as an unnamed trailing argument. All items in the OID registry will be examined, and any items that contain the provided string in its OID, name, type, origin, or URL will be matched. If no search string is provided, the entire OID registry will be displayed.</p>
parallel-update	<p>Use multiple concurrent threads to apply a set of add, delete, modify, and modify DN operations read from an LDIF file.</p> <p>As with other tools like <code>ldapmodify</code>, changes in the LDIF file to be processed should be ordered such that if there are any dependencies between changes (for example, if one add change record creates a parent entry and another add change record creates a child of that parent), prerequisite changes come before the changes that depend on them. When this tool is preparing to process a change, it will determine whether the new change depends on any other changes that are currently in progress, and if so, will delay processing that change until its dependencies have been satisfied. If a change does not depend on any other changes that are currently being processed, then it can be processed in parallel with those changes.</p> <p>This tool will keep track of any changes that fail in a way that indicates they succeed if re-tried later (for example, an attempt to add an entry that fails because its parent does not exist, but its parent may be created later in the set of LDIF changes), and can optionally re-try those changes after processing is complete. Any changes that are not retried, as well as changes that still fail after the retry attempts, will be written to a rejects file with information about the reason for the failure so that an administrator can take any necessary further action upon them.</p>

<p>populate-composed-attribute-values</p>	<p>Populate entries in one or more backends with attribute values generated by one or more composed attribute plugins.</p> <p>This tool uses the configuration from a specified set of composed attribute plugin instances to identify which entries to update and what changes to apply. It may be used as an alternative to exporting the data to LDIF and re-importing to ensure that existing entries have an appropriate set of composed attribute values.</p> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.</p>
<p>profile-viewer</p>	<p>View information in data files captured by the Directory Server profiler.</p> <p>Profiler data files are generated by the Profiler plugin. To create these data files, set the profile-action attribute of the Profiler configuration object to 'start' to begin collection. Set the profile-action attribute to <code>stop</code> to end collection and have the plugin write the file to <code>logs/profile.{timestamp}</code>.</p>
<p>re-encode-entries</p>	<p>Re-encode all or a specified portion of the entries in a local DB backend.</p> <p>This tool may be used to initiate a task that will cause a local DB backend to re-encode all or a specified subset of the entries that it contains. The contents of the entries will not be altered, but this provides a useful mechanism for applying significant changes to the way that entries are actually stored in the backend (for example, to apply encoding changes if a feature like data encryption or uncached attributes or entries is enabled).</p> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.</p>

rebuild-index	<p>Rebuild index data within a backend based on the Berkeley DB Java Edition. Note that this tool uses different approaches to rebuilding indexes based on whether it is running in online mode (as a task) rather than with the server offline. Running in offline mode will often provide significantly better performance and require significantly less database cleaning, particularly for indexes containing keys that match a large number of entries and have high index entry limit and exploded index entry threshold values. Also note that rebuilding an index with the server online will prevent the server from using that index while the rebuild is in progress, so some searches may behave differently while a rebuild is active than when it is not.</p> <p>An index must be rebuilt if the database already contains data when the index is configured. The backend containing the provided base DN must be a local DB backend. The types of indexes that can be rebuilt include system indexes, attribute indexes, VLV indexes, and JSON field indexes.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.</p>
register-yubikey-otp-device	<p>Registers a YubiKey OTP device with the Directory Server for a specified user so that the device may be used to authenticate that user in conjunction with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. Alternately, it may be used to deregister one or more YubiKey OTP devices for a user so that they may no longer be used to authenticate that user.</p>
reload-http-connection-handler-certificates	<p>Reload HTTPS Connection Handler certificates.</p> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.</p>

<code>remove-attribute-type-from-schema</code>	<p>Safely remove an attribute type definition from the server schema.</p> <p>The tool will perform an appropriate set of validation before actually removing the attribute type from the schema. The below conditions must be satisfied before the attribute type may be removed.</p> <ul style="list-style-type: none"> ▪ The requester must have the <code>update-schema</code> privilege. ▪ The attribute type must not be referenced by any other schema element. ▪ The attribute type must not be defined in any schema file that is included with the Directory Server. Only custom attribute types may be removed from the schema. ▪ The attribute type must not be referenced in the server configuration (for example, it must not be indexed by any backend). ▪ The attribute type must not be present in any entry that exists in any backend. <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
<code>remove-backup</code>	<p>Safely remove a backup and optionally all of its dependent backups from the specified Directory Server backend.</p> <p>This tool deletes the specified backup archive and updates the backup descriptor accordingly. If there are other (incremental) backups that depend on this backup, they will need to be removed before the base backup can be removed, unless you choose the <code>--force</code> option.</p> <p>If you choose the <code>--force</code> option, the specified backup and all other backups depending on it are removed. You can use the <code>--showDependencies</code> option to see what incremental backups depend on a given base backup.</p> <p>As an alternative to removing a specific backup, you can automatically remove backups outside of specified count or age criteria. The <code>--retainFullBackupCount</code> argument can be used to indicate that the specified number of full backups should be retained, and any other full backups in the directory are eligible to be removed (along any incremental backups that depend on them). The <code>--retainFullBackupAge</code> argument can be used to indicate that any full backups (and dependent incremental backups) older than the specified age are eligible to be removed.</p>
<code>remove-defunct-server</code>	<p>Remove a server from this server's topology.</p> <p>This tool will remove the specified server from the topology. In general, the <code>uninstall</code> tool should be used to remove a server from the topology. The <code>remove-defunct-server</code> tool should only be used if a prior attempt to uninstall a server was unsuccessful or the system where the server was installed is no longer available, leaving the server permanently inaccessible from the topology. If the defunct server is online and is able to reach other servers in the topology, running <code>remove-defunct-server</code> from it will cleanly remove it from the topology. If it cannot reach the other servers, then <code>remove-defunct-server</code> must also be run from one of the online servers.</p>

remove-object-class-from-schema	<p>Safely remove an object class definition from the server schema.</p> <p>The tool will perform an appropriate set of validation before actually removing the object class from the schema. The below conditions must be satisfied before the object class may be removed.</p> <ul style="list-style-type: none"> ▪ The requester must have the update-schema privilege. ▪ The object class must not be referenced by any other schema element. ▪ The object class must not be defined in any schema file that is included with the Directory Server. Only custom object classes may be removed from the schema. ▪ The object class must not be referenced in the server configuration. ▪ The object class must not be present in any entry that exists in any backend. <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.</p>
replace-certificate	<p>Replace the listener certificate for this PingDirectory Server server instance.</p>
restore	<p>Restore a backup of a Directory Server backend.</p> <p>Only one backend may be restored at a time by the restore command. The Directory Server should be stopped unless task connection options are supplied for a running server. You can list the backups contained in a particular backend backup directory. A backup taken on one system can be restored on another system.</p> <p>This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the Directory Server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.</p>
revert-update	<p>Revert this server package's most recent update.</p>
review-license	<p>Review and/or indicate your acceptance of the license agreement defined in <code>legal/LICENSE.txt</code>.</p>

rotate-log	<p>Trigger the rotation of one or more log files.</p> <p>If the file argument is provided one or more times to specify the target log file paths, then only those log files will be rotated. If the file argument is not given, then the server will trigger rotation for all supported log files.</p> <p>You must have the config-read and config-write privileges to run this tool, and you must have the necessary access control rights to create and monitor entries in the task backend.</p> <p>This tool schedules an operation to run within the Directory Server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the <code>manage-tasks</code> tool.</p>
sanitize-log	<p>Sanitize the contents of a server log file to remove potentially sensitive information while still attempting to retain enough information to make it useful for diagnosing problems or understanding load patterns. The sanitization process operates on fields that consist of name-value pairs. The field name is always preserved, but field values might be tokenized or redacted if they might include sensitive information. Supported log file types include the file-based access, error, sync, and resync logs, as well as the operation timing access log and the detailed HTTP operation log. Sanitize the audit log using the <code>scramble-ldif</code> tool.</p>
schedule-exec-task	<p>Schedule an exec task to run a specified command in the server. To run an exec task, a number of conditions must be satisfied: the server's global configuration must have been updated to include <code>com.unboundid.directory.server.tasks.ExecTask</code> in the set of allowed-task values, the requester must have the <code>exec-task</code> privilege, and the command to execute must be listed in the <code>exec-command-whitelist.txt</code> file in the server's <code>config</code> directory. The absolute path (on the server system) of the command to execute must be specified as the first unnamed trailing argument to this program, and the arguments to provide to that command (if any) should be specified as the remaining trailing arguments. The server root is used as the command's working directory, so any arguments that represent relative paths are interpreted as relative to that directory.</p>
search-and-mod-rate	<p>Perform repeated searches against an LDAP directory server and modify each entry returned.</p>
search-logs	<p>Search across log files to extract lines matching the provided patterns, like the <code>grep</code> command-line tool. The benefits of using this tool over <code>grep</code> are its ability to handle multiline log messages, extract log messages within a given time range, and the inclusion of rotated log files.</p>
searchrate	<p>Perform repeated searches against an LDAP directory server.</p>
server-state	<p>View information about the current state of the Directory Server process.</p>
set-delegated-admin-aci	<p>Request that the Directory Server assign appropriate ACI for configured delegated administrators of the Delegated Admin API.</p>

setup	<p>Perform the initial setup for a server instance.</p> <p>This tool features both interactive and non-interactive modes for accepting the product license terms and initially configuring a server instance.</p>
start-server	<p>Start the Directory Server.</p>
status	<p>Display basic server information.</p> <p>This tool prints information about the server, such as version, connection handlers, and data sources. Some information may not be available if the server is not running, or if authentication credentials are missing or do not have sufficient privileges, or if the invoking user does not have sufficient file system access rights.</p>
stop-server	<p>Stop or restart the server.</p> <p>This tool is used to stop or restart the local instance of the server (by omitting LDAP connection options), or a remote server (by interacting with it over LDAP). In addition, this tool is used to schedule the server for shutdown at a later time using the server's task interface.</p>
subtree-accessibility	<p>List or update the set of subtree accessibility restrictions defined in the Directory Server.</p>
sum-file-sizes	<p>Calculate the sum of the sizes for a set of files.</p> <p>This tool is used to find the sum of the sizes of one or more files. If any of the files specified is a directory then it will be recursively processed.</p>
summarize-access-log	<p>Examine one or more access log files from Ping Identity, UnboundID, or Nokia/Alcatel-Lucent 8661 server products to display a number of metrics about operations processed within the server.</p>
transform-ldif	<p>Apply one or more changes to entries or change records read from an LDIF file, writing the updating records to a new file. This tool can apply a variety of transformations, including scrambling attribute values, redacting attribute values, excluding attributes or entries, replacing existing attributes, adding new attributes, renaming attributes, and moving entries from one subtree to another.</p>
uninstall	<p>Uninstall the Directory Server.</p> <p>This tool removes the entire server or individual server components from the file system. If this server is a member of a replication topology, you must first remove references to this server in the other servers using the dsreplication disable command.</p>
update	<p>Update a deployed server so its version matches the version of this package.</p>

<code>validate-acis</code>	This tool may be used to validate a set of access control definitions contained in an LDAP server (including Sun/Oracle DSEE instances) or an LDIF file to determine whether they are acceptable for use in the PingDirectory Server. Note that output generated by this tool will be LDIF, but each entry in the output will have exactly one ACI, so entries which have more than one ACI will appear multiple times in the output with different ACI values.
<code>validate-file-signature</code>	Validate file signatures. For best results, file signatures should be validated by the same instance used to generate the file. However, it might be possible to validate signatures generated on other instances in a replicated topology.
<code>validate-ldap-schema</code>	Validate an LDAP schema read from one or more LDIF files.
<code>validate-ldif</code>	Validate the contents of an LDIF file against the server schema.
<code>verify-index</code>	Verify that indexes in a backend using the Berkeley DB Java Edition are consistent with the entry data contained in the database.
<code>watch-entry</code>	Launch a window to watch an LDAP entry for changes. If the entry changes, the background of modified attributes will temporarily be red. Attributes can be modified as well. This tool is primarily intended to demonstrate replication or synchronization functionality.

Saving options in a file

Directory Server supports the use of a tools properties file (`config/tools.properties`) to simplify command-line invocations by reading in a set of options for each tool from a text file.

Properties files are convenient when quickly testing Directory Server in multiple environments.

Each property takes the form of a name-value pair that defines predetermined values for a tool's options.

Directory Server supports the following types of properties:

- Default properties that apply to all command-line utilities
- Tool-specific properties

Creating a tools properties file

You can set properties that apply to all tools or are tool-specific. These properties serve as defaults for the command-line options they represent.

Steps

1. Use a text editor to open the default tools properties file (`config/tools.properties`) or a different properties file.

Note:

If you use a file other than `config/tools.properties`, invoke the tool with the `--propertiesFilePath` option to specify the path to your properties file.

2. Set or change properties that apply to all tools.

Use the standard Java properties file format (name=value) to set properties. For example, the following properties define a set of LDAP connection parameters.

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
baseDN=dc=example,dc=com
```

Note:

Properties files do not allow quotation marks of any kind around values.

Escape spaces and special characters.

Whenever you specify a path, do not use ~ to refer to the home directory. The server does not expand the ~ value when read from a properties file.

3. Set or change properties that apply to specific tools.

Tool-specific properties start with the name of the tool followed by a period. These properties take precedence over properties that apply to all tools. The following example sets two ports: one that applies to all tools (`port=1389`) and a tool-specific one that **ldapsearch** uses instead (`ldapsearch.port=2389`).

```
hostname=server1.example.com
port=1389
ldapsearch.port=2389
bindDN=cn=Directory\ Manager
```

4. Save your changes and close the file.

Evaluation of command-line options and file options

You can specify options for a command-line tool on the command line, in a properties file, or both.

Options you specify on a tool's command line take priority over options in a properties file.

Consider the following scenarios.

Command-line options	Directory Server uses ...
No command-line options	The options in the default <code><server-root>/config/tools.properties</code> file
Command-line options other than the <code>--propertiesFilePath <my-properties-file></code> option	The command-line options, which take priority if the options are also in the <code><server-root>/config/tools.properties</code> file The file options for options that are only in the default <code><server-root>/config/tools.properties</code> file
Only the <code>--propertiesFilePath <my-properties-file></code> option	The options in <code><my-properties-file></code>
The <code>--propertiesFilePath <my-properties-file></code> option and other command-line options	The command-line options, which take priority if the options are also in <code><my-properties-file></code> The file options for options that are only in <code><my-properties-file></code>
The <code>--noPropertiesFile</code> option and other command-line options	Only the options you specify on the command line, ignoring the default properties file

Example

Consider this example properties file that is saved as `<server-root>/bin/tools.properties`:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

Directory Server checks command-line options and file options to determine the options to use, as explained below.

- All options presented with the tool on the command line take precedence over any options in a properties file.

In the following example, the command runs with the options specified on the command line (`--port` and `--baseDN`). With the `port` value both on the command line and in the properties file, the command-line value takes priority. The command uses the `bindDN` and `bindPassword` values specified in the properties file.

```
$ bin/ldapsearch --port 2389 --baseDN ou=People,dc=example,dc=com \
  --propertiesFilePath bin/tools.properties "(objectclass=*)"
```

- If you specify the properties file using the `--propertiesFilePath` option and no other command-line options, Directory Server uses only the options in the specified properties file:

```
$ bin/ldapsearch --propertiesFilePath bin/tools.properties \
  "(objectclass=*)"
```

- If do not specify any command-line options, Directory Server attempts to locate the default properties file in the following location:

```
<server-root>/config/tools.properties
```

By moving your `tools.properties` file from `<server-root>/bin` to `<server-root>/config`, you do not have to specify the `--propertiesFilePath` option. That change shortens the previous command to the following command.

```
$ bin/ldapsearch "(objectclass=*)"
```

Sample dsconfig batch files

The `config/sample-dsconfig-batch-files` directory contains **dsconfig** batch files that you can use to configure various aspects of the server. For example, these files can enable additional security capabilities or take advantage of features that might require customization from one environment to another.

Each file includes comments that describe the purpose and benefit of its configuration change. You can choose which of the changes you want to apply.

You need to customize some of the batch files to provide values that might vary from one environment to another. To apply a batch file that requires changes, copy it to another directory and edit the copy. Leave the files in the `config/sample-dsconfig-batch-files` directory unchanged so that they can be updated when you upgrade the server. To specify the path to the file that contains the changes to apply, use the **dsconfig** tool (`bin/dsconfig` on UNIX-based systems or `bat\dsconfig.bat` on Windows) with the `--batch-file` argument.

You should also provide the arguments needed to connect and authenticate to the server. The `--no-prompt` argument ensures that the tool does not block while waiting for input if any necessary arguments are missing. Consider this example.

```
bin/dsconfig --hostname localhost \
  --port 636 --useSSL --trustStorePath config/truststore \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPasswordField admin-password.txt \
  --batch-file config/hardening-dsconfig-batch-files/reject-insecure-
request.dsconfig \
  --no-prompt
```

Running task-based tools

Directory Server has a Tasks subsystem that allows you to schedule basic operations, such as **backup**, **restore**, **rotate-log**, **schedule-exec-task**, **stop-server**, and others. All task-based tools require the `--task` option that explicitly indicates the tool is to run as a task rather than in offline mode.

The following table shows the options that you can use for task-based operations:

Options for task-based operations

Option	Description
<code>--task</code>	Indicates that the tool is invoked as a task. The <code>--task</code> option is required. If you invoke a tool as a task without this <code>--task</code> option, then a warning message is displayed stating that it must be used. If the <code>--task</code> option is provided but the tool was not given the appropriate set of authentication arguments to the server, then an error message is displayed and the tool exits with an error.
<code>--start <startTime></code>	Indicates the date and time, expressed in the format 'YYYYMMDDhhmmss', when the operation is to start. A value of '0' causes the task to be scheduled for immediate execution. After the scheduled run, the tool exits immediately.
<code>--dependency <taskID></code>	Specifies the ID of a task upon which this task depends. A task does not start execution until all its dependencies have completed execution. You can use this option multiple times in a single command.
<code>--failedDependencyAction <action></code>	Specifies the action this task takes if one of its dependent tasks fail. Valid action values are: <ul style="list-style-type: none"> ▪ CANCEL (the default) Cancels the task. ▪ DISABLE Disables the task so that it is not eligible to run until you manually enable it again. ▪ PROCESS Runs the task.

Option	Description
<code>--startAlert</code>	Generates an administrative alert when the task starts running.
<code>--errorAlert</code>	Generates an administrative alert when the task fails to complete successfully.
<code>--successAlert</code>	Generates an administrative alert when the task completes successfully.
<code>--startNotify</code> <emailAddress>	Specifies an email address to notify when the task starts running. You can use this option multiple times in a single command.
<code>--completionNotify</code> <emailAddress>	Specifies an email address to notify when the task completes, regardless of whether it succeeded or failed. You can use this option multiple times in a single command.
<code>--errorNotify</code> <emailAddress>	Specifies an email address to notify if an error occurs when this task executes. You can use this option multiple times in a single command.
<code>--successNotify</code> <emailAddress>	Specifies an email address to notify when this task completes successfully. You can use this option multiple times in a single command.

PingDirectoryProxy Server Administration Guide

PingDirectoryProxy is a fast and scalable LDAPv3 gateway for the PingDirectory server. Administrators can configure the PingDirectoryProxy server architecture to control how client requests are routed to backend servers.

Introduction to the PingDirectoryProxy Server

This section gives an overview of PingDirectoryProxy features and components.

PingDirectoryProxy is a fast and scalable LDAPv3 gateway for the PingDirectory. Administrators can configure the Directory Server architecture to control how client requests are routed to backend servers.

Overview of the PingDirectoryProxy features

The following overview describes PingDirectoryProxys features and capabilities.

The PingDirectoryProxy is a fast, scalable, and easy-to-use LDAP proxy server that provides high availability and additional security for the PingDirectory while remaining largely invisible to client applications. From a client perspective, request processing is the same, whether communicating with the Directory Server directly or going through the Directory Server.

The PingDirectoryProxy provides the following features:

- High availability

The Directory Server allows you to transparently fail over between servers if a problem occurs as well as ensuring that the workload is balanced across the topology. If a client does not support following referrals, the Directory Server can follow them on the client's behalf.

Data mapping and transformation

The Directory Server can perform distinguished name (DN) mapping and attribute mapping to allow clients to interact with the server using older names for directory content. It allows clients to continue working when they would not be able to work directly with the Directory Server, either because of changes that have occurred at the data layer or to inherent design limitations in the clients.

Horizontal scalability and performance

Reads can be horizontally scaled using load balancing. In large data centers, if the data set is too large to be cached or to provide horizontal scalability for writes, the Directory Server can automatically split the data across multiple systems. This feature allows the Directory Server to improve scalability and performance of the Directory Server environment.

Load balancing and failover

You can spread the workload across multiple proxies in a large data center using load-balancing algorithms. Load balancing is also useful when a server becomes degraded or non-responsive because client process requesting directs to a different server.

Security and access control

The Directory Server can add additional firewall capabilities as well as constraints and filtering to help protect the Directory Server from attacks. You can use a Directory Server in a DMZ as opposed to allowing clients to directly access the Directory Server in the internal network or providing the data in the DMZ. It can help provide secure access to the data and you can define what actions clients are allowed to do. For example, you can prevent clients from making modifications to data when connected through a VPN no matter what their identity or permissions.

Tracking of operations across the environment

In the past, administrators have complained that when they see a request in the access log they have no idea where it came from and cannot track it back to a particular client. The Directory Server contains controls that allow administrators to track requests back to the client that issued them. Whenever the Directory Server forwards a request to the Directory Server, it includes a control in the request so that the Directory Server's access log has the IP address of the client, address and connection ID of the Directory Server. In the response back to the client, it similarly includes information about the Directory Server that processed the request, such as the connection ID and operation ID. This feature makes it easier for administrators to monitor in their environment.

Monitoring and management tools

Because the Directory Server uses many of the components of PingDirectory, it can leverage them to provide protocol support, logging, management tools for configuration and monitoring, and schema. You can use the DataMetricsServer, the `dsconfig` tool, and the administrative console to manage the Directory Server.

Overview of the Directory Server components and terminology

This section describes each Directory Server component in more detail.

The Directory Server provides the following components and functionalities for the proxy capabilities:

- Locations
- LDAP External Servers
- LDAP Health Checks
- Load-Balancing Algorithms

- Data Transformations
- Request Processors
- Server Affinity Providers
- Subtree Views
- Connection Pools
- Client Connection Policies
- Entry Balancing

About locations

You can assign a location to the Directory Server and each of the backend LDAP external servers for routing requests and failover response preferences.

Locations define a group of servers with similar response time characteristics. Each location consists of a name and an ordered list of preferred failover locations. These locations can determine how to route requests so that the server forwards requests to Directory Server in the same data center over those in remote locations.

For example, a deployment consists of three data centers, one in New York, one in Chicago, and one in Los Angeles. In the New York data center, applications that reside in this data center prefer communicating with directories in this data center. If none of the servers are available, it prefers to failover to the data center in Chicago rather than the data center in Los Angeles, so the New York location contains an ordered list in which the Chicago location is preferred over the Los Angeles data center for failover.

Follow these guidelines for assigning locations in Directory Server:

- If you have multiple data centers, assign a separate location for each one.
- In most environments, all Directory Proxy Server instances should have the same configuration except for the attribute that specifies the location of the Directory Proxy Server itself.

For more information about configuring locations, see [Configuring Locations](#).

About LDAP external servers

PingDirectoryProxy allows you to configure different types of LDAP external servers.

You can configure information about the directory server instances accessed by PingDirectoryProxy. The default configuration for each type is tuned to be the best possible configuration for each.

The configuration information includes the following:

- Server connection information, such as IP address, port, and security layer
- Location
- Authentication information
- Methods for authenticating and authorizing clients
- Server-specific health checks
- Types of operations allowed

For example, some LDAP external servers might allow only reads and others allow reads and writes so that the Directory Server can recognize this and accommodate it.

For more information about configuring LDAP external servers, see [Configuring LDAP External Servers](#).

About LDAP health checks

LDAP health checks provide information about the status and availability of LDAP external servers. Configure the Directory Proxy Server health checks that work best for your environment.

PingDirectoryProxy provides the following health checks:

Measure the response time for searches and examine the entry contents

The health check might retrieve a monitoring entry from a server and base the health check result on whether the entry was returned, how long it took to be returned, and whether the value of the returned entry matches what was expected.

Monitor the replication backlog

If a server falls too far behind in replication, then the Directory Proxy Server can stop sending requests to it. A server is classified as `degraded` or `unavailable` if the threshold is reached for the number of missing changes, the age of the oldest missing change, or both.

Consume Directory Server administrative alerts

If the Directory Server indicates there is a problem, such as an index that must be rebuilt, then it flags itself as `degraded` or `unavailable`. When the Directory Proxy Server detects this, it stops sending requests to the server. The Directory Proxy Server detects administrative alerts as soon as they are issued by maintaining an LDAP persistent search for changes within the `cn=alerts` branch of the Directory Server.

When the Directory Proxy Server is notified by the Directory Server of a new alert, it immediately retrieves the base `cn=monitor` entry of the Directory Server. If this entry has a value for the `unavailable-alert-type` attribute, then the Directory Proxy Server considers it unavailable. If this entry has a value for the `degraded-alert-type` attribute, then the Directory Proxy Server considers it `degraded`. Clients of the Directory Proxy Server can use a similar mechanism to detect and react when a Directory Proxy Server flags itself as `degraded` or `unavailable`.

Monitor the busyness of the server

If a server becomes too busy, you can mark it as `degraded` or `unavailable` so that less heavily-loaded servers are preferred.

Results

The health check results contain the following server states:

Available

Completely accessible for use.

Degraded

The server can be used if necessary but has a condition which can make it less desirable than other servers. For example, it is slow to respond or has fallen behind in replication.

Unavailable

Completely unsuitable for use. For example, the server is offline or is missing critical data.

Health check results include a numeric score that has a value between 1 and 10. This score helps rank servers with the same state. For example, two servers are available and one has a score of 8 and the other a score of 7, you can configure the Directory Proxy Server to prefer the server with the higher score.

The results of health checks are made available to the load-balancing algorithms to help determine where to send requests. The Directory Server attempts to use servers with a state of `available` before trying servers with a state of `degraded`. It never attempts to use servers with a state of `unavailable`.

Some load-balancing algorithms also take the health check score into account, such as the health-weighted load-balancing algorithm that prefers servers with higher scores over those with lower scores. You should configure the algorithms that work best for you environment.

Frequency

The Directory Server periodically invokes health checks to monitor each LDAP external server and initiates health checks in response to failed operations. It checks the health of the LDAP external servers at

intervals configured in the LDAP server's `health-check-frequency` property. The Directory Proxy Server contains safeguards to ensure that only one health check is in progress at any time against a backend server to avoid affecting its ability to process other requests.

To associate a health check with an LDAP external server and set the health check frequency, you must configure the `health-check` and `health-check-frequency` properties of the LDAP external server.

For more information about configuring the properties of the external server, see [Configuring an external server using `dsconfig`](#) on page 920.

Server states and search response times

In some cases, an LDAP health check defines different sets of criteria for promoting and demoting the state of a server. A `degraded` server might need to meet more stringent requirements to be reclassified as `available` than originally for it to be considered `degraded`.

If response time is used in the process of determining the health of a server, then the Directory Server might have a faster response time threshold for transitioning a server from `degraded` back to `available` than the threshold used to consider it `degraded` in the first place. This threshold difference helps avoid cases in which a server repeatedly transitions between the two states because it is operating near the threshold.

For example, the health check used to measure search response time is configured to mark any server as `degraded` when the search response time is greater than 1 second. You can configure that the response time must be less than 500 ms before the server is made available again so that the Directory Server does not flip back and forth between `available` and `degraded`.

For more information about configuring health checks, see [Configuring Server Health Checks](#).

About load-balancing algorithms

Load-balancing algorithms determine which server in a set of similar servers to use to process a client request.

The PingDirectoryProxy provides the following load-balancing algorithms:

Fewest operations

Forwards request to the backend server with the fewest operations currently in progress.

Single server

Sends requests to the same server and doesn't attempt to fail over to another server if the target server is unavailable.

Weighted

Administrators explicitly assign numeric weights to individual servers or sets of servers to control how likely they are to be selected for processing requests relative to other servers.

Health-based weighting

Uses the health check score to assign weights to each of the servers so that a server with a higher score gets a higher percentage of the traffic than a server with a lower score. The proportion of traffic received is the difference between their health check scores.

Failover

Sends requests to a given server first. If that server fails, then the request sends to another specified server as specified in the ordered failover server list.

For more information about configuring load balancing, see [Configuring Load Balancing](#).

Algorithm criteria

The algorithm takes the following criteria into account:

Location of the server

Servers in the same location as the Directory Server are preferred over those in alternate locations.

Health of the server

Servers that are `available` are preferred over those that are `degraded`. In some cases, the health check score can be used to further differentiate between servers with the same health check state.

Route requests consistency

Requests from a single client can be consistently routed to the same directory server instance to avoid problems such as propagation delay from replication.

Operation retries

Retries the operation in an alternate server if the request fails or the operation times out. You can control if the retry is allowed and, if so, how many times to retry and the time out interval.

About proxy transformations

Proxy transformations are used to rewrite requests and responses as they pass through the Directory Server. Proxy data transformations are helpful for clients that use an old schema or that contain a hard-coded schema.

Use the Directory Server proxy transformations to:

- Provide a distinguished name (DN) and attribute mapping altering both requests to the server as well as responses from the server.
For example, a client sends a request to `o=example.com` even though the directory server handling the request uses `dc=example,dc=com`. The Directory Server can transparently remap the request so that the server can process it and map it back to the original DN of the client request when the value is returned.
- Alternatively, if a client tries to use the attribute `userID`, the Directory Server can map it to `uid` before sending the request on to the backend LDAP server. The Directory Server then remaps the response to `userID` when the value is returned.
- Suppress a specified attribute so that it is never returned to clients. Also, it can cause the server to reject requests which target that particular attribute.
- Prevent entries that match a given search filter from being returned to clients.

For more information about configuring proxy transformations, see [Configuring Proxy Transformations](#).

About request processors

A request processor encapsulates the logic for handling an operation, ensuring that a given operation is handled appropriately.

The request processor can:

- Process the operation directly
- Forward the request to another server
